can examine strategic judgement. The "fit" or "alignment" paradigm is perhaps one of the most pervasive in strategy. Good strategy requires at a minimum alignment with changing external conditions. In simple terms, the proposition is that there is an organizational structure that fits the level of contingency factor whether it is environmental uncertainty, organizational characteristics, technological characteristics or strategy design interdependence so that an organization in fit creates significant and positive implications for performance. This idea that fit between organization structure and contingency factor leads to superior performance has been empirically supported in both qualitative and quantitative studies (Donaldson, 1995). Given this distinguished history, it might reasonably be expected that executives would frequently make decisions based on the principles of organization congruence (Priem, 1994).

Most early theories of structural contingency focused on how the fit between bivariate variables (i.e., structure-environment alignment, strategy-structure alignment or strategy-environment alignment) are associated with increased firm performance. However, information technology (IT) is becoming an important substitute for organization structure in modern organisation (Sauer & Willcocks, 2003). For example, Oracle's ability to transform itself into an Internet-enabled business would not have been possible without an appropriate technology base. The wrong technology base would have made such an initiative a massive technological and organizational challenge because of the custom integration required. Emerging evidence indicates that structure and technology are complementary. Where structures create boundaries for management control, technology permits those boundaries to be traversed thereby enabling more complex commercial activities to be effectively integrated and managed.

EMPIRICAL INVESTIGATION OF STRATEGIC JUDGMENT

The "integrative framework" developed by Lee (1989, 1991) in a series of papers regarding the management of information systems provides a suitable approach to the study of judgment. Lee's integrative framework formally presented in his 1994 paper combines three levels of "understandings": the subjective, the interpretive and the positivist. According to Lee, the three understandings are "far from being mutually exclusive and irreconcilable"; in fact, "they may be utilised as mutually supportive and reinforcing steps in organisational research". Priem and Cycyota (2000) also support this view by claiming that both qualitative and quantitative studies are necessary to increase our understanding of strategic judgement.

In the case of e-business, qualitative work can be useful in exploratory investigation that may highlight issues more formal approaches may miss. For example, case studies of the most spectacular strategic information systems initiatives Baxter Healthcare and American Airline's SABRE indicate that these IT/e-business systems were largely accidental success stories (Clemons, 1986). However, these subjective and interpretive studies cannot test hypotheses adequately, because of the close contact needed with research subjects and the resulting small sample size. Quantitative studies provide the crucial positivist link that complements exploratory work in a way that can generate more widely generalizable insights. Notable examples, include the study of IT's contribution to performance in the retail industry (Powell & Dent-Micallef, 1997), and the investigation of organizational antecedents to e-business adoption (Srinivasan, Lilien, & Rangaswamy, 2002).

The following sections focus on measurement techniques, which can be used to examine individual judgment. These techniques can be grouped into two categories: (1) composition methods, and (2) decomposition methods (Priem & Harrison, 1994).

Composition Methods

Composition methods focus on the processes that underlie individual judgments. Composition involves methods such as verbal protocol analysis, information searches and cause mapping to gather interpretive information from executives about the processes that lead them to make certain judgments. These types of techniques would be useful in identifying the variables that executives use in their strategic decision making, but which are not included in current management theory (Priem & Harrison, 1994).

Decomposition Methods

Decomposition techniques focus on the interactions that take place surrounding the judgment itself. The technique requires that the variables or judgment attributes be known a priori. The substantive nature of those variables must come from existing strategy theory (Priem & Harrison, 1994), and contingency theory provides an excellent starting point.

In this case, decomposition methods are required to focus on executive choices in response to a series of decision scenarios (i.e., behavioural simulations regarding the environment, firm structure and the strategy making process). The variance in executive choice is evaluated against these factors of interest, which can be manipulated across scenarios, using conjoint or choice analysis techniques.1 Figure 1 shows the way we can manipulate the important choices outlined in structural contingency theory. Paired comparisons (or stated preferences) are collected and then used to evaluate direct and interaction effects. In this way, we reveal the direction and strength of the three factors considered central to contingency theory. For example, an executive faced with a stable environment would lean towards

a planned strategy and decentralized structure according to contingency prescriptions. Respondent rankings on each path reflect the perceived utility respondents have for each combination of variables.

This combination of composition and decomposition techniques enables one to test whether the prescriptions of at least one well-known theory (i.e., contingency theory) influences executive judgment. The extent to which these prescriptions are already "obvious" to, or widely known by, practising executives will shed new light on the role of judgment in IT strategy and change.

CONCLUSION

We have outlined the importance of executive judgment to the strategic choice process and its particular relevance to the study of e-business, where environmental turbulence increases the relevance of managerial discretion. By separating the outcomes from the actual decision choice, we can begin to more fully understand how these strategic choices influence firm performance. Until now the process of strategic choice has largely been treated as a "black box" where it is assumed that measured outcomes are the result of deliberate choices.

One of the reasons contingency theory has become so popular is that it provides managers with prescriptive advice regarding which configurations lead to higher performance. Further examination of executive judgments to ascertain whether executives are making decisions based on the idea of alignment or fit is required. This will help in our understanding of whether material taught by academics in business schools is actually being used by students in industry. Are executives using the ideas of alignment or fit as prescribed in theory or are they making judgments based on other factors? The answer to this question has important implications for relevance and improving the linkage between theory and practice.

Understanding the processes that occur in strategy development will lead to greater knowledge of the decisions that executives make in uncertain environments and hyperturbulent contexts. This understanding is important if we want to develop e-business related research that is applicable to practitioners. It is this type of research that will guide executives in the strategic management of change and allow them to gain advantage from leverage their investments in e-business technology.

KEY TERMS

Contingency Theory: A meta-theory, which argues that firm performance is defined by the environment-strategy-structure relationship, where the organization's strategy is contingent on the external environment and the organization structure is contingent on the firm's strategy.

E-Business Technology: Any technology, which enables an organization to conduct business electronically, with the overall aim of improving firm performance.

Executive Judgment: A decision that an executive makes, when they do not have a full understanding of the decision problem, based on their mental models of the environment and their vision for the organization.

External Environment: Factors which are external to an organization, such as new technology or product developments, changing rates of market growth, which an organization must respond to.

Fit/Alignment: Terms used to explain the relationship between IT and strategy. The IT strategy should work in synergy with the organizations strategy. These terms have their roots in the meta-theory contingency theory.

Strategic Choice: The choices that executives make which impact on the strategic direction of the organization. These choices exist as the intended strategies of the organization.

Strategic Decision-Making: The process of making important decisions (usually made by the top management team) to put executive choices into action by implementing strategies.

ENDNOTE

[1] There are a number of conjoint analysis methods, which can be used to test executive judgments. Each of the methods uses a variation of regression to decompose an executive's judgment. The most appropriate for evaluating executive judgments is metric conjoint analysis. For example, Priem (1994) used metric conjoint analysis to examine the judgments of CEO's in manufacturing firms. The outcome of this research was that the executives in manufacturing firms often make contingent judgments, regarding key strategy variables.

Explicit and Tacit Knowledge: To Share or Not to Share

Iris Reychav
Bar-Ilan University, Israel

Jacob Weisberg
Bar-Ilan University, Israel

INTRODUCTION

The question of whether or not it is "worthwhile" for employees to share their knowledge has received a great deal of attention in the literature, which focuses on the technological factors that motivate knowledge sharing (Duffy, 2000). However, the ethical aspect regarding the question of knowledge ownership is discussed in only a partial way in Wang's (2004) model, where he examines employees' desire to share (or not to share) the knowledge they possess. This internal conflict is based on employees' having to choose between their own personal interests and their ethical understanding about organizational ownership of all employee-based knowledge. This article will elaborate on and examine the implications of knowledge sharing at the individual level. Employees, who manage to find the balance between their own personal interests and their ethical understanding about organizational ownership of employee-based knowledge, will engage in a high rate of knowledge sharing activities in the organization.

Goals of Managing Organizational Knowledge Sharing. An organization's desire to manage its knowledge sharing activities is based on the need to capture, catalog and store the organization's knowledge and transform it into knowledge that is both easily and immediately accessible to the organization and its members (Gupta & Govindarajan, 2000). The goal of knowledge sharing is to support and encourage the creation, transference, application and use of knowledge within the organization (Reychav & Weisberg, 2005). Scholars, researchers and practitioners alike express an increasing interest in the subject of organizational knowledge sharing between the individual employee and the organization, and among employees themselves (Almashari, Zairi, & Alathari, 2002).

Types of Knowledge. One of the classifications of organizational knowledge differentiates between two types of knowledge: *explicit knowledge* and *tacit knowledge* (Polanyi, 1958); *explicit knowledge* represents the knowledge that is accessible to all organization employees, while *tacit knowledge* represents the personal knowledge possessed by individual employees. Organizations seek to obtain employees' tacit knowledge and convert it into explicit knowledge, which can then be easily transferred to the organization's technological systems and networks. In this manner, the knowledge is distributed throughout the entire organization (Inkpen & Dinur, 1998; Ruppel & Harrington, 2001), thereby increasing the organization's human capital (its employees).

Conflicts of Interest. Organizations invest in developing their human capital (Nahpiet & Ghoshal, 1998). As a result, employees expand their knowledge and expertise in order to create a personal competitive advantage within the organization and the market (Carlile, 2002). Knowledge is a resource and individuals who possess knowledge use it to acquire positions of power and control both within the organization and outside of the organization. Therefore, organizations that attempt to gain their employees' knowledge (mainly of the tacit type) and make it accessible may, in the process, create a conflict of interests between the individual who possesses the knowledge and the organization that is interested in acquiring this knowledge (Storey & Barnett, 2000).

Hence, the main question is: Why would employees be motivated to share their personal knowledge with the organization at the risk of losing their relative power and advantage over the organization and the market? This question is even more complicated in light of the employee's other conflicting considerations: the understanding that the organization has ownership rights over the personal knowledge the employee acquires while employed by the organization, conflicting with employees' desire to realize their own personal interests by achieving a position of power/status.

The advancement and development of information and communication technologies have expanded organizations' formal capabilities regarding knowledge transference (Jarvenpaa & Staples, 2001). These technologies have also served to encourage the organization to centralize and control their information, based on the perception that knowledge belongs to the organization (Brynjolfsson, 1994). However, as soon as the organization is interested in and begins to operate according to norms and procedures, including the use of technological tools to transfer organizational knowledge, conflicts may arise within the organization at the employee level. These conflicts most often involve employees who possess a significant amount of organizational knowledge.

These employees may experience a conflict when they realize that they have to disseminate and store their knowledge within the organization in order to achieve a competitive advantage in the market at the risk of losing their own personal power and status within the organization (Jarvenpaa & Staples, 2001).

On the one hand, the accepted norm regarding knowledge sharing in organizations claims that all knowledge, such as ideas, processes, innovations, documentation, and computer programs developed and created by employees during their time of employment with the organization, belongs to the organization rather than to the individuals who initiated it (Constant, Kiesler, & Sproull, 1994).

This concept isn't stated in any contract or agreement signed between the employee and the organization, but is implied and understood through the organization's ethical values system, based on the idea that organizational knowledge is an asset that belongs to the organization.

On the other hand, the tacit knowledge residing within the sole control of an individual employee is considered personal knowledge of a specific type, as it is based on the subjective understanding, intuition, feelings, ideals, experience, values and emotions rooted in the individual (Polanyi, 1966, p.7).

BACKGROUND

Explicit knowledge, characterized by structured and constant knowledge, may be documented and distributed through technological systems and networks (Duffy, 2000; Martensson, 2000). Technological tools, such as the Internet, computerized libraries, documentation systems, and electronic group applications, all contribute to the transfer of knowledge within organizations (Tampose, 1996). However, the main contribution of these technological tools is to increase the compatibility of diverse organizational factors by reducing physical and personal constraints (DeLong, 1996). Even so, the existence of technological tools in an organization doesn't necessarily mean that employees will utilize them for the purpose of sharing knowledge. The extent of the actual use of technological tools depends upon the extent of the employees' motivation to utilize the technology (O'Dell & Grayson, 1998). Therefore, organizations have begun to understand that technology isn't a complete solution to knowledge sharing problems, because the way to promote knowledge sharing is to focus on the direct factors that effect employee behavior (Poole, 2000).

Ethics and Knowledge Sharing. Employees' ethical perceptions regarding the organization's ownership of its employees' knowledge affects their tendency to share their explicit knowledge with the organization. On the other hand, employees' willingness to share their tacit knowledge is based on their personal interests and the social and economic benefits they receive in exchange for sharing knowledge (Constant et al., 1994). Employees' transfer of tacit knowledge in the organization, based on their experience and expertise, may stem from a variety of considerations regarding personal interests, according to which employees believe that their explicit knowledge belongs to themselves, rather than to the organization. Organizations frequently engage in knowledge transfer that relates to technical aspects of the organization; this serves as an example of standards or documents that characterize products or services produced by the organization. This type of knowledge transfer is an accepted ethical activity of knowledge owned by the organization.

Knowledge: Organizational or Employee Ownership? The term "ownership" is widely used in the fields of law (Boyer, 1981), philosophy (Locke, 1978) and psychology (Markus, 1984). The distinction between organizational and employee ownership of knowledge was first presented by Jarvenpaa and Staples (2001).

1. **Organizational ownership of knowledge and expertise-related assets:** An employee's understanding regarding organizational ownership of knowledge-based assets mainly relates to the employee's explicit knowledge, which may be easily identified by the organization. Social Identity Theory can explain employees' ongoing behavior regarding the transfer of knowledge to the organization as being based on employees' desire to fulfill the goals of the organization they belong to (Tyler, 1999). Employees view their colleagues as necessary sources of information upon which completion of organizational tasks depend. Therefore, coworkers turn to one another in order to receive direction and guidance. Employees' feelings of belongingness and identification about their organization affect their level of knowledge sharing within the organization.
2. **Employee ownership of knowledge and expertise-related assets:** Employees' willingness to share their knowledge with the organization can be explained by two classical psychological theories:
    a. **Association theory:** Numerous psychological studies dealing with employee ownership of knowledge are based on Association Theory (Heider, 1958), which states that the individual who worked to create the knowledge asset and who, ultimately, controls the knowledge in the present time and also in the past, is the one who "owns" that knowledge asset. This theory suggests that because employees create the knowledge, they also own that knowledge. A good example of this differentiation between ownership and knowledge is conceptualized by

the subject of ownership rights and organizations' intangible assets. In the U.S., intangible assets are listed under the name of the individual employee who created the idea; however, the organization reserves the right to use this asset freely, without incurring any additional obligation toward that employee. From a legal standpoint, the organization's use of the knowledge asset in no way undermines the ownership rights of employees who have created that knowledge. On the contrary, employees' personal ownership of the knowledge they possess or create serves to increase their own feelings of self-worth as well as their sense of value and contribution to the organization.

b. **Exchange theory:** The idea of exchange relationships among organizational members was first presented in Homan's (1958) study. This study defined a *social exchange relationship* as a tangible activity or activities between at least two parties, which cannot be clearly identified and is based on the receipt of mutual reward. Furthermore, the idea of exchange relationships became a leading principle in psychological theory (Thibaut & Kelley, 1959) and was used to predict behavior by noting the behavioral characteristics of parties participating in exchange relationships.

Additional studies expanded the idea of exchange relationships to a more general approach, which included relationships between an individual and others within the same social network (Emerson, 1962). The idea of "exchange" crystallized into what Blau (1964) called Exchange Theory, which discusses employees' expectations to receive economic and social benefits as a reward for their contribution in exchange relationships with other organization members (Blau, 1964).

The Theoretical Model. According to the Association Theory described above, it seems that the employees, who are the owners of the knowledge, will hesitate to share their knowledge with the organization. However, from the employees' point of view, understanding the results that stem from sharing their knowledge may serve to increase their knowledge sharing behavior in order to achieve maximum benefits, in accordance with Blau's Exchange Theory.

This article presents a two-phase, multidimensional model (see Figure 1), which describes the considerations that motivate employees' willingness to share knowledge, actual knowledge-sharing activities, and the resulting outcomes at the employee level. In addition, employee involvement in the organizational knowledge sharing process is also discussed.

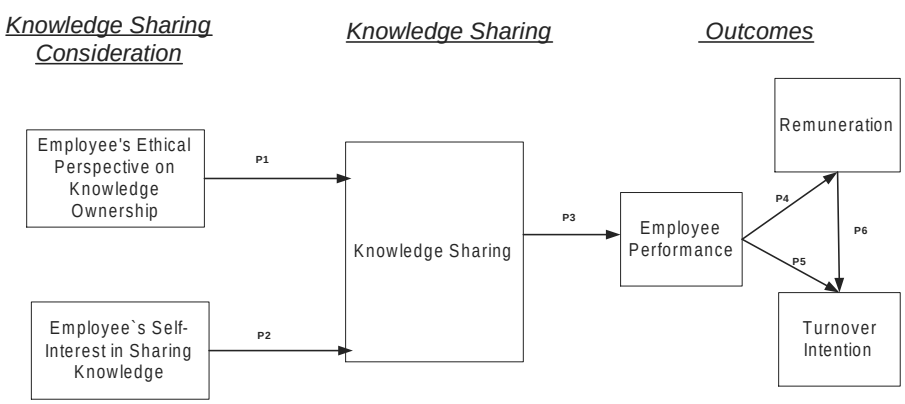
Phase 1: Knowledge-Sharing Variables

In its first phase, the model attempts to examine two seemingly contrasting affects:

A. The employee's ethical perception of organizational ownership regarding the knowledge created within the framework of the organization.
B. The effects of the employees' personal interests on their willingness to share knowledge with the organization.

Knowledge Ownership and Personal Interests. The organization desires to manage all organizational knowledge in such a way as to ensure its immediate accessibility to all

Figure 1. The impact of employee ethical perception and self interest in knowledge sharing on organizational outcomes



organization members. In contrast, employees express an interest to use the organizational knowledge they possess to realize personal goals such as achieving personal power/status within the organization.

The connection between employees' personal ownership of knowledge and that of the organization reveals that the more employees believe in their personal ownership of the knowledge asset, the more their trust regarding organizational ownership of that same knowledge increases (Jarvenpaa & Staples, 2001). In other words, the combination of the ethical perception about organizational ownership of employee knowledge and employees' personal interests affects employees' behavior regarding their desire to help achieve organizational goals.

Therefore, we suggest the following proposition:

Proposition 1: Employees' perception that knowledge acquired within the organization belongs to the organization is positively related to their intention to share knowledge.

Employees' willingness to share knowledge may be based on personal interests that focus more on protecting both their source of power/status and their advantageous position within the organization. Employees develop economic and social exchange relationships with the organization in an attempt to maximize their own personal interests within the organization (Culnan & Armstrong, 1999; Kim & Mauborgne, 1998). Therefore, we suggest the following proposition:

Proposition 2: Employees' feelings that they can maximize their own personal interests by sharing knowledge within the organization are positively related to their intention to engage in knowledge sharing.

Organizational Knowledge Sharing Processes. There are two processes by which employees share knowledge; these two processes take place simultaneously (Reychav & Weisberg, 2005). The first is the transfer of knowledge from the organization to its members (**knowledge transfer**), while the second is **knowledge exchange** among organization members.

Knowledge sharing processes were further expanded into three knowledge-sharing categories (Reychav & Weisberg, 2006), which include:

1. The transfer of explicit knowledge from the organization to its members: The explicit knowledge transfer process takes place within the framework of a one-directional learning process between the organization and the employee and among organization members;
2. The transfer of explicit knowledge from employees to the organization: The sharing of explicit knowledge is considered an ethical activity that takes place among organization members out of their commitment to their workplace (Jarvenpaa & Staples, 2001, p. 153); and
3. The conversion of tacit knowledge into explicit knowledge and its dissemination among organization members: The tacit knowledge transfer process takes place among organization members and is based on the conversion of tacit knowledge into explicit knowledge. This process reflects employees' considerations concerning their personal interests (Wang, 2004). When employees' feelings regarding knowledge ownership are positive, and when they identify their own personal interests as being similar to those of the organization, their belief that the knowledge they possess actually belongs to the organization increases (Jarvenpaa & Staples, 2001).

Phase 2: Knowledge Sharing Outcomes

In its second phase, the model suggests the implications of knowledge sharing at the individual level and as it relates to the organization's accumulated knowledge as a whole. In the current article, we propose an expansion of Wang's (2004) model, which focuses solely on the factors that contribute to employee knowledge sharing. In an organization, the more knowledge employees share, the more it has a direct effect on achieving better individual performance and, as a result, better organizational performance.

Knowledge Sharing and Performance. Prahalad and Hamel's (1990) studies have focused on the link between organizational knowledge and performance and consider organizational knowledge to be one of the most important developing abilities an organization can possess. Organizational knowledge is an intangible asset (Itami & Roehl, 1987) and can significantly affect organizational performance (Schoemaker, 1992).

The transfer of knowledge among an organization's business units significantly contributes to improving their performance (Darr, Argote, & Epple, 1995; Szuanski, 1996). The knowledge gathered through correct knowledge management in an organization leads to improved organizational performance. These improvements then serve as a way to measure how efficiently the organization is utilizing its knowledge (Dess & Shaw, 2001; Egan, Yang, & Bartlett, 2004). Therefore, we suggest the following proposition:

Proposition 3: Employees' level of engagement in knowledge sharing activities is positively related to their performance level.

From the organization's point of view, explicit knowledge sharing has a positive affect on organizational performance (Almashari et al., 2002). This type of knowledge sharing is based on an ethical values system, which includes standards

founded on trust and commitment between the organization and its members. This ethical values system is also clearly defined within the framework of the official work contract signed by both the organization and the employee. From the employees' point of view, considerations relating to personal interests may prevent employees from sharing their knowledge, especially in a competitive work environment where an employee's performance is judged in comparison with the performance of other employees. This strategy attempts to motivate employees to improve their performance in comparison with that of their coworkers, in exchange for future economic or social remuneration from the organization (Wang, 2004).

Performance and Remuneration. Receiving remuneration based on high performance levels is linked to high productivity and quality levels (MacDuffie, 1995). Applebaum, Bauley, Berg and Kallenberg (2002) found a positive connection between receiving remuneration for successful performance and developing a sense of commitment and trust on the part of the employee. This link between an employee's participation in organizational processes and receiving remuneration is presented at several levels: personal, group, and intergroup (Bartol & Srivastava, 2002). Therefore, we suggest the following proposition:

Proposition 4: Employees' performance is positively related to the remuneration they will receive.

Performance and the Intention to Leave. Today's knowledge-based organizations concentrate on identifying "knowledge workers" who can help develop and strengthen organizational relationships (connections through which knowledge can be distributed and that contribute toward improving employee performance within the organization (Capelli, 2000). Employees' increased involvement in improving organizational performance prevents the feelings of responsibility often experienced by employees toward the organization that motivate their desire to help other employees and the organization in general (Blau & Boal, 1987). Therefore, we suggest the following proposition:

Proposition 5: Employees' performance level is positively related to their intention to leave the organization.

Remuneration and the Intention to Leave. Receiving economic and social remuneration both affect employees' tendencies to leave in the following ways:

1. Receiving material remuneration: Organizations that adopt and engage in profit-sharing programs with their employees are known to have a smaller turnover rate (Azfar & Danniger, 2001).
2. Receiving nonmaterial remuneration: Nonmaterial remuneration is expressed in appreciation and promotion within the organization, which may lead to increased employee involvement and a decrease in his or her intention to leave (Faraj & Sproull, 2000). Therefore, we suggest the following proposition:

Proposition 6: Employees' remuneration is positively related to their intention to leave.

FUTURE TRENDS

Great importance is placed on understanding the conflict existing between the organization and the employee and the organization's attempt to help employees find a positive balance between their personal interests and the interests of the organization.

In the future, organizations will need to take the importance of the "human factor" in management more into consideration. As a result, there will be an increased tendency to allocate the necessary resources needed to preserve and protect the organization's "human capital." As a result, this human capital will have a more significant bearing on employees' organizational knowledge sharing.

The current article presented an empirical study comprised of direct factors motivating employees to engage in knowledge sharing activities within the organization. These factors relate to the combination of personal interests and ethical perceptions regarding organizational ownership of employees' knowledge. We believe this combined understanding can lead to increased knowledge sharing within organizations, while the documentation and retrieval of explicit knowledge on the part of the employee will also increase.

Future research studies should attempt to examine the effects of culture, industry, Hi-Tech and Low-Tech on different firms' willingness to share their knowledge with other firms in the market. Collaborative knowledge sharing among firms may be the basis for significant technological breakthroughs and meaningful changes in the social and economic values systems we are currently familiar with.

CONCLUSION

"Is it truly worthwhile for employees to share their knowledge with their organization?" This question has been widely discussed in the literature that focuses on knowledge management and sharing in organizations. In particular, the emphasis has been on motivating employees to share their knowledge by utilizing technology and computerized tools and systems (Hoff & Weenan, 2004; Hulpic, Pouloudi, &

Rzevski, 2002). Nevertheless, it appears that technological tools have a rather insignificant and indirect effect when it comes to motivating employees to create and transfer knowledge (O'Dell & Grayson, 1998). The current article combined employees' perceptions about organizational ownership over employees' knowledge, on the one hand, and employees' personal interests, on the other, as having an influence on knowledge sharing within the organization.

Knowledge retention is based on the ethical behavior of those individuals who share information, ideas, suggestions, expertise and experience. Knowledge sharing among organization employees is identified as an ethical and necessary activity in order to complete business activities and tasks within the organization. The employee's decision to interact with other members is directed by the organization's ethical values system, which encourages employees to share their knowledge in order to preserve the organization's accepted values system.

Considerations regarding personal interests and whether or not knowledge sharing is worthwhile motivate employees to share their knowledge with the organization and their coworkers, based on a desire to receive economic or social remuneration. The distinction described in the current article between knowledge sharing processes and the factors that motivate an employee's considerations and decisions based on ethical aspects and personal interests is necessary in defining appropriate strategies for managing organizational knowledge-sharing processes.

Wang, C.C. (2004). The influence of ethical and self-interest concerns on knowledge: An empirical study. *International Journal of Management, 21*(3), 370-381.

KEY TERMS

Ethics: Ethics permits a system of moral standard or values (Wang, 2004). Ethical concerns permeate all human actions and interaction that arise in connection with core values as honesty or justice (Kakabadse, Kakabadse, & Kouzmin, 2002).

Human Capital: Human Capital is a combination of employee's education, training, experience (Becker, 1964).

Knowledge: Knowledge is an organized combination of ideas, rules, procedures, and information (Marakas, 1999, p.264).

Knowledge Management: Knowledge Management is an economic view of the strategic value of organizational knowledge that facilitate the acquisition, sharing and utilization of knowledge (Smith & Lyles, 2003, p.12)

Knowledge Sharing: Knowledge Sharing is an exchange or transfer process of facts, opinions, ideas, theories, principles and models within and between organizations include trail and error, feedback and mutual adjustment of both the sender and receiver of knowledge (Szulanski, 1996).

Organizational Knowledge: Organizational knowledge is equated with professional intellect (Quinn, Philip, & Sydney, 1996). Organizational knowledge is a metaphor, as it is not the organization but the people in the organization who create knowledge.

Organizational Norms: Organizational Norms is a set of rules for human behavior in the organization. Organizational Norms regard information sharing as usual, correct and socially expected work place behavior (Constant et al., 1994, p.404; Jarvenpaa & Staples, 2001, p.153).

Tacit Knowledge: Tacit knowledge is knowledge that has not been formalized or cannot be formalized or made explicit (Nonaka & Takeuchi, 1995). Tacit knowledge is based on the individual's subjective insights, intuitions and is deeply rooted in actions experience, ideals, values and emotions (Polanyi, 1966).

Exploiting Context in Mobile Applications

Benou Poulcheria
University of Peloponnese, Greece

Vassilakis Costas
University of Peloponnese, Greece

INTRODUCTION

Pervasive computing is nowadays becoming a reality, exploiting the capabilities offered by both computing infrastructure and communication facilities. The pervasive computing environment encompasses a multitude of diverse devices, operating systems, protocols, and standards. It includes mobile devices such as cellular phones, smart phones, PDAs, and handheld computers for information access, smart cards, and smart labels for identification and authentication, smart sensors, and actuators that perceive the surroundings and react accordingly. Voice technologies such as automatic speech recognition (ASR), text to speech (TTS) and VoiceXML enable the construction of convenient user interfaces and Web services are a key mechanism for interoperability. Wireless wide area networking allows long distance communication through cellular radio while wireless local and personal area networking and standards such as the Wi-Fi, Bluetooth and IrDA allow short distance communication through radio waves and infrared beams.

In the mobile and pervasive computing environment, software engineering should not treat diversity and mobility as problems to overcome, but seek methods of which it could take advantage instead. In these environments, the selection of purpose-oriented and timely information, tailored to user preferences and media characteristics will ensure optimised information delivery. To this end, the context—the information that surrounds the human-computer interaction—plays a key role and is rapidly changing in mobile settings, and the understanding of it is indispensable for application designers in order to choose, capture and exploit it. The importance of the context is to use it to make context-aware applications, that is, those applications that are interested in who, where, when and what, in order to determine why the situation occurs and adapt their behavior accordingly.

BACKGROUND

The Concept of Context

An important dimension of mobile computing is "mobility", which is primarily concerned about people moving in space and doing their personal, social and professional activities in a wide temporal space. The informative support of the mobile user can be accomplished through terminals, which are movable and operate regardless of the location and time and offer wireless access to information and services. Although mobility—spatial and temporal—is an important aspect of mobile computing, it constitutes only one dimension of the "context".

The term "context" is defined as "the interrelated conditions in which something exists or occurs" in Merriam-Webster's dictionary. In the domain of context-aware computing, researchers have defined context as "location, identities of nearby people and objects, and changes to these objects" (Schilit & Theimer, 1994), "location, identities of the people around the user, the time of day, season, temperature, etc." (Brown, Bovey, & Chen, 1997) and "knowledge about the user's and the device's state, including surroundings, situation and location" (Schmidt & Laerhoven, 2001).

Dey and Abowd (1999) propose a more generic definition according to which context is any information that can be used to characterize the situation of an entity. An entity is a person or object that is considered relevant to the interaction between a user and an application, including the user and the application themselves. Dey's definition is more comprehensive and generic and makes it easier for an application designer to enumerate the context for a given application and choose the appropriate desirables.

The contextual information can be classified, according to which entity it concerns, into the following categories (Schilit, Adams, & Want, 1994):

- **User Context:** User identity, location, collection of nearby people, social situation, activity, user's profile, and so forth.

- **Computing Context:** Hardware characteristics, software characteristics, network connectivity, communication bandwidth, nearby resources such as printers, displays and other devices and so forth.
- **Physical Context:** Lighting, noise level, temperature, humidity, and so forth.
- **Time Context:** Time of the day, week, month, season of year, time zone, and so forth.

Orthogonally to these classifications, context can be divided into two broad classes: *primary* and *secondary context*. Primary context derives directly from sensors or information sources while secondary context is inferred from the primary context. For example the name of a city is a secondary context because it derives from GPS coordinates through a relation mechanism.

Context can be also distinguished according to a range of temporal characteristics and it can be classified as *static* or *dynamic*. Static context does not change very quickly (or at all; e.g., a person's date of birth), while dynamic context does (e.g., the location of a person who is driving). When applications are not only interested in the current state of the context (*present context*), but past context is of importance too, *context histories* are stored; in some situations there is a necessity for context prediction (*future context*).

The interactions between context sources and context sinks can be characterized as "context push", when the context sources update periodically context information in context sinks and "context pull", when the sinks demand information from the context sources.

The types of context, according to the manner of its acquisition, can be divided in three categories:

- **Sensed context:** This context is acquired from the environment by means of physical or software sensors (identity, temperature, time).
- **Derived context:** This kind of contextual information is computed (for example the name of the city from GPS coordinates).
- **Context explicitly provided:** The context that the user provides explicitly (for example the entries in the user profile).

Defining Context-Aware Applications

Context-awareness is a concept that consists of two notions: the notion of perceiving the *context* and the adaptivity that derives from the awareness. Adaptivity or adaptability is defined as the ability of a service/application to react to its environment and change its behavior according to the context. Context-aware computing was first introduced by Schilit and Theimer (1994) as the use of software that adapts according to the location of use, the collection of nearby people and objects, as well as to changes to such elements over time. Fickas, Korteum, and Segall (1997) define context-aware applications (called environment-directed) as applications that monitor changes in the environment and adapt the operation according to predefined or user-defined guidelines. Dey and Abowd (1999) characterize a system as context-aware if it uses context to provide relevant information and/or services to the user, where relevancy depends on the user's task.

The functions that a context-aware application should implement (Schilit et al., 1994) are:

- **Proximate selection:** A user interface-level technique where the nearby located objects are emphasized or otherwise made easier to choose.
- **Automatic contextual reconfiguration:** A process of adding new components, removing existing components, or altering the connections between components due to context changes.
- **Contextual information and command:** Queries on contextual information can produce different results according to the context in which they are issued. Similarly, context can parameterize "contextual commands".
- **Context-triggered actions:** "If-then" rules used to specify how context-aware systems should be adapted.

Dey and Abowd (1999) propose that the features that context-aware applications may support are:

- **Presentation** of information and services to the user or use context to propose appropriate selections.
- **Automatic execution** of a service according to context changes.
- **Tagging of context** to information for later retrieval.

Related Work

The first context-aware system was the Active Badge System developed at Olivetti Research Lab. In case an employee on duty was not in his office, this would direct phone calls to the closest appliance according to the employees' location in the office environment. An evolution of this system is the ParcTab system, which was developed at the Xerox Palo Alto Research Center, relied on PDAs to offer a range of context-aware office applications (Schilit et al., 1994). Besides the above projects, a number of efforts have resulted in context-aware applications that can be categorized as follows (Dockhorn, 2003):

- **Conceptual frameworks:** They focus on the architectural aspect of context-aware systems and introduce methods of gathering, interpreting and disseminating

context to the interested parties. Examples of this approach are the projects: Context Toolkit by Georgia Institute of Technology (Dey, Abowd, & Salber, 2001) and Cooltown by Hewlett-Packard (Kindberg et al., 2002).

- **Service platforms:** They allow the rapid creation, deployment, and dynamic discovery of services, in order to provide the appropriate functionality according to user context. Examples of service platforms are the M3 architecture from the University of Queensland (Indulska, Loke, Ratotonirainy, Witana, & Zaslavsky, 2001) and the Platform for Adaptive Applications from the Lancaster University (Efstratiou, Cheverst, Davies, & Friday, 2001).
- **Appliance environments:** They try to support interoperability among collections of appliances. Examples of such environments are the Ektara environment from MIT (DeVaul & Pentland, 2000) and the Universal Information Appliance from IBM (Eustice, Lehman, Morales, Munson, Edlund, & Guillen, 1999).
- **Computing environments:** They provide context-aware computing that decouples users from devices and enables applications to perform tasks on behalf of the user. Projects of this category are the PIMA by IBM (Banavar, Beck, Gluzberg, Munson, Sussman, & Zukowski, 2000) and Portolano by the University of Washington (Esler, Hightower, Anderson, & Borriello, 1999).

AN ARCHITECTURE FOR CONTEXT-AWARE MOBILE APPLICATIONS

The Requirements

The dynamic environments, in which the mobile applications operate, constitute a challenge in order to propose a new software architecture that exploits the context and facilitates the design of applications which enhance the user's mobile experience with suitable services.

The requirements that have to be met by such an application are:

- **Capture** contextual information from sensors and users.
- **Store** part of the contextual information for later exploitation.
- **Interpret** information, at an abstract level, in order for it to be more meaningful.
- **Transit** the information to the application modules.
- **Adapt** the application behavior according to the context.

The main goal of our approach is the adaptation process, which consists of two components: first, the design of an architecture which supports adaptation at run-time and secondly, the provision of design of the core application itself in order to be context-aware. One evident question concerning the adaptation, is "which are the real adaptation tasks that a context-aware mobile application has to implement?" Placing the end-user in the middle of the concern, thus employing a user-centered approach (Vredenburg, Isensee, & Righi, 2001), the adaptation operation (Kappel, Retschitzegger, & Schwinger, 2001) should consist of the following:

- **Content adaptation:** Determine which content elements are hidden or revealed according to context changes.
- **Operation adaptation:** The choosing of and switching between the functional components of a service/application according to the context.
- **Presentation adaptation:** The tailoring of the system's user interface and interactive behavior to the individual needs of the user and system capabilities.

Another issue with regard to the adaptability that should be decided is "where the adaptation process to the context takes place". It could occur (1) within the application and it is *called laisser-faire adaptation*; (2) exclusively outside the application, called *application transparent adaptation*; and (3) within the application as well as out of it, called *application-aware adaptation* (Satyanarayanan & Ellis, 1996). Our approach adopts the application-transparent adaptation, since mixing context management code with the application code renders the application code more complex, difficult to maintain and impossible to reuse. This indicates the decoupling of context-independent activities of the application from the contextual concerns, as well as the separation of contextual data from the application's data.

In the following paragraphs, we first present context modelling, which is a required underpinning for any context-aware application and subsequently present our proposed framework that satisfies the above requirements.

Context Modeling

One of the major issues in context-aware applications is the representation of context, in such a way that facilitates the context reasoning and sharing. Insofar a lot of context models have been proposed, some based on proprietary representation schemes and others on more formal data models.

The existing context models belong to one or more of the following categories:

- **Key-value models:** The simple key-value data structures, which were first introduced by Schilit, Theimer,

and Welch (1993) in PARC's mobile computing environment. This representation provides a fast and easy way to set and update context but it is only feasible in situations where (key, value) pairs obtained from the environment exactly match those in the model; for example, the pair (temperature, 50) matches itself only, while it does not match the pair (temperature, 50.1). Moreover, this model lacks any structure and is thus difficult to manage when the number of keys and/or values increases.

- **Web-based model:** In this context model, each entity (person, place, or thing) corresponds to an unstructured web page, retrieved via a URL. The Cooltown project (Kindberg et al., 2002) relies on this model, which is intended to be used by humans rather than by applications.
- **Markup schemes models:** Using markup languages—such as XML—is another method to model contextual information in a flexible and structured manner. Profiles are a typical example of this kind of context modeling approach. For example, CC/PP (composite capabilities preferences profile) is an RDF-based framework (resource description framework) to describe user preferences and devices' capabilities and characteristics. However the usage of profiles for context representation becomes difficult when the relationships and constraints of context are complex. The models under this category are extensions to the above standard, with no fixed hierarchy and try to cover the higher dynamics of contextual information.
- **Object-oriented models:** They are based on an object-oriented approach in which context information is structured around a set of entities. This modeling often uses a variation of the Entity Relationship model and stores the contextual information in relational databases. Although the object-oriented models employ the benefits of encapsulation and reusability, they are usually designed for a specific context domain.
- **Ontology-based models:** Ontologies are believed to be the most suitable model for the representation and reasoning of context information, for the following reasons (Mokhtar, Fournier, Georgantas, & Issarny, 2005): (1) they enable knowledge sharing through a common set of concepts, (2) they allow efficient reasoning so as to deduce high-level from low-level context and (3) they enable interoperability.

The Context-Aware Architecture

The overall proposed system architecture is depicted in Figure 1, while its operation and individual modules are discussed in the following paragraphs.

Context Manager

The *context manager* is the system module that is responsible for the capturing of the context from different sources, the interpretation of it in a higher level format, the storage of the context and the distribution of it to the *adaptation manager*.

The *context gatherer* subsystem is in charge of the capturing of context either from hardware sensors (e.g., location sensors, identification sensors, motion sensors, etc.) or software sensors (processing power, available hardware components, storage systems, software components, current time, etc.) or through the import of relevant profiles. These profiles could be:

- **User profile:** It contains information about the user and his/her desired application's features. User-pertinent data could be his/her name, date of birth, address, occupation, hobbies, available technical equipment, billing plans, activities over time, etc. Computer-relevant data could be application-independent, like font size, preferred language, content characteristics (e.g., text, audio or video), or application- dependent, like the kind of stocks for which the user wishes to be informed when price changes occur.
- **User agent profile:** It describes the capabilities of devices e.g. display size, memory, operating system, browser characteristics, etc.
- **Network profile:** It describes network characteristics like supported bandwidths, bearer type and so forth.
- **Application profile:** It holds application-specific information, which can be used for dynamic composition of modules from distinct services.

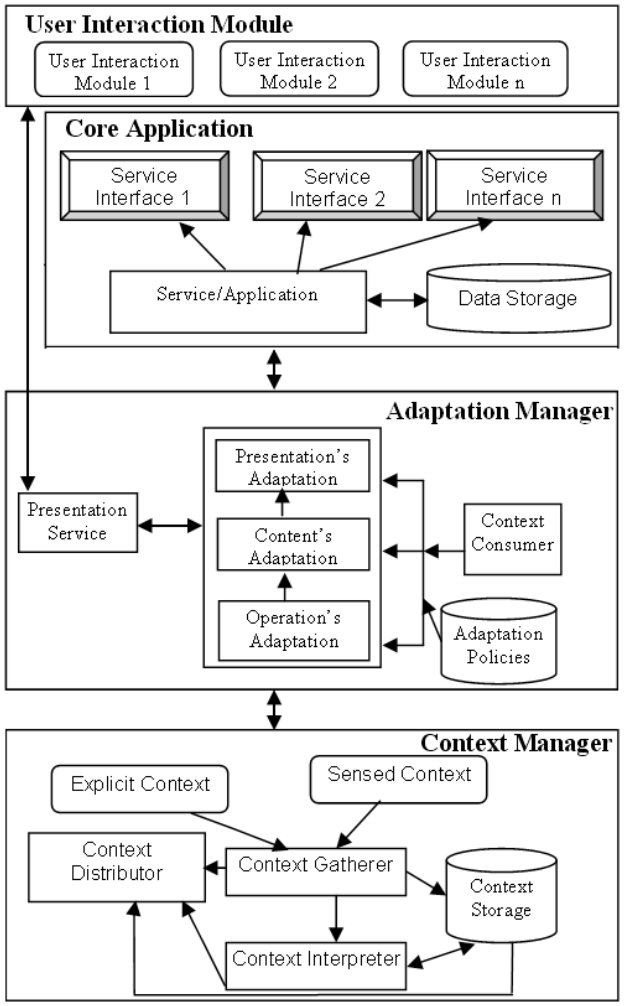
The *context interpreter* gathers information from *context gatherer* and *context storage* and conducts aggregation and inference activities. The resulting context is either passed to the *context distributor* or stored to the *context storage* for later retrieval.

The *context distributor* makes contextual information uniformly available to the *adaptation manager*. It provides information in two different modes: *request-response* and *event triggered*, supporting the "push" and "pull" character of the context. In *request-response* mode it grants context only on explicit request while in *event triggered* mode the provision of context is fired from specific events.

Core Application

The *core application* consists of a number of services that materialize the desired functionality. These services are not context-aware and their behavior remains the same in the different context situations. Furthermore these services expose their functionalities in a number of distinct and predefined

Figure 1. System architecture



alternatives called *service interfaces* (e.g. multimedia or plain text version) in order to support the diverse preferences during the operation adaptation process.

Adaptation Manager

The adaptation process occurs explicitly in the boundaries of the *adaptation manager* and could be accomplished through three concrete steps: the operation, the content and the presentation adaptation. The *adaptation policie*s repository contains the adaptation rules according to which the adaptation process takes place (e.g., *If* condition *x* is met *then* message *y* is triggered). The *presentation service* is the particular instance of a specific adaptation operation which is forwarded to the *user interaction module3.*

The *operation adaptation module* carries out the service's composition, which is the process of collecting the suitable application services in the desired version. These services are matched according to the adaptation rules, which depend on the context situation. The context data are passed as input to this process.

The *content adaptation module* materializes the *content adaptation* that follows the *operation adaptation*. It makes the choice of the appropriate content, the language, the compression of data etc, in order to suit the client's display characteristics, network capabilities and user preferences.

The *presentation adaptation module* conducts the *presentation adaptation* that occurs after the *content adaptation*. It makes the transcoding and the modality transformation with a view to satisfying the clients' claims.

The *context consumer* is the bearer of the context to the *adaptation manager*. Additionally the services subscribe to it, in order to be informed by the "push" notifications upon context changes.

User Interaction Module

The user interaction module presents data and selection choices to the end user in different modalities. The adaptive user interfaces have been produced as a result of the adaptation process, considering both individual needs and changing conditions in the application environment.

In many existing projects in the area of context-aware computing, capturing and implementation of context have been made in an ad-hoc and per application manner. In the proposed architecture the management of the context is encapsulated in a single module (context manager) and it may be reused from any other application; moreover, it can evolve to include other aspects of context that have not yet been foreseen and determined. The implementation of context adaptation logic (adaptation manager) can be supported by utilizing the aspect-oriented paradigm and reflective programming techniques, which assist in managing cross-cutting concerns and dynamically discovering and invoking functionality, respectively.

FUTURE TRENDS

Although research has addressed a number of issues related to context understanding, modeling, reasoning and knowledge sharing, further investigation of them is needed to clarify the relevant concepts. Best practices for analysts to elucidate user requirements pertinent to context adaptability and frameworks for designers and implementers that will facilitate the development of context-aware applications should also be surveyed. In the implementation phase, in particular, the ability to separate handling of context-awareness from application logic is highly desirable, since it will decrease the complexity of application development and will make incorporation of context-aware aspects to existing, non context-aware applications easier.

Currently, context-aware services have not been adopted by the masses to the initially anticipated extent. The reasons for this lag need to be surveyed, and feedback from the existing or potential user groups should be collected and analyzed. Social and legal issues as well as privacy and security concerns related to context awareness should be also considered.

CONCLUSION

In this paper, we have discussed the issues of context and context-awareness in the provisioning of mobile services, identified context categories, presented modeling and acquisition techniques, as well as methods of context exploitation. We have presented a generic architecture for supporting context-aware applications, which provides facilities for managing context, performing functional adaptation and tailoring the user interface to suit the current context parameters. The profound understanding of context will facilitate the process of choosing, managing and utilizing it, in order to provide context-aware applications, those ones that deliver the correct service, to the correct user, at the correct place and time, and in the correct format, with the minimum distraction of the user.

KEY TERMS

Adaptivity or Adaptability: It is the ability of a service/application to react to its environment and change its behavior according to the context.

Application-Aware Adaptation: It is the adaptation process to context, which takes place within the application as well as out of it.

Application Transparent Adaptation: It is the adaptation process to context, which takes place exclusively outside the application.

Context: Context is any information that can be used to characterize the situation of an entity. An entity is a person, or object that is considered relevant to the interaction between a user and an application, including the user and the application themselves.

Context-Aware: Context-aware is a system that uses context to provide relevant information and/or services to the user, where relevancy depends on the user's task.

Laisser-Faire Adaptation: It is the adaptation process to context, which takes place inside the application.

Service: It is piece of an information product that materializes a concrete functionality.

Exploiting the Strategic Potential of Data Mining

Chandra S. Amaravadi
Western Illinois University, USA

INTRODUCTION

Data mining is a new and exciting technology to emerge in the last decade. It uses techniques from artificial intelligence and statistics to detect interesting and useful patterns in historical data. Thus traditional techniques such as regression, Bayesian analysis, discriminant analysis, and clustering have been combined with newer techniques such as association, neural nets, machine learning, and classification (Jackson, 2002).

Applications of data mining have ranged from predicting ingredient usage in fast food restaurants (Liu, Bhattacharyya, Sclove, Chen, & Lattyak, 2001) to predicting the length of stay for hospital patients (Hogl, Muller, Stoyan & Stuhlinger 2001). See Table 1 for other representative examples. Some of the important findings are: (1) corporate bankruptcies can be predicted from variables such as the "ratio of cash flow to total assets" and "return on assets," (2) gas station transactions in the U.K. average £20 with a tendency for customers to round the purchase to the nearest £5 (Hand & Blunt, 2001), (3) 69% of dissatisfied airline customers did not contact the airline about their problem, (4) sales in fast food restaurants are seasonal and tend to peak during holidays and special events (Liu et al., 2001), (5) patients in the age group over 75 are 100% likely to exceed the standard upper limit for hospital stays (Hogl et al., 2001). In recent years, data mining has been extended to mine temporal, text, and video data as well. The study reported by Back, Toivonen, Vanharanta, and Visa (2001) analyzed the textual and quantitative content of annual reports and found that there is a difference between them and that poor organizational performance is often couched in positive terms such as "improving," "strong demand," and so forth. Both applications and algorithms are rapidly expanding. The technology is very promising for decision support in organizations. However, extracting knowledge from a warehouse is still considered somewhat of an art. This article is concerned with identifying issues relating to this problem.

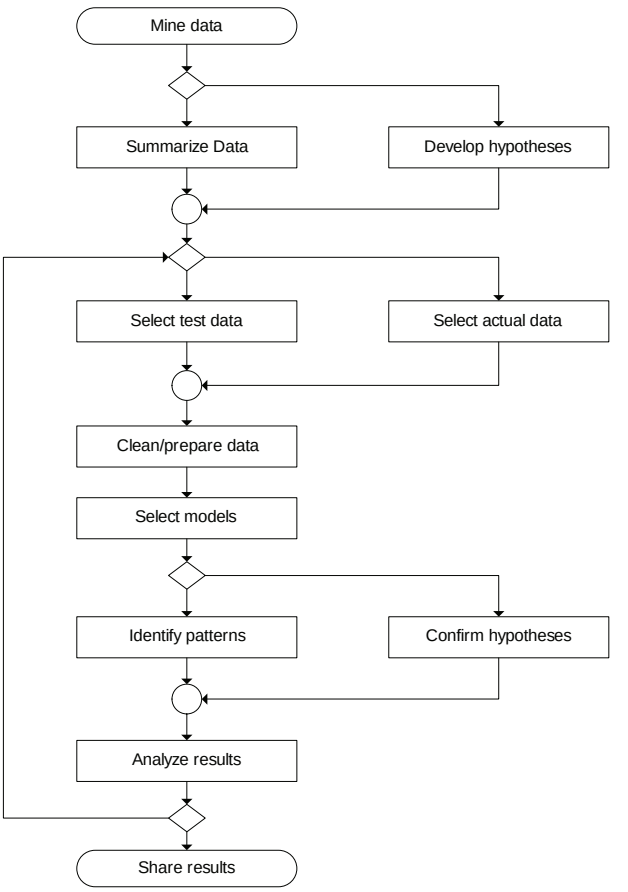
Table 1. Examples of data mining applications

• Predicting supplies in fast food restaurants (Liu, Bhattacharyya, Sclove, Chen & Lattyak 2001).
• Quality of health care (Hogl, Muller, Stoyan & Stuhlinger 2001).
• Analyzing Franchisee sales (Chen, Justis & Chong 2003).
• Predicting customer loyalty (Ng & Liu 2001).
• Mining credit card data (Hand & Blunt 2001).
• Analyzing annual reports (Back et al. 2001).

BACKGROUND

The mining process is often labeled as knowledge discovery in databases (KDD). An extended KDD model is presented in Figure 1. As illustrated in the figure, mining is carried out in two modes: "data-driven" or "hypothesis-driven" ("question-driven"). The *data-driven* approach is also referred

Figure 1. The extended KDD process



to as exploratory data mining and is often carried out to develop a preliminary understanding of the data. As a first step, data are summarized to identify their characteristics. Typical measures such as frequency distribution, mean, variance, and so forth are computed. For credit card data, what is the average monthly spending for customers? What credit card products are most frequently purchased? Based on results from this step, models are selected and the mining is performed.

Hypothesis-driven methods attempt to verify whether or not a particular pattern exists (Hogl et al., 2001). In this mode, the process starts with the identification of hypotheses that are motivated by business concerns. Each hypothesis can be thought of as a micro theory (MT) about the domain or an assumption to be verified.

The space of patterns that can be explored in data mining is very large and is restricted by computational constraints. Large data sets with high dimensionality will preclude data driven methods. Hypothesis driven approaches are more tractable and therefore more appealing. But even with these approaches, organizations still lack the resources to mine all available data. Formulation of good hypotheses is therefore important and will influence data selection.

The mining data are partitioned into a test set and the evaluation set (Jackson, 2002). The test set is generally 10-20% of the actual data. Neural nets and machine learning algorithms typically require more test data. Models developed with the test set are validated with the actual data. In the question driven approach, the required columns are selected depending on the hypothesis to be tested. This is a difficult problem ("curse of dimensionality") in data mining and sometimes referred to as *feature selection*. The large number of attributes such as demographic variables in a warehouse makes data selection a challenging process because the variables contributing to a pattern cannot be known a priori. Selection of irrelevant attributes adds to computational complexity and perhaps even misleading results. At the present time, the best method is trial and error.

Mining starts with data that are often integrated from several sources. Integration can present challenges due to differences in formats or attribute definitions. The data are cleaned and transformed by (Peacock, 1998): (a) checking for file transfer errors, where some of the records are not properly loaded or some of the columns are missing, (b) standardizing formats or codes such as converting from text to numeric codes or vice versa (1-married, 2-single, etc.), (c) dealing with sparse records; missing values are either filled or the record is deleted, (d) performing required calculations such as debt/equity, number of faculty/student, student credit hour per faculty, and so forth, (e) identifying and deleting outliers. Outliers are detected during the process of data summarization.

Data selection is followed by *model selection*. As shown in Table 2, mining techniques are broadly classified into summarization/visualization, clustering, classification, association, and sequence with a choice of algorithms in each. The limitations and conditions of each algorithm have to be borne in mind when selecting a suitable algorithm. For example, the decision tree approach may produce erroneous results for data with small training sets. Similarly, time series analyses are computationally expensive and cannot be effectively carried out on large data sets (Kumar, 2002).

Testing with the model will result in initial results. The test data are iteratively used to refine the model, and the analysis is run on the evaluation set. Results can take the form of cluster plots, dependency rules, regression coefficients, bar graphs, and so forth. These are analyzed to identify patterns and discussed with functional area specialists to ensure that they are meaningful in the organizational context. Findings are then shared.

THE KDD PROCESS AND DOMAIN UNDERSTANDING

Data mining results in the identification of patterns. Identifying those that are relevant and interesting to the organization is dependent on the analyst's skill, experience, and understanding of the *organizational context* of the data. To develop a general understanding of the organization, the analyst can look through the company's annual reports, Web site, and news articles. The analyst can also meet with managers working in the area to become familiar with its goals, objectives, and critical issues. For example, a manager may be concerned about how to improve catalog mailings. Another may be concerned about increasing catalog sales. While this general understanding is critical in KDD activities, the analyst must also develop a detailed understanding of the data, that is, the relationships among variables. We will discuss the relationship between important KDD activities and this understanding.

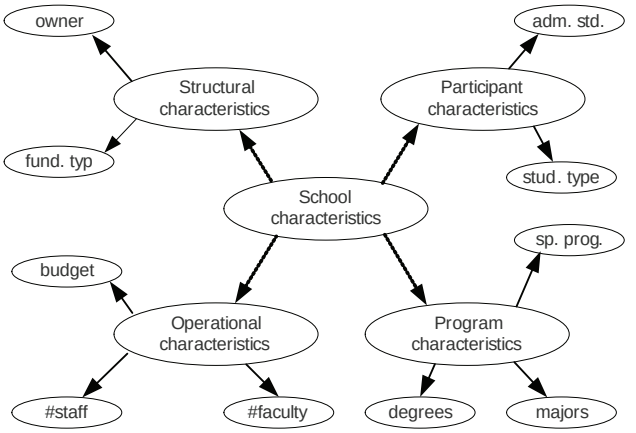
Data Selection/Hypothesis Formation

Knowledge of the domain is essential in pre-mining as well as post-mining activities. Hypothesis formation, data selection, and transformation require conceptualizing relationships among attributes (dimensions) and their impact. For example, converting numerical income data in a bank warehouse to categorical attributes ("hi," "mid," "lo") requires knowledge of expected income levels. Generally miners anticipate two types of patterns: (a) attributes concerning an entity or issue of interest such as computer defects, user complaints, employees/suppliers, and so forth; (b) attributes influencing organizationally relevant behavior such as hiring/firing, bankruptcy, and hospital stay. Some questions that might be asked are:

- What are the most common customer complaints?
- Which service engineers handled the most complex machine problems?
- What types of manufacturing defects are most likely in a computer? When are they most likely to occur?
- How long is an 80-year-old patient likely to stay in a hospital?
- What are the hiring/firing patterns in a company?
- What factors influence personal bankruptcies?

Data selection and transformation are dependent on issue of interest in the relevant functional area. For instance, an insurance organization with a 10^2 x 10^7 warehouse may be interested in demographic factors affecting claims. Dimensionality is somewhat high, but there are no guidelines for the analyst regarding selection of attributes. Random trial and error techniques will be limited by available resources. Statistical methods to support feature extraction have been found only marginally better than trial and error techniques (Lin & McClean, 2001). A model of the domain will aid in extracting relevant data. Both formal and informal techniques will suffice. Causal mapping has been proposed as one of the methods to understand interdependencies in high dimensional data (Fayyad & Stolorz, 1997). A *causal map* or influence diagram depicts cause-effect relationships between decision variables (Eden & Ackermann, 2004). The technique can be made more informal by simply omitting the signs ("+"/"-") on the cause maps. An example domain model is shown in Figure 2.

Figure 2. A domain model for understanding school similarities



Model Selection

Mining models are classified into descriptive or predictive. *Descriptive* techniques describe the data, while *predictive* techniques attempt to predict behavior or variable of interest. Examples of the former include data summarization and clustering, while examples of the latter include regression, association, and dependency analysis (Jackson, 2002). Model selection is governed by a number of factors including the limitations of the technique as well as the mining objectives. As evidenced from Table 2, different techniques are applicable in different situations. For instance, factors influencing catalog sales can be identified from a regression or dependency analysis. The information regarding the service engineers handling the most complex machine problems is easily obtained from a bar graph of service engineers and machines serviced. This is a type of problem that is best visualized. In general, descriptive techniques are useful in identifying information about an entity of interest, while predictive techniques are useful for understanding behavior.

There has been a tendency to treat models as black boxes, but models are sophisticated and require grappling with them while analyzing data. Model parameters also require domain understanding. For instance, regression and dependency analysis require understanding dependent and

Table 2. Popular mining techniques and representative modeling issues (Amaravadi & Daneshgar, 2003)

Technique	Popular algorithms	Application
Summarization/ Visualization	Descriptive statistics, OLAP, graph, 3D plots	Data exploration, average values, outliers
Association	A priori, hash tree, partitioning, and sampling	Relationships among attributes as pertaining to target variable
Classification	CART, ID 3, $C_{4.5}$, K-NN, neural nets, discriminant analysis, and Bayesian classification	To predict class membership
Clustering	K-means, K-Mediod, hierarchical methods.	Determine naturally occurring groups
Prediction	Regression, Bayesian analysis	Predict value of target variable.
Time series analysis	Simple trend analysis, exponential, Box-Jenkins, seasonal ARIMA models	Trends that vary with time, longitudinal variation

University5	Res	Commut	2,502	205	431	71

independent variables. Similarly, cluster analysis requires understanding similarity characteristics and the number of expected clusters. Also of great importance to the data miner is the efficacy of models in different situations. See the work by Lin and McClean (2001) for a comparative discussion of the effectiveness of classification models.

Testing

Once micro theories are identified and data sets are selected/transformed, the next step in the KDD process is testing. As already noted, testing proceeds in two stages, first with "test data" to develop the model and then with the evaluation set to guard against overfitting. As mentioned, the DM techniques include clustering, association, classification, and dependency analysis. The hypothesis test list is used by the analyst as a guide in selecting a suitable technique. For instance, an assumption about the reliability of a supplier could be confirmed by an association analysis between suppliers, delivery times, and the number of times the specifications were met 100%. It should be noted that the raw data may not be available in this form, and therefore may require tabulating and aggregation especially with respect to the variable, "specifications being met 100%." If the association analysis confirms some vendors meeting these criteria, this is again tested on the remainder of the data in the second stage. A number of situations may arise with tested hypotheses: (a) the hypothesis is supported in its entirety at the 90% confidence level or higher, (b) the hypothesis is not supported at the 90% confidence level, but at a lower level of confidence, (c) the hypothesis is not supported at any confidence level. Situations "a" and "c" are clear-cut, resulting in confirmation or disconfirmation of the MT, but "b" will probably be more common. A finding such as "70% of the time patients who are 65 are likely to take one week to recover from surgery" is only partially useable. In such cases, analysts can change the attributes and run the analysis again. Thus the process is carried out iteratively with the strategy being modified.

Case Study of AACSB Schools

The author was part of a committee that was involved in a data mining study involving AACSB schools. The objective of the study was to identify schools that were similar to the author's university. This mini-case illustrates some of the ideas discussed in this article. Part of the sample data is illustrated in Table 3 and is available from the AACSB

Web site (www.aacsb.edu). The names of the schools are disguised for confidentiality. The columns are explained in the appendix.

Collecting the data was labor intensive, as it was listed as a Web page profile for each individual school. The data were printed, and the information was manually entered into a database. Leaving out the international schools, there were a total of 423 colleges of business in the U.S. Eliminating the top tier and private schools resulted in approximately 63 records (of universities), each with 26 attributes. The labels for the data are duplicated, and this needs to be understood. It should be noted that the data are also sparse with values missing from a number of records.

The raw data are overwhelming to the novice. A cluster analysis with all the variables yielded no clustering. This is predictable both because of the size and because of extraneous columns. It is clear that an understanding of university characteristics is required to reduce the number of columns. Discussions with committee members resulted in the model illustrated in Figure 2. As evidenced from the diagram, a school's character is composed of four sets of factors, structural, operational, geographical, and participant. There are sub-factors for each of these. Thus operational characteristics include the "budget," "#faculty" and "#staff." This model is invaluable in reducing dimensionality. For example, it is clear that columns such as "tuition," "OpBudget/FTFac," "FT students/FT faculty," and "number of accounting degrees" are not relevant and can be safely dropped. Also instead of having three separate variables for "FT," "FTEQ," and "FTPHD," only one, which is "FTEQ," can be chosen. Other variables can similarly be collapsed, leading to a dimensionality reduction of 50%. Records for which values were missing were dropped. Since cluster analysis can be carried out with only non-numerical data, columns with text are either dropped or converted to values assigned on a numerical scale. A decision was made to take the latter course of action. The analysis showed good results with *six* clusters. There were 11 universities in the peer group of Western, including University#2 in Table 3. For brevity the cluster results are not reproduced here. The case highlights the importance of understanding the data context as well as the subjectivity involved in the mining process.

FUTURE TRENDS

It is expected that new technologies such as mobile commerce, RFID, digital videography, and smart dust are going to multiply the data that organizations collect. Warehouses with 100 TB are expected to become common in 10 years (Kimball, 2003). Competition will force organizations to delve deeply into these data resources. In some cases, mining will be extended to real time data.

While hardware will undoubtedly evolve, mining techniques that are already tried by large data sets will be further tested with massive data sets. Efficient algorithms will be critical. Unfortunately, algorithm complexity tends to be a function of the number of records and number of dimensions, both of which will continue to plague miners. Algorithms with a complexity of $O(N^2)$ where N is the number of records will not be suitable (Fayyad & Stolorz, 1997). The problem seems formidable without change in paradigms. Dealing with large data sets will always present challenges and paradigms such as parallel computing may need to be introduced (ibid). Mining image data such as customer shopping patterns will present even greater challenges, one of which will be the visualization of data. Trends and patterns need to be presented in their natural context, which will also increase demands on the mining hardware and software. Mining is of utmost importance in a number of scientific and industrial applications, all of which will have the effect of driving advances in technology.

CONCLUSIONS AND IMPLICATIONS

The mining literature has focused mostly on applications, algorithms, and techniques. There has been comparatively less emphasis on pre- and post-mining activities. It is important for IS researchers to address this lacunae. We have discussed some of these activities as part of the KDD process. Pre-mining activities such as data selection and transformation are influenced by the questions of interest. We have suggested domain modeling augmented by traditional analysis techniques as a way to understand the issues at hand. The AACSB case study clearly illustrates the importance of such models.

The potential of mining has been barely scratched. Organizations have sizeable and expanding repositories of data. Competition will always force organizations to tweak every aspect of its operations for the utmost efficiency. To exploit mining, a theoretical framework is required for understanding the relationship between the domain and KDD activities. Also of strategic importance is an understanding of the applicability of models to different data and organizational contexts.

KEY TERMS

Association: A technique in data mining that attempts to identify similarities across a set of records, such as purchases that occur together across a number of transactions.

Classification: A technique in data mining that attempts to group data according to pre-specified categories such as "loyal customers" vs. "customers likely to switch."

Clustering: A technique in data mining that attempts to identify the natural groupings of data, such as income groups to which customers belong.

Data Driven: If the data drive the analysis without any prior expectations, the mining process is referred to as a data driven approach.

Dimensionality: Dimensionality refers to the number of attributes. For instance, in sales data, "product," "sales location," and "time" are attributes.

Micro Theories: Beliefs that need to be tested during the data mining process.

Overfitting: A condition that occurs when there are too many parameters in a model. In such cases, the model learns the idiosyncrasies of the test data set. This can happen in models such as regression, time series analysis, and neural networks.

Question Driven: In question-driven (hypothesis-driven) approaches, the analysis is preceded by an identification of questions of interest.

APPENDIX: EXPLANATION OF VARIABLES

ATTRIBUTE NAME	**DESCRIPTION**
Name	Name of institution
Cl	Carnegie classification
Mission	Teaching, intellectual contribution, service
Research	Applied, instructional, or basic
Commun	Whether urban or rural
OpBudget	Operating budget
OpBud/FTFac	Operating budget/Full time faculty member
UGrad	Undergraduate tuition
MBA	MBA tuition
FTEQ	Full time equivalent faculty
FT	Full time faculty
FTPHD	Full time PhD
FTSt/FTFac	Full time students per full time faculty
UGrad	Residential or commuter students
Grad	Residential or commuter students
FT	Number of full time undergraduate students
PT	Number of part time undergraduate students
TDegrees	Total number of undergraduate degrees awarded
AcctDegs	Undergraduate accounting degrees awarded
FT	Full time graduate enrollment
PT	Part time graduate enrollment
Tdegrees	Total number of graduate degrees awarded
FT	Full time degrees in special programs

INTRODUCTION

The Unified Modeling Language (UML) allows to visualize, to specify, to build and to document the devices of a system that involves a great quantity of software. It provides a standard form for writing the models of a system, covering so much of the conceptual aspects (such as processes of the business and functions of the system) as the concrete ones (such as the classes written in a specific programming language, schemas of databases and software components).

In 1997, UML 1.1 was approved by the OMG becoming the standard notation for the analysis and the design oriented to objects. UML is the first language of modelling in which a metamodel in its own notation has been published. It is a strict subset called Core. It is a self-referential metamodel.

It is a very expressive language that covers all of the necessary views to develop and to deploy systems. UML is a language that provides three extension mechanisms (Booch, Rumbaugh, & Jacobson, 1999): stereotypes, tag values, and constrains. The stereotypes allow to create new types of elements of model based on the elements that form the metamodel UML extending the semantics of the same one, the tag values are an extension of the properties of an element of UML, allowing to add new information to the specification of the same one, and the constrains are an extension of the semantics of UML that allow to add new rules or to modify the existent ones.

The organization of this overview is given in the following way: first, we present the stereotypes according to the standard of OMG; second, we expose the analysis of works that extend UML using stereotypes in diverse real domains; third, we make an analysis of the stereotypes of UML; and we finish giving a general conclusion where we focus ourselves in the distinction of the works according to their inclusion or not of the created stereotypes in the metamodel of UML.

STEREOTYPE ACCORDING TO THE STANDARD OF OMG

A stereotype provides a form of classifying elements in such a way that they work in some aspects as if they were instances of a new constructor of the "virtual"

Attributes	
BaseClass	This specifies the names of one or more elements from UML modeling to which the stereotype is applied, such as classes, associations.
Icon	This is the geometric description of the icon that will be used to present an image of the element of the marked model with the stereotype.

metamodel. A stereotype could also be used to indicate a meaning or different use between two elements with identical structure. A stereotype can also specify a geometric icon to be used to present elements with the stereotype.

USING STEREOTYPES IN DIVERSE REAL DOMAINS

UML adapts to any technique, because it has extension mechanisms that don't need to redefine the nucleus UML, allowing to obtain a modeling more appropriate to the different particular domains. All of the extensions should follow the standard proposed by the OMG (2001).

Modeling of Business with UML

UML was initially designed to describe aspects of a software system. For the modeling of business, UML needed to be extended to identify and to visualize resources, processes, objectives and rules more clearly. These are the primary concepts that define a business system. The Eriksson-Penker Business Extensions (Eriksson & Penker, 1999) provide

new stereotypes for their model. In a diagram of class of UML, they represent a process through a specific symbol that corresponds to an activity stereotyped in an activity diagram. The resources used by the process are modeled with a stereotyped dependence *«supply»* and the resources controlled by the process are modeled with a stereotyped dependence *«control»*.

Modeling of Web Applications with UML

In Baresi, Garzotto, and Paoloni (2001), they propose a framework denominated W2000, for the design of Web applications. They combine the use of UML and HDM (Hypermedia Model). The Web applications require the integration of two different, but interrelated, activities: the design hypermedia that is focused in the navigation way and the structure of the information, and the functional design that is focused in the operations. Among their main purposes is the extension to the standard of UML of the dynamic diagrams.

It uses *«node type»* like stereotype of UML to define a node type that allows to reach different structures of information and defines the symbol "@" to indicate that a node stereotyped with *«node type»* will be the node for defect where all the users begin to navigate.

They propose a symbol called "index" that allows the users of a navigation to select one of the elements from a list of indexes.

The "collection links" define how the users can navigate between the core and the members of a collection, and they add a symbol to graphically represent the pattern "Index + Guided Tour".

For the functional design, they define the diagrams of scenarios, and these are represented through an extended sequence of diagrams of UML. The extensions refer as much to objects as to the step of messages. The objects are organized in entities (components and nodes), semantic associations and collect. The "free navigation" is represented with dotted lines and the "constrained navigation" is represented with a line with a diamond in it.

In 1999, Jim Conallen, Principal Consultant of Conallen Inc., Object Oriented Application Development in Conallen Inc., presented in their paper an extension to UML, in a formal way, to model applications Web.

The extension was presented at several other conferences in 1999, including the Rational Users Conference in Seattle (July 1999), and two Wrox Press ASP conferences in Washington, DC (September 1999) and in London (November 1999).

Various summaries and introductions to the extension have or will appear in the *Communications of the ACM* (ASPToday, *http://www.asptoday.com/articles/19990517.htm*), and in the UML Resources Web site at Rational Software. A full explanation of this work is currently being prepared for the book, *Building Web Applications with UML* (Conallen, 2002), published in the Object Technology Series of Addison-Wesley Longman.

This article presents an extension of UML for Web application designs. Part of the extension mechanism of UML is the ability to assign different icons to stereotyped classes. A list of prototype icons for the most common class stereotypes can be found as an appendix. It defines two new stereotypes to model the difference between the executed methods in the server and the executed functions in the client. In a page, a method that executes on the server will be stereotyped as *«server method»* and functions that run on the client *«client method»*. This solves the problem of distinguishing attributes and methods of a page object. It proposes the modeling of a page with two stereotyped classes, *«server page»* and *«client page»*. They define several stereotypes to represent the associations, such as: *«builds»* that is modeled with an unidirectional association from the server page to client page, *«redirects»* to model the redirection to other *«server page»*, *«links»* for defined associations between pages clients and other pages (client or server). Also, they define stereotypes to model components, *«server component»* and *«client component»*, for Forms *«form»*, for Framesets *«frameset»*. Other defined stereotypes, *«scriplet»* for cached client page, and *«xml»* for a hierarchical data object that can be passed to and from a Web server and client browser.

In Gorshkova and Novikov (2001), a UML extension capable to refine the design of the client part of Web application is defined. Several new diagrams are specified which provide a precise definition of the content of Web pages and navigation between them. The composition diagram is a special case of class diagram. We use it to express the structure of the Web pages and identify their content: how they are connected together and what data is carried from one page to another. The main notion of the composition diagram is the page, defined as an autonomous block of screen. Each screen in the navigation diagram is mapped into several pages in the composition diagram. The tool may provide links from pages to screens and vice versa to show their relationship. A page is modeled in the composition diagram as a class stereotyped *«page»*. A page may play the role of container for other pages. Nested pages are modeled as aggregated classes. The page has elements like buttons, links and input fields. They are modeled as attributes of the corresponding page. The *«form»* stereotype is a child of *«page»*. It is used to model HTML forms. The navigable association between source and target pages is stereotyped *«link»*. Each *«link»* has a tag context with expression as value.

In Koch, Baumeister, and Mandel (2000), the authors define a set of stereotypes that are used in the construction of intuitive analysis and design models in the development of Web applications. These models are the navigation space model, the navigation structure model, and the static presentation models.

The basis of the navigation design is the conceptual model, and the outcome is a navigational model, which can be seen as a view over the conceptual model. The navigational model is defined in a two-step process. In the first step, the navigational space model is defined, and in the second, the navigational structure model is built. The navigation space model defines a view on the conceptual model showing which classes of the conceptual model can be visited through navigation in the Web application. The navigational structure model defines the navigation of the application. It is based on the navigation space model, but also additional model elements are included in the class diagram to perform the navigation between navigational objects: menus, indexes, guided tours, queries, external nodes, and navigational contexts.

The static presentational model is represented by UML composition diagrams that describe how the user interfaces are built. They define stereotypes to be able to build these diagrams.

The set of defined stereotypes is the *«Navigational Class»*. It represents a class whose instances are visited during navigation. The *«Direct Navigability»* are associations in the navigation model. These associations are interpreted as direct navigability from the source navigation class to the target navigation class. An *«Index»* is modeled by a composite object which contains an arbitrary number of index items. A *«Guided Tour»* is an object which provides sequential access to the instances of a navigational class. A *«Query»* is represented by an object which has a query string as an attribute. This string may be given, for instance, by an OCL select operation. A *«Menu»* is a composite object which contains a fixed number of menu items. A *«Presentational class»* models the presentation of a navigational class or an access primitive, such as an index, a guided tour, query, or menu. A *«Frameset»* is a top-level element which is modeled by a composite that contains (lower level) presentational objects but may also contain an arbitrary number of nested framesets. An area of the frameset is assigned to each lower level element, so called *«frame»*, the same stereotype is also used in Eriksson and Penker (1999). A *«window»* is the area of the user interface where framesets or presentational objects are displayed, and also defined are *«text»*, *«anchor»*, *«button»*, *«image»*, *«audio»*, *«video»* and *«form»*. A *«collection»* is a list of text elements that is introduced as a stereotype to provide a convenient representation of composites. An *«anchored collection»* a list of anchors.

Real-Time Systems Modeling with UML

In Selic and Rumbaugh (1998), a set of constructs that facilitate the design of software architectures in the domain of real-time software systems is described. The constructs, derived from field-proven concepts originally defined in the ROOM methodology (http://wwweb.org/smo/bmc/mb/mb35.html) are specified using the UML standard. In particular, it showed how these architectural constructs can be derived from more general UML modeling concepts by using the powerful extensibility mechanisms of UML. The following stereotypes are defined as UML extension: *«protocol»*, *«protocolRole»*, *«port»*, *«capsule»,* and *«chainState»*.

A protocol role is modeled in UML by the *«protocolRole»* stereotype of Metamodel Class ClassifierRole. A protocol is modeled in UML by the *«protocol»* stereotype of Metamodel Class Collaboration with a composition relationship to each of its protocol roles representing the standard relationship that a collaboration has with its "owned elements". A port object is modeled by the *«port»* stereotype, which is a stereotype of the UML Class concept. A capsule is represented by the *«capsule»* stereotype of Class. The capsule is in a composition relationship with its ports, sub-capsules (except for plug-in sub-capsules), and internal connectors. A state whose only purpose is to "chain" further automatic (triggerless) transitions onto an input transition is defined as a stereotype *«chainState»* of the UML State concept.

In Toetenel, Roubtsova, and Katwijk (2001), the paper shows an extension UML with mechanisms for specifying temporal constrains and properties. It defines schemes for the translation of UML specifications into semantically equivalent XTG-based (eXtended Timed Graphs) specifications such as the properties given on UML specification can be proved on the XTG specification. The realization of the approach uses the extensibility interface of the Rational Rose UML Tool (Rational Rose 98i, 2000).

ANALYSIS OF UML STEREOTYPES

In Gogolla and Henderson-Sellers (2002), the paper takes up ideas from Gogolla (2001) where stereotypes have been introduced for relational database design. The expressiveness of UML stereotypes has been analyzed, and some concrete suggestions have been made for the improvement of the UML metamodel. Use OCL to define precise stereotypes.

In Riesco, Martellottto, and Montejano (2003) and Riesco, Grumelli, Maccio, and Martellotto (2002), proposals of "evolutionary stereotypes" are presented. These are incorporated into the modeling tool in such a way that they can extend the UML metamodel, including the new elements with their corresponding semantics. In this way, the environment of a tool can dynamically change its appearance and functionality to allow software engineers to use the stereotypes previously defined in the diagrams.

The Clark, Evans, Kent, Brodsky, and Cook study[1] proposes a new metamodelling facility (MMF) containing: Metamodelling Language (MML); Metamodelling Tools (MMT); a satisfaction checker (for instance, does X satisfy constraint C from model M?); to check that a model satisfies

its metamodel; to check that a metamodel satisfies the MML rules; to check that MML satisfies the MML rules.

CONCLUSION

UML is a universal language adopted for the modeling of applications in a wide range of domains. It is an open language, which provides extension mechanisms in order to extend the metamodel. The UML extension mechanisms include: Tag values, Constrains and Stereotypes.

In particular, the stereotypes should be carefully declared and should only be used when the message to be communicated could not be expressed in any other UML terms. In order to achieve a better use of stereotypes, there are certain necessary conditions. The UML metamodel should be adjusted and support tools should be provided for the complete part of the UML metamodel dealing with stereotypes.

The papers analyzed in this work propose a varied number of stereotypes to extend UML, with the purpose of using this language to model particular domains, such as Web applications, real-time systems, business modeling, XML, and so forth.

After the reading and the analysis of these papers, it has been detected that only in three of them (Gogolla, 2001; Riesco, Grumelli, Maccio, & Martellotto, 2002; Selic & Rumbaugh, 1998) the addition of stereotypes is defined as a UML complete extension. This occurs through the incorporation of new elements to the metamodel with new semantic that assures the consistency of the metamodel UML.

In the other analyzed papers, the stereotypes are presented being used in their specific context, but without extending the metamodel UML. This is a clear deficiency in their definitions, since the maintenance of the metamodel UML in a consistent way is very difficult, or even impossible, as their stereotypes are not explicitly added to the metamodel UML. Besides, this means that the stereotypes won't be available to be used in generic solutions to problems belonging to the selected particular domain.

KEY TERMS

Class Diagram: Show the classes of the system, their interrelationships, and the collaboration between those classes.

Extension Mechanisms: Specify how model elements are customized and extended with new semantics.

Metamodel: An abstraction which defines the structure for a UML model. A model is an instance of a metamodel. Defines a language to describe an information domain.

Object Constraint Language (OCL): A notational language for analysis and design of software systems. It is a subset of the industry standard UML that allows software developers to write constraints and queries over object models.

OMG: Has been "Setting The Standards For Distributed Computing™ through its mission to promote the theory and practice of object technology for the development of distributed computing systems. The goal is to provide a common architectural framework for object-oriented applications based on widely available interface specifications (OMG, 2001).

Real Domains (Particular or Specific): The different application areas that can require to be modeled with UML. For example: Web applications, real-time system, XML, business modeling, frameworks, communication protocols, workflows, geographical information systems, and so forth.

Stereotype: Allows to create new types of elements of modeling, based on the elements that form the goal-pattern UML, extending its semantics.

Extreme Programming for Web Applications

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

The engineering environment of Web Applications is in a constant state of technological and social flux. These applications face challenges posed by new implementation languages, variations in user agents, demands for new services, and user classes from different cultural backgrounds, age groups, and capabilities.

We require a methodical approach towards the development *life cycle* and maintenance of Web Applications that can adequately respond to this constantly changing environment. In this article, we propose the use of an *agile methodology* (Highsmith, 2002), namely Extreme Programming (XP) (Beck & Andres, 2005), for a systematic development of Web Applications. In general, agile methodologies have show to be cost-effective for projects with certain types of uncertainties (Liu, Kong, & Chen, 2006) and, according to surveys (Khan & Balbo, 2005), been successfully applied to Web Applications.

The organization of the article is as follows. We first outline the background necessary for the discussion that pursues and state our position. This is followed by a discussion of the applicability and feasibility of XP practices as they pertain to Web Applications. Then the shortcomings of XP towards Web Applications are highlighted, and suggestions for improvement are presented. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND

Over the last decade, Web Applications have become increasingly large and complex as they respond to the expectation of sophisticated services. The need for managing increasing size and complexity of Web Applications and the necessity of a planned development was realized in the late 1990s (Coda, Ghezzi, Vigna, & Garzotto, 1998; Powell, Jones, & Cutts, 1998). This led to the introduction of the notion of Web Engineering (Ginige & Murugesan, 2001), which subsequently has been treated comprehensively (Kappel, Pröll, Reich, & Retschitzegger, 2006).

In the last few years, a number of methods for realizing Web Applications have been proposed including, but not limited to, Web Site Design Method (WSDM) (De Troyer & Leune, 1998), Object-Oriented Hypermedia Design Method (OOHDM) (Schwabe & Rossi, 1998), and Web Object-Oriented Model (WOOM) (Coda, et al., 1998). However, the focus in these approaches has been on specific aspects of Web Applications (like modeling, designing, or implementing) rather than on the *process*.

We adopt the most broadly-used and well-tested *agile methodology*, namely XP, for the development of Web Applications. There are several differences between traditional software and Web Applications (including aspects of delivery, legality, privacy, security, and *usability*) that makes the realization of XP challenging.

XP is a test-driven, "lightweight" methodology designed for small teams that emphasizes customer satisfaction and promotes teamwork. XP was created to tackle uncertainties in development environment, and in doing so, put more emphasis on the social (people) component (engineer, customer, and end-user). The XP practices are set up to mitigate project risks (dynamically changing requirements, new system due by a specific time line, and so on) and increase the likelihood of success. The use of XP has been suggested for a "rapid application development" of Web Applications (Maurer & Martel, 2002; Wallace, Raggett, & Aufgang, 2002), however, a detailed analysis has not been carried out.

It is not the purpose of this article to evaluate the merit of XP on its own or with respect to other *agile methodologies*; such assessments have been carried out elsewhere (Mnkandla & Dwolatzky, 2004).

ENGINEERING WEB APPLICATIONS USING EXTREME PROGRAMMING

In this section, we discuss in detail how the *twelve practices* put forth by XP manifest themselves in the development of Web Applications (Table 1).

We note that some of these practices such as *Testing*, *Refactoring*, or *Pair Programming* are not native to XP and were discovered in other contexts previously. In this sense, by aggregating them in a coherent manner, XP bases itself on "best" practices. These practices are also not necessarily mutually exclusive and we point out the relationships among them where necessary. We also draw attention to the obstacles in the realization of these practices that pose challenges to the deployment of XP for Web Applications.

Table 1. XP practices corresponding to process workflows in a Web application

Process Workflow	XP Practices
Planning	40-Hour Week, The Planning Game (Project Velocity)
Analysis (Domain Modeling, Requirements)	On-Site Customer, The Planning Game (User Stories)
Design	Metaphor Guide (Natural Naming), Simple Design, Refactoring
Implementation	Collective Ownership, On-Site Customer, Metaphor Guide, Coding Standards, Pair Programming, Continuous Integration
Verification and Validation	On-Site Customer, Testing (Unit Tests, Acceptance Tests)
Delivery	Small Releases

1. *The Planning Game.* The purpose of *The Planning Game* is to determine the scope of the project and future releases by combining business priorities and technical estimates. For that, it first solicits input from the "customer" to define the business value of desired features and uses cost estimates provided by the programmers. This input documented in form of *user stories* (Alexander & Maiden, 2004). A *user story* is a user experience informally expressed in a few lines with a Web Application such as navigating or using a search engine. The estimation is limited to the assessment of *project velocity*, a tangible metric that determines the pace at which the team can produce deliverables. The plan is iterative: it is prone to modifications based on the current reality. For example, a new user story may lead to revisitation and evolution of the current plan.
2. *Small Releases.* The idea behind *Small Releases* is to have a simple system (an evolutionary prototype) into production early, and then via short cycles, iteratively, and/or incrementally, reach the final system. To have a concrete proof-of-concept up-and-running can be used to solicit feedback for future versions and can help convince customers and managers of the viability of the project. This is useful for Web Applications that are highly interactive such as those making broad use of fill-out-forms. However, there is cost associated with prototypes and, therefore, their number should be kept under control.
3. *Metaphor Guide.* The use of metaphors (Boyd, 1999) is prevalent in all aspects of software development. A *Metaphor Guide* is an effort to streamline and standardize efforts for naming software objects and is available for team-wide use. The main concerns in naming are of sensitivity to the domain under consideration (that is, use of terminology of the application area) and familiarity (as user background is assumed to be non-technical). *Natural naming* (Keller, 1990) is a technique initially used in source code contexts that encourages the use of names that consist of one or more full words of the natural language for program elements in preference to acronyms or abbreviations. Indeed, natural naming strengthens the link between the underlying conceptual entity and its given name. For example, DeviceProfile is a combination of two real-world metaphors placed into a natural naming scheme.
4. *Simple Design.* The motivation behind a *Simple Design* is that in XP's view, requirements are *not* complete when the design commences. This is inline with the reality of Web Applications which have to respond to the market pressures and the competition that are beyond their control, or other unavoidable circumstances such as variations in implementation technology. Therefore, the design is minimal based on *current* (not future) requirements. It aims for simplicity, and to ensure "good" design, its quality (specifically, structural complexity) is improved by frequent revisitations; that is, *Refactoring*. The interfaces of Web Applications are particularly amenable for simple design as they are likely to change often during the process. Design patterns (Van Duyne, Landay, & Hong, 2003) are forms of reusable knowledge based on past experience and expertise that can lead to simplified design.
5. *Testing.* There is a strong emphasis in XP on validation and verification of the software at all times. By being test-driven, there is transition from one phase to another only if the tests succeed. The tests range from *unit tests* (using tools such as HTMLUnit, HTTPUnit, XMLUnit, XSLTUnit, and JUnit) written by programmers to acceptance tests involving customers

(to satisfy customer requirements). There are variations in user agents (browsers) with respect to their support for information representation (markup or style sheet) languages. Therefore, interface testing is uniquely critical to Web Applications. As part of that activity, syntactical validation of documents being served is critical. A detailed treatment of tools, techniques, and methods for testing Web Applications as well as for test plans is given in (Nguyen, Johnson, & Hackett, 2003).

6. *Refactoring.* The artifacts created during analysis or design may need to evolve for reasons such as discovery of "impurities" (or code "smells") or obsolescence. The refactoring (Fowler, Beck, Brant, Opdyke, Roberts, 1999) methods are structural transformations that help eradicating the undesirables without changing the functionality of the application. Examples of such smells include inconsistent names of classes, operations, or attributes that hinder communication, redundancy (duplication), classes with unnecessary responsibility (non-cohesivity), and so on. The goal of *Refactoring* is to improve the design of the system throughout the entire development.
7. *Pair Programming.* This is one of the practices of XP that highlights the social aspects of engineering. The idea behind *Pair Programming* is to encourage collaborative work. In some controlled experiments (Williams & Kessler, 2003), Pair Programming has been shown to produce better code at similar or lower cost than programmers working alone. Empirical studies (Katira, 2004) have shown that some level of compatibility among partners in Pair Programming is necessary for it to be effective. The notion of Pair Programming can be extended to artifacts created during early stages (namely, analysis and design phases) of the development process that focus on modeling (Kamthan, 2005). For example, the use of the Unified Modeling Language (*UML*) (Booch, Jacobson, & Rumbaugh, 2005) for visual modeling of Web Applications has been suggested (Conallen, 2003). A pair can be responsible for several other practices such as using *Refactoring* to obtain a *Simple Design*, *Continuous Integration*, and *Testing*. The *On-Site Customer* can be a partner in a pair but only as a co-pilot.
8. *Collective Ownership.* According to the XP philosophy, one of reasons for inertia in modifications to software is that when change is warranted, the team has to wait for specific personnel to carry it out. Therefore, in XP, all the code belongs to all the programmers and anyone can change code anywhere in the system at any time. However, for such an arrangement to be effective, configuration management that provides trace of person, date/time, and of nature and location of the change carried out is needed.
9. *Continuous Integration.* In an incremental and iterative approach of XP, standalone units (such as a corporate logo, navigation icons, and so on) are created and then integrated. However, it is not automatic that if the individual parts work, then their sum would also work. For example, a graphical navigation bar may work well individually, but not when included in an Extensible HyperText Markup Language (XHTML) document due to, say, incorrect encoding or link syntax. By "continuous," XP means integrating and building the software system multiple times a day. The advantage of *Continuous Integration* is minimal propagation of errors (limited to the last addition).
10. *40-Hour Week.* The term *40-Hour Week* is to be taken figuratively rather than literally. It simply implies that, due to the emphasis on the social aspect in XP, "overwork" is not recommended. XP believes that excessive overtime leads to low productivity in the long-term. For example, tired programmers are prone to more mistakes, which in turn may slow down progress of the project.
11. *On-Site Customer.* The availability of a full-time *On-Site Customer* helps in understanding the application domain, determining requirements, setting priorities, and answering questions as the programmers have them. In XP, every contributor to the project, including the customer, is an integral part of the *entire* team. This has two major implications for the team: its structure is not hierarchical and it requires physical proximity of the participants to function.
12. *Coding Standards.* There are a variety of languages for expressing information in Web Applications, which can be served using any general or special-purpose programming language. It is critical that instances based on these languages be communicable to stakeholders and interoperable with respect to user agents. For example, for *Pair Programming* and for *Collective Ownership* to be effective, there needs to be a common understanding. *Coding Standards* provide means for doing that. It is known (Schneidewind & Fenton, 1996) that, when applied judiciously, standards can contribute towards quality improvement.

CHALLENGES TO THE DEPLOYMENT OF EXTREME PROGRAMMING FOR WEB APPLICATIONS

In this section, we highlight certain caveats of applying XP practices as-is as well as certain aspects that are essential to Web Applications but are not covered by these practices *per se*.

- XP does not mandate a rigorous feasibility study, including a formal means for cost estimation, as part of *The Planning Game*. A feasibility study could, for instance, determine if one could take advantage of reuse. For example, the functionality of a Web Application for different classes of desktop computers should not be all that different.
- The notions of *Pair Programming*, *40-Hour Week*, and *On-Site Customer* make sense for a development in a non-distributed environment only. This would present a coordination obstacle if a Web Application were being developed in different natural languages, each in different parts of the world.
- Testing for accessibility or *usability* of Web Applications can be prohibitive for small-to-medium size enterprises, particularly if it involves specialized rooms, dedicated infrastructure with video monitoring and recordings for subsequent analysis. Also, testing cannot always detect all errors in systems. For example, that user supplied correct address, or that internal documentation corresponds to source code, are beyond the scope of testing. Furthermore, testing is only one approach to verification and defect removal. XP does not include any support for formal inspections (Wiegers, 2002), although that is somewhat ameliorated by support for *Pair Programming*, which can be viewed as "informal" inspections.

Finally, we point out that agility is not a panacea (Boehm & Turner, 2004) and there are several issues associated with *agile methodologies* in general, and XP in particular. For example, XP is not applicable to large (greater than 15) team sizes, distributed development, or for very large projects. There is no explicit support for metrics or rigorous measurement in XP. XP does not explicitly take into account the licensing conditions under which the software is developed. For example, Web Applications that are Open Source or outsourced will not be able to comply with some of the practices mandated by XP. However, XP provides a feasible first step from an ad-hoc approach to an organized view of developing Web Applications.

FUTURE TRENDS

Some degree of cost estimation is relevant to any software development. COCOMO II (Boehm, Abts, Brown, Chulani, Clark, Horowitz, et al., 2001) provides a rigorous approach to cost estimation, and could assist in *The Planning Game*. However, that would require some adjustments in measures and calibrations of data, as Web Applications are different from traditional applications for which the COCOMO II cost estimation model is defined.

Since XP is driven by testing, there is an urgent need for unit testing frameworks (Hamill, 2004) for Web Applications beyond those that are currently available for testing documents of markup languages.

For a widespread acceptance of the proposed use of XP in Web Applications, its adoption in initiatives for *standard*-izing the development of Web Applications (IEEE, 2003) will be crucial.

An extension of XP to Web Applications developed within the Semantic Web architecture (Hendler, Lassila, & Berners-Lee, 2001), such as interfaces to traditional reasoners for ontological inferencing, would be of interest.

Finally, for large-scale Web Applications, a "heterogeneous" process environment approach that mixes agility with discipline (Boehm & Turner, 2004) could be useful. A natural extension of the previous discussion would be to deploy a simplified version of the Unified Process (UP) (Jacobson, Booch, & Rumbaugh, 1999), which is a process *framework* that can be tailored to produce a process model, to Web Applications. Indeed, such a "WebUP" would, on one hand, be model-driven, iterative, customer-centric, and would, on the other hand, still emphasize a top-down team hierarchy and document-based communication.

CONCLUSION

Web Applications continue to increase in size and complexity, and to sustain and manage this growth, require a systematic approach towards their development. For that, there is a need to move away from thinking at the implementation language level and focus on abstractions created *earlier* in the process. At the same time, we wish to avoid the bureaucracy in development processes that have plagued Software Engineering in the past.

XP provide one such viable option for development of small-to-medium size Web Applications for new or not-well-understood domains, and where close collaboration within the team and with the customer is encouraged. The aforementioned shortcomings inherent to XP are largely resolvable, and pave the way towards improvements as well as considerations for other process models tailored to Web Applications.

KEY TERMS

Agile Development: A philosophy that embraces uncertainty, encourages team communication, values customer

satisfaction, vies for early delivery, and promotes sustainable development.

Coding Standard: A documented agreement that addresses the use of a formal (such as markup or programming) language.

Pair Programming: A practice that involves two people such that one person (the primary person or the pilot) works on the artifact while the other (the secondary person or the co-pilot) provides support in decision making and provides input and critical feedback on all aspects of the artifact as it evolves.

Refactoring: A structural transformation that provides a systematic way of eradicating the undesirable(s) from an artifact while preserving its behavioral semantics.

Semantic Web: An extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning.

Web Application: A Web site specific to a domain that behaves more like an interactive software system and will, in general, require programmatic ability on the server-side and may integrate/deploy additional software (such as application servers, media servers, or database servers) for some purpose (such as dynamic delivery of resources).

Web Engineering: A discipline concerned with the establishment and use of sound scientific, engineering, and management principles and disciplined and systematic approaches to the successful development, deployment, and maintenance of high quality Web Applications.

Facilitating Roles an E-Instructor Undertakes

Ni Chang
Indiana University South Bend, USA

INTRODUCTION

A discussion of roles that an instructor plays in the traditional classroom does not seem to be an innovative focus in the educational field. Yet, such discussions continue because of the topic's paramount impact on student learning. Discussions regarding the roles that an online instructor plays in a virtual learning environment are essential because teaching and learning via course management systems are completely different from that in the face-to-face setting and are still in their infancy, thereby requiring a great deal of exploration.

BACKGROUND

Roles of an Online Instructor: The Paradigm Shift

Traditional face-to-face meetings differ distinctively from online teaching (Coppola, Hiltz, & Rotter, 2001; Lim & Cheah, 2003) largely due to the following reasons. The former relies heavily on a specific location and time, whereas the latter is independent of time and location. The former mostly constitutes speaking and listening, while the latter is exercised primarily by reading and writing. The former makes an instructor and learners easily visible to one another, while the latter leaves the instructor and all learners in individual and invisible locations (Pelz, 2004; Sloan Consortium, 2006). The former expects learners to have a moderate level of self-regulation, whereas the latter requires learners to have a higher level of self-regulation (Pelz, 2004; Sloan Consortium, 2006). All the changes from the familiar to the unfamiliar explicitly generate a sizable barrier for online teaching and learning. Removing barriers to student success necessitates the online instructor to undertake a variety of responsibilities (Lim & Cheah, 2003; Morris, Xu, & Finnegan, 2005). Discovering what roles an instructor ought to play in a virtual learning environment is conducive to and vital in the successful facilitation of student learning.

MAIN FOCUS: ROLES UNDERTAKEN BY AN E-INSTRUCTOR

In the following text, the roles of an e-instructor are characterized horizontally by two categories on the basis of a study conducted by the author (Chang, 2007): Pedagogical Efficacy (8 roles) and Affective Promotion (19 roles). These roles are also set apart vertically by three distinct stages: Course Development (7 roles), Course Delivery (18 roles), and Course Completion (2 roles). To address these roles one by one, the author will present them in the form of stages, namely, Course Development, Course Delivery, and Course Completion. The first two stages contain both categories of Pedagogical Efficacy and Affective Promotion with the last stage showing only Pedagogical Efficacy.

COURSE DEVELOPMENT

During the Course Development stage, under the category of Pedagogical Efficacy, the instructor assumes four roles from those of gaining technological skills to those of getting the course ready for teaching. The instructor is responsible for acquiring necessary and useful technological skills and becomes familiar with the learned skills through practice. In the same stage, the instructor engages in research to decide the content of a course plan, which is in line with what Wilson, Varnhagen, Krupa, Kasprzak, Hunting, and Taylor (2003) found from their interviews of eight e-instructors. The researchers noticed that the information covered in virtual learning environments was not equivalent in amount to that in face-to-face meetings. One of the interviewees in the Wilson et al. (2003) study noted, "I went from about 13 individual classes or modules to about six modules." Followed by the decision-making, the instructor lays out a course plan appropriate for the students' learning needs. The reduction in content should not only be measured in quantity, but also be in quality. The environment set for learning should be responsive to students' needs and their learning levels (Berge, 1995). Topics for discussions need to be meaningful and related to students' experiences and interests to attract and maintain students' learning and desire for an in-depth study of concepts and tasks (Lim & Cheah, 2003).

During the stage of Course Development, student affective learning should be seriously attended to. Three roles are involved in this teaching process. An e-course instructor

ought to keep in mind that designing an online course is by no means "curriculum conversion" (Palloff & Pratt, 1999), because this practice is insufficient to guide students in their acquisition of knowledge in a self-controlled manner (Chang, 2007). Learning through a virtual classroom seems intimidating to some and confusing to others. To minimize the degree of apprehension and anxiety, much work is necessary, such as an analysis of the learning environment (Tessmer, 1990) and offering details of requirements and expectations (Lim & Cheah, 2003). The purpose is to avoid the phenomenon that "an instructional design project may produce a theoretically sound but practically unable product" (Tessmer, 1990, p. 56). Additionally, if the same course is repeated in a following semester, redesigning/revising should be something that an online instructor needs to exercise based on the instructor's self-reflections and voices from students taught in the previous semester.

COURSE DELIVERY

It is through the stage of Course Delivery that interaction between students and the instructor transpires. During the interaction with students, an instructor, undertaking four roles, works as an academic guide instead of attempting, as much as possible, to remove the instructor from actual course delivery (Lim & Cheah, 2003; Morris et al., 2005). Over the course of this process, the instructor not only is a learner acquiring knowledge both in content areas and technological skills, but also needs to lecture students. Lecturing still is one of the appropriate instructional methods employed via the Internet or face-to-face meetings. Lectures would address both technology and content in order to prepare students for online learning and to avoid unnecessary confusion later in the learning process. During the lecture, the instructor should exercise caution as not to drive students further away by making a poor presentation, as some students are already intimidated by the idea of learning with computers. Lectures can also be viewed as the time when the instructor responds to students' emails and when he or she interacts with students about their assignments via course management systems. The way that the instructor offers assistance to a learner works as a form of scaffolding or individualized instruction.

Individualized instruction transpires as each communication between the instructor and a student is tailored to specific needs or misconceptions that a student expresses through emails or a submitted assignment. Lim and Cheah (2003) supported this notion with the analysis of a questionnaire and two focus-group interviews. The researchers found that feedback provoked students' thinking and enhanced reflection. In this sense, reviewing the student's submitted work should not be restricted by a traditional responsibility: granting a grade. Reading student submitted assignments works as an informative process that helps the instructor be aware of the status of the student's learning and the quality of the instructor's facilitation. In this sense, awarding a grade itself is not an end to the cycle of communication between the student and instructor. The circular communication continues if a student is willing to continue working on the assignment based on the instructor's feedback. This exercise corresponds to Pelz's (2004) argument that the instructor's thinking is stimulated by the student's work, with an emphasis on helping the student to reach a high level of reflective expression. Moreover, this assessment process provides opportunities for the instructor to improve the course design and teaching strategies. To an e-instructor, this practice is part of ongoing assessment. Ongoing assessment is essential in the process of teaching and learning, as it allows an instructor to continue to improve the work by constant reflections on students' posted work. It is a way to guide students on the side as an effort to keep online learning on the right track (Berge, 1995). Teaching is intellectual work; examining one's teaching and asking questions about ongoing teaching are part of it (Anthony, 1999). Analyzing the process of teaching in a detailed and organized way is scholarly (Shulman, 1993).

Although pedagogical efficacy is significant in student learning, student emotional involvement in learning is equally essential to the success of learning and should be taken into serious account. There are 14 roles regarding affective promotion during this stage, three times more roles than those in the Course Development stage. To ease the transition from the mode of speaking and listening to that of frequently reading and writing and to help students establish self-responsibility, self-time management, self-motivation, and a sense of autonomy, the instructor's appropriate and incremental support in these aspects is pivotal (ESRC Economic and Social Research Council, 2002). An e-instructor should be purposefully committed to employing various strategies to encourage learners to become owners of their own learning (Morris et al., 2005; Pelz, 2004) in hopes that students would actively participate in online discussions and activities. In learning with computers, some students jump right in, whereas others resist the situation. These students usually struggled, to a certain degree, due to the dramatic shift of the learning paradigm (Wilson et al., 2003). Monitoring students' learning can help students ease into the transition and boost their self-confidence in online learning when the instructor provides just-in-time needed support and assistance. Furthermore, to gradually help students transit from the familiar to the unfamiliar learning environment, the instructor frequently sent out email, reminding students of matters requiring their attention at an appropriate time. In the reciprocal interaction with students, it is fundamental for the instructor to understand that one student's question may be representative of others' and that emerging problems in the process of teaching and learning may become a potent opportunity for the instructor to reexamine the course design and instructional strategies. These can be the basis for the

instructor to clarify topics under discussion and to modify course content and ongoing approaches to teaching (Anthony, 1999; Chang, 2001b). These endeavors may lessen the learners' anxiety level to a certain degree.

To further set up an emotionally supportive learning environment, assessments of the effect of course design and delivery are continuous throughout each semester. The instructor purposefully organizes a course by evaluating it based on unexpected e-mail messages and communications with students. For example, in receiving email messages, the instructor may learn which assignments are most helpful to students in their acquisition of knowledge. Students may also consciously and unconsciously share what they like or dislike about an assignment. E-mail messages also are an avenue for students to reveal their thoughts and feelings concerning an ongoing course. In the meanwhile, to avoid commotion and chaos, an e-instructor ought to make known to the students that assistance is readily available to them via e-mail. Students are not left completely alone in a novel learning environment.

Although many researchers have paid much attention to an issue of course management (see Berge, 1995, Coppola et al., 2001; Morris et al., 2005), this effort is actually intended to motivate students and maintain their desire to learn. It is of primary importance that an instructor asks questions while engaging in instruction throughout a semester. Asking questions and searching for answers are actions that can lead to quality learning (Chang, 2001b). It is beneficial also for the instructor to take advantage of every available opportunity to solicit feelings and reactions with regard to online course delivery for supporting and strengthening student learning. In a geographically isolated learning setting, it would make e-students feel comfortable and encourage their conscious learning efforts if an instructor cares about their well-being and sincerely listens to their feelings and problems that they have about online learning. This is a way to support and sustain students' affective learning. To this end, the instructor must maintain an open mind to learn about and understand students in order to provide supportive assistance to their learning at a level compatible to their needs and interests.

Because online teaching and learning is still in its infancy, many unexpected events may occur during the Course Delivery stage. It requires an instructor to remain flexible and creative. For instance, even if an instructor introduces students to the "Comment" feature of Microsoft Word in corresponding feedback, some students still are unable to adopt this feature for various reasons. Some may lack the updated software, may have different platforms, or may feel ill at ease using the technical skill. Under these circumstances, the instructor's flexibility and creativity should come into play by developing other useful methods to benefit student learning. For instance, instead of using the Microsoft Word feature to submit their work as an attachment, an e-instructor, when reading student posted homework, may place a question in {{{{}}}}, for example, {{{{How does this statement relate to the criterion?}}}}} or a comment in [[[[[]]]]], for example, question may be made at the end of the triple dashes inside the created symbols, such as this {{{{How does this statement relate to the criterion? --- Since the teacher has detailed knowledge of the students, the curriculum is designed to suit their learning level. Therefore, I think that this statement supports the criterion.}}}}.

During the Course Delivery, the instructor functions as a traditional instructor. With the utilization of Announcement on a course management system and e-mail, students can be informed of class-related information as well as business unrelated to the course content. Due to different platforms or operation systems that the students and the instructor use, files that students send as attachments sometimes cannot be read. For troubleshooting the problem, the instructor can write the student an e-mail note, providing step-by-step instruction to save time that the student may otherwise have to spend on communicating with personnel at HelpDesk. This endeavor and immediate assistance also strengthen students' emotional involvement in learning, which, in turn, is beneficial to effective inquiry.

Motivation may become extrinsic if students are unduly influenced by words of praise from their teachers (Starko, Sparks-Langer, Pasch, Frankes, Gardner & Moody, 2003). However, according to Chang (2007), acknowledging students' submissions and effort allow the instructor to recognize students' work without excessive praise, to encourage their continuous endeavors, and to promote their intrinsic motivation. Before electronic feedback is provided, the first sentence is often, "Thank you for your submission." The sentence at the end of feedback usually could be, "Keep up with the good work!" and/or "Thank you for your time and work." If a revision is needed, the message may be, "Thank you for your time and cooperation." If a response to the instructor's question is prompt, the student receives a reply, such as "Thank you for your quick response. I appreciate your effort." Sometimes, the instructor recognizes students' hard work by highlighting, "Keep up your good work."

Patience plays an important role in online teaching. Sometimes, an explanation of an assignment needs to be repeated and/or is given in various ways. Sometimes, one concept may require several elaborations. If some students are unable to follow given guidelines, the instructor needs to provide directions for needed materials. If students fail to understand or misunderstand underscored points embedded in readings, they are asked to reread required class materials and/or offered guidance, if needed. If a student has difficulty locating a document online, the instructor helps provide the direction and alternative assistance. If a student fails to follow the direction, the instructor provides further detailed instruction and also may attach the article that the student intends to obtain.

COURSE COMPLETION

During the third stage of Course Completion, an instructor primarily assumes two roles under the category of Pedagogical Efficacy by focusing attention on decision making and reflection for the next semester's instructive preparation. An e-instructor needs to discern as well as to reflect upon the data collected through the entire semester in order to perform general analytical work. The collected data may include students' e-mail, feedback from students concerning their submissions, student surveys, and records of conversations between students and the instructor at different occasions and in different formats. From these resources, answers to the instructor's questions may be obtained that may further improve cyber instruction. Some of these questions may be: What has been achieved in the past semester? What has been viewed as a failure? What lessons should be drawn to improve future online instruction? Anthony (1999) agreed that making inquiries and seeking solutions is a reflective practice; "Teaching is reflective and informed" (p. 3). Targeted curriculum and a suitable learning condition chiefly stem from reflection and the use of pedagogical and content knowledge.

The results of reflective thinking, in turn, enable the instructor to make informed decisions for future course design and instructional strategies in the virtual learning environment. The process is cyclical (Chang & Petersen, 2006; Chang, 2001a).

FUTURE TRENDS

Redden (2005) underscored the significance of students' affective involvement in student learning: "We ignore emotions in the cyber classroom at our own risk. We may want to focus on learning outcomes, but we cannot ignore the process that facilitates or hampers those outcomes" (n.p). Hall (2002) further noted that affective learning had been recognized as more potent and influential than academic efforts in student learning. How to promote students' emotional involvement in online learning requires more research efforts. Online learning isolates learners and the instructor geographically, leaving the community members feeling lonely and, sometimes frustrated. As learners move from the familiar to the unfamiliar learning environment, they need emotional support and promotion in order to be successful learners. Redden (2005) noted the notion that emotions affect learning is indeed in line with brain research results. To build an emotional foundation for successful learning and to reduce the level of discomfort, Redden suggested that the instructor must be "visible" in order to render emotional support. Despite the fact that much of the literature has underlined the importance of establishing a friendly and healthy learning community and has recognized that students are able to lend helping hands to one another for successful learning (Pelz, 2004), socialization would be short-lived or a forced participation without an instructor's commitment to it. Therefore, future efforts should be exerted to explore and discover mechanisms to promote students' affective learning, namely, how and when an e-instructor enters into the interaction in order to heighten the intructor's visibility to students. Additional research may also focus on the promotion of students' affective involvement in learning through an e-instructor's appropriate communication compatible to each student's individual level of cognition revealed via the student's submitted homework. That is, what and how much an e-instructor needs to say so that students would be likely to read constructive feedback to better their learning. Research efforts may be extended to ways to encourage and strengthen learners' self-regulation and self-motivation and to the continuous discovery of roles that an e-instructor plays in a virtual learning classroom.

CONCLUSION

The chapter classifies the 27 roles into two distinctive categories: Pedagogical Efficacy and Affective Promotion. The instructor assumes eight roles in the category of Pedagogical Efficacy. These roles are intended to promote student learning, ranging from assisting students in gaining technological skills to teaching them academic content. This category also demonstrates that the instructor is responsible for acquiring technological skills and becomes familiar with newly learned skills through practice. Throughout the teaching and learning process, the instructor develops meticulous plans and designs an e-course appropriate for the students' learning needs. Reflection enables the instructor to reexamine the whole process of teaching and learning and to make useful informed decisions in order to develop an improved course in the future.

In comparison with Pedagogical Efficacy, there are 19 roles that the instructor assumes in the category of Affective Promotion—twice as many roles as in Pedagogical Efficacy. Ways to help promote affective learning include interactive communication about an issue or an assignment, encouragement, acknowledgement, technical assistance, troubleshooting, and other logistics.

These 27 roles identified through the aforementioned discussion are seemingly familiar to some educators. However, despite the superficial overlapping nature, the roles addressed here are not completely the same as those carried out in the traditional classroom. This is largely due to the paradigm shift that has entirely altered how teaching and learning is exercised. It is inappropriate for an online instructor to blindly adopt what the instructor has utilized in the traditional classroom to interact with students in a virtual learning environment.

On the whole, an e-instructor not only has to know content knowledge and pedagogical skills, but also has to be equipped with technological know-how. Apart from these, the instructor should possess a set of strategies in order to appropriately facilitate learning while maintaining and increasing learners' emotional involvement in a novel learning environment. The ideology of consistent efforts made to explore the responsibilities of an e-instructor is likely to be advantageous to students' successful learning.

KEY TERMS

Affective Promotion: encompasses endeavors and strategies made by an e-instructor in fostering students' emotional involvement in e-learning and in setting up an emotionally supportive learning environment to facilitate student learning.

Knowledge Building (I): Refers to an e-instructor, who keeps professionally up-to-date through self-development and learning alongside students and who attains technological knowledge and skills by attending relevant workshops and by frequent interaction with a computer.

Knowledge Building (S): Refers to the e-students' enhancement of content-bound knowledge and skills as well as their understanding of computer technology via various mechanisms that an e-instructor employs to guide students in an effort to achieve their mutual academic goals.

Instructive Preparation: Is related to avenues in which an e-instructor is engaged to make decisions based on information at hand as well as collected through previous experiences of working with students in order to help plan instruction suited to learners' needs.

Meaningful Management: Refers to an e-instructor who manages a course in ways that may help ease students' unnecessary frustration resulting from their being situated in a novel learning environment. This type of course management aims to promote students' affective learning in the virtual classroom.

Pedagogical Efficacy: Refers to the growth and development of both faculty and students concerning academics-oriented knowledge and skills ranging from content-specific areas to technological skills through efforts exerted by an e-instructor.

Purposeful Commitment: Refers to an e-instructor who is committed to helping students become owners of their own learning by the instructor becoming visible through various means in the shared virtual classroom in order to support learning.

Purposeful Organization: Refers to an e-instructor who is committed to helping students become owners of their own learning, achieved when the instructor becomes visible through various means in the virtual classroom.

Reflective Practice: Refers to an e-instructor's consistent behaviors in assessing the course by an ongoing, even daily, basis as well as at the end of a semester in order to motivate learners to succeed in learning.

Factors for Global Diffusion of the Internet

Ravi Nath
Creighton University, USA

Vasudeva N.R. Murthy
Creighton University, USA

INTRODUCTION

There is overwhelming evidence that the use of the Internet-enabled applications and solutions provide unprecedented economic growth opportunities. However, the Internet diffusion rates remain low in many countries. According to the International Telecommunications Union (ITU), in 2004, less than 3% of the Africans used the Internet, whereas the average Internet subscription rate for G8 countries (Canada, France, Germany, Italy, Japan, Russia, the UK, and the US) is about 50%. Also, in nearly 30 countries the Internet penetration rates still remain below 1% (ITU, 2006). So, what are the key factors that explain this wide variation in Internet subscription rates in countries around the world? An understanding of these factors will be highly useful for policy makers, economic developmental agencies and political leaders in establishing and implementing suitable national developmental strategies and policies.

BACKGROUND

The Internet is playing a pivotal role in the economic development of nations. The adoption of the Internet and related business applications such as e-business, voice over IP (VoIP), mobile commerce, and integrated supply chains have become the primary drivers of the growth of economic activities in many countries (Dedrick, Gurbaxani, & Kraemer, 2003; Kenny, 2003, Koh & Chong, 2002). For example, it is estimated that during the 1990's, investments in information and communication technologies contributed around 10 to 20 percent to the output growth of the economies of the countries such as Canada, Finland, and the United States (Lawrence, 2002). In fact , the recently published *Global Information Technology Report 2005-2006*, and Global *Competitiveness Report 2006-2007* attribute the enhanced degree of competitiveness of such high ranking economies as the United States, Singapore, Switzerland, and Nordic countries to their high levels of networked readiness and technological readiness. An important factor of technological readiness is the high level usage of the internet. *Global Technology Report 2006-2007* (p. 10) observes a positive correlation between the global competitiveness index for 2006-2007 and technological readiness index for 2005-2006 in a large number of countries emphasizing the key role played by the usage of information and communication technology (ICT). Accelerated economic growth rates in India and China are also prime example of how ICT in concert with appropriate economic, intellectual property protection, and infrastructure improvement policies promote rapid economic development.

GLOBAL INTERNET DIFFUSION FACTORS

Several factors have been observed to determine the penetration rates of the internet in various countries. These factors include the availability of reasonably-priced telecommunications infrastructure, access to personal computers, educational and training opportunities for individuals, income levels, and innovative capability of the country (Beilock & Dimitrova, 2003; Chinn & Fairlie, 2007; Dewan, Ganley, & Kraemer, 2006; Dholakia, Dholakia, & Kshetri, 2003; Kiiski & Pohjola, 2002; Oyelaran-Oyeyinka & Lal, 2005; Meijers, 2006; Murthy, 2004; Nath & Murthy, 2003, 2004). Also, the rule of law (e.g., property rights, strong legal system) governing the country's trading system, government regulations and market liberalization policies, and credible payment systems (e.g., credit cards, digital wallet, and cash) are necessary for migrating to digital commerce.

Human Capital Development Factors

It is difficult to realize the full potential of the Internet if people cannot read or write or have a basic understanding of the computer and its functions. Therefore, an individual needs a minimum level of computer and language literacy to use the Internet and accrue its benefits. One way to assess this is to consider measures such as:

a. Adult literacy rate
b. Percent of school age children enrolled in schools
c. Per capita spending on education

Many studies including those by Baliamoune-Lutz (2003) and Nath and Murthy (2003) have concluded that literacy rates and tertiary enrollment are strong predictors of Internet diffusion. Also, literate population is more accepting of

information and communication technology (ICT) innovations which subsequently lead to increased acceptance of advanced technologies such as the Internet.

Technological Factors

Availability and reliability of the telecommunications infrastructure is clearly important for people to use the Internet. This includes the bandwidth, the number of Internet hosts, the reliability of electric power, and the percent of the population of a nation that have access the Internet. In addition, people who are familiar and comfortable with using other technologies such as a phone, a mobile phone and a personal computer are more likely to adopt and use the Internet. Specific variables that one may consider are:

a. Number of personal computers per 100 inhabitants.
b. Telephone lines per 100 inhabitants.
c. Cell phone subscribers per 100 inhabitants
d. Number bandwidth (bits) per capita
e. Reliability of electrical power

One key aspect of the new economy is the availability of cost-effective information and communication technologies (ICT) and the above listed items represent leading indicators of ICT (Baliamoune-Lutz, 2003). Several studies have established that countries with higher penetration rates of personal computers, telephones, and mobile phones, sufficient bandwidth and reliable supply of electricity that powers most ICT devices, also tend to have more Internet users (Nath & Murthy, 2003, 2004).

Economic Factors

How expensive is it to get an Internet connection? If the cost is prohibitively high relative to the income, then the Internet penetration rate is likely to be low. The two variables that are relevant here are:

a. Real gross domestic product per capita (in US purchasing parity $)
b. Average monthly cost of 20 hours of Internet access.

Kiiski and Pohjola (2002) found that, across countries, GDP per capita and Internet access costs were the best predictors of growth in Internet hosts. Further, more recently Nath and Murthy (2004) using data from 62 countries, demonstrated that higher "average monthly cost of 20 hours of Internet access" had a significant negative impact on the Internet diffusion rates.

Political Factors

A nation's political and economic policies and environment are important in determining the diffusion rate of the Internet. Some nations restrict the use of the Internet (e.g., Iran and North Korea). Also, the economic policies of the government affect the extent to which citizens use the Internet. Variables that measure "political and economic" policies include:

a. **Economic Freedom Index (EFI):** Beach and O'Driscoll (2003) define this index as the "…. absence of government coercion or constraint on the production, distribution, or consumption of goods and services beyond the extent necessary for citizens to protect and maintain liberty itself." This index aggregates several factors covering broad issues such as corruption, non-tariff barriers to trade, the fiscal burden of government, the rule of law and efficiency of the judiciary, regulatory hurdles for businesses, labor market restriction, and black market activities. Complete details regarding the development and description of this index can be found in Beach and O'Driscoll (2003). The values of EFI can vary from 1 to 5. A value of 1 indicates set of national policies that promote economic freedom and a value of 5 signifies policies that are least conducive to economic freedom.
b. **Innovation Capability of the Country:** This variable is calculated as the product of the number of patents granted per million inhabitants and gross tertiary enrollment rate. Note that the number of patents reflects the nation's innovation intensity and the enrollment rates denote the degree of investment in human capital. Thus, this measure reflects a country's capability, ability to provide a conducive environment for augmenting technological advance and its capacity for innovation in technologies and products (McArthur & Sachs, 2000).

In a study of the diffusion of the Internet across countries, Nath and Murthy (2003) have shown that both the economic freedom index and the innovation capability of a country play a positive role towards the diffusion of the Internet. These findings have been further supported by Baliamoune-Lutz (2003) and Nath and Murthy (2004).

Cultural Factors

Cultural factors do impact the rate of diffusion of the internet. Culture is defined as: "the collective programming of the mind which distinguishes the members of one human group from another (Hofstede, 1991, p.5)." In his book titled *Culture's Consequences,* Hofstede (1980) suggested four dimensions of culture.

a. **Power Distance (PD):** Power distance is defined as "the extent to which the less powerful members of institutions and organizations within a country expect and accept that power is distributed unequally" (Hofstede, 1991, p.27). In cultures with high power distance, decisions are centralized and subordinates are often fearful of disagreeing with their superiors. On the other hand, cultures with low power distance are more participative and have less tolerance for the lack of autonomy. In a society with low power distance, we expect people to be more innovative and willing to try new things.
b. **Individualism versus Collectivism (IND):** This dimension relates to the way people live together. Individualism "pertains to societies in which the ties between individuals are loose: everyone is expected to look after himself or herself and his or her immediate family" (Hofstede, 1991, p.51). On the other hand collectivism "pertains to societies in which people from birth onwards are integrated into strong, cohesive groups, which throughout people's lifetime continue to protect them in exchange for unquestioning loyalty" (Hofstede, 1991). Cultures with high individualism value personal time and achievement. Such societies are expected to be more innovative and open to new ideas.
c. **Uncertainty Avoidance (UA):** Uncertainty avoidance refers to "the extent to which the members of a culture feel threatened by uncertain or unknown situations" (Hofstede, 1991, p. 113). A culture high in uncertainty avoidance is rule oriented, has less tolerance for opinions and behaviors different from its own, and avoids taking risks. There is also resistance to change. Cultures with high uncertainty avoidance are expected to be less innovative and less accepting of new things.
d. **Masculinity versus Femininity (MAS):** This is possibly the most controversial dimension of culture advocated by Hofstede. In highly masculine cultures "men are supposed to be assertive, tough and focused on material success; women are supposed to be more modest, tender and concerned with the quality of life" (Hofstede et al., 1998). The more modern and popular perspective on this dimension is to view the masculine and feminine culture in terms of competitiveness and material success versus nurturing behavior and quality of life, as opposed to gender roles for the sexes.

There is considerable evidence supporting that cultural factors influence the use of various technological innovations. Yaveroglu and Donthu (2002) have shown that the use of cell phones, home computers, and microwave ovens is high in countries with low power distance, low uncertainty avoidance, and high individualism. Yeniyurt and Townsend (2003) investigated the role that culture plays in the acceptance of new products. Their findings indicate that lower acceptance of new products is related to power distance and uncertainty avoidance. With respect to the adoption of enterprise resource planning (ERP) software, national culture is shown to have a significant influence on its adoption rate (van Everdingen & Waarts, 2003). Cultural considerations even play a role in how information systems, in general, are designed, implemented, and used (Gallupe & Tan, 1999; Jarvenpaa & Leidner, 1998; Montealegre, 1997; Nelson & Clark, 1994; Straub, 1994; Watson, Ho, & Raman, 1994). For instance, Straub (1994) showed that in Japan, workers prefer fax over e-mail because of the intricacies of the Japanese language and other cultural factors. With respect to the role of culture on Internet diffusion, Nath and Murthy (2004) have shown that "uncertainty avoidance" and "masculinity" are positively associated with the diffusion of the Internet.

FUTURE TRENDS

The outlook for the Internet and its usage looks very promising. First, the broadband access to the Internet will increase rapidly allowing people very high-speed access to the Internet. Consequently it will be possible for the users to download rich content with little delay. New technological innovations such as WiMax will also accelerate the diffusion of broadband Internet services in a cost effective manner. Second, Internet access costs will decline due to global competition and economic reforms taking places in many countries around the world. Third, as many nations become receptive to economic reforms and provide additional economic freedom opportunities to its citizens, entrepreneurship will thrive, incomes will rise, information economies will increase and more people will use the Internet and become fully vested in the information economy. Overall, the existing digital divide will narrow considerably. In addition, mobile phone access to the Internet will yield unprecedented economic benefits to citizens at the "bottom of the pyramid" around the world.

CONCLUSION

A clear and vivid understanding of the factors that determine the Internet usage is crucial for researchers, practitioners, and policy makers around the world. Researchers who wish to study international information technology issues and their economic implications must be cognizant of these factors in assessing computer user behaviors and technology adoption patterns. Also, an understanding of inter-national differences with respect to these factors can improve IT/IS research design strategies and enhance the implementation of research studies in different national settings.

At the policy level, national policy makers and political leadership can benefit by incorporating the insights gleaned from this research into their deliberations resulting in more informed macro-level strategic policies. Without a cohesive and carefully crafted national development strategies and policies, nations are likely to miss out on the benefits of the Internet and thus leave a large portion of the population way behind on the economic ladder.

KEY TERMS

Economic Freedom Index: A measure of the absence of government constraints on the economic activities of a nation.

Hofstede's Cultural Dimensions: Four factors proposed by Hofstede along which cultures might differ.

Internet Diffusion Rate: Percent of population of a nation having access to the Internet.

Power Distance (PD): A measure of the unequal distribution of power in a society. Cultures with high power distance are centralized whereas cultures with low power distance are more participative and individuals like more autonomy.

Uncertainty Avoidance (UA): A measure of how well a culture accepts uncertainty. A culture with high uncertainty avoidance is mostly rule oriented and is less tolerant of divergent opinions and behaviors.

Faculty Competencies and Incentives for Teaching in E-Learning Environments

INTRODUCTION

In 2001, Michele Bunn offered her readers *timeless* and *timely* issues in distance education. There were predictions that virtual universities would shift from a teacher-centered to a student-centered learning environment. Although emerging technologies have allowed for more student-centered approaches, university instructors remain a key factor in the success or failure of distance education efforts in university settings. Shifts in technological advances over the past five years have made the term "distance education" less accurate. Learners are not necessarily located away from campuses, but instead choose the flexibility to learn asynchronously. Therefore, we will use the term e-learning, rather than distance education.

Timeless issues impacting e-learning typically include the core values of universities in regard to strategic planning, faculty competence, and incentives. Administrative decision-making determines relevant *timely* issues that tend to fall into three categories: (1) student-related issues, (2) instructional issues, and (3) organizational issues (Bunn, 2001). These three areas will frame our discussion.

BACKGROUND

The research on distance education faculty participation in the 1990s focused on the need to provide appropriate technological infrastructure, faculty training, and support for course development efforts. Enhancing faculty participation required that resources be directed to adequate levels of support and training so that instructional technologies were used for the benefit of students (Howard, Schenk, & Discenza, 2004).

While faculty recognized the potential of technology-enhanced instruction, intervention strategies were necessary to alter how people perceived and reacted to distance education technologies. Incentives such as release time, mini-grants, continuing education stipends, and recognition in the promotion and tenure process, were recommended to encourage faculty participation (Dooley & Murphrey, 2000; Murphrey & Dooley, 2000).

Today, technological infrastructure at universities is often in place. Many universities now include wireless technology and require students to come to the university armed with their own laptops and technological skills. Similarly, many faculty enter the profession equipped with technological competence. The need for training and support, while still important to some, has become replaced by the need to locate the appropriate resource personnel to create advanced multimedia. University instructors continue to want incentives to participate in e-learning due to the time and effort required to participate effectively. Most importantly, time and effort spent on e-learning activities is time diverted from scholarly work in research and the development of new knowledge. In addition, many faculty often lack the mechanics of how online teaching differs from lecture in terms of instructional material development, communication channels, interactions, and more authentic forms of assessment.

STUDENT-RELATED ISSUES

According to Bunn (2001), timeless student-related issues for e-learning incorporate the "policies and practices that define how students are treated in the administrative system. These timeless issues include the basic approaches to recruitment, enrollment, retention, and graduation" (p. 58).

Students are viewed as clients or customers with choices for their courses and programs. The view of a student as a customer poses a timely issue in regard to student-centered instructional design and delivery.

E-learning draws on the ability of learners to be self-directed, thus, incorporating adult learning principles (andragogy) in the design and delivery of content (Richards, Dooley, & Lindner, 2004). Andragogy is based on the following six assumptions about the learner: (1) learner's need to know; (2) self-concept of the learner; (3) prior experience of the learner; (4) readiness to learn; (5) orientation to learning; and (6) motivation to learn (Knowles, Holton, & Swanson, 1998).

Educators, who put their interests and needs (intentional or unintentional) over those of the learners, restrict meaningful learning. The ultimate goal of an educator should be to facilitate learning (Leamnson, 1999). This will require the educator to be a teacher, coach, mentor, facilitator, motivator, and/or authoritarian depending on the learners' personal characteristics.

Developing learning activities that require learners to draw on and share their prior experiences facilitates deeper and more meaningful learning. Noted philosopher, educator, and author, John Dewey (1938) stated that the education process begins with experience and that "all genuine education come about through experience" (p. 13). For example, learner-led threaded discussion groups can be used to help learners think about how course materials can be used in various contexts.

It is necessary for the educator to maintain a sense of community regardless of where the learning takes place. While this is readily accomplished in a classroom setting, it requires more planning and effort for e-learning courses (Brown, 2001). Grow (1991) theorized that in asynchronously delivered courses, an educator's traditional role of providing feedback is less important than the role of motivator, coach, or delegator, implying that the instructor must establish a learning climate. Effective learning seems to require student engagement (Kearsley & Shneiderman, 1999). However, instructor behaviors alone cannot determine student success rate. Success is at least partially controlled by student behavior. Previous research has shown, for example, that length of engagement in an asynchronously delivered course was positively related to a student's perception of learning (Lindner, Hynes, Murphy, Dooley, & Buford, 2003).

Learners can be successful in a variety of settings, and few, if any, differences in performance will be identified based on delivery method. While the delivery method may not impact success, delivery strategies do. Delivery strategies can be defined as those methods used to engage students in the instructional materials. It can be argued that through various interactions, engagement results in learning—not grades (Merrow, 2003). Moore (1989) developed a model for describing interactions used to engage learners in a distance education environment. His model included three types of interaction: (1) learner to learner; (2) learner to content; and (3) learner to instructor. Hillman, Willis, and Gunawardena (1994) expanded this model to include an additional type of interaction: learner to technology (interface). Zhang and Fulford (1994) expanded the model yet again to include vicarious interaction. Vicarious interaction captures the value to a learner of the interactions between others in the learning environment—the learning benefits of watching, reading, (or listening to) others interact. Discussion boards, for instance, are said to encourage vicarious interaction. Vicarious interaction contributes to overall perceived interaction, learner satisfaction, and quite possibly learning (Kawachi, 2003; Swan, 2004).

Figure 1. Vicarious interaction (Based on Hillman, Willis, & Gunawardena, 1994; Moore, 1989)

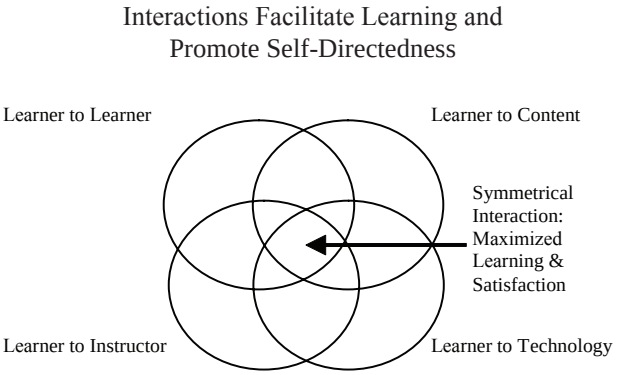

Figure 1 illustrates the interconnectedness among the types of interactions. To maximize learning and increase satisfaction in e-learning environments, opportunities for learner to learner, learner to content, learner to instructor, and learner to technology interactions should be included, and vicarious interaction should be encouraged. The authors believe that students will self-select the amount of each type of interaction necessary to maximize their learning and satisfaction. This individually balanced or "symmetrical" selection of interaction opportunities should facilitate deeper and more meaningful learning, increase overall learning satisfaction, and promote self-directedness among learners. The challenge for faculty members is to remain up-to-date with the ever-increasing range of technologies developed to support the various types of interaction. Acquiring the knowledge needed for the systematic selection of these tools into an instructional design, as well as the skills needed for their day-to-day management in instructional settings, presents tremendous challenges for faculty members.

INSTRUCTIONAL ISSUES

The focus of this article is on university faculty competencies and incentives for participation in e-learning. The student-related issues directly impact the philosophical beliefs and values of the faculty as they create instructional content and develop delivery strategies. If the learner is the customer, then timeless instructional issues will focus on the creation and delivery of courses for the learner (Bunn, 2001). Learner-centered instructional methods based on emerging technologies require new perspectives on developing materials, delivering courses, and creating faculty incentives for innovation and experimentation (Bunn, 2001).

Although university faculty have general technical competence, they usually do not have experience in the design and delivery of online courses and programs (andragogy, instructional design, etc.). Academic institutions are generally concerned that faculty are both *willing* to create content for online delivery and *able* to create effective instructional materials (Furnell, Evans, & Bailey, 2001).

As we reflect on instructional issues related to the delivery of courses online or at a distance, it is important to recognize the competencies required of faculty to teach in these environments. Murphrey and Dooley (2006) reported seven core areas as necessary for working in the e-learning arena: (1) proficiency with computers and programs, including interface design, (2) organizational skills, (3) instructional design, (4) evaluation and assessment strategies, (5) adult learning theory, (6) written communication skills, and (7) student/teacher relationships to build a sense of community. Each of these areas is critical in creating engaging and effective instruction for delivery online. In many ways these competencies are not very different from those required for traditional face-to-face instruction. The differences lie in the way in which each area can be accomplished and the magnitude by which the area impacts overall effectiveness. For example, organizational skills are important in both traditional and e-learning settings. However, when a faculty member lacks this skill and is operating in an e-learning setting, the overall negative impact can be much more due to the nature of the environment.

Magjuka, Shi, and Bonk (2005) share 10 critical design and administrative issues related to online education. These issues include which student group to serve, how the online program will be treated relative to other programs, the extent of blended versus stand-alone delivery, faculty load assignments, use of funds for course development versus faculty training, source of interactivity, course design versus faculty led interactions, content management system selection, and corporate partnerships/alliances. Faculty competencies and incentives will impact how an institution addresses each of these areas. Faculty must be competent in the delivery of course material in an online environment while at the same time recognize and embrace the incentives offered by administration to engage in these activities.

ORGANIZATIONAL ISSUES

Timeless organizational issues are directly related to student and instructional issues. They are inseparable from "technology, infrastructure, human resources, and administration" (Bunn, 2001, p. 62). Timely issues related to the organizational system include a reorganization of thinking and operation, seeking "cost-efficient ways to 'deliver' knowledge" (Bunn, 2001, p. 65).

In addition to concerns about faculty e-learning competence, many institutions struggle with providing appropriate incentives for online course development. Many institutions encourage faculty participation by paying additional stipends or salary for the development and delivery of online instruction. This is sometimes distributed in the form of mini-grants or additional summer salary for faculty not on 12-month contracts. In some cases faculty members receive "overload" funding for teaching additional sections in addition to their faculty teaching load. Additionally, many institutions have "distance education" affiliated with continuing education and pay faculty a fee per student for delivery of online instruction. These entrepreneurial models work well to reward faculty for their time and expertise.

FUTURE TRENDS

Instructors who have e-learning competence, well-developed instructional materials, and sought-after content are quite marketable. There is a trend for faculty to teach for other institutions using a distributed virtual faculty model. The University of Phoenix has been quite successful in the recruitment of distributed faculty to teach their online courses. This is cost effective for the institution and allows faculty to earn extra dollars, much like with consulting services. Furnell et al. (2001, p. 285) purport that "… [A]cademics could take encouragement from the observation that, in a virtual market, they (as subject experts) are no longer geographically constrained to providing their services to a single [institution], and could well find wider employment in the ODL [online distance learning] domain.

CONCLUSIONS

It must be recognized that teaching online requires a unique set of competencies (Richards et al., 2004) and attention to faculty incentives (Furnell et al., 2001). Bunn (2001) emphasized that timeless issues involve the fundamental core

values of the institution. Faculty participation in distance education, e-learning, or whatever the name of the future may be must consider both the willingness (incentives) and ability (e-learning competencies) of the faculty to be successful. Fundamentally, attention to vicarious interaction and learner-centered approaches is key. Faculty participation is therefore both a timeless and timely issue impacting the design and delivery of instruction for e-learning environments.

KEY TERMS

Andragogy: Design and instructional philosophy based on the following six assumptions about the adult learner: (1) learner's need to know; (2) self-concept of the learner; (3) prior experience of the learner; (4) readiness to learn; (5) orientation to learning; and (6) motivation to learn (Knowles et al., 1998).

Competence: A measure of perceived level of ability by faculty in the use of electronic technologies often associated with distance education (Jones, Lindner, Murphy, & Dooley, 2002).

E-Learning: "The appropriate application of the Internet to support the delivery of learning, skills, and knowledge in a holistic approach not limited to any particular course, technologies, or infrastructures" (Henry, 2001, p. 249).

Incentive: Intrinsic or extrinsic motivational factors that impact faculty decisions to participate in distance education.

Instructional Issues: Determining the instructional needs, resource availability, curriculum design, course development, and faculty capacity and incentives for effective delivery of distance education (Bunn, 2001).

Learner-Centered Instruction: Any formal or nonformal education that accounts for a learner's cognitive and metacognitive factors, motivational and affective factors, developmental and social factors, and individual differences (APA, 1997).

Organizational Issues: Developing infrastructure, technical systems, resource allocations, professional development, and organizational restructuring necessary for the efficient delivery of distance education (Bunn, 2001).

Student-Related Issues: Policies and practices that impact the needs of the learner (client or customer) in terms of recruitment, enrollment, retention, and graduation (Bunn, 2001).

Vicarious Interaction: A student's perception of the interactions between others in the learning environment (Zhang & Fulford, 1994).

Financial Trading Systems Using Artificial Neural Networks

Bruce Vanstone
Bond University, Australia

Gavin Finnie
Bond University, Australia

INTRODUCTION

Soft computing represents that area of computing adapted from the physical sciences. Artificial intelligence techniques within this realm attempt to solve problems by applying physical laws and processes. This style of computing is particularly tolerant of imprecision and uncertainty, making the approach attractive to those researching within "noisy" realms, where the signal-to-noise ratio is quite low. Soft computing is normally accepted to include the three key areas of fuzzy logic, artificial neural networks, and probabilistic reasoning (which include genetic algorithms, chaos theory, etc.).

The arena of investment trading is one such field where there is an abundance of noisy data. It is in this area that traditional computing typically gives way to soft computing as the rigid conditions applied by traditional computing cannot be met. This is particularly evident where the same sets of input conditions may appear to invoke different outcomes, or there is an abundance of missing or poor quality data.

Artificial neural networks (henceforth ANNs) are a particularly promising branch on the tree of soft computing, as they possess the ability to determine non-linear relationships, and are particularly adept at dealing with noisy datasets.

From an investment point of view, ANNs are particularly attractive as they offer the possibility of achieving higher investment returns for two distinct reasons. Firstly, with the advent of cheaper computing power, many mathematical techniques have come to be in common use, effectively minimizing any advantage they had introduced (see Samuel & Malakkal, 1990). Secondly, in order to attempt to address the first issue, many techniques have become more complex. There is a real risk that the signal-to-noise ratio associated with such techniques may be becoming lower, particularly in the area of pattern recognition, as discussed by Blakey (2002).

Investment and financial trading is normally divided into two major disciplines: fundamental analysis and technical analysis. Articles concerned with applying ANNs to these two disciplines are reviewed.

BACKGROUND

There are a number of approaches within the literatures, which deal with applying ANN techniques to investment and trading. Although there appears to be no formal segmentation of these different approaches, this review classifies the literature into the topics proposed by Tan (2001), and augments these classifications with one more category, namely, hybrid. These categories of ANN, then, are:

- **Time series:** Forecasting future data points using historical data sets. Research reviewed in this area generally attempts to predict the future values of some time series. Possible time series include Base time series data (e.g., closing prices), or time series derived from base data, (e.g., indicators--frequently used in technical analysis).
- **Pattern recognition and classification:** Attempts to classify observations into categories, generally by learning patterns in the data. Research reviewed in this area involved the detection of patterns, and segregation of base data into "winner" and "loser" categories as well as in financial distress and bankruptcy prediction.
- **Optimization:** Involves solving problems where patterns in the data are not known, often non-polynomial (NP)-complete problems. Research reviewed in this area covered the optimal selection of parameters, and determining the optimal point at which to enter transactions.
- **Hybrid:** This category was used to distinguish research, which attempted to exploit the synergy effect by combining more than one of the previous styles.

There appears to be a wide acceptance of the benefit of the synergy effect, whereby the whole is seen as being greater than the sum of the individual parts.

Further, the bias in this style of research toward technical analysis techniques is also evident from the table, with one-third of the research pursuing the area of pattern recognition and classification. Technical analysis particularly lends itself to this style of research, as a large focus of technical analysis concerns the detection of patterns in data, and the

examination of the behavior of market participants when these patterns are manifest.

USING NEURAL NETWORKS TO DEVELOP TRADING SYSTEMS

This section briefly considers the characteristics of each of the four main categories previously described. The selected articles were chosen as they are either representative of current research directions, represent an important change in direction for this style of research, or represent a novel approach.

Research into Time Series Prediction

The area of time series predictions is normally focused on attempting to predict the future values of a time series in one of two primary ways, either:

- Predicting future values of a series from the past values of that same series
- Predicting future values of a series using data from different series

Typically, current research in this area focuses on predicting returns, or some variable thought to correlate with returns (e.g., earnings). Some researchers focus on attempting to predict future direction of a series (e.g., increasing from last known value, decreasing from last known value, no change). Research of this nature is essentially a classification problem, and is discussed in that section.

The following articles were selected and reviewed as they are representative of the current research in Time Series Prediction (Austin et al., 1997; Chan & Foo, 1995; Falas et al., 1994; Hobbs & Bourbakis, 1995; Quah & Srinivasan, 2000, Wang et al., 2003; Yao & Poh, 1995). The articles reviewed consider both fundamental and technical data. For example, Falas et al. (1994) used ANNs to attempt to predict future earnings based on reported accounting variables. They found no significant benefit using ANNs compared to the logit model and concluded that the accounting variables chosen were not appropriate earnings predictors. This conclusion represents one of the major problems encountered when working with ANNs, namely, their non-existent explanatory capability. It is not unusual to find conclusions of this type when reviewing ANN research with non-correlation often being reported as wrongly chosen input variables. Quah et al. (2000) use mainly accounting variables to predict excess returns (with limited success). Chan et al. (1995) use ANNs to predict future time series values of stock prices, and use these "future" values to compute a variety of technical indicators. The ANN produced showed particularly promising results, the authors conclude that the networks ability to predict allows the trader to enter a trade a day or two before it is signalled by regular technical indicators, and that this accounts for the substantially increased profit potential of the network.

In many ways, these two primary prediction methodologies relate quite closely to technical analysis strategies. For example, the use (and projection) of a moving average over a series of stock prices could be regarded as predicting future values of a series (the moving average) from past values of the same series. Indicators in technical analysis are often composed of a number of constituent data items, like price, volume, open-interest, etc. These indicators are commonly used to give indications of future direction of price.

Research into Pattern Recognition and Classification

Pattern recognition techniques and classification techniques have been grouped together, as their goal is normally not to predict future values of a time series, but to predict future direction of a time series. For example, the primary goal of chartists (a style of technical analyst) is to attempt to predict trend turning points by studying chart price action, looking for certain patterns. Chartists have noticed that these patterns tend to re-occur, and are reasonably reliable indicators of the future direction of price trends. There are a great deal of these chart patterns, and different analysts attach different weightings to the predictive power of any given pattern. Also, these patterns normally need to be confirmed by values from another time series (such as volume) to be considered "reliable." For more detail on this area, the reader is encouraged to refer to Pring (1999). Non-pattern matching techniques, which also attempt to predict future direction of a time series are also classification problems. Quite often, in addition to predicting future direction of a time series, classification research attempts to classify stocks into two main groups, namely "winners" and "losers" as in bankruptcy and financial distress predictions.

The following articles were selected and reviewed as they are representative of the current research in pattern recognition and classification (Baba & Handa, 1995; Baba et al., 2004; Baba & Nomura, 2005; Baba et al., 2001; Baek & Cho, 2000; Enke & Thawornwong, 2005; Fu et al., 2001; Kamijo & Tanigawa, 1990; Michalak & Lipinski, 2005; Mizuno et al., 1998; Skabar & Cloete, 2001; Suh & LaBarre, 1995; Tan & Quek, 2005). As previously described, the research can generally be classified as "winner" and "loser" detection or pattern matching. The work of Tan et al. (2005), and later, Tan and Dihardjo uses the concept of "winner" and "loser" classification, as does Longo et al. (1995) and Skabar et al. (2001). Specifically, Skabar et al. (2001) do not predict "winners" and "losers," but predict two disparate categories,

namely "up" and "down" (direction of returns). The work of Kamijo et al. (1990) provides an excellent example of pattern matching with the authors building ANNs to identify "triangle" patterns in stock market data (the "triangle" is a specific pattern used in technical analysis).

Classification involving pattern matching could also be validly discussed under the previous section on time series prediction, due to the fact that pattern constructs must occur in specific time order, and the majority of patterns are not time invariant. This leads to the desire of researchers to identify time invariant patterns, or attempt to determine a fixed period of time in which a pattern should occur. The work of Fu et al. (2001) provides examples of using genetic algorithms to "fix" the length of patterns, making them suitable for study using ANNs.

Research into Optimization

The focus of optimization is directed toward research that uses soft-computing specifically to attempt to optimize an otherwise accepted achievable result. Typical of this style of research article, an already accepted result is discussed, then considered for optimization. The optimization is characteristically proven by excess returns compared to the un-optimized case.

For an example of this style of optimization using ANNs, an index arbitrage timing has been proposed by Chen et al. (2001) and Zimmerman and Grothmann (2005). Their model attempts to optimise the correct entry point timing for index arbitrage positions. Current arbitrage models propose establishing an arbitrage position immediately an opportunity arises; the neural network approach is to attempt to locate the timing when there will be a maximum basis spread for the arbitrage, thereby increasing profit potential. Their research concludes that the neural model significantly outperforms the traditional approach.

Research into Ensemble Approaches

Research is classified as an ensemble approach if it combines work from more than one of the areas described next, effectively attempting to leverage the synergy effect by achieving an end result greater than that expected from each of the individual constituents. Among soft-computing research, there is a growing trend towards using the ensemble approach to analysis.

The following articles were selected and reviewed as they are representative of the current research in ensembles (Abdullah & Ganpathy, 2000; Baba et al., 2002; Chenoweth et al., 1995; Doeksen et al., 2005; Jang et al., 1991; Leigh et al., 2002; Liu & Lee, 1997; Wong & Lee, 1993). The majority of the ensembles draw their components from a variety of soft computing methods. The use of ANNs and genetic algorithms (GAs) together is quite popular, and is used by Leigh et al. (2002) to combine pattern recognition techniques with price forecasting. Another approach combining ANNs and GAs is provided by Baba et al. (2002) using ANNs for their predictive ability, and GAs to determine the best way to react to that information. Some ensembles combine multiple ANNs, for example, Jang et al. (1991) combine two ANNs, one that takes a short-term view of market movement, with one that takes a longer-term view. They then build a model, which reacts to a weighted output sum of the outputs of both models. Both Liu and Lee (1997) and Abdullah et al. (2000) also used ensembles of ANNs and concluded that the predictive ability of the ensemble approaches exceeded that of the individual ANNs. Other research reviewed combined ANNs with fuzzy logic and expert systems.

FUTURE TRENDS

Essentially, the field of financial trading is in a state of transition between traditional pricing models, the efficient market hypothesis, and ideas about behavioral finance. The challenge that presents itself is how best to unify financial trading pricing models. There is much debate about the validity of the efficient market hypothesis, which effectively contends that prices cannot be predicted using methods such as technical analysis. There is a large body of evidence that appears to contradict the efficient market hypothesis, and there seems little chance of academically moving forward en-masse unless an alternative valid pricing model exists. This offers substantial opportunity for soft computing research techniques, particularly neural models. These models are capable of acting as universal approximators, and determining complex non-linear relationships. The goal with these methods is to attempt to mine deep relationships, which can shed new light about the behaviour of markets and prices. These new relationships would inherently provide more scope for developing feasible and effective pricing models.

CONCLUSION

This article has surveyed recent and key literature in the domain of applying artificial neural networks to investment and financial trading. Within the context of investment discipline, this survey shows that the majority of this type of research is being conducted in the field of technical analysis. As discussed earlier, soft computing is particularly data intensive, and it is suggested that this observation goes someway to explaining this obvious bias in research.

Within the area of soft computing styles, the survey finds that the majority of research is within the area of both hybrid systems and pattern recognition and classification. It is suggested the reason for this is that the technical analysis approach lends itself towards the pattern recognition and classification

areas. Also, many hybrid systems include pattern recognition and classification as one of their constituents.

KEY TERMS

Continuation Pattern: A pattern in technical analysis, which suggests, on the balance of probabilities, that price trend will continue in its current direction.

Fundamental Analysis: The use of company reported financial data to determine an intrinsic (or fair value) for a security. Used to identify cases where companies are undervalued, with a view to profiting from the future price movements. This style of analysis is generally long-term.

Noisy Data: This term is generally used to describe data and datasets where there is a low signal-to-noise ratio. Any algorithm attempting to filter out the signal has to be capable of identifying and dealing appropriately with noise. In this sense, noise is that element of the data, which obscures the true signal.

Reversal Pattern: A pattern in technical analysis, which suggests, on the balance of probabilities, that price trend will change direction.

Technical Analysis: The study of the behavior of market participants, as reflected in the technical data. Used to identify early stages in trend developments, with a view to profiting from price movements. This style of analysis is generally short term.

Technical Data: Technical data is the term used to describe the components of price history for a security. These components are open price, low price, high price, close price, volume traded, and open interest.

Technical Indicators: Technical indicators are produced as results of various computations on technical data. They are primarily designed to confirm price action.

Triangle Pattern: A triangle is a particular pattern observed using technical analysis. There are a variety of circumstances under which a triangle can occur, and dependant on the circumstances, the triangle can be either a reversal or continuation pattern.

Focused Requirements Engineering Method for Web Application Development

Ala M. Abu-Samaha
Amman University, Jordan

Lana S. Al-Salem
SpecTec Ltd & MEP, Greece

INTRODUCTION

The requirements phase of the system/application development process typically involves the activities of requirements elicitation, analysis, validation, and specification. The main goal of such a process is "to develop a requirements specification document which defines the system to be procured and which can act as a basis for the system design" (Sawyer, Sommerville, & Viller, 1996). Hence the underpinning assumption of the requirements engineering (RE) process is to transform the operational needs of an organisation into complete, consistent, and unambiguous system/application specifications through an iterative process of definition and validation (Pohl ,1994).

The Web engineering (WE) literature provides a limited number of methods and techniques that can be used to manage the RE process in a Web development context [*e³-value* framework (Gordijn, Akkermans, & van Vliet, 2000), SOARE approach (Bleistein, Aurum, Cox, & Ray, 2004), e-prototyping (Bleek, Jeenicke, & Klischewski, 2002), AWARE (Bolchini & Paolini, 2004), and SSM/ICDT (Meldrum & Rose, 2004)]. Despite the availability of such a limited number of Web requirements engineering (WRE) methods, many researchers criticised such methods for their failure to address the necessity to align the Web application' requirements to the organisation's business strategy. Hence, the recommendation of many researchers (Al-Salem & Abu-Samaha, 2005a; Bleistein 2005; Bleistein, Cox, & Verner, 2004; Vidgen, Avison, Wood, & Wood-Harper, 2002) is to utilise a general WRE framework for the development of Web applications that can align the application's requirements to the organisation's business needs and its future vision. The objective of such a WRE framework is to incorporate the elicitation/analysis of business strategy as part of the application's RE process.

This chapter presents a WRE method that extends Sommerville and Kotonya's viewpoint-oriented requirements definition (VORD) and Kaplan and Norton's balanced scorecard (BSC) to elicit the Web application' requirements and to plan/analyze the business strategy, respectively. In addition, eWARE (extended Web application requirements engineering) deploys the concept of "requirements alignment" to attain business objectives during the requirements discovery, elicitation, and formalisation process to identify the services of the Web application that will achieve the business objectives in order to improve the organisation's profitability and competitiveness. The chapter is organised into a number of sections. The second section of this chapter provides a background to Web applications in terms of definition and differentiating characteristics. The third section provides a discussion of eWARE method in terms of phases and activities. This section is divided into two subsections to cover the activities of the two prominent phases of the eWARE process in more detail. The fourth and fifth sections provide a discussion of possible future trends in WRE and a number of concluding remarks.

BACKGROUND

Web applications provide organisations an unprecedented chance to stretch their existence beyond the typical boundaries of an organisation to include customers, trading partners, and suppliers.Little attention has been paid to the process of RE for Web application development, in comparison to other areas of the development process [modelling, design, and coding] (Ginige & Murugesan, 2001). Hence, Web applications can be defined as "applications that tend to be used to integrate and streamline an organisation's business processes beyond organisational (customers, agents, suppliers, others) and geographical borders; provide an organisation with competitive products and services that give it a strategic advantage over its competitors in the marketplace; promote business innovation; and/or improve operational efficiency" (Al-Salem & Abu-Samaha, 2005a).

There is a pressing need in the WE discipline for RE approaches and techniques that (a) take into account the multiplicity of user profiles and the various stakeholders involved [a stakeholder is defined as "anyone who can share information about the system, its implementation constraints or the problem domain" (Potts, Takahashi, & Anton, 1994)]; (b) eliciting overall functionality and the business environ-

ment of the Web application; (c) specifying technical and nontechnical requirements of the Web application, and (d) aligning the Web application' requirements to the overall business strategy (Bleistein et al., 2005; Ceri, Fraternali, Bongio, Brambilla, Comai, & Matera, 2003; Ginige & Murugesan, 2001; Kautz & Madsen, 2003; Lowe, 2003; Meldrum & Rose, 2004; Nuseibeh & Easterbrook, 2000; Vidgen et al., 2002). More importantly, a Web application must be developed with an emphasis on how the services of such an application can achieve the business vision and strategy and fulfil the business processes (Haire, Henderson-Sellers, & Lowe, 2001).

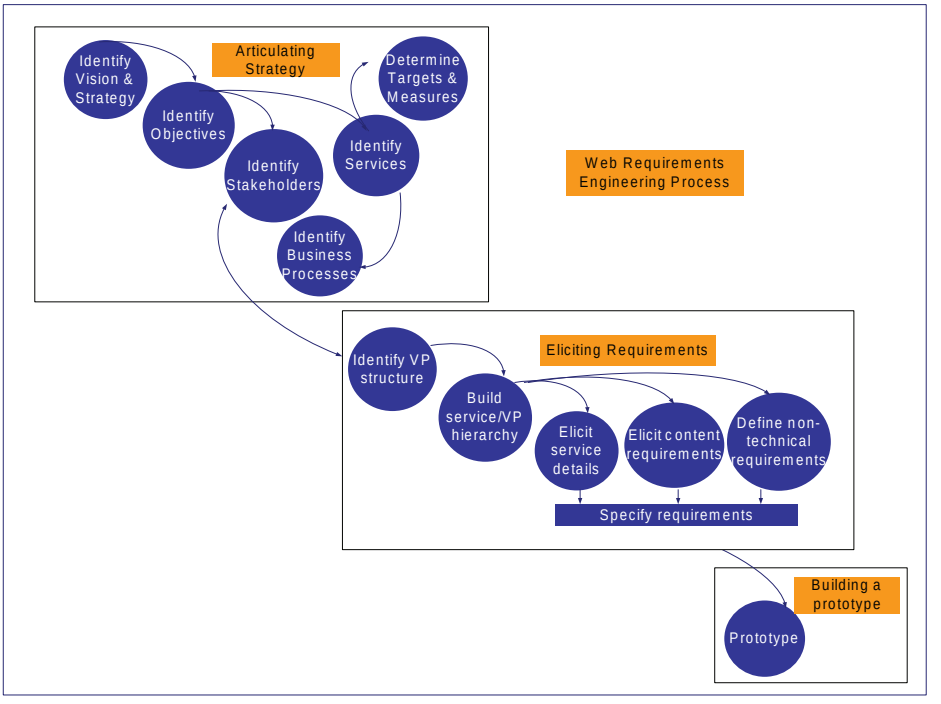
eWARE Process

eWARE process can be best perceived as a series of activities grouped into three phases; strategy articulation via BSC, Web application' requirements elicitation via VORD, and prototype building; Figure (1) presents the phases and activities of eWARE. Such a process aims to develop a Web application requirements specification (WRS) document that is aligned with business strategy and detailed enough to be used for contractual purposes.

The strategy articulation phase of eWARE can be best thought of as a structure of many layers. The vision of the organisation is at the top of the structure, while the strategic objectives are presented in the next layer of the structure followed by the Web application services. The next layer of the structure contains the measurements and targets for meeting the strategic objectives. The level of detail tends to increase as we move down the structure of the strategy. This articulation of the organisation's vision, objectives, and measurements aims to translate the future vision of the organisation into detailed and prioritised Web application requirements (this will be fully covered in the coming subsections).

The requirements elicitation phase of the eWARE process is used to produce a WRS document based on requirements collected during the strategy articulation phase. Requirements elicitation relies on the identification of the relevant viewpoints (VPs), their sub-VPs, and requirements for each viewpoint (VP). Kotonya and Sommerivlle (1996) define a VP as anyone who may have some direct or indirect influence on the system/application requirements. Goals and objectives of the different stakeholder groups need to be identified to define success or failure measures for each stakeholder. Moreover, nonfunctional requirements {NFR) need to be

Figure 1. The eWARE process



identified; these include some of the "-ilities" of the Web application, such as reliability, supportability, maintainability, affordability, and so forth. Finally, in the prototyping phase of the eWARE process, the system/application stakeholders consider the unclear set of requirements, and agree on prototyping the ambiguous requirements to verify them. Moreover, the user interface (UI) and Web site structure are presented in a throw away prototype.

The mentioned WRE phases and activities are perceived to be iterative and incremental in nature where unmet targets are questioned. This cyclic view of the WRE process will trigger the strategy articulation phase to enter in a feedback loop in order to refine services and change requirements of the Web application in order to enhance the organisation's chance to achieve its set vision and strategy.

Strategy Articulation Phase

As mentioned earlier, the strategy articulation phase of eWARE process aims to align the Web application' requirements to the organisation's business strategy through a process of strategy analysis. eWARE delivers such alignment via eBSC (extended Balanced Score Card). According to eBSC, aligning the Web application' requirements to the business objectives yields four perspectives to focus upon (stakeholders, strategic objectives, internal processes, and Web application services). Figure 2 provides a diagrammatic representation of the perceived relationship between the four perspectives.

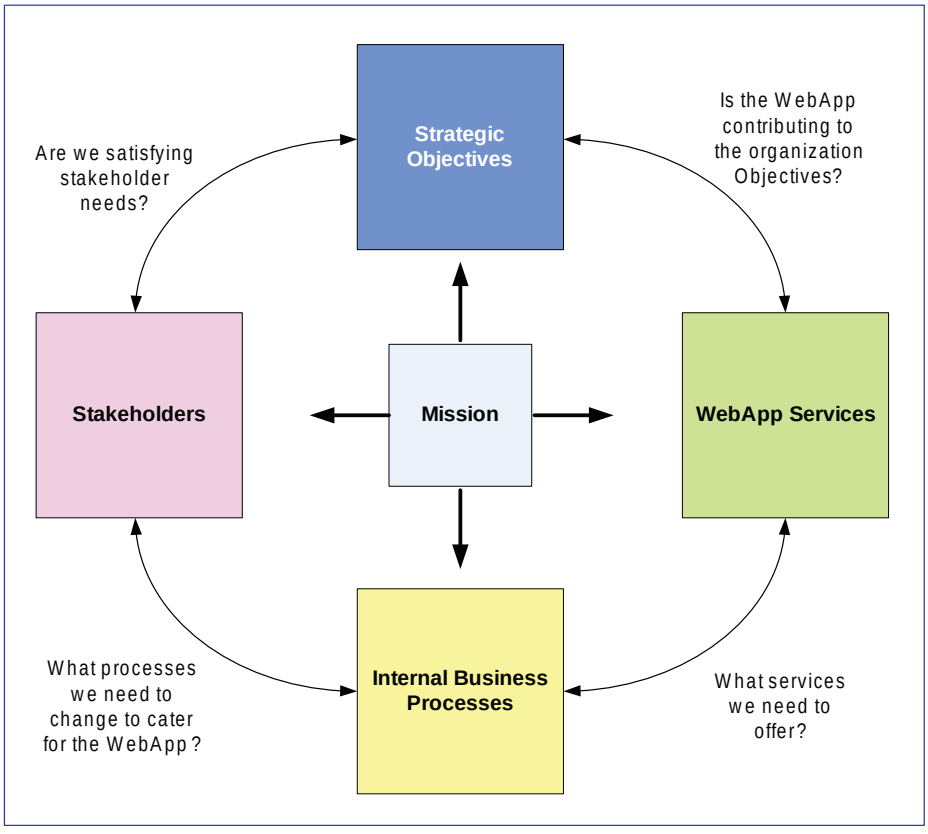
Strategic Objectives Perspective

Objectives are statements that clarify what the strategy aims to achieve. Hence, organisations pursue strategies in the belief that, when implemented, they will enable the organisation to better achieve its strategic objectives.

Web Application Services Perspective

The Web application services are the collection of functionality, quality, content, and all what the Web application must provide in order to achieve the strategic objectives of the

Figure 2. eBSC perspectives



organisation and to meet the expectations of its stakeholders. This perspective is considered as a precondition to process improvement, stakeholder satisfaction, and business objectives' realisation. Hence, the development team, comprising of requirement engineers and end user representatives, must be empowered to select which services (functionalities) of the Web application will be included, in order to deliver the optimal business solution. Decisions and trade-offs need to be made between new services elicited through the eBSC process, and less important original functionalities that may have to be excluded, being less strategically important.

Stakeholders[1] Perspective

The stakeholder perspective is arguably the most important perspective in the Web application development process. As mentioned earlier, a stakeholder is defined by Potts et al. (1994) as "anyone who can share information about the system, its implementation constraints or the problem domain." According to Potts et al. (1994), the list of stakeholders will include end users, indirect users, other customer representatives, and developers. Since a stakeholder is, in essence, a requirements source; it can be an application user, a competitor, or even a third party. Hence, if the stakeholder represents a customer, then the requirements elicitation effort will focus on new customer acquisition, customer retention, and customer profitability. The goal of using eBSC is to classify the organisation's strategy by stakeholder, which will lead to introducing Web application services for each group to meet their strategy or objective. The organisation must determine whom it serves and how their requirements can be met.

Internal Process Perspective

Organisations' activities can be grouped into "business processes" that describe the way work is to be implemented. Some of the organisation's activities will be affected by the introduction of a Web application, since such applications have the potential to significantly change an organisation's work practices and procedures (Ginige & Murugesan, 2001; Pressman, 2004). The internal process perspective focuses on key processes at which the organisation must excel in order to add value to its stakeholders through the Web application.

Figure 3. Web application cause and effect relationships

When designing a score card, the starting point will be asking "what strategies do we have to put in place to satisfy the wants and needs of the key stakeholders?" The inclusion of BSC within the WRE process aims to help clarify, consolidate, and gain consensus around the business–Web application strategy of the organisation, and to translate the business strategy into Web application services (requirements) to ensure that the elicited requirements are strategy focused. Hence, a strategy can be best described as a series of cause and effect relationships that provide a translation from future vision to Web requirements, as shown in Figure (3).

eVORD for Eliciting Web Requirements

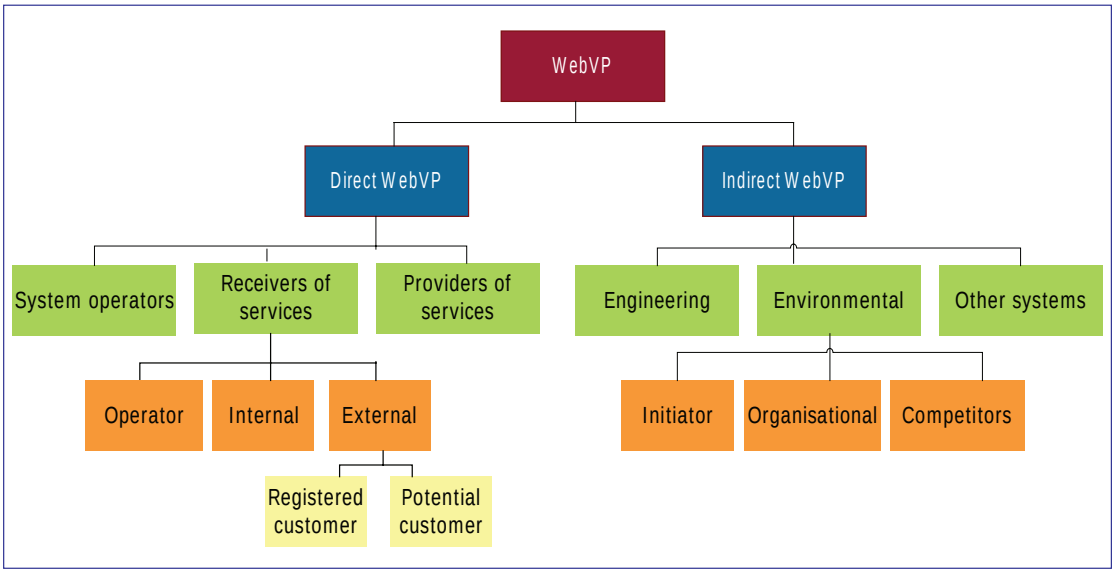
The second phase of the proposed WRE process presents the requirements elicitation phase of the Web application development process. eWARE delivers such elicitation via eVORD (extended viewpoint-oriented requirements definition). According to eVORD, templates are created to describe each viewpoint (VP), service, nonfunctional requirement (NFR), and content. As mentioned earlier, Kotonya and Sommerville (1996) define a VP as anyone who may have some direct or indirect influence on the system/application requirements. The VORD requirements engineering process includes activities concerned with VP identification, VP service description, cross-viewpoint analysis to discover inconsistencies, omissions, and conflicts, and developing an object-oriented model of the system/application from the VP analysis. In addition, a VP diagram is used to show the relationships among VPs, while sequence diagrams illustrate the interactions among VPs.

Web Application Viewpoints (WebVPs) Identification and Structuring

The construction of Web applications involves a great number of stakeholders who have different views of the Web application. These perspectives are partial or incomplete descriptions of the system/application, and reflect the environment in which the system/application will operate in. The integration of multiple views can contribute to augment the overall understanding of the Web application. The authors recommend the use of a new and amended list of VPs for developing Web applications. These WebVPs' abstracts have been identified as a starting point that acts as a template for WebVPs classes and hierarchy. Figure (4) shows a high-level abstract of WebVPs structure.

WebVPs can be classified into *direct VPs* that interact directly with the Web application and fall into two subclasses (receivers and providers of services), and *indirect VPs* that have "interest" in some or all of the services that are delivered by the system but do not interact directly with it; hence, they provide high-level organisational requirements and constraints. Indirect VPs fall into a number of subclasses: *environmental WebVPs,* which reflect the requirements of the business domain, that is, legalisation, localisation, taxa-

Figure 4. Abstract of WebVPs structure



tion, and competitors; *engineering WebVPs,* which reflect the requirements of the development team, that is, software engineers, team leaders, and creative designers; and *system WebVPs,* which include all existing information systems that the application being analysed needs to interface to, that is, payment systems and supplier systems.

Eliciting Requirements Details

The second step of this phase is concerned with documenting the details of each WebVP (identified in the previous step) and its associated services. For every identified WebVP, a number of templates are used to elicit and specify its requirements. The authors have extended and adapted VORD templates to cater to the particularities of Web applications development (please refer to Al-Salem & Abu-Samaha, 2005a and Al-Salem & Abu-Samaha, 2005b for more details).

Documenting Requirements

The objective of the requirements process is to deliver a requirements specification document that defines the system/application to be developed (Sawyer, Viller, & Sommerville, 1997). This document is used for contractual purposes, and can be used as a basis for facilitating a competitive tendering for the system/application design and implementation (IEEE, 2004). The authors have enhanced the typical software requirements specification (SRS) document to reflect the changes introduced to eVORD and eBSC, as depicted in Figure (5).

FUTURE WORK

The domain of RE, in general, and WRE, in particular, is evolving with the ever-changing contexts of software en-

Figure 5. Software requirements specification (SRS) document template

Table of Contents

gineering and information systems development projects. Despite the availability of many requirements, engineering methods, processes, techniques, and tools, such artefacts are in need of constant extensions and enhancements to bring such artefacts to the changing contexts of the development projects. The presented eWARE method is an extension of two existent methods used to align requirements of a Web application to the organisation's business strategy. eWARE needs to be tested further in different industrial settings to validate the applicability of the method. As well, eWARE, like many other RE methods, needs to be supported through the development of a computer aided software engineering (CASE) tool to facilitate the generation of the WRS document. Compared to similar WRE methods (Bleek et al., 2002; Bleistein et al., 2004; Bolchini & Paolini, 2004; Gordijn et al., 2000; Meldrum & Rose, 2004), eWARE provides its users with a number of benefits: it extends the BSC approach to help with the formulation of Web application strategy as a stage in the WRE process in advance to requirements elicitation; it provides a prioritisation framework synchronised with business strategy; it extends VORD to elicit requirements for Web applications; and it creates a WRS document that specifies both the business strategy and requirements for the Web application. Such advantages proved to be valuable in Web application development projects, as Web applications are different in many aspects when compared to other applications. The differing characteristics of Web applications can be summarized as diverse and volatile requirements, vast and unknown end users, multiple stakeholders, adaptable architecture, short development life cycle, high visibility, heavy content, integration with backend databases and third party applications, Web applications' relevance and direct effect on business, and multidisciplinary development team.

CONCLUSIONS

There are two general opinions on whether current software engineering methods and techniques are applicable to face the challenges of developing a Web application. One opinion advocates the need for a new "software engineering" discipline that handles the Web application particularities (Ginige & Murugesan, 2001, Murugesan, 1999; Murugesan, Deshpande, Hansen, & Ginige, 1999). In contrast, the other opinion believes that current software engineering methods, tools, and techniques are applicable to Web application development. For example, McDonald and Welland (2001) recommended developing new methods, techniques, and approaches to address the challenges of developing Web applications in order to increase the possibility of their success. This implies the need for a new breed of WRE methods, tools,and working practices. In contrast, Pressman (2004) argues that Web applications are a natural evolution of existing applications/systems offering a solution to classical problems exhibited by previous information systems (IS). The authors of this chapter hold a middle position in between these two opinions. The authors perceive Web applications as a natural evolution of "traditional" information systems, yet they believe that such applications possess special characteristics that need to be provided for by the "traditional" RE method(s). Hence, existing RE methods are considered valid for WRE, though they need to be enhanced and extended to cater to the distinguishing features of Web applications.

The chapter has presented a WRE approach that enables businesses to develop/procure Web application(s) capable to achieve the organisations' business strategic objectives, and to effectively harness their business processes. The combination of BSC (Kaplan & Norton 1993, 1996a & b) and VORD (Kotonya & Sommerville 1996) within eWARE process provides the development team with the ability to translate strategy into Web application requirements and to incorporate views from different complementary perspectives. Hence, eWARE is a Web-specific RE process to cope with the complex aspects of requirements elicitation, alignment, and specification for Web applications development/procurement. eWARE views Web applications as organisational initiatives and as such, it takes into account the need to address strategic objectives, business processes issues, requirements details of services, NFR, and integration with other systems.

KEY TERMS

Balanced Score Card (BSC): "A multidimensional framework for describing, implementing and managing

strategy at all levels of an enterprise by linking objectives, initiatives and measures to an organisation's strategy" (Kaplan & Norton, 1993, 1996 a & b).

eWARE (extended Web application requirements engineering): "A strategy-focused requirements engineering method used to align Web application requirements to business strategy and to elicit legal, technological, business, marketing and content requirements".

A Requirement: "A condition or capability that must be met or fulfilled by a system to satisfy a contract, standard, specification, or other formally imposed documents." (*IEEE Standard, 610*,12-1990).

Requirements Engineering (RE): "The process of discovering that 'purpose' by identifying stakeholders and their needs, and documenting them in a form that is amenable to analysis, communication, and subsequent implementation" (Nuseibeh & Easterbrook, 2000).

Stakeholder: "Anyone who can share information about the system, its implementation constraints or the problem domain, including end users, indirect users, other customer representatives and developers" (Potts et al., 1994).

Viewpoint (VP): "Any one who may have some direct or indirect influence on the system requirements" (Kotonya & Sommerville, 1996).

Viewpoint Oriented Requirements Definition (VORD): "A software requirements engineering approach used to organise both the elicitation process and the requirements themselves into viewpoints" (Sommerville, 1995).

Web Business Application (WebApp): "An application that tends to be used to integrate and streamline an organisation's business processes beyond organisational (customers, agents, suppliers, others) and geographical borders; to provide an organisation with competitive products and services that give it a strategic advantage over its competitors in the marketplace; to promote business innovation and/or to improve operational efficiency" (Al-Salem & Abu-Samaha, 2005a).

ENDNOTE

[1] Throughout eWARE, a stakeholder /viewpoint is used interchangeably.

A Formal Definition of Information Systems

Manuel Mora
Autonomous University of Aguascalientes, Mexico

Ovsei Gelman
Universidad Nacional Autónoma de México, Mexico

Francisco Cervantes
Universidad Nacional Autónoma de México, Mexico

Guisseppi Forgionne
University of Maryland, Baltimore County, USA

INTRODUCTION

Since its conceptualization in the 1960s (Adam & Fitzgerald, 2000), information systems (IS) has undertaken a hard effort to be recognized as a scientific discipline. Nowadays, indicators such as the existence of undergraduate, master, and doctoral programs; research centers focused on IS topics; specialized conferences and journals; and professional and academic associations suggest that the IS discipline is a scientific field that is independent from its root disciplines (e.g., computer science, management science, accounting, and behavioral sciences).

On the other hand, during this 50-year path, the discipline of information systems can be critiqued for the multiple self-identities perceived by the different stakeholders (e.g., IS researchers, IS practitioners, and IS users). Gelman, Mora, Forgionne, and Cervantes (2005) point out the following weaknesses IS exhibits, making it a still immature field:

i. the scarce utilization of deductive and formal (e.g., logical-mathematical) research models and methods (Farhoomand, 1987, p. 55);
ii. the lack of a formal and standard set of fundamental well-defined concepts used in the discipline (Banville & Landry, 1989, p. 56; Alter, 2001, p. 3; Wand & Weber; 1990, p. 1282); and
iii. the excessive number of availiable micro-theories (Barkhi & Sheetz, 2001, p. 11).

Additionally, the partial, disparate, and not consensual conceptualizations of what is the focus of study in IS is(Alter 2003; Benbazat & Zmud, 2003), along with the lack of integration of multiple research methodologies to cope with the complexity of the phenomena of study (Mingers, 2001), also suggest that the maturity-development process for the IS discipline still is an ongoing process.

Gelman et al. (2005), based on a profound study of the term *information system* (Mora, Cervantes, Mejia, & Weitzenfeld, 2002), confirmed that the fundamental concepts used in most IS research are based on few and misused core concepts from what is the Theory of Systems (Ackoff, 1960, 1971), and that the few proposals for formalization (Wand & Weber, 1990; Mentzas, 1994; Alter, 2001, 2003) are still incomplete. Furthermore, although Systems Science concepts were used in the two most comprehensive IS research frameworks reported in the IS literature (Ives, Hamilton, & Davis, 1980; Nolan & Wetherbe, 1980), a recent study also identified conceptual inconsistency and incompleteness in both frameworks from a formal systemic view (Mora, Gelman, Cano, Cervantes, & Forgionne, 2006). Hence, it can be inferred that the utilization of an informal, conflicting, and ambiguous communicational system in the IS discipline (Banville & Landry, 1989) and the lack of a comprehensive IS research framework have hindered the development of a cumulative research tradition and delayed the maturation of the field (Wand & Weber, 1990; Farhoomand, 1987).

As reported in Mora et al. (2002) and extended in Gelman et al. (2005), the formalization of the core concepts used in the IS discipline becomes a relevant and mandatory, as well as urgent, research purpose. This article furthers this purpose by utilizing the core principles from the Theory of Systems and a recent IS research framework (Mora et al., 2006) to extend and update the conceptualizations reported in previous studies. Formal definitions are updated and built upon the terms *system* (Ackoff, 1971; Gelman & Garcia, 1989), *organization, business process,* and *information system* (Mora et al., 2002; Gelman et al., 2005). Finally, this article examines the implications for IS research and practice.

BACKGROUND

The term *information system* has been defined in textbooks and research papers usually in non-formal terms. Table 1 shows a sample of the main definitions posed in the literature. An examination of these definitions suggests that the IS no-

Table 1. A sample of informal definitions of what an information system is

Definition	Reference
An IS is a system composed of subsystems of hardware, programs, files and procedures to get a shared goal.	Senn (1989, p. 23)
An IS is a system composed of application software, support software, hardware, documents and training materials, controls, job roles and people that uses the software application.	Hoffer, George, and Valachi (1996, p. 8)
An IS is a system composed of inputs, models, outputs, technology, data bases and controls.	Burch and Grudnitski (1989, p. 58)
A complete information system is a collection of subsystems defined by functional or organizational boundaries.	Ives et al. (1980, p. 910)
MIS is an integrated man-machine system for providing information to support the operation, management, and decision-making functions in an organization. The system utilizes computer software and software, manual procedures, management and decision models and a database.	Nolan and Wetherbe (1980, p. 3, quoting Davis, 1974)
We conceptualize the IT artifact as the application of IT to enable or support some task(s) embedded within a structure(s) that itself is embedded within a context(s).	Benbazat and Zmud (2003, p. 186)

tion: (i) lacks fundamental standardized and formal concepts (Alter, 2001); (ii) lacks competitive formal macro-structures to cumulate theories (Farohoomand & Drury, 2001, p. 14), and (iii) has an excessive variety of micro-theories (Barkhi & Sheetz, 2001).

There have been few, if any, efforts to formalize the the core concepts of IS. Despite attempts to reduce ambiguity, which have increased consequently the quality of the definitions, these proposals (Wand & Weber, 1990; Alter, 2001) have relied on partial views—for example, syntactical and structural perspectives that hide core semantic information—of the concept *system* formulated in the Systems Science literature (Sachs, 1976; Mora et al., 2002). Another study (Mentzas, 1994) offers a more articulated definition than exhibited in Table 1, by the identification of five subsystems and their functional properties. Nevertheless the resulting definition still lacks formalization and is based on a common-sense language that has been critiqued in the IS literature (Banville & Landry, 1989). Therefore, the concept *information system* still has multiple meanings. A systems-based research stream (Paton, 1997; Alter, 2001; Mora et al., 2002) combined with an ontological perspective (Wand & Weber, 1990) suggest that formal foundations from the Theory of Systems (Xu, 2000, p. 113) can reduce this ambiguity and strengthen the rigor that a scientific discipline requires to mature and simultaneously be relevant and useful for practitioners.

THE FORMALIZATION OF THE CONSTRUCT *INFORMATION SYSTEMS*

Formalization reported in this article is adapted and extended from previous definitions of the formal concepts of *system-I, system-II,* and *general system* (Gelman & Garcia, 1989). In turn, the concepts *organization* ***O(X)****, Information System* ***IS(X),*** and *envelop* ***EE(X)*** are updated from Mora et al. (2002), and the original concept of *environment* ***W(X)*** is replaced by the French term *entourage* ***ENT(X).*** To complete this set of formal definitions, Mora et al. (2006) also introduce the following concepts: *high-level business process* ***HLBP(X)****, low-level business process* ***LLBP(X)****, socio-political business process* ***SSBP(X)****, supra-suprasystem* ***SSS(X)****, non-entourage* ***NENT(X),*** and *world* ***W(X).*** Updates are mainly based on ideas reported by Oliva and Lane (1998) on soft systems and originally developed by Checkland (2000). As in similar works from the authors and related literature (Wand & Weber, 1990; Wand & Woo, 1991), we follow a conceptual development based on an ontological path to define primitive concepts and postulates to derive the set of updated and new definitions.

Formal Definition 1

System-I: An object of study **X,** formalized as ***system-I*** and denoted as $\boldsymbol{S_I(X)}$**=<B(X),RB(X),E(X)>,** is a whole **X** that fulfills the following conditions: (I.1) it has a *conceptual structure* **§(X)** that defines its set of *attributes* **B(X**), its set of *events* **E(X),** and its set of *range of attributes* **RB(X)**; (I.2) for any subset **B'(X)** of *attributes* of **B(X),** the set of *events* **E(X)** associated with **B(X)** differs in at least one element from the set of *events* **E'(X)** associated with **B'(X).**

Therefore, to define a situation of study as a *system-I* implies to specify $\boldsymbol{S_I(X)}$ **= <§(X)> =<B(X), E(X), RB(X)>** and to fulfill condition I.2.

Formal Definition 2

System-II: An object of study **X,** formalized as ***system-II*** and denoted as $\boldsymbol{S_{II}(X)}$**=<**$\mathbf{C_X}$**,** $\boldsymbol{\Re_s(C_X')}$**>** is a whole **X** that fulfills

the following conditions: (II.1) the whole **X** is a set $\mathbf{C_X}$ of elements $\mathbf{X_1, X_2, ..., X_k}$, called *subsystems*, where each $\mathbf{X_i}$ for i=1,2,..., k can be formalized as $\boldsymbol{S_I(X_i)}$ or $\boldsymbol{S_{II}(X_i)}$; (II.2) there is a collection finite $\mathbf{\Re_S(C_X')}$ of *set-relations* where $\mathbf{\Re_S(C_X')=\{\Re_1(C_X'), \Re_2(C_X'),...\}}$ on the set $\mathbf{C_X'=\{C, S_I(X)\}}$ and where each *set-relation* $\mathbf{\Re_p(C_X')=\{ {}_p\Re_1 , {}_p\Re_2 , ... \mid {}_p\Re_n = < X_i, {}_ia_j , X_j > \text{ or } {}_p\Re_n = < X_i, {}_ia_X , S_I(X)> \text{ or } {}_p\Re_n = < S_I(X), {}_Xa_j , S_j>}$ and $\mathbf{{}_ia_j}$ stands by the output-input parameters or acts between the two elements}; and (II.3) exists at least a *non-directed-path* among two any items X_i and X_j in the *set-relation* $\mathbf{\Re_S(C_X')}$.[1]

Formal Definition 3

General System: An object of study **X,** formalized as ***general system*** and denoted as $\boldsymbol{S_G(X)}$, is a whole **X** that can be defined simultaneously as a *system-I* $\boldsymbol{S_I(X)}$ and as a *system-II* $\boldsymbol{S_{II}(X)}$.

Postulate 1: Any *general system* $\boldsymbol{S_G(X)}$ defined as *system-I* $\boldsymbol{S_I(X)}$ can be mapped onto a *system-II* $\boldsymbol{S_{II}(X)}$ and vice versa.

Auxiliary Formal Definition 1

Universe: In a general sense a whole **UX** is called the ***universe of a system*** **X** and is denoted as ***U(X)*** if (III.1) **UX** can be formalized as $\boldsymbol{S_G(UX)}$ and (III.2) the whole **X** is a *subsystem* of **UX.**[2]

Auxiliary Formal Definition 2

World: In a general sense a whole **WX** is called the ***world of a system X*** and is denoted as ***W(X)***, if (IV.1) **WX** can be formalized as $\boldsymbol{S_G(WX)}$ and (IV.2) given the $\mathbf{S_{II}(U(X)) = <C_{U(X)}, \Re_S(C_{U(X)}')>}$ then $\mathbf{C_{U(X)} = \{X, W(X)\}}$.

Auxiliary Formal Definition 3

Suprasystem: In a particular sense a whole **SX** is called the ***suprasystem of a system*** **X** and is denoted as ***SS(X),*** if (V.1) **SX** can be formalized as $\boldsymbol{S_G(SX)}$ and (V.2) the whole **X** is a *subsystem* of **SX.**[3]

Auxiliary Formal Definition 4

Entourage: In a particular sense a whole **EX** is called the ***entourage of a system X*** and is denoted as ***ENT(X)***, if (VI.1) **EX** can be formalized as $\boldsymbol{S_G(EX)}$ and (VI.2) given the $\mathbf{S_{II}(SS(X)) = <C_{SS(X)}, \Re_S(C_{SS(X)}')>}$ then $\mathbf{C_{SS(X)} = \{X, ENT(X)\}}$.[4]

Auxiliary Formal Definition 5a

Non-Entourage: In a particular sense a whole **NEX** is called the ***non-entourage of a system X*** and is denoted as ***NENT(X)***, if (VIIa.1) **NEX** can be formalized as $\boldsymbol{S_G(NEX)}$ and (VIIa.2) **NEX** is the *world* of ***SS(X)***.[5]

Auxiliary Formal Definition 5b

Environment[6]*:* In a general sense a whole **ENVX** is called the ***environment of a system X*** and is denoted as ***ENV(X)***, if (VIIb.1) **ENVX** can be formalized as $\boldsymbol{S_G(ENVX)}$ and (VIIb.2) **ENVX** is the *world* of ***SS(X)***.[7]

Auxiliary Formal Definition 6

Supra-Suprasystem: In a particular sense a whole **SSX** is called the ***supra-suprasystem of a system*** **X** and is denoted as ***SSS(X),*** if (VIII.1) **SSX** can be formalized as $\boldsymbol{S_G(SSX)}$ and (VIII.2) there exists a whole S**X** that is a *subsystem* of ***SSS(X)*** and X is in turn is a *subsystem* of SX.

Auxiliary Formal Definition 7

Envelope: A whole **EEX** is called the ***envelope of a system X*** and is denoted as ***EE(X)***, if (IX.1) **EEX** can be formalized as $\boldsymbol{S_G(EEX)}$ and (IX.2) the whole **EEX** is the *entourage* of the *suprasystem* of **X.**

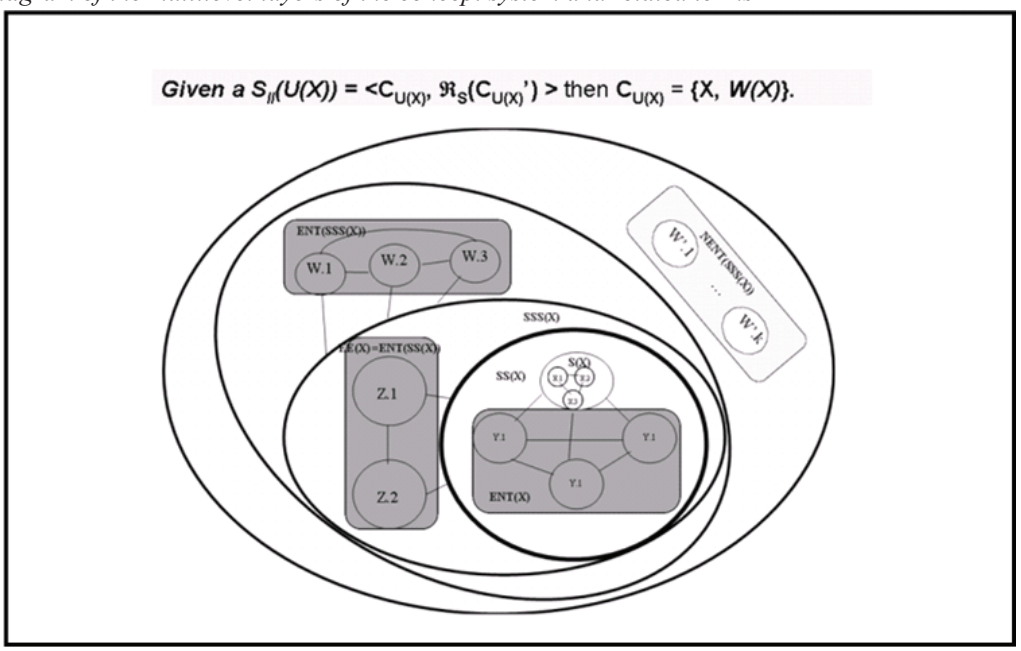
Postulate 2: Any *general-system* $\boldsymbol{S_G(X)}$ has a *world* **W(X)** and a *universe* ***U(X)***.

Hence, the first formal definition of the concept *system, system-I,* forms an external view that sees the *system* as a single unit with special characteristics called *attributes* and potential acts to execute called *events*. In turn, the second formal definition, *system-II,* represents the internal view that sees the system as a graph. Furthermore, the definitions of the *set-relations* $\Re_{S1}(C_X')$, $\Re_{S2}(C_X')$, ..., $\Re_{Sm}(C_X')$ consider the *system* as a multi-digraph, instead of a digraph, and therefore eliminates some limitations of classic digraph-like definitions critiqued in the Systems Theory literature (Sachs, 1976). Auxiliary definitions and the second postulate help to support the expansionist systemic perspective that indicates every system always belongs to another larger system (Ackoff, 1971). Figure 1 exhibits a general graphic interpretation of such formal definitions.

Formal Definition 4

Socio-Political Business Process as *System:* An object of study **X** is called a *socio-political* ***business process*** and denoted as **SSBP(X)**, if it satisfies the following conditions: (X.1) **X** can be defined as a *system-II* $\mathbf{S_{II}(X)=<C_X, \Re_S(C_X')>}$, where $\mathbf{C_X =\{S_G(Soc\text{-}SS), S_G(Pol\text{-}SS)\}}$ and $\mathbf{S_G(Soc\text{-}SS), S_G(Pol\text{-}SS)}$ are respectively called the social and the political subsystems; and $\mathbf{\Re_S(C_X')=\Re_S(X, S_I(X))=\{\Re_1(C_X'), \Re_2(C_X'), ..., \Re_6(C_X') \mid \Re_1(C_X')=\{ {}_1\Re_1 = < X_{Soc\text{-}SS}, {}_{Soc\text{-}SS}a_{Pol\text{-}SS}, X_{Pol\text{-}SS}>\}, ..., \Re_6(C_X')=\{ {}_6\Re_1 = <X_{Pol\text{-}SS}, {}_{Pol\text{-}SS}a_X, S_I(X)> \} \}}$; and (X.2) $\mathbf{\Re_S(X, S_I(X))}$ satisfies condition (II.3).

Figure 1. A diagram of the multilevel layers of the concept system and related terms



Formal Definition 5

Low-Level Business Process as *System:* An object of study **X** is called a ***low-level business process*** and denoted as **LLBP(X),** if it satisfies the following conditions: (XI.1) **X** can be defined as a *system-II* $\mathbf{S_{II}(X)}=<\mathbf{C_X}, \Re_S(\mathbf{C_X'})>$ where $\mathbf{C_X}$ **=**$\{\mathbf{S_G(T\text{-}SS)}, \mathbf{S_G(P\text{-}SS)}, \mathbf{S_G(T\&I\text{-}SS)}, \mathbf{S_G(M\&P\text{-}SS)}, \mathbf{SSBP(LSP\text{-}SS)}\}$ and $\mathbf{S_G(T\text{-}SS)}, \mathbf{S_G(P\text{-}SS)}, \mathbf{S_G(T\&I\text{-}SS)}, \mathbf{S_G(M\&P\text{-}SS)}, \mathbf{SSBP(LSP\text{-}SS)}$ are respectively called the ***task***, ***people***, ***tools&infrastructrure***, ***methods&procedures,*** and ***socio-political subsystems*****;** and $\Re_S(\mathbf{C_X'})= \Re_S(\mathbf{X, S_I(X)})$ $=\{\Re_1(\mathbf{C_X'}), \Re_2(\mathbf{C_X'}), \ldots, \Re_{24}(\mathbf{C_X'}) \mid \Re_1(\mathbf{C_X'})=\{{}_1\Re_1 = <\mathbf{X_{T\text{-}SS}}, {}_{\mathbf{T\text{-}SS}}\mathbf{a_{P\text{-}SS}}, \mathbf{X_{P\text{-}SS}}>\}, \ldots, \Re_{24}(\mathbf{C_X'})=\{{}_{24}\Re_1=<\mathbf{X_{P\text{-}SS}}, {}_{\mathbf{P\text{-}SS}}\mathbf{a_X}, \mathbf{S_I(X)}>\}\}$**;** and (XI.2) $\Re_S(\mathbf{X, S_I(X)})$ satisfy condition (II.3).

Formal Definition 6

High-Level Business Process as *System:* An object of study **X** is called a ***high-level business process*** and denoted as **HLBP(X)**, if it satisfies the following conditions: (XII.1) **X** can be defined as a *system-II* $\mathbf{S_{II}(X)}= <\mathbf{C_X}, \Re_S(\mathbf{C_X'})>$ where $\mathbf{C_X}$ **=**$\{\mathbf{LLBP(C\text{-}SS)}, \mathbf{LLBP(O\text{-}SS)}, \mathbf{LLBP(I\text{-}SS)}, \mathbf{SSBP(HSP\text{-}SS)}\}$ and **LLBP(C-SS), LLBP(O-SS), LLBP(I-SS), SSBP(HSP-SS)** are respectively called the ***control***, ***operational***, ***informational,*** and ***socio-political subsystems*****;** and $\Re_S(\mathbf{C_X'})= \Re_S(\mathbf{X, S_I(X)}) =\{\Re_1(\mathbf{C_X'}), \Re_2(\mathbf{C_X'}), \ldots, \Re_{20}(\mathbf{C_X'}) \mid \Re_1(\mathbf{C_X'})=\{{}_1\Re_1 = <\mathbf{X_{C\text{-}SS}}, {}_{\mathbf{C\text{-}SS}}\mathbf{a_{O\text{-}SS}}, \mathbf{X_{O\text{-}SS}}>\}, \ldots, \Re_1(\mathbf{C_X'})=\{{}_{20}\Re_1 = <\mathbf{X_{C\text{-}SS}}, {}_{\mathbf{C\text{-}SS}}\mathbf{a_X}, \mathbf{S_I(X)}>\}\}$**;** (XII.2) and $\Re_S(\mathbf{X, S_I(X)})$ satisfy condition (II.3).

Formal Definition 7

Organization as a *System:* An object of study **X** is called an ***organization*** and denoted as **O(X)**, if it satisfies the following conditions: (XIII.1) **X** can be defined as a *system-II* $\mathbf{S_{II}(X)}= <\mathbf{C_X}, \Re_S(\mathbf{C_X'})>$ where $\mathbf{C_X}$ **=**$\{\mathbf{S_G(X.1)}, \mathbf{S_G(X.2)}, \ldots \mathbf{S_G(X.k)}\}$ and $\Re_S(\mathbf{C_X'})= \Re_S(\mathbf{X, S_I(X)})= \{\Re_1(\mathbf{C_X'}), \Re_2(\mathbf{C_X'}), \ldots, \Re_p(\mathbf{C_X'}) \mid$ for N=1,2,...p, each set-relation $\Re_N(\mathbf{C_X'})$ has item-relations ${}_N\Re_{1,N}\Re_{2,N}\Re_{3,\ldots}$ of the format < X.i, ${}_i\mathbf{a}_j$, X.j> or < X.i, ${}_i\mathbf{a}_X$, $S_I(X)$> or < $S_I(X)$, ${}_X\mathbf{a}_j$, X_j> and ${}_\mathbf{i}\mathbf{a}_\mathbf{j}$ stands by the output-input parameters or acts between the two elements X.i and X.j}; (XIII.2) $\Re_S(\mathbf{X, S_I(X)})$ satisfies condition (II.3); and (XIII.3) for j=1,2, … , k either $\mathbf{S_G(X.j)= HLBP(X.j)}$**, or** $\mathbf{S_G(X.j)= SSBP(X.j)}$ or $\mathbf{S_G(X.j)= S_{II}(X.j)}=<\mathbf{C_{X.j}}, \Re_S(\mathbf{C_{X.j}'})>$ where $\mathbf{C_{X.j}}$ **=**$\{\mathbf{BP(X.j.1)}, \mathbf{BP(X.j.2)}, \ldots, \mathbf{BP(X.j.n)}\}$ and $\Re_S(\mathbf{C_{X.j}'})$ exists.

Several features should be noted from previous definitions: (a) the *item-relations* $\Re_1$, $\Re_{2,\ldots,a}$ and so on take into account at least all possible interrelationships between any two subsystems and the whole system; (b) a *high-level business process* can be considered a *general system* with three low-level business processes: control, operational, informational, and a socio-political business process; and (c) an *organization* is a *general system* composed of at least two *general systems* that in turn can be either a *high-level business process* or a *system-II* composed of *high-level business processes.* Figure 2, adapted from Mora et al. (2006), exhibits a diagram of an *organization* ***O(X)***.[8]

An extended cybernetic-based paradigm (Gelman & Negroe, 1981, 1982) is used in Figure 2, where ***S_{II}(X.1)*** and

$S_{II}(X.2)$ are conceptualized as a driving-org-subsystem and a driven-org-subsystem respectively, $S_{II}(X.3) = HLBP(X.3)$ for an *information-org-subsystem,* and $S_{II}(X.4) = SSBP(X.4)$ for a *socio-political-org-subsystem.* Interactions between subsystems are not shown. However, it must be noted that general definitions of what is an *organization* can adopt other management perspectives such as Porter's added-value chain (Porter & Millan, 1985). In that case, it would be necessary to consider three *subsystems* of the *primary activities,* the support activities, and the top management activities. With these previous antecedents, the formalization of the term *information system* is straightforward.

Formal Definition 8

Information System as *System:* An object of study **X** is called an ***Information System*** and is denoted as ***IS(X)*** if it fulfills either one of the following conditions: (XIV.1) ***IS(X)*** is the ***HLBP(X.3)*** of an ***O(X)*** or (XIV.2) ***IS(X)*** is the ***LLBP(I-SS)*** of a ***HLBP(X.i)*** and that belongs to a ***O(X).***

Figure 2 also presents a visualization of the formal concept of *information system.* Due to the diagram's style, all notation related to the *item-relations* of all *systems-II* are hidden as are *item-relations* into the *subsystems* of the *information system.* The posed formal definition indicates that an *information system,* as a *system,* can correspond either to the general organizational function or area of *information systems* (e.g., ***IS(X)*** is the ***HLBP(X.3)***) or to the specific view of an *information system* as part of any business process (e.g., ***IS(X)*** is the ***LLBP(I-SS)*** of a ***HLBP(X.i)***). It is congruent with the systemic perspective that any *information system* is a *system* that is part of a larger system—that is, a *high-level business process* that in turn is the *suprasystem* of the *information system,* denoted as ***SS(IS)***.

FUTURE TRENDS

From a theoretical perspective, the development and utilization of formal definitions help to advance standardization, theoretical soundness and completeness, and academic maturation. Ambiguous, informal, and non-standard concepts of the main objects of study or the main phenomena studied by the discipline obfuscate its development and diminish its theoretical accumulation. Previous frameworks developed by the authors and this update constitute a conceptual tool to model and specify an *information system* at the level of detail demanded by researchers and practitioners. In Gelman et al. (2005), four possible applications of the utilization of the formal definitions were presented under a theoretical and practice perspective: (i) formal integration of the common-sense concepts used in the informal definitions of what is an *information system*; (ii) elimination of the ambiguity caused by the "Siamese Twin Problem" (Alter, 2001, pp. 30-31); (iii) analysis of failures on information systems through the systemic classification of problems; and (iv) generation of conceptual and dynamic simulation models of information systems. In this updated article, based on recent research frameworks for the IS discipline (Mora et al., 2006), we have presented the usefulness of the concept. Figure 3 compares the previous systemic IS research frameworks with the proposal offered here. The four past issues are reviewed under this updated framework:

Figure 2. Diagram of the overall and systemic perspective of what are an organization and an information system

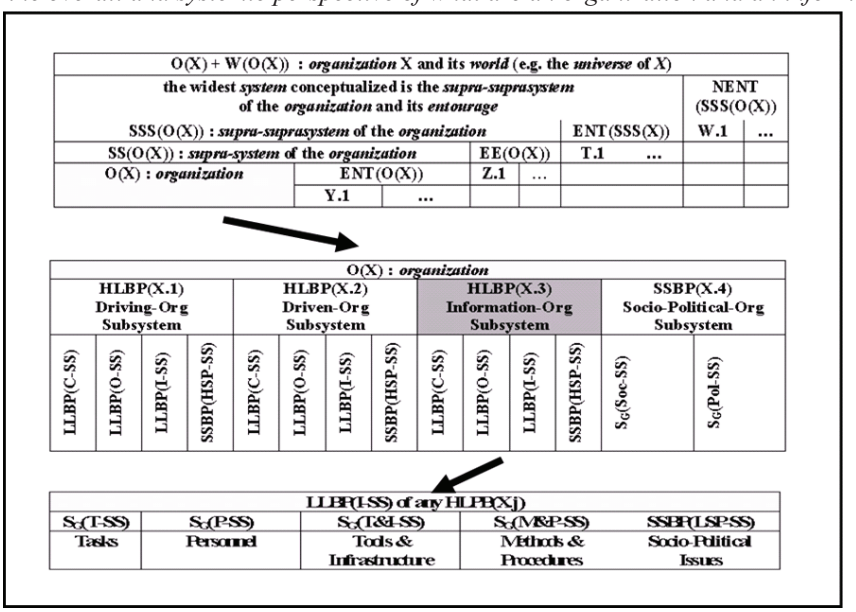


Figure 3. Comparison map of the systemic concepts for IS research frameworks

Mapping of Concepts		
Ives' et al Framework	**Nolan and Wetherbe's Framework**	**Mora et al's Framework**
<external environment> : legal social, cultural, economic, educational, resource and industry/trade systems	**Not explicitly considered**	**EE(O(X))** (the systems to be modeled at this level of analysis are determined by the researcher)
Not explicitly considered	**<environment of the organization>** : competitors, government, suppliers, customers, etc.	**ENT(O(X))** (the systems to be modeled at this level of analysis are determined by the researcher)
The concept of **<organizational environment>** used by Ives et al, really does not considers the environment of an organization, but organization's attributes per se such as: goals, tasks, structure, volatility and management philosophy/style	**<organization>** The 5 subsystems of <organization>: goals and value SS, psychosocial SS, managerial SS, structural SS and technical SS	**O(X)** **Goals & Value SS, psychosocial SS, and structural SS,** are considered in the **SSBP(X.4)** and the **SSBP(HSP-SS)** for any **HLBP(X.j).** The same applies for the organization's attributes posited by Ives' et al such as: goals, tasks, volatility and management philosophy/style.
Not explicitly considered		The **managerial** and **technical SS** respectively corresponds to the **HLBP(X.1) (e.g. the driving-org subsystem)** and to **HLBP(X.2) (e.g. the driven-org subsystem)**
<user environment> + <use process>	**Not explicitly considered but implicit in the 5 subsystems above reported**	Any **HLBP(X.j)** and **SSBP(X.4)** of the **O(X)**
<IS development environment> + <IS development process>	**<MIS Technology> : (hardware, software, data base, procedures and personnel)** (Development, operations and maintenance aspects are considered in this concept)	**HLBP(X.3)** and **SSBP(X.4)** (e.g. **the high-level business process** that corresponds to the **information-org subsystem** and the **socio-political general subsystem** of the ***organization*** **O(X)**)
<IS operations environment> + <IS operations process>		
<Information Subsystem> (attributes of content, presentation, time, etc)	**Not explicitly considered as system but as the output of the MIS technology-based system**	**LLBP(I-SS)** of any **HLBP(X.j)** and that is conformed by the **SG(T-SS) +SG(P-SS) + SG(T&I-SS) + SG(M&P-SS) + SSBP(LSP-SS)** (e.g. **the low-level business process** that corresponds to the **informational subsystem** of any **high-level business process** in an **O(X)**)

(1) The informal definition from Hoffer et al. (1996) establishes that "an IS is a system composed of application software, support software, hardware, documents and training materials, controls, job roles and people that use the software application." This notion can be conceptually mapped to the proposed framework (and consequently to the formal definitions) under the second interpretation of what is an information system (e.g., condition (XIV.2) of the formal definition 8: ***IS(X)*** is the ***LLBP(I-SS)*** of a ***HLBP(X.i)*** and that belongs to a ***O(X)***). Given this condition and condition (XI.1) of the formal definition 5 (e.g., **X** can be defined as a *system-II* $\mathbf{S_{II}(X)}$= $\langle \mathbf{C_X}, \Re_S(\mathbf{C_X}')\rangle$ where $\mathbf{S_{II}(X)}$= $\langle \mathbf{C_X}, \Re_S(\mathbf{C_X}')\rangle$ where $\mathbf{C_X}$ ={$\mathbf{S_G(T\text{-}SS)}$, $\mathbf{S_G(P\text{-}SS)}$, $\mathbf{S_G(T\&I\text{-}SS)}$, $\mathbf{S_G(M\&P\text{-}SS)}$, **SSBP(LSP-SS)**} and $\mathbf{S_G(T\text{-}SS)}$, $\mathbf{S_G(P\text{-}SS)}$, $\mathbf{S_G(T\&I\text{-}SS)}$, $\mathbf{S_G(M\&P\text{-}SS)}$, **SSBP(LSP-SS)** are the ***task***, ***people***, ***tools&infrastructrure***, ***methods&procedures,*** and ***socio-political subsystems, respectively***), then the elements <application software, support software, hardware> correspond to the $\mathbf{S_G(T\&I\text{-}SS)}$, and <documents and training materials > and <people> correspond to $\mathbf{S_G(M\&P\text{-}SS)}$ and $\mathbf{S_G(P\text{-}SS)}$ respectively. The remainder <job roles> element can be modeled as the system's attribute $\boldsymbol{B(P\text{-}SS)}$=$\{_{IW}\beta_1$=<job roles>} and specifies all possible <job roles> by the definition of the range of attributes $\boldsymbol{RB(P\text{-}SS)}$=$\{_{IW}\mathbf{R}\beta_1$={operational-user; staff-user; executive-user; etc.}}, if $\mathbf{S_G(P\text{-}SS)}$ is further formalized as a $\mathbf{S_I(X)}$.

(2) As reported in Gelman et al. (2005), the systemic properties of *organization* and *hierarchy* mapped onto the concept of *information system* are useful to resolve the "Siamese Twin Problem" (Alter, 2001) that indicates the

fallacy of studying an *information system* without studying its w*ork system.* The *hierarchy* property of *systems* and the *Expansionism Approach* suggest that any *system* should not be studied in isolation. A framework and formal definitions support scientific study and indicate that any *information system* should be viewed as part of a larger *system*—that is, the *high-level business process* (e.g., Alter's w*ork system* concept). A Synthetic Thinking view (Ackoff, 1960), that the behavior of every system can be best understood when studied in relationship to its *suprasystem* and wider systems, is also achieved.

(3) Formal definitions and the updated framework exhibited in Figures 1, 2, and 3 are simple but powerful conceptual lenses to study holistically complex problems as the failures of *information systems* implementations. According to the classification of problems based on the Theory of Systems by Ackoff (1973, p. 666), the failures of *systems* are caused by the conflicts between the system's purpose and the environment's purpose, the system's purpose and the subsystems' purposes, and the system with itself—for example, the environmentalization, humanization, and self-control problems. Thereby, the systemic formalisms posed can be used and extended through the addition of parameters in the set of *a-actions* in the *item-relations*, to model social, technical, and political features through the specification of *attributes* and *events* assigned to *subsystems* in the *system's entourage* ***ENT(IS(X)).*** These features either can be the *driving, driven,* and *socio-political subsystems* of the *organization* ***O(X)*** or the *control, operational,* and *socio-political* subsystems of any ***HLBP(X.j).*** For example, soft features, such as <top management support>, <environmental hostility>, <environmental dynamism>, and <organizational climate>, once specified and measured, can be easily assigned as subsystems *attributes* of this ***ENT(IS(X))***.

(4) Complex conceptual and dynamic-based simulations models of *information systems* can be specified with the integration of the hard (e.g., System Dynamics) and soft systems approach. A case in point is the recent development of a conceptual and system dynamic-based simulation model of the implementation process of decision-making support systems (Mora, 2003; Mora, Cervantes, Gelman, & Forgionne, 2004) that generated satisfactory predictive results for several well-known statistical and case-study reports in the literature.

(5) Finally, according to Mora et al. (2006), the framework exhibited in Figure 3 and rooted in the formal definitions of the concepts *system-I, system-II,* and *general system,* and the updated or new concepts (*suprasystem, supra-suprasystem, envelop, entourage, world, universe, low-level business process, high-level business process, organization,* and *information systems*) offer evidence that previous IS research frameworks were insufficiently comprehensive. The new framework:

(i) is congruent with formal definitions of system; (ii) permits the modeling of all variables reported as sub-systems or attributes of sub-systems; (iii) includes the time variable if required through the consideration of the state of the system; (iv) and integrates both technical and socio-political perspectives. (Mora et al., 2006, p. 8)

In summary, this article updates the formal definitions of the concepts of *systems* developed by some of authors in 1989, and offers adjustments to previous definitions elaborated in 2002 and 2005 and applied to the concept of *information system.* All definitions are based on, and congruent with, formal principles from the Theory of Systems. As reported in Gelman et al. (2005), these findings enable researchers and practitioners to:

(i) avoid ambiguity from informal definitions; (ii) account for practically all informal definitions; (iii) specify and customize a structure of the concept IS with the level of detail demanded by the modelers; and (iv) build complex systemic models of organizations that use IS.

CONCLUSION

This updated article supports the thesis that formalisms—from the Theory of Systems—are required in the field of information systems to reach the rigor and maturation needed for a respectable scientific discipline. Given that posed formalisms offer a non-trivial way to understand and model an information system, their utilization will contribute toward the maturation of our field. However, gains will not be free since researchers and practitioners could be required to add to their conceptual tools the utilization of these logical-mathematical models. This article also can be considered as a research basis for the emergent topic of formal ontologies for information systems. Nevertheless, we believe that future contributions based on computerized ontologies should be theoretically deepened on Theory of Systems.

KEY TERMS

Attribute (Informal Definition): A substantial feature of a whole that is perceived by an observer with the potential to produce or cause a product or effect.

Event (Informal Definition): An act performed by a whole or to the whole that is perceived by an observer directly or through its consequences on other(s) whole(s).

Subsystem: Any immediate inner system that is subsumed to the system.

Suprasystem: The immediate outer system that subsumes any system.

System (Informal Definition): A whole composed of subsystems, and at the same time included in a suprasystem in such way that some particular properties of the whole and of the subsystems are lost when they are considered analytically—for example, by separation of the parts of the whole.

Theory of Systems: A research paradigm based on an expansionist world view, synthetic and holistic thought, and teleological principles that is suitable and effective for studying complex phenomena.

ENDNOTES

1 It must be noted that: (i) condition II.3 assures that for any two elements X_i and X_j in the multi-digraph of **X**, X_i is reachable from X_j and vice versa that implies the nonexistence of an isolated element X_i; (ii) it is a recursive definition that permits a *subsystem* to have *subsystems;* and (iii) this definition supports the output/input relationships between any *subsystem* and the whole *system.* Therefore, to define a situation of study as a *system-II* implies to specify: $\boldsymbol{S_{II}(X)=<C_X, \Re_S(C_X')>}$ where $\boldsymbol{C_X=\{S_I(X_I)}$ **or** $\boldsymbol{S_{II}(X_I)\}}$ for i = 1,2, ..., k; $\boldsymbol{\Re_S(C_X')=\{\Re_{S1}(C_X'), \Re_{S2}(C_X'), \ldots\}}$ and the fulfillment of the condition II.3.

2 Then, the universe of **X** includes the element.

3 Note that **U(X)** is the broadest system considered as a *suprasystem* of **X.**

4 **W(X)** is the broadest system considered as an entourage of **X.**

5 It must be noted that **NENT(X)** is the set of all elements that are not part of the system **X** nor its entourage **ENT(X)**.

6 Readers could note that *non-entourage* and *environment* represent the same concepts. However, both terms are used to enable the researcher or analyst to use the term better suited to the level of details used in the analysis of a system.

7 It must be noted that **ENV((X)** is the set of all elements that are not part of the suprasystem **X**.

8 Figure 2 also presents in advance the graphical interpretation of an *information system.* Both are reported in the same figure due to space limitations.

Formal Development of Reactive Agent-Based Systems

INTRODUCTION

Recent advances in both the testing and verification of software based on formal specifications have reached a point where the ideas can be applied in a powerful way in the design of agent-based systems. The software engineering research has highlighted a number of important issues: the importance of the type of modelling technique used; the careful design of the model to enable powerful testing techniques to be used; the automated verification of the behavioural properties of the system; and the need to provide a mechanism for translating the formal models into executable software in a simple and transparent way.

An agent is an encapsulated computer system that is situated in some environment and that is capable of flexible, autonomous action in that environment in order to meet its design objectives (Jennings, 2000). There are two fundamental concepts associated with any dynamic or reactive system (Holcombe & Ipate, 1998): the environment, which could be precisely or ill-specified or even completely unknown and the agent that will be responding to environmental changes by changing its basic parameters and possibly affecting the environment as well. Agents, as highly dynamic systems, are concerned with three essential factors: a set of appropriate environmental stimuli or inputs, a set of internal states of the agent, and a rule that relates the two above and determines what the agent state will change to if a particular input arrives while the agent is in a particular state.

One of the challenges that emerges in intelligent agent engineering is to develop agent models and agent implementations that are "correct." The criteria for "correctness" are (Ipate & Holcombe, 1998): the initial agent model should match the requirements, the agent model should satisfy any necessary properties in order to meet its design objectives, and the implementation should pass all tests constructed using a complete functional test-generation method. All the above criteria are closely related to stages of agent system development, i.e., modelling, validation, verification, and testing.

BACKGROUND: FORMAL METHODS AND AGENT-BASED SYSTEMS

Although agent-oriented software engineering aims to manage the inherent complexity of software systems (Wooldridge & Ciancarini, 2001; Jennings, 2001), there is still no evidence to suggest that any methodology proposed leads toward "correct" systems. In the last few decades, there has been strong debate on whether formal methods can achieve this goal. Software system specification has centred on the use of models of data types, either functional or relational models, such as Z (Spivey, 1989) or VDM (Jones, 1990), or axiomatic ones, such as OBJ (Futatsugi et al., 1985). Although these have led to some considerable advances in software design, they lack the ability to express the dynamics of the system. Also, transforming an implicit formal description into an effective working system is not straightforward. Other formal methods, such as finite state machines (Wulf et al., 1981) or Petri Nets (Reisig, 1985) capture the essential feature, which is "change," but fail to describe the system completely, because there is little or no reference to the internal data and how these data are affected by each operation in the state transition diagram. Other methods, like statecharts (Harel 1987), capture the requirements of dynamic behaviour and modelling of data but are informal with respect to clarity and semantics. So far, little attention has been paid in formal methods that could facilitate all crucial stages of "correct" system development, modelling, verification, and testing.

In agent-oriented engineering, there have been several attempts to use formal methods, each one focusing on different aspects of agent systems development. One was to

formalise the PRS (procedural reasoning system), a variant of the BDI architecture (Rao & Georgeff, 1995), with the use of Z, in order to understand the architecture in a better way, to be able to move to the implementation through refinement of the specification, and to be able to develop proof theories for the architecture (D'Inverno et al., 1998). Trying to capture the dynamics of an agent system, Rosenschein and Kaebling (1995) viewed an agent as a situated automaton that generates a mapping from inputs to outputs, mediated by its internal state. Brazier et al. (1995) developed the DESIRE framework, which focuses on the specification of the dynamics of the reasoning and acting behaviour of multiagent systems. In an attempt to verify whether properties of agent models are true, work has been done on model checking of multiagent systems with reuse of existing technology and tools (Benerecetti et al., 1999, Rao & Georgeff, 1993). Toward implementation of agent systems, Attoui and Hasbani (1997) focused on program generation of reactive systems through a formal transformation process. A wider approach is taken by Fisher and Wooldridge (1997), who utilised Concurrent METATEM in order to formally specify multiagent systems and then directly execute the specification while verifying important temporal properties of the system. Finally, in a less formal approach, extensions to Unified Modelling Language (UML) to accommodate the distinctive requirements of agents (AUML) were proposed (Odell et al., 2000).

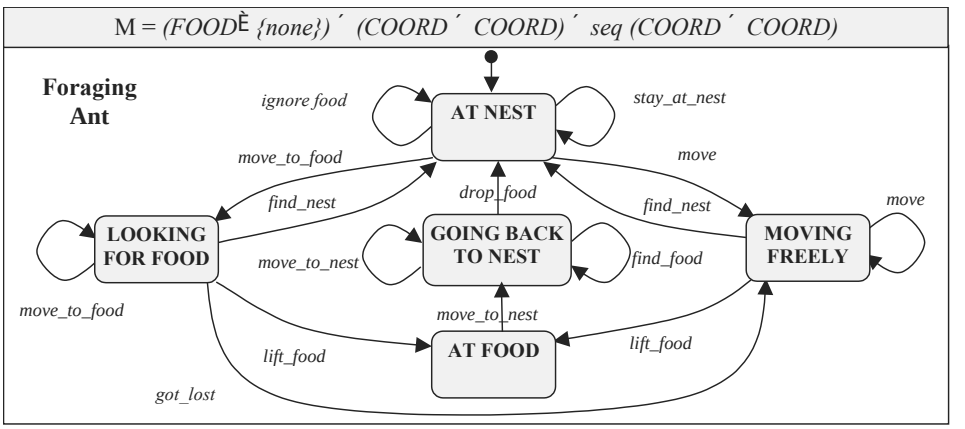
X-MACHINES FOR AGENT-BASED SYSTEM DEVELOPMENT

An X-machine is a general computational machine (Eilenberg, 1974) that resembles a finite state machine but with two significant differences: there is memory attached to the machine, and the transitions are labeled with functions that operate on inputs and memory values. The X-machine formal method forms the basis for a specification language with great potential value to software engineers, because they can facilitate modelling of agents that demand remembering as well as reactiveness. Figure 1 shows the model of an ant-like agent that searches for food but also remembers food positions in order to set up its next goals. Many other biological processes seem to behave like agents, as, for example, a colony of foraging bees, tissue cells, etc. (Kefalas et al., 2003a; Gheorghe et al., 2001; Kefalas et al., 2003b). Formally, the definition of the X-machine requires the complete description of a set of inputs, outputs, and states; a memory tuple with typed elements; a set of functions and transitions; and finally, an initial state and a memory value (Holcombe, 1988).

Having constructed a model of an agent as an X-machine, it is possible to apply existing model-checking techniques to verify its properties. *CTL** is extended with memory quantifier operators: M_x (for all memory instances) and m_x (there exist memory instances) (Eleftherakis & Kefalas, 2001). For example, in the ant-like agent, model checking can verify whether food will eventually be dropped in the nest by the formula: $AG[\neg M_x(m_1 \neq \text{none}) \vee EFM_x(m_1 = \text{none})]$, where m_1 indicates the first element of the memory tuple.

Having ensured that the model is "correct," we need to also ensure that the implementation is "correct," this time with respect to the model. Holcombe and Ipate (1998) presented a testing method that under certain design-for-test conditions can provide a complete test-case set for the implementation. The testing process can be performed automatically by checking whether the output sequences produced by the implementation are identical to the ones expected from the agent model through this test-case set.

Figure 1. An X-machine that models an ant.



A methodology for building complex agent systems by aggregating a set of behaviors of individual agents is available, namely, communicating X-machines. It is demonstrated that they are a powerful extension to the X-machines that also facilitate modelling of multiagent systems (Kefalas et al., 2003a).

FUTURE TRENDS

There are currently three directions to future work. First, there is a need to investigate potential applications. We already identified the area of biology-inspired agent-based systems, such as modelling of biological cells and tissues, as an area that can largely benefit from formal modelling, verification, and testing. Second, current research is underway to extend the testing and verification methods in order to be applicable for communicating asynchronous and possibly nondeterministic systems. Last, there has been an attempt to build tools around the X-machine formal method in order to facilitate the actual agent development process. A markup language, namely X-Machine Definition Language (XMDL), has been defined, and around it, a number of prototype tools, such as a modeller, an automatic translator to Prolog, an animator, and a model checker, have been constructed.

CONCLUSION

Because the X-machine method is fully grounded in the theory of computation, it is fully general and will be applicable to any type of computational task. The paradigm of the X-machine is also convenient when it comes to implementing the models in an imperative programming language. In fact, the translation is more or less automatic. The existence of the powerful testing method described lays the foundation for the method to be used in potentially critical applications. Finally, the model-checking developments will lead to a situation in which one of the key issues in agent software engineering can be solved, namely, how can we guarantee that the agent system constructed will exhibit the desired emergent behavior, or at least substantial progress toward this goal will be achieved.

KEY TERMS

Agent: An agent is an encapsulated computer system that is situated in some environment and that is capable of flexible, autonomous action in that environment in order to meet its design objectives. Agents normally exhibit autonomous, reactive, proactive, and social behaviors.

Communicating X-Machine: A communicating X-machine is a set of stream X-machine components that are able to communicate with each other by exchanging messages.

CTL*: A temporal logic formalism used in model checking. *CTL** employs operators, such as *A* (for all paths), *E* (there exists a path), *X* (next time), *F* (eventually), *G* (always), *U* (until), and *R* (release), that facilitate the construction of temporal logic formulas that correspond to desirable properties of a model.

Formal Methods: Formal methods are rigorous techniques based on mathematical notation that can be used to specify and verify software models.

Model Checking: Model checking is a formal verification technique that determines whether given properties of a system are satisfied by a model. A model checker takes a model and a property as inputs, and outputs either a claim that the property is true or a counterexample falsifying the property.

X-Machine: A deterministic stream X-machine is an 8-tuple $(\Sigma, \Gamma, Q, M, \Phi, F, q_0, m_0)$, where Σ, Γ is the input and output finite alphabet, respectively; Q is the finite set of states; M is the (possibly) infinite set called memory; Φ is the type of the machine, that is, a finite set of partial functions φ that map an input and a memory state to an output and a new memory state, $\varphi: \Sigma \times M \rightarrow \Gamma \times M$; F is the next state partial function that, given a state and a function from the type Φ, denotes the next state—*F* is often described as a state transition diagram, $F: Q \times \Phi \rightarrow Q$; q_0 and m_0 are the initial state and memory, respectively.

Formalization Process in Software Development

Aristides Dasso
Universidad Nacional de San Luis, Argentina

Ana Funes
Universidad Nacional de San Luis, Argentina

INTRODUCTION

Nowadays, software engineering (SE) is considered more frequently an engineering discipline. Several definitions have been proposed by different authors, and many of them agree in affirming that SE is the application of principles and systematic practices for the development of software. That is—as it was established by the IEEE (1990)—SE is the application of engineering to the software.

As a general rule all engineering applications use mathematics or mathematical tools as a basis for their development. However, software engineering is an exception to this rule. Not all the techniques and software development methods have a formal basis. Formal methods[1] (FM) rely on mathematical foundations.

FM are a collection of methodologies and related tools, geared to the production of software employing a mathematical basis. There are a number of different formal methods each having its own methodology and tools, specially a specification language.

As it is expressed in Wikipedia (2006) and Foldoc (2006), we can say that FM are "mathematically based techniques for the specification, development and verification of software and hardware systems."

FM are based on the production of formal specifications—for which they have a formal language to express it. Sometimes there is also a method to use the language in the software development process.

The aims of FM can vary according to the different methodologies, but they all shared a common goal: the production of software with the utmost quality mainly based on the production of software that is error free. To achieve this, the different FM have developed not only a theory, but also different tools to support the formal process.

FM can cover all the steps of the life cycle of a software system development from requirement specification to deployment and maintenance. However, not all FM have that capacity, and not always it is convenient to apply them. It is necessary to make an evaluation between pros and cons before applying FM in the software development process.

FORMAL METHODS

It is important to make a distinction between a formal notation or language and a formal system. A formal notation is used to produce a formal specification, and it has a formal syntax and semantics. A formal system, besides these two components, includes a proof system—the deductive mechanism of the formal system. The syntax is described by a grammar and defines the set of well-formed formulas of the language. The meaning of these formulas is given by the semantics of the language. Finally, the syntactic manipulations of these formulas are achieved by using the inference mechanism of the formal system, which allows the derivation of new well-formed formulas from those present in the language.

Alagar and Peruyasamy (1998) establish that the difference between a FM and a formal system is the automatic support for specification and the availability of mechanized proofs.

All FM are based on mathematical formalisms, but we can distinguish two different development approaches. On the one hand, we can find the transformational methods based in transformations and on the other hand, those based in the "invent and verify" principle. The former rely for development on a calculus or transformation, where the engineer starts with an expression and then following predefined rules applies them to obtain an equivalent expression. Successive calculations lead to implementation. In FM relying on "invent and verify" technique, the engineer starts by inventing a new design, which afterward needs to be verified as correct. From this verified design implementation follows.

There are several styles of formal specification. Some are mutually compatible, while others are not. Table 1 shows a possible classification of the different styles.

Formal languages have formal definitions, not only of their syntax, but also of their semantics. Table 2 shows a possible classification for the different formal semantic definitions styles.

In NASA's Langley Research Center site for formal methods there is a nice definition and also an explanation of different degrees of rigor in FM (http://shemesh.larc.nasa.gov/fm/fm-what.html):

Table 1. Summary of specification language characteristics

Model-oriented. Based on mathematical domains. For example numbers, functions, sets, and so forth. Concrete.	**Property-oriented**. Based on axiomatic definitions. Abstract.
Applicative. Does not allow the use of variables.	**Imperative or State-oriented**. Allows the use of variables.
Static. Does not include provisions for handling time.	**Action**. Time can be considered in the specification. There are several ways of doing this: considering time as linear or branching, synchronous, asynchronous, and so forth.

Table 2. Summary of semantic definitions styles of specification languages

Operational. Concrete, not well suited for proofs. The meaning of a system is expressed as a sequence of actions of a simpler computational model.
Denotational. Abstract, well suited for proofs. The meaning of a system is expressed in the mathematical theory of domains.
Axiomatic. Very abstract, normally only limited to conditional equations. The meaning of the system is expressed in terms of preconditions and postconditions.

"Traditional engineering disciplines rely heavily on mathematical models and calculation to make judgments about designs. For example, aeronautical engineers make extensive use of computational fluid dynamics (CFD) to calculate and predict how particular airframe designs will behave in flight. We use the term 'formal methods' to refer to the variety of mathematical modelling techniques that are applicable to computer system (software and hardware) design. That is, formal methods is the applied mathematics of computer system engineering, and, when properly applied, can serve a role in computer system design analogous to the role CFD serves in aeronautical design.

Formal methods may be used to specify and model the behavior of a system and to mathematically verify that the system design and implementation satisfy system functional and safety properties. These specifications, models, and verifications may be done using a variety of techniques and with various degrees of rigour. The following is an imperfect, but useful, taxonomy of the degrees of rigour in formal methods:

Level-1:
Formal specification of all or part of the system.

Level-2:
Formal specification at two or more levels of abstraction and paper and pencil proofs that the detailed specification implies the more abstract specification.

Level-3:
Formal proofs checked by a mechanical theorem prover.

Level 1 represents the use of mathematical logic or a specification language that has a formal semantics to specify the system. This can be done at several levels of abstraction. For example, one level might enumerate the required abstract properties of the system, while another level describes an implementation that is algorithmic in style.

Level 2 formal methods goes beyond Level 1 by developing pencil-and-paper proofs that the more concrete levels logically imply the more abstract-property oriented levels. This is usually done in the manner illustrated below.

Level 3 is the most rigourous application of formal methods. Here one uses a semi-automatic theorem prover to make sure that all of the proofs are valid. The Level 3 process of convincing a mechanical prover is really a process of developing an argument for an ultimate skeptic who must be shown every detail.

Formal methods is not an all-or-nothing approach. The application of formal methods to only the most critical portions of a system is a pragmatic and useful strategy. Although a complete formal verification of a large complex system is impractical at this time, a great increase in confidence in the system can be obtained by the use of formal methods at key locations in the system."

As it is said in NASA's definition of the levels of degree of rigor, they are imperfect; others exist. Most of the FM included next have as an integral part not only a language but also a methodology included, and most of the time this methodology implies different levels of rigor in its use. For

example, RAISE—that has its own method—presents three degrees of formality (The RAISE Method Group, 1995):

- **Formal Specification Only:** Where formality is only applied to the specification procedure.
- **Formal Specification and Rigorous Development:** Where formality is applied to the specification procedure as previously, and rigor to the development process. This means that the developer starts writing abstract specifications, goes on developing more concrete ones and recording the development relations between them. These relations are then examined; however, they are not justified.
- **Formal Specification and Formal Development:** Where formality is applied not only to the specification but also to the development process including justification.

FM finds more adepts in critical software development, where the presence of errors can have grave human, economic, and social consequences. NASA, as well as other government bodies in the USA, Europe, and elsewhere, is using FM especially in avionics and systems where the utmost reliability is needed. Some examples from NASA are Small Aircraft Transportation System (SATS) (http://shemesh.larc.nasa.gov/fm/fm-now-sats.html) and Formal Analysis of Airborne Information for Lateral Spacing (AILS). Also, NASA's contractors use FM (http://shemesh.larc.nasa.gov/fm/fm-now-ails.html). For more information on these and other projects see http://shemesh.larc.nasa.gov/fm/fm-main-research.html.

Next we present a not all-inclusive list of FM. For more information on these and other FM see http://vl.fmnet.info. This site has links to the sites of many other FM.

- **Abstract State Machines (ASM):** "[M]ethodology for describing simple abstract machines which correspond to algorithms" (http://www.eecs.umich.edu/gasm/).

- **Z Notation:** Based on Zermelo-Fraenkel set theory and first order predicate logic (http://www.zuser.org/z).

Of course a question to ask oneself is why there are so many flavors of FM. There are undoubtedly several possible answers to this question. One is that since there are many ways to describe a system, not everyone agrees on a particular style. Why are there so many different programming languages? The answer to this question could be also the answer to our question. We can also say not all the FM addressed the same problem. Some of them are geared to system design, others to domain description; some deal with time, while others do not consider it, and so forth.

PROS AND CONS

The issue of whether FM are useful or not was discussed in the literature around 10 years ago—see for example work by Bowen and Hinchey (1995a, 1995b) and Luqi and Goguen (1997).

The use of formal specifications has benefits ranging from the possibility of building unambiguous specifications, to the possibility of proving system properties, to automatic code generation. Formal specifications provide a deep understanding of software requirements that reduce the possibility of making mistakes and omissions.

By using formal specifications it may be possible to prove system consistency; however, verification is an expensive and time-consuming task, and it requires a high level of expertise in algebra and mathematical logic.

Formal specifications can be used as the basis for the derivation of test cases. This has been treated by Aichernig (1999, 2001a, 2001b, 2001c)) among others.

Most opponents give as a main reason the fact that FM make difficult the communication with the end users when requirements must be validated. However, lately there is an ongoing interest in the combined use of semi-formal notations and formal specifications to overcome this problem and the ambiguity and inconsistency inherent in semi-formal notations. This kind of integration is intended to improve understandability—given by graphical notations—and to gain in unambiguity—offered by formal specifications.

According to Pons and Baum (2000), we can carry out integration in four different ways:

1. **Supplemental:** Where the informal notations are enriched with formal concepts.
2. **Extension:** Where the formal notations are extended with concepts from others paradigms, for example, from the object-oriented paradigm.
3. **Interface:** Where formal notations are provided with graphic interfaces to help in the development of models.
4. **Semantics:** Where the semantics of an accepted semi-formal modeling language is given by a formal language.

There is an important number of theoretical works that deal with the integration of graphical notations and mathematically precise formalisms. Proof of this are the growing interest in providing a more traditional methodology such as UML with formal basis, either through the OCL language or by giving to UML graphic language a formal semantics—see the works of the 2U Consortium (2003) and The Precise UML Group (2003). The extensive work done on formalizing Java and Java Machine can be seen in work by Hartel and Moreau (2001) and Bertelsen (2003). Other good examples can be found in work by Amálio, Stepney, and Polack (2003), DeLoach and Hartrum (2000), France (1999), Funes and George (2003), Moreira and Clark (1996), Kim and Carrington (2000), Lano (1991), Meyer and Souquieres (1999), Reggio and Larosa (1997), and Weber (1996), among others.

Finally, we should not forget the important role FM have in the development of systems where security and reliability are crucial. Hung et al. (2002) cite three factors that were the traditional arguments in favor of FM: first the growing number of applications with minimal or zero tolerance for errors, second social, environmental, and economic consequences of design errors in hardware and software products, raising social awareness and concern, and third there are a number of standards and regulatory organizations enforcing quality standards for electronic products.

EXAMPLES

Just so the reader can get the flavor of FM we present in this section an example of specifications for a stack of natural numbers using the RAISE Specification Language (RSL) (The RAISE Language Group, 1992).

The first specification in Example 1 illustrates the use of the property-oriented style, which is abstract and whose definitions are given by axioms. The second specification given for the stack is model-oriented, based in the use of

Example 1. A stack of natural numbers in RSL (using static applicative praoperty-oriented style)

```
scheme STACK_0 =
class
  type
    Stack
  value
    empty: Stack,
    push: Nat × Stack → Stack,
    pop: Stack ~→ Stack ,
    top: Stack ~→ Nat
  axiom
    ∀e: Nat, s: Stack • pop(push(e, s)) ≡ s,
    ∀e: Nat, s: Stack • top(push(e, s)) ≡ e,
end
```

Example 2. A stack of natural numbers in RSL (using static applicative model-oriented style)

```
scheme STACK_1 =
class
  type
    Stack = Nat *
  value
    empty: Stack,
    push: Nat × Stack → Stack,
    pop: Stack ~→ Stack ,
    top: Stack ~→ Nat
  axiom
    empty ≡ <>,
    ∀e: Nat, s: Stack • push(e, s) ≡ <e> ^ s,
    ∀s: Stack • pop(s) ≡ tl s
          pre s ≠empty,
    ∀s: Stack • top(s) ≡ hd s
          pre s ≠empty
end
```

concrete types (see Example 2). Both specifications use RSL static and applicative style.

The *Stack* type in Example 1 is given by an abstract type since we do not say explicitly how a stack is going to be implemented or of what type its elements are. The stack is defined by the main operations needed to manage it. To formally specify its behavior, we give the signature of three functions: *pop*, *push*, and *top*, the constant *empty* that represents the empty stack, and a set of axioms to express the intended meaning of these operations. The axioms define the essential properties that must always be true when the operations are applied.

The operations *pop* and *top* are partial functions that are not defined for the empty stack. This fact is reflected by the absence of axioms about *pop(empty)* and *top(empty)*. The operation *push* is a total function.

The first axiom states that pushing an element *e* into a stack *s* and then doing a *pop* returns the former stack *s*. The second axiom states that every time we push an element *e* into a stack and then apply *top* to the resulting stack, we get the last pushed element *e*.

But, where is the formalism in this specification? We must not forget that as any FM, RSL has defined formally not only its syntax but also its semantic. This allows, for instance, the use of axioms, which are truths that must be preserved all along the specification and that in turn can be proved—or not, if the specification has errors or inconsistencies. So the formalism can be found in the fact that using the underlying semantic—in this case logic and algebra—the specification can be subjected to proof, and therefore any errors can be found.

In this example, the axioms specify the behavior of the stack—remember that axioms must always be true; if they are not, then there is an error in the specification.

So, besides the abstractness and precision given by a formal specification language, one of the major reasons for expressing specifications in a formal language is the possibility of proving properties of the specifications. Formulating properties and then trying to prove them is a way of ensuring correctness and detecting errors.

The second example—see Example 2—is a refinement of the first one. Here, we define the *Stack* type not as a sort but as a list of natural numbers—the * next to **Nat** indicates list of **Nat** in RSL.

The axioms that define the operations on the stack are defined using the primitive operations for lists in RSL—remember that everything in RSL has its semantics formally defined, and that includes the type list as well as the elementary operations on the type. The operation *empty* is defined as the empty list. To *push* an element into the stack corresponds to adding the element at the head of the list, returning the resulting augmented stack. To *pop* an element from the stack corresponds to remove the head of the list and return the resulting reduced stack; and to get the *top* of the stack corresponds to get the head of the list and return it. Note that since *pop* and *top* have a pre-condition establishing that they cannot be applied to the empty stack, they are partial functions.

In RAISE—as in many other FM—besides being formal when specifying, we can also be formal in the development process. Software can be developed in a sequence of steps. We can start writing a suitably abstract specification and proceed developing more concrete and detailed ones until the final specification can be automatically translated to a programming language. Each step in the development must conform to the previous and must be proved as a correct development step. For example, we should prove that the specification STACK_1 is a correct development for STACK_0, that is, to prove that STACK_1 implements STACK_0, that is, STACK_0 and STACK_1 are in the implementation relation. In RAISE this means that the specifications have to meet two requirements:

- **Property of Preservation:** All properties that can be proved about STACK_0 can also be proved for STACK_1.
- **Property of Substitutivity:** In any specification an instance of STACK_0 can be replaced by an instance of STACK_1, and the resulting specification should implement the former specification.

FUTURE TRENDS

Although traditional methods seem to be the most popular nowadays, the use of FM has grown to occupy more and more a place in software engineering for development of systems where security and reliability are important. However, its use continues being expensive and limited.

Besides its leading role in the development of critical systems, there is also a growing interest in proposing methods and techniques to use formal specifications combined with semi-formal notations to give more rigor to the first phases of the development process.

If formal techniques become in the future the foundations of a new generation of CASE tools, is possible that a bigger portion of software practitioners will adopt them, making formal methods a truly practical tool for all kinds of systems.

CONCLUSIONS

FM are methods based primarily in formal, mathematical notation and principles. They are ideal for defining unambiguously not only the requirements, but also every stage in system development including implementation since there are FM that have translators to programming languages.

Because of their profound roots in logic and algebra, they seem harder to understand and learn. However the FM community aware of this view has been making efforts in producing tools that make their use easier.

KEY TERMS

Action-Oriented Formal Specification Language: Time can be considered in the specification. There are several ways of doing this: considering time as linear or branching, synchronous, asynchronous, and so forth.

Applicative-Oriented Formal Specification Language: Does not allow the use of variables.

Axiomatic Semantics: The meaning is given in terms of conditions, pre and post.

Denotational Semantics: The meaning is given in terms of mathematical functions.

Imperative or State-Oriented Formal Specification Language: Allows the use of variables.

Model-Oriented Formal Specification Language: Based on mathematical domains. For example, numbers, functions, sets, and so forth. Concrete.

Operational Semantics: The meaning is given in terms of rules that specify how the state of a computer—real or formal—changes while executing a program.

Property-Oriented Formal Specification Language: Based on axiomatic definitions. Abstract.

Semantics: In a language, it is the meaning of a string, as opposed to syntax, that describes how the symbols of the language are combined. Most programming languages have their syntax defined formally (traditionally in BNF), while formal specification languages have also their semantics defined formally.

Specification: A document describing what a system should do, what a problem is, or what a domain is all about. In formal methods this document is written in a formal language.

Static-Oriented Formal Specification Language: Do not include provisions for handling time.

Verification: The process of determining whether or not the products of a specification phase fulfill a set of established requirements. Sometimes this is also used to indicate the process of proving that a more concrete specification preserves the properties of a more abstract specification.

ENDNOTE

[1] Some authors use the singular while others employ the plural in referring to FM. We can refer to Ricky W. Butler (2006):

"Some of you are saying, 'Formal Methods is ...? What's wrong with these people, ain't nobody learned them no grammar!' In an age in which few people care about the proper use of language, your concern is commendable; however, in this instance, your concern is also unwarranted.

In these pages, we are using the term formal methods to refer to a particular collection of knowledge. Just as the plural-sounding term fluid dynamics is treated as singular, so too may the term formal methods be treated as singular. A legitimate argument can be made as to the acceptability of treating the term as plural, but no legitimate argument can be made as to the necessity of doing so."

INTRODUCTION

The model driven architecture (MDA) is an initiative proposed by the object management group (OMG), which is emerging as a technical framework to improve productivity, portability, interoperability, and maintenance (MDA, 2003).

MDA promotes the use of models and model-to-model transformations for developing software systems. All artifacts, such as requirement specifications, architecture descriptions, design descriptions, and code are regarded as models. MDA distinguishes four main kinds of models: computation independent model (CIM), platform independent model (PIM), platform specific models (PSM), and implementation specific model (ISM).

A CIM describes a system from the computation independent viewpoint that focuses on the environment of and the requirements for the system. In general, it is called domain model. A PIM is a model that contains no reference to the platforms that are used to realize it. A PSM describes a system with full knowledge of the final implementation platform. In this context, a platform is "a set of subsystems and technologies that provide a coherent set of functionality which any application supported by that platform can use without concern for the details of how the functionality is implemented" (MDA, 2003, p. 2-3). PIMs and PSMs are expressed using the unified modeling language (UML) combined with the object constraint language (OCL) (Favre, 2003; OCL, 2004; UML, 2004).

The idea behind MDA is to manage the evolution from CIMs to PIMs and PSMs that can be used to generate executable components and applications. In MDA is crucial to define, manage, and maintain traces and relationships between different models and automatically transform them and produce code that is complete and executable.

Metamodeling has become an essential technique in model-centric software development. The metamodeling framework for the UML itself is based on architecture with four layers: meta-metamodel, metamodel, model, and user objects. A metamodel is an explicit model of the constructs and rules needed to build specific models, its instances. A meta-metamodel defines a language to write metamodels. OCL can be used to attach consistency rules to models and metamodels. Related OMG standard metamodels and meta-metamodels such as meta object facility (MOF), software process engineering metamodel (SPEM) and common warehouse model (CWM) share a common design philosophy (CWM, 2001; MOF, 2005; SPEM, 2005).

MOF defines a common way for capturing all the diversity of modeling standards and interchange constructs. MOF uses an object modeling framework that is essentially a subset of the UML core. The four main modeling concepts are "classes, which model MOF metaobjects; associations, which model binary relationships between metaobjects; data types, which model other data; and packages, which modularize the models" (MOF, 2005, p. 2-6). The query, view, transformation (QVT) standard depends on MOF and OCL for specifying queries, views, and transformations. A query selects specific elements of a model, a view is a model derived from other model, and a model transformation is a specification of a mechanism to convert the elements of a model, into elements of another model, which can be instances of the same or different metamodels (QVT, 2003).

The success of MDA depends on the existence of CASE (computer-aided software engineering) tools that make a significant impact on software processes such as forward engineering and reverse engineering processes (CASE, 2006). This article explains the most important challenges to automate the processes that should be supported by MDA tools. We propose an integration of knowledge developed by the community of formal methods with MDA. We describe a rigorous framework that comprises the metamodeling notation NEREUS and bridges between MOF-metamodels and NEREUS, and between NEREUS and formal languages. NEREUS can be viewed as an intermediate notation open to many other formal specifications. We analyze metamodeling techniques for expressing model transformations such as refinements and refactorings. Our approach focuses on interoperability of formal languages in model driven development (MDD).

This article is organized as follow. We first analyze the limitations of the existing MDA-based CASE tools. Then, we describe the bases of rigorous MDA-based processes. Next, we show how the formalization of MOF metamodels and metamodel-based model transformations allows us automatic software generation. Finally, we highlight the key directions in which MDA is moving forward.

BACKGROUND

To date, there are about 120 UML CASE tools that vary widely in functionality, usability, performance, and platforms (CASE, 2006). Some of them can only help with the mechanics of drawing and exporting UML diagrams. The mainstream object-oriented CASE tools support forward engineering and reverse engineering processes and can help with the analysis of consistency between diagrams. Only a few UML tools include extension for real time modeling. The tool market around MDA tools is still in flux and only about 10% of them provide some support for MDA. Table 1 exemplifies a taxonomy of the UML CASE tools (CASE, 2006).

The current techniques available in the commercial tools do not allow generating complete and executable code and after generation, the code needs additions. A source of problems in the code generation processes is that, on the one hand, the UML models contain information that cannot be expressed in object-oriented languages while, on the other hand, the object-oriented languages express implementation characteristics that have no counterpart in the UML models.

Moreover, the existing CASE tools do not exploit all the information contained in the UML models. For instance, cardinality and constraints of associations and preconditions, postconditions, and class invariants in OCL are only translated as annotations. It is the designer's responsibility to make good use of this information either selecting an appropriate implementation from a limited repertoire or implementing the association by himself.

On the other hand, many CASE tools support reverse engineering, however, they only use more basic notational features with a direct code representation and produce very large diagrams. Reverse engineering processes are facilitated by inserting annotations in the generated code. These annotations are the link between the model elements and the language. As such, they should be kept intact and not be changed. It is the programmer's responsibility to know what he or she can modify and what he or she cannot modify.

UML CASE tools provide limited facilities for refactoring on source code through an explicit selection made for the designer. However, it will be worth thinking about refactoring at the design level. The advantage of refactoring at UML level is that the transformations do not have to be tied to the syntax of a programming language. This is relevant since UML is designed to serve as a basis for code generation with MDA (Sunye et al., 2001).

Techniques that currently exist in UML CASE tools provide little support for validating models in the design stages. Reasoning about models of systems is well supported by automated theorem provers and model checkers, however, these tools are not integrated into CASE tools environments. Another problem is that as soon as the requirements specifications are handed down, the system architecture begins to deviate from specifications (Kollmann & Gogolla, 2002). Only research tools provide support for formal specification and deductive verification.

All of the MDA CASE tools are partially compliant to MDA features. They provide good support for modeling and limited support for automated transformation. In general, they support MDD from the PIM level and use UML class diagrams for designing PIMs. Some of them provide only one level of transformation from PIM to code (Codagen, Ameos, Arcstyler) and, in general, there is no relation between QVT and the current existing MDA tools. As an example, OptimalJ from Compuware supports MDD from PIM level. It allows generating PSMs from a PIM and a partial code generation. It distinguishes three kinds of models: a domain model that correspond to a PIM model, an application model that includes PSMs linked to different platforms (Relational-PSM, EJB-PSM and Web-PSM), and an implementation model.

Table 1. UML CASE tools

Basic drawing tools	Visio
Main stream object oriented case tools	Rational Rose, Argo/UML, Together, UModel, MagicDraw, MetaEdit+, Poseidon
Real time/embedded tools	Rapsody, Rational Rose Real Time, RapidRMA
MDA-based tools	OptimalJ, AndroMDA, Ameos, Together Architect, Codagen, ArcStyler, MDE Studio, Objecteering

The transformation process is supported by transformation and functional patterns.

The MDA-based tools use MOF to support OMG standards such as UML and XMI (XML metadata interchange). MOF has a central role in MDA as a common standard to integrate all different kinds of models and metadata and to exchange these models among tools; however, MOF does not allow capturing semantic properties in a platform independent way and there is no rigorous foundations for specifying transformations among different kinds of models.

A lot of research work has been carried out dealing with the advanced metamodeling techniques and formalization of different kinds of transformations. For instance, the main task of USE tool (Gogolla, Bohling, & Ritchers, 2005) is to validate and verify specifications consisting of UML/OCL class diagrams. Key (Ahrendt et al., 2002) is a tool based on together (CASE, 2006) enhanced with functionality for formal specification and deductive verification.

Akehurst and Kent (2002) propose an approach that uses metamodeling patterns that capture the essence of mathematical relations. The proposed technique is to adopt a pattern that models a transformation relationship as a relation or collections of relations, and encode this as an object model. Hausmann (2003) defined an extension of a metamodeling language to specify mappings between metamodels based on concepts presented in Akehurst et al. (2002). Kuster, Sendall, and Wahler (2004) compare and contrast two approaches to model transformations: one is graph transformation and the other is a relational approach. Czarnecki and Helsen (2003) describe a taxonomy with a feature model to compare several existing and proposed model-to-model transformation approaches.

RIGOROUS MODEL-DRIVEN DEVELOPMENT

Developing or reengineering a system in an MDA perspective should be done through automated transformation with the help of tools. Figure 1 illustrates the different processes and artifacts beyond this idea. Forward engineering and reverse engineering processes should be supported in MDA tools. Forward engineering is the process of transforming higher-level or abstract models into concrete ones. Reverse engineering reconstructs higher-level models from low ones. Reengineering is the process that transforms one concrete representation to another, while reconstituting the higher-level models along the way. We describe a rigorous framework compliant to MDA forward engineering processes. A model-driven development is carried out as a sequence of model transformations that includes, at least, the following steps: construct a CIM, transform the CIM into a PIM that provides a computing architecture independent of specific platforms, transform the PIM into one or more PSMs, each one suited for specific platforms, and derive code directly from the PSMs.

A model transformation is the process of converting one model into another model preserving some kind of equivalence relation between them. We can distinguish two types of transformations to support model evolution from CIMs to ISMs: refinements and refactorings. A refinement is the process of building a more detailed specification that conforms to another that is more abstract. On the other hand, a refactoring means changing a model leaving its behavior unchanged, but enhancing some non-functionality quality factors such as simplicity, flexibility, understandability, and performance.

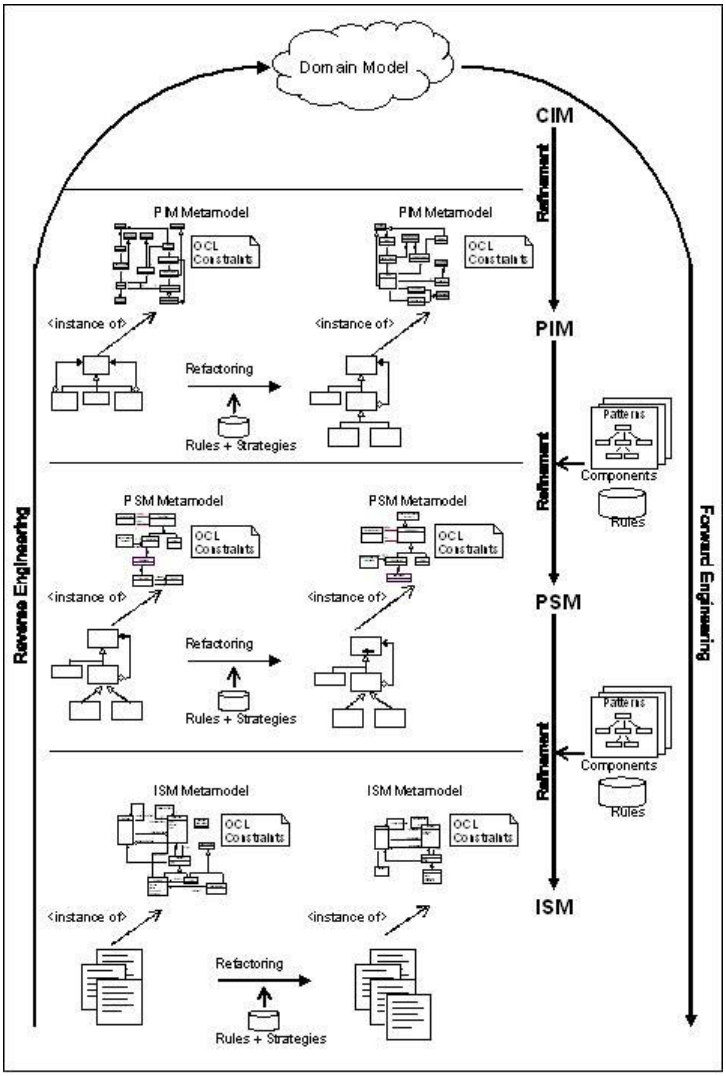
Metamodeling is a powerful technique to specify families of models and model transformations. Figure 1 shows the different correspondences that may be held between several models and metamodels and their interrelations. A CIM is related to one or more PIM-metamodels. A PIM-metamodel is related to more than one PSM-metamodels, each one suited for different platforms (e.g., .NET, J2EE, or relational). The PSM-metamodels correspond to ISM-metamodels. A metamodel is a description of all the concepts that can be used in the respective level. For instance, a metamodel linked to a relational platform refers to concepts of table, foreign key and column. An ISM-metamodel includes concepts of programming languages such as constructor and method.

The following types of model transformations can be distinguished:

- **CIM to PIM refinement:** It describes how a CIM that is an instance of a MOF-metamodel is transformed into a PIM that is an instance of a specialized metamodel for a specific computation dependent model.
- **PIM to PSM refinement:** It describes how a PIM that is an instance of a MOF-Metamodel is transformed into a PSM that is an instance of a specialized MOF-metamodel for a specific platform.
- **PSM to ISM refinement:** It describes how a PSM is transformed into code (which is an instance of MOF-metamodel for a platform and specific language technologies).
- **Refactoring:** It specifies how a model in a given level is transformed into a new restructured model in the same level (for instance, PIM to PIM, PSM to PSM, ISM to ISM). The source and target models are instances of the same MOF-metamodel.

Metamodel transformations are a specific type of model transformations that impose relations between pairs of metamodels. A metamodel-based transformation is a specification of a mechanism to convert the elements of a model, that are instances of a particular metamodel, into elements of another model, which can be instances of the same or different metamodels. We specify metamodel-based model

Figure 1. Rigorous model-driven development



transformations as OCL contracts that are described by means of a transformation name, parameters, preconditions, postconditions, and additional operations.

The MDA-based processes are based on the adaptation of reusable components and systems of transformations rules. We analyzed basic techniques for MDA-based processes such as refactoring (Kerievsky, 2004; Long, Jifeng & Liu, 2005; Mens, Demeyer, Du Bois, Stenten, & Van Gorp, 2004) and design pattern (France, Kim, Ghosh, & Song, 2004; Gamma, Helm, Johnson, & Vlissides, 1995).

Pereira and Favre (2006) propose a metamodeling technique to define refactorings at different abstraction levels (e.g., PIM, PSM, and ISM). A transformational system based on behaviour-preserving model-to-model transformations was defined. To reason about correctness and robustness we propose to specify refactorings as OCL contracts that are based on metamodels capturing common properties to a family of refactorings.

Martinez and Favre (2006) describe a metamodeling technique to define design pattern components from an MDA perspective. In this context, we propose a "megamodel" for defining reusable components that integrates different kinds of models with their respective metamodels. We analyze metamodel-based model transformations among levels of PIMs, PSMs and ISMs. We illustrate the approach to define reusable design pattern components using the popular Gamma patterns (Gamma et al., 1995).

FORMALIZATION OF MDA-BASED PROCESSES

UML and OCL are too imprecise and ambiguous when it comes to simulation, verification, validation, and forecasting of system properties and even when it comes to generating

models/implementations through transformations. Although OCL is a textual language, OCL expressions rely on UML class diagrams (i.e., the syntax context is determined graphically). OCL does also not have the solid background of a classical formal language. In the context of MDA, model transformations should preserve correctness. To achieve this, the different modeling and programming languages involved in an MDD must be defined in a consistent and precise way. Then, the combination of UML/OCL specifications and formal languages offers the best of both worlds to software developer. In this direction, we define NEREUS to take advantage of all the existing theoretical background on formal methods, using different tools such as theorem provers, model checkers, or rewrite engines in different stages of MDD.

Favre (2006) proposes a rigorous framework to model driven developments. The bases of this approach are the metamodeling notation NEREUS and, bridges between UML/OCL and NEREUS and between NEREUS and algebraic languages.

NEREUS can be viewed as an intermediate notation open to many other formal specifications, such as algebraic, functional or logic ones. NEREUS is suited for specifying MOF. Most of the MOF concepts for metamodels (entity, associations, and packages) can be mapped to NEREUS in a straightforward manner. This language is relation-centric which means that it expresses different kinds of UML relations (dependency, association, aggregation, and composition) as primitives to develop specifications. In Favre (2006), we show how to integrate NEREUS with algebraic languages using the common algebraic specification language (CASL) (Bidoit & Mosses, 2004).

The formalization of MDA-based processes implies to specify metamodels and metamodel-based transformations.

On the one hand, we define a bridge between MOF-metamodels and NEREUS that is based on a system of transformation rules to convert automatically UML/OCL into NEREUS specifications. Starting from UML class diagrams, an incomplete algebraic specification can be built by instantiating reusable schemes and components, which already exist in the NEREUS predefined library. Analyzing OCL specifications, it is possible to derive axioms that will be included in the NEREUS specification. Preconditions written in OCL are used to generate preconditions in NEREUS. Postconditions and invariants allow us to generate axioms in NEREUS. Thus, an incomplete specification can be built semi-automatically (Favre, 2005; Favre, Martinez, & Pereira, 2003).

On the other hand, we formalize transformations (refinements and refactorings) as OCL contracts that are translated into NEREUS specifications by instantiating reusable schemes.

We have applied the approach to transform UML/OCL class diagrams into NEREUS specifications, which in turn, are used to generate object-oriented code (Favre, 2005; Favre et al., 2005). The process is based on the adaptation of MDA-based reusable components. NEREUS allows us to keep a trace of the structure of UML models in the specification structure that will make easier to maintain consistency between the various levels when the system evolves. All the UML model information (classes, associations, and OCL specifications) is overturned into specifications having implementation implications. The transformation of different kinds of UML associations into object-oriented code was analyzed, as well as, the construction of assertions and code from algebraic specifications. The proposed transformations preserve the integrity between specification and code. The transformation process is based on reusable components.

In Favre and Martinez (2006) we describe how formalize MOF- metamodels and metamodel-based transformations exemplifying with MDA design pattern components.

In contrast to other works, our approach is the only one focusing on interoperability of formal languages in model-driven software development. There are UML formalizations based on different languages that do not use an intermediate language such as NEREUS. However, this extra step provides some advantages. NEREUS would eliminate the need to define formalizations and specific transformations for each different formal language. The metamodel specifications and transformations can be reused at many levels in MDA. Languages that are defined in terms of NEREUS metamodels can be related to each other because they are defined in the same way through a textual syntax.

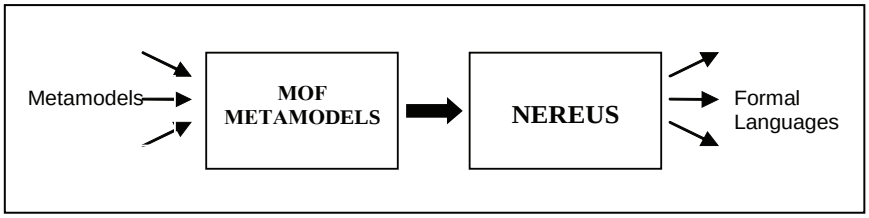
Any number of source languages (modeling language) and target languages (formal language) could be connected without having to define explicit model/metamodel transformations for each language pair. NEREUS embraces changes at different levels of abstraction (Figure 2).

FUTURE TRENDS

Nowadays, there exists an increased demand of reengineering of legacy systems towards new technologies. Advanced MDA tools should reverse existing code to abstract models to facilitate platform migration. It will probably take several years before a full round trip engineering based on standards occurs (many authors are skeptical about this). The existing MDA-based tools do not provide sophisticated transformation from PIM to PSM and from PSM to code.

To solve problems basic research on formalisms and theories will have to be carried out dealing with software evolution in MDA. If MDA becomes a commonplace, adapting it to formal development will become crucial. Formal and semi-formal techniques can play complementary roles in software development processes. This integration is benefi-

Figure 2. Interoperability of formal languages



cial for both graphical and formal specification techniques. On the one hand, semi-formal techniques have the ability to visualize language constructs allowing a great difference in the productivity of the specification process, especially when the graphical view is supported by means of good tools. On the other hand, formal specifications allow us to produce a precise and analyzable software specification before implementation and to define semi-automatic forward engineering processes.

The integration between ontology (that are essentially CIMs) and MDA will occupy a central place in MDD (Djuric, Gasevic, & Devedzic, 2006). The use of formal specification will make it possible to perform automated reasoning about ontology. A new type of MDA tools that do a more intelligent job might emerge. Probably, the next generation of tools might be able to describe the behavior of software systems in terms of domain models and translate it into executable programs on distributed environment.

CONCLUSION

There is a great number of UML CASE tools in existence that facilitates code generation and limited support for reverse engineering. Unfortunately, the current techniques available in these tools provide little automation for MDD. The formalization of metamodels and metamodel-based model transformations can help to overcome these problems. We propose to integrate knowledge developed by the community of formal methods with MDA. A rigorous framework for MDD was defined. It is comprised of a metamodeling notation NEREUS, a "megamodel" for defining MDA components and the definition of metamodeling/model transformations based on MOF and NEREUS. We define basic techniques for forward engineering and reverse engineering.

We define systems of transformation rules that allow translating MOF-metamodels to formal specifications and implementations. A bridge between NEREUS and algebraic languages was defined by using CASL. Our approach focuses on interoperability of formal languages.

We want to define foundations for MDA tools that permit designers to directly manipulate the visual models they have created. However, meta-designers need to understand metamodels and metamodel transformations.

This research is still evolving and additional issues will have to be tackled in order to fit advances in MDD.

KEY TERMS

CASE Tool: Computer aided software engineering (CASE); a tool to aid in the analysis and design of software systems.

Forward Engineering: The process of transforming a model into code through a mapping to a specific implementation language.

MDA (Model Driven Architecture): A framework based on UML and other industry standards for visualizing, storing, and exchanging software design and models. It separates the specification of functionality from the specification of the implementation of that functionality on a specific technology platform.

Metamodel: A model that defines the language for expressing a model.

Meta-Metamodel: A model that defines the language for expressing a metamodel.

Model Transformation: The process of converting one model into another model preserving some kind of equivalence relation between them.

OCL (Object Constraint Language): A notational language for analysis and design of software systems that allows software developers to write constraints and queries over object models such as UML models.

Refactoring: A change to a system that leaves its behavior unchanged but enhances some nonfunctional quality factors such as simplicity, flexibility, understanding and performance.

Reverse Engineering: The process of transforming code into a model through a mapping from a specific implementation language.

UML (Unified Modeling Language): An OMG standard language for visualizing, specifying, constructing, and documenting the artifacts of a software-intensive system.

A Framework for Communicability of Software Documentation

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

The role of communication is central to any software development. The documentation forms the *message carrier* within the communication infrastructure of a software project.

As software development processes shift from predictive to adaptive environments and serve an ever more hardware diverse demographic, new communication challenges arise. For example, an engineer may want to be able to remotely author a document in a shell environment without the need of any special purpose software, port it to different computer architectures, and provide different views of it to users without making modifications to the original. However, the current state of affairs of software documentation is inadequate to respond to such expectations.

In this article, we take the position that the ability of documents to be able to communicate at all levels intrinsically depends upon their *representation*. The rest of the article proceeds as follows. We first outline the background necessary for later discussion. This is followed by a proposal for a quality-based framework for representing software documentation in descriptive markup and application to agile software documentation. Next, challenges and avenues for future research are outlined. Finally, concluding remarks are given.

BACKGROUND

Since the origins of software, and subsequently the recognition of software engineering as a discipline, documentation has had an important role to play. The use of documentation in software has a long and rich history (Furuta, Scofield, & Shaw, 1982; Goldfarb, 1981; Knuth, 1992).

There are various means that have been used for expressing software documentation. The documents could for example be expressed in structured natural language text (mimicking typewriting); Rich Text Format (RTF) and its implementations such as Microsoft Word; Hypertext Markup Language (HTML), which supports multiple language characters and symbols that can reach a broad demographic worldwide, incorporates features of print publishing, and supports hyperlinking; the Portable Document Format (PDF); and TEX/LATEX and their variations that are oriented to mathematical typesetting. However, these traditional means suffer from one or more of the following limitations: they are proprietary and can only be authored or rendered by a proprietary software; the focus is not on software engineering but other disciplines such as generic office or scientific use; and the focus is mainly on the presentation or processing rather than on representation.

Descriptive markup (Goldfarb, 1981) is based on a rich model of text known as the ordered hierarchy of content objects (OHCO) (Coombs, Renear, & DeRose, 1987; DeRose, Durand, Mylonas, & Renear, 1997) that lends a hierarchical structure to documents. The Standard Generalized Markup Language (SGML) and its simplification the Extensible Markup Language (XML) are exemplary of descriptive markup. SGML/XML are both *meta-markup* mechanisms that lend a suitable basis for a concrete serialization syntax for expressing information in a software document. They define a document in terms of its OHCO structure with mnemonic names, usually inspired by the domain being addressed, for the content objects of the data. There is a large and increasing base of markup languages based on SGML/XML.

The focus in this article is primarily on XML. Indeed, the use of XML for software process documents has been proposed (Clements et al., 2002; Mundle, 2001). The DocBook/XML markup language has been deployed for software user documentation. These efforts, however, are oriented towards technology rather than descriptive markup or communicability (or quality in general); they do not provide comparisons with other means of representations, and they do not include details of challenges posed during document engineering.

DESCRIPTIVE MARKUP AND REPRESENTATION OF SOFTWARE DOCUMENTATION

We look at a software document from two viewpoints, namely that of a *producer* and that of a *consumer*. Based on that, the representation requirements that we consider pertinent for software documentation are the following:

- **Communicability Concerns for a Document Producer:** A provider, who is responsible for both internal

and external documentation, could be interested in any of the following aspects: be able to express the domain under consideration well; have the flexibility of authoring and serving documents in different modalities; readily move documents between computing environments and over networks; easily manage the collection of documents, particularly as they scale (grow in number).

- **Communicability Concerns for a Document Consumer.** A consumer, whose main concern is external documentation, could be interested in any of the following aspects: access the documents on the device he/she is using that may be stand alone or connected to the Internet, and in the natural language/characters of choice; read or listen to the documents in the way he/she prefers that they should be presented; may want to simply look at the table of contents before reading further, or look up the definition of a term used in the main document. In some sense, a consumer would like a document to be "personalized."

These requirements motivated the proposal of a communicability framework, which we now discuss in detail.

A Framework for Communicability of Descriptive Markup-Based Software Documentation

The discussion of software documents and their representations that follows is based on the framework given in Table 1.

Semiotics (Nöth, 1990) is concerned with the use of symbols to convey knowledge. From a semiotics' perspective, a representation can be viewed on three interrelated levels: *syntactic, semantic,* and *pragmatic*. Our concern here is the pragmatic level, which is the practical knowledge needed to use a language for communicative purposes. Indeed, the goal of pragmatic quality is comprehension (Lindland, Sindre, & Sølvberg, 1994), and communicability is a prerequisite to that.

We acknowledge that there are time, effort, and budgetary constraints on producing a software document. We therefore include *feasibility*, a part of decision theory, as an all-encompassing factor to make the representation framework practical.

We now consider other aspects of the framework in more detail, starting with the principles underlying documents and their descriptive markup realizations.

Document Engineering Principles with a Descriptive Markup Perspective

The principles presented here are inspired by the established software engineering principles (Ghezzi, Jazayeri, & Mandrioli, 2003).

- **[DEP1] Separation of Concerns:** There are various concerns in document production and delivery, and to manage them effectively, each of these semantically different concerns need to be addressed separately. In particular, separation by parts, time, quality, and views are of special interest. SGML/XML provide means for separating structure, presentation, and logic in a document.
- **[DEP2] Abstraction:** This principle is based on the idea that it is often necessary in documents to highlight only the essentials while suppressing the details. The provision for table of contents and index of terms in a document are examples of abstraction. In descriptive markup, this could be realized by using mnemonic labels `<section>` and `<term>` to encapsulate the name of a section and a special term, respectively and

Table 1. A high level view of the elements of a framework for communicability of software documentation

Software Document		
Pragmatic goal	Communicability	Feasibility
Quality attributes of concern	Evolvability, Heterogeneity, Interoperability, Processability, Renderability, Traceability, Universality	
Engineering principles	Abstraction, Anticipation of Change, Formality, Generality, Incrementality, Modularity, Separation of Concerns	
Representation model	Descriptive Markup	

collating such appearances to obtain the desired result. Other examples in SGML/XML include the use of comments (`<!-- ... -->`) and in general metadata, the use of entities, or the use of a style sheet to hide content that one typically does not want rendered.

- **[DEP3] Modularity:** This principle is one way to realize separation by parts and therefore a special case of [DEP1] but is significant enough to be included separately here. [DEP2] is a prerequisite for modularity, which is essential for flexibility of future documents (Malloy, 2005). SGML and particularly XML provide various opportunities for modular documents, for example, by basing OHCO structure on a parent-child hierarchy, by including the concept of entities, or by "hiding" attributes inside the definition of an element in a document.
- **[DEP4] Anticipation of Change:** This principle is based on the premise that change in a (nontrivial) document is inevitable and to accommodate change we must be adequately prepared. By being text based (rather than binary) and being vendor and device independent, SGML/XML support this principle.
- **[DEP5] Incrementally:** This principle is related to [DEP1] and [DEP4] and is based on the notion that creating a representation of a document in increments should be encouraged. SGML/XML are in agreement with this. Indeed, it is a common markup practice to develop documents iteratively (in manageable steps) and check for conformance after each iteration.
- **[DEP6] Generality:** This principle is based on the assertion that the more general a document representation is, the broader the audience it can reach and the more reusable in different situations it is. SGML/XML are neutral to user context, vendor, domain, device, network, or programming language. They also support the largest character set currently available, namely the Universal Character Set (UCS)/Unicode.
- **[DEP7] Formality:** This principle, by requiring a formal (logical) syntax and semantics, aims to reduce the potential of ambiguity, contradictions, or misinterpretations and enables a more precise description of documents. XML has a well-defined syntax and semantics (Renear, Dubin, Sperberg-McQueen, & Huitfeldt, 2002). The Document Type Definition (DTD) provides a grammar for structural and data type constraints on the syntax and content of the elements and attributes in SGML/XML documents. In the case of XML, the capabilities of DTD have been strengthened in other grammar languages such as XML Schema and RELAX NG.

Attributes Impacting Communicability of a Software Document

In the following discussion we consider communicability as a "meta-concern" and discuss the low level list of attributes to address it. We also highlight relevant relationships between these attributes and with the abovementioned principles where needed.

- **[CA1] Evolvability:** This attribute especially depends on [DEP1-5]. Once a software document is created, it is highly likely that it will be maintained for corrective, adaptive, or perfective purposes. For example, a user manual may need to be transformed on computers with different capabilities for users with individual needs. The Resource Description Framework (RDF) and Dublin Core Metadata Element Set (DCMES) provide support for metadata (such as author information, date/time, history, or versioning) that can help track modifications.
- **[CA2] Heterogeneity:** This attribute especially depends on [DEP4-6] and is related to [CA3]. The elements of a document may need to be represented in a variety of different forms such as text, graphic, mathematical symbols, and so forth, and subsequently aggregated. Therefore, a representation must accommodate the possible compound or heterogeneous nature of a document. SGML/XML documents can be heterogeneous, where fragments of different markup (or even nonmarkup as long as the characters in it do not violate the document's character encoding) could be placed in a single document. XML Inclusions (XInclude) allows multiple possibilities of reuse: using a fragment of another document, a fragment of the current document, or an entire document (Figure 1).
- **[CA3] Interoperability:** This attribute is related to [CA2]. The heterogeneous forms in a document not only need to coexist in the same information container but also need to "talk" (interface) with each other and with the parent document. Namespaces in XML is a mechanism for uniquely identifying XML elements and attributes of a markup language, thus making it possible to create heterogeneous documents that unambiguously mix elements and attributes from multiple different XML documents (Figure 2).
- **[CA4] Processability:** This attribute depends on all [DEP1-7] and supports [CA5]. At times, we may need to manipulate (recast/transform, extract/filter, query, and so on) software documents to suit different circumstances. Support for querying XML documents is provided by XQuery and client- or server-side tree-based processing of XML documents is enabled by the Document Object Model (DOM) for which stable implementations are available. Extensible

Figure 1. Opportunities of reuse for a software document in an XML environment

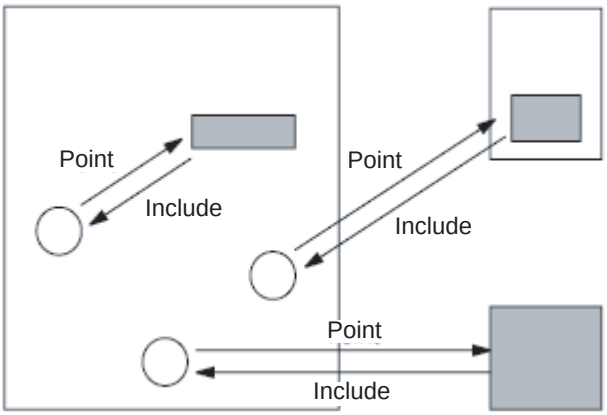

Figure 2. A heterogeneous software document in a descriptive markup transformation environment

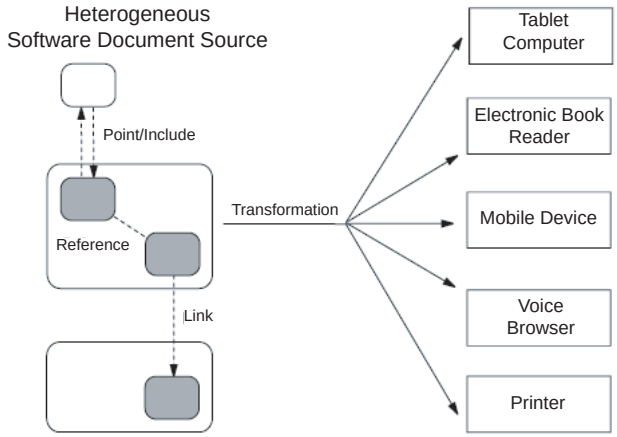

Stylesheet Language (XSL) is a style sheet language for associating presentation semantics with arbitrarily complex XML documents, while its companion XSL Transformations (XSLT) is a style sheet language for transforming XML documents into other documents, including nonXML, documents (Figure 2).

- **[CA5] Renderability:** This attribute especially depends on [DEP1-2]. A software document must ultimately be rendered to a user's environment, and therefore presentation semantics (such as fonts, horizontal and vertical layout, pagination, and so on). The Document Style Semantics and Specification Language (DSSSL) is a style sheet language for SGML documents (that inspired XSL/XSLT). The Cascading Style Sheets (CSS) is a style sheet language for presenting simple XML documents on devices and agents with a variety of different configurations such as in Figure 2.
- **[CA6] Traceability:** This attribute depends on [DEP1,3]. A trace from `A` to `B` requires identification and location of, and means to reach, `B` from `A`. XML provides an `id` attribute for local identification of an element that can be used in conjunction with the Uniform Resource Identifier (URI) for global identification. HyTime, an ISO Standard, provides sophisticated linking functionalities for SGML documents including multi-directional links and linking to nonSGML data such as video clips. XML Linking Language (XLink) extends the unidirectional linking support in HTML and provides powerful bidirectional linking capabilities necessary for hypertext.
- **[CA7] Universality:** This attribute depends on [DEP6], and its underlying premise is that software documents should be created for all, irrespective of their individual context. XML is in agreement with the standards for accessibility and internationalization.

Application of the Framework: The Case of Agile Documentation

The bureaucracy inherent to traditional predictive software development processes and their perhaps over emphasis on documentation has in the last decade led to a shift to adaptive environments such as Extreme Programming (XP) and the Unified Process (UP). Although they are not document driven, documents continue to play an important role in stakeholder communication.

The term *agile document* was introduced in (Ambler, 2002) to imply customer-oriented, lightweight documents that could serve XP and UP. A collection of patterns for writing effective agile software documentation is given in (Rüping, 2003). Many of the patterns in it that deal with presentation and representation of documents can be concretely dealt with in our framework. For example, communicability aspects of structuring individual documents patterns are given by [CA1-7], layout and typography patterns are subsumed by [CA4, 5], whereas infrastructure and technical organization patterns are covered by [DEP1] and [CA1-4, 6].

Challenges to the Descriptive Markup Approach to Software Documentation

There are a few technical challenges to representations in descriptive markup. For example, descriptive markup in its source form, particularly when there are complex (usually

nonlinear) structural relationships involved, can be error prone for direct authoring and is not considered very readable. There are openly available and mature SGML/XML authoring tools that ameliorate this to a certain extent. The processing based on DOM or transformations based on XSLT lead to in-memory tree, which is not always efficient for large documents for demanding situations (say, being transformed over a low bandwidth network in real time). One solution to this approach has been to use XSLT compilers instead of interpreters. Similarly, event-based processing such as Simple API for XML (SAX) could complement the DOM.

FUTURE TRENDS

As software documents become increasingly large in size and number and aim to serve diverse users, a systematic document engineering process is highly desirable. There are currently limited efforts in that direction (Glushko & McGrath, 2005).

XML, like any other technology, has its own set of issues if not used appropriately while authoring or processing (Harold, 2003) or if used beyond its scope (Megginson, 2005). In fact, addressing the issue of quality in all early software representations is crucial. To do that, an evaluation of XML using the Cognitive Dimensions of Notations (CDs) (Green, 1989), a generic framework for describing the utility of information artifacts by taking the system environment and the user characteristics into consideration, would be of interest.

A natural amplification of the previous discussion is a closer synergy with the current knowledge representation initiatives that are based on descriptive markup. The Semantic Web has recently emerged as an extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning (Hendler, Lassila, & Berners-Lee, 2001) and could provide much more powerful representations of knowledge in a software document.

Finally, in spite of its broad use, documentation is not automatically useful by itself: Its value is realized only if it is well done (Weinberg, 1998), which could be viewed as one of or a combination of more than one dimensions of communicability. As documents become more like interactive applications, where they act as *user interfaces* to services provided by the software, the significance of assuring and evaluating their communicability will only increase.

CONCLUSION

Representation of documents so as to assure their communicability to the participants at all levels is critical. One way to foster that is by *partitioning* communicability into a manageable number of dimensions that could be dealt with directly and by choosing a suitable means of representation of software documents such as descriptive markup. The principles and attributes presented in our framework provide a basis for communicability dimensions and the SGML/XML *family* provides established technologies for descriptive markup.

The most important requirement for communicability from both the producer's and the consumer's standpoint is that they should have *options*. Indeed, if software documents are seen as carriers of commonsense knowledge (Minsky, 2000), then we should not seek one uniform way to present or represent them. This is echoed in the Redundant Recoding principle (Green, 1989), which is the ability to express information in a representation in more than one way, each of which simplifies different cognitive tasks. For that, documents need to be systematically created and strive for high quality. They also need to become *intelligent*, which in computational context usually implies that they carry *knowledge* amenable for automated processing. The Semantic Web provides a vehicle for representing knowledgeable software documents in descriptive markup.

KEY TERMS

Agile Document: A customer-oriented lightweight document that need not be perfect but just good enough.

Descriptive Markup: A model of text that focuses on the description of information using markup delimiters for consumption by both humans and machines.

Document Engineering: A discipline that is concerned with principles, tools, and processes that improve the ability to create, manage, and maintain documents.

Knowledge Representation: The study of how knowledge about the world can be represented and the kinds of reasoning that can be carried out with that knowledge.

Ontology: An explicit, formal specification of a conceptualization that consists of a set of terms in a domain and the relations among them.

Semiotics: The field of study of signs and their representations.

Single Source Approach: A technique that encourages a once-only creation of a resource, such as a document, in a manner so that it could be reused or repurposed for different contexts.

Framing Political, Personal Expression on the Web

Matthew W. Wilson
University of Washington, USA

INTRODUCTION

The World Wide Web, as a collection of Web sites, Web services, and Web-enabled technologies, is a space of expression and contestation—a social construction of sorts. Additionally, the Web, as a locus of investigation, is gaining attention from scholars in the social sciences, feminist and critical theorists, as well as more recent poststructural reconceptualizations across many disciplines. One unifying interest is precisely the topic of this article: How might we recognize what is considered *political* and *personal* in a virtual space? To what sense can we distinguish political and personal expression online? This article frames the diverse perspectives for interrogating political and personal expression on the Web, while offering considerations for why these sorts of projects are at all necessary or useful.

The determinacy of virtual, Web-based locations as political and/or personal is a complex endeavor. Does a pro-choice posting to an anti-abortion online discussion group constitute a political act? What is potentially meant by "political"? Several discussion forums or news groups contain categories like "politics" or "government and politics" (see *Yahoo! Groups* for example); and yet, such groups may or may not be perceived as "political". This perception of "being political" is dependent on certain philosophical tensions about what can be considered political in certain spaces and times. Other Web sites seek to build politics through the Web, via such movements as e-democracy, online deliberation, or public participation geographic information systems (Davies & Novack, forthcoming; Dragicevic & Balram, 2006). However, while building politics is certainly political, surficial analysis of such online-coalition building endeavors may resist or gloss the multiple political implications for constructing a politics. Therefore this entry contains a discussion of politics and "the political"; each as a perspective has certain methodological and empirical contingencies. Namely, how do we study online interactions? What sorts of data might we collect? Furthermore, how are we, as researchers, already implicated in our studies of online interactions?

This entry proposes a diversity of approaches in studying interactions within the Web as informed by both the information sciences and the humanities and is organized into four sections: first, a background section which contemplates more traditional debate in political theory made relevant to studies of the Web; a second section which proposes (post)modernist and poststructuralist framings for researching personal and political expression; third, a section offering future research questions in this research area; and finally, conclusions that reflect upon research on the Web.

BACKGROUND

While certain academic traditions analyze political encounters as separate from those situations that are supposedly personal, critical interruptions in these traditions have shown that the personal and political are quite interrelated and inseparable, if not fictitious designations of expression. Most obvious of these critical interruptions are the women's and GLBT (gay, lesbian, bisexual, and transgender) movements, with the blurring of these boundaries as central to an active social movement. These interruptions highlight the co-constitutiveness of the political and the personal, and render suspect analyses that enforce a strict dualism. Therefore, it may be as no surprise that analyses of interactions on the Web are similarly complex—given that the Web is simultaneously coded as personal and political, public and private. Identity and embodiment—or what constitutes the "self"—are intriguingly negotiated in virtuality, making a mess of any rigid enforcement of public/private, political/personal evaluation of online culture. This section explores these public/private, political/personal frameworks as a background for studies of interaction on the Web.

Publicness and Privateness

Social interaction over the Web, or what Steven Johnson (1997) argues is an "interface culture", is acutely part of everyday life, although admittedly this is not the case for everyone. Out-of-the-box high-speed, wireless networking allows computers and mobile-computing devices to find use across the space of the home, from the kitchen refrigerator to the bedroom Web-enabled television, and throughout the local neighborhood, within grocery stores, cafés, and

while walking the sidewalks of busy metropolitan streets. Johnson's central thesis is that our contemporary culture is one of *interfaces*—a rearranging/repackaging/refiltering of digital data to serve various information consumers. Web sites like *WifiMug.org* point computer-savvy-sans-caffeine users to local coffeeshops, which have free wireless Internet access, and handy power outlets. Others, like *BlogHer.org*, collect women-authored Web-logs (or blogs), to build a sense of "women-friendly" online political community. What about contributing to online discussions on transportation planning while sitting in bed could be experienced or reinforced as a public, political act within a place coded as private? Furthermore, how might we theorize the privateness of certain discussions of personal violence, in a supposedly public, online forum? The Web is certainly a site where that which is coded public and private meets in virtual contradiction. Analyses of online interaction that seek to code separately what is considered public from private, are engaged in projects that frame their observations by a certain transformation of expression, *pace* Habermas (1979), from the private to the public individual. The Internet, some argue, enables this transformation of expression, from private mobile devices into actively participating citizens of a public (Stromer-Galley, 2003a, 2003b). However, these sorts of framings are a slippery slope, susceptible to a problematic dualism of the political and personal.

Political and Personal

Central to the popular critique that "the personal *is* political", feminists have challenged the public-private dualism as misrecognition of the political status of supposedly private, personal acts. As Nancy Fraser (1992) argues, that which is "private" is conceptualized within public-private frameworks as some "prepolitical starting point" (p. 130). The moment requiring critical intervention occurs when the public-private dualism discriminates personal claims as separate from and irreconcilable with political claims. Feminist political geographers Michael Brown and Lynn Staeheli (2003) offer a framework to organize these diverse critical interventions into three moments of "the political": the distributive, the antagonistic, and the constitutive. These three moments are essentially research perspectives, and can be appropriately translated to online interaction research. The *distributive* is an interrogation of which individuals and groups have unequal access to certain resources; studies of Internet and interface accessibility are good examples of the distributive approach (e.g., Servon, 2002). The *antagonistic*, Brown and Staeheli continues, is a recognition of the oppositional conflict which structures the political, similar to studies of partisan-politic Web forums (e.g., Stromer-Galley, 2003a). Finally, the *constitutive* research perspective looks to analyze the productive dimension of the political; research which analyzes the assertion of identity by appropriating online discussion forums might take a more constitutive approach (e.g., Wincapaw, 2000). Each of these perspectives on political research is also interestingly contingent on the collections of interfaces, protocols, software, and hardware within our constructed and engineered (Web-based) spaces of interaction. The following section discusses these emerging spaces of interaction, and then proposes two ways of framing expression within these spaces.

METHODOLOGICAL-THEORETICAL FRAMINGS FOR INTERNET RESEARCH

Methods of analysis of political and personal expression over the Internet are especially complex due to the dynamic and differential development of Web-based systems. Those interested in social studies of the Internet should consider new developments in interaction design, particularly the advancement of *Web 2.0*, but must remain conscious of the differential development of Web-based systems, from the simple-yet-elegant, HTML Web sites (such as *Craigslist.org*) to the more interactive, AJAX Web sites (such as *Flickr.com*). The Web, with its various interfaces of carefully designed interaction, privileges, and constrains various methods of online research (Cherny & Weise, 1996; Crampton, 2003; Davis, 1999; Graham, 1998; Kitchen, 1998; White, 2006). Web developers explicitly construct certain operations and logs of data collection within their Web sites; researchers may or may not have access to these datasets, and furthermore, may or may not be able to analyze the data even as it becomes accessible. However, beyond the data acquisition dilemma for online interaction research, researchers should additionally consider the nuanced implications of interface and interaction design.

Web sites have become more interactive, with recent developments such as *Flickr*, *Blogger*, and the suite of *Google* Web-applications. Many of these more recent developments fall under the paradigm of *Web 2.0*. This ethos of Web development focuses intensely on the design of interactions—leading toward not only technical or programmatic changes in Web software development, but also (more importantly) advances new concepts in user interaction (Garrett, 2002, 2005). Web sites architected from a notion of *Web 2.0*, follow design protocols that create a seamless experience for users; Web pages have the look and feel of a computer desktop application, with interactive menus and nearly instantaneous feedback. Clicking controls on the Web page no longer require jarring page reloads; instead, components within a Web page update and change, never requiring the user to adjust to a new page or layout. Beyond aesthetic and cinematic changes to the interaction design, *Web 2.0* also introduces such technologies as RSS (Rich Site Summary) feeds, which employ XML (Extensible Markup Language) standards, allowing users to be served with vari-

ously tailored information content, instead of the "hide and seek" paradigm of more traditional Web design.

Given these various nuances in Web construction (albeit differentially), with new interfaces and new ways of interacting, the opportunities for studying expression are diverse. With better systems of interaction come enhanced user experiences (Garrett, 2002). Although this equation of enhanced experience with more application-like Web environments might be problematic (or indicative of more *distributive*, political research), researchers have the opportunity to explore how these enhanced online interactions shift or enable identity formation in different ways (Balsamo, 1996; Foster, 2005; Gray, 1995; Halberstam & Livingston, 1995; Haraway, 1997; Schuurman, 2002; Turkle, 1995). As these virtual spaces become impacted by new concepts in Web design, political inquiry becomes impacted by new ways of "being political" online. Unfortunately, research to date has not explored these social and political implications for the *Web 2.0* design/development movement and the sorts of expression that are accordingly enabled or disabled (however, scholars are beginning to recognize this; see Erickson, 2007). The following sub-sections propose two broad methodological-theoretical approaches for investigating these expressions.

(Post)modernist Perspectives

The interpretation of human behavior on the Web is subject to certain philosophical traditions, whether explicit or implicit. In other words, we must ask an obvious, yet revealing, question of our observations of online behavior: "how can we know this?" If our online selves are fully knowable to ourselves, and thereby to others, then certain methodologies are applicable for interrogating these senses of virtual self. In other words, epistemologies of behavior and the "self" inform the data we collect and interpret. Particularly *modern* of these epistemologies of behavior and self is the observational behavior, or behavior that can be directly observed (or indirectly observed through proxy or mediator). These sorts of observations could be characterized as modern, as part of the progression of modernity, by continually adding to our knowledge of our increasingly comprehendible self, through actual, observed behavior.

> *I am looking for numbers. Scientific surveys, focus group, usability studies, Internet traffic statistics, log file analysis etc.—data that helps give a quantifiable sense of* what people say they want *with the Internet and politics/government/media as well as* what people actually do *online in those areas.* (Clift, 2001, emphasis mine)

Steven Clift, one leading figure in the e-democracy movement, posted the previous statement to his online democracy listserve. This is an appropriate example of observational behavior, or "what people say they want" and "what people actually do". Clift is calling for "numbers"—for quantified, observed behavior. It is important to note here that "numbers" and statistics obtained about online behavior are not necessarily indicative of a *modernist* approach; instead, it is how these data are employed— "how we say we know this to be what it is" —that makes these data subject and suspect to foundational critique (Lawson, 1995).

What then of *postmodern* approaches to research? The *post* indicates an important nuance in the interpretation of these "numbers" —namely, that any observation of behavior (online or otherwise) is always-already within a "hall of mirrors". This "hall of mirrors" metaphor underlines the partiality of all observation, interpretation, and representation—that all observation is confined, in some sense, by an amusement park "filled with hucksters and con artists" (Shaviro, 1995, p. 44). Data are always framed and relational; there is no observational, transferable, or generalizable truth to human behavior. Regardless of foundational perspective or belief, there is always data. Data collection that interrogates expression on the Web might include methods of collecting user data (profiles, geographic-demographic positioning, etc.), as well as collecting "user-using-Web site" data (logs of system use, including operations and queries performed, travel to/from hyperlinks, etc.) (e.g., Golder & Huberman, 2006). Other more "interpretive" data collection includes user interviews (focus groups, surveys, etc.) and user ethnographies (e.g., Stromer-Galley, 2003a; Wincapaw, 2000). System developers also look for broader Web site data, including performance statistics and traffic-time profiles. Again, the power in representing this data relies upon certain philosophical underpinnings. A post-structural approach works to reveal these underpinnings, through continual reflection on these projects of inquiry.

Post-Structuralist Perspectives

What might a post-structural perspective bring to projects around political and personal expression on the Web? *Post-structuralism* refers specifically to a theoretical approach informed by French theorists (notably, Michel Foucault), and more broadly serves to identify approaches which challenge and complicate structuralist and foundationalist accounts of ideology, hegemony, subjectivity, resistance, and dominance. The Web, under this perspective, is an immense discursive and material formulation, constituting new identities and subjects through various operations of power (Foucault, 1990 [1978]). Furthermore, the Web is a "space" in precisely the sense of the poststructural, feminist geographer Doreen Massey (2005): as "constituted through interactions" and thereby reliant upon the "existence of multiplicity" (p. 9). Web developers and designers, users, lurkers, and researchers negotiate this (virtual) space of multiplicities, each of which have partial and hybrid identities/subject positions.

Power operates, from a Foucaultian perspective, upon these identities or subject positions to constitute a sense of self and other—even as they are already mediated by their status as a technician, designer, user, and/or researcher.

Specific to studies of online interaction, one thread of research (possibly described as posthuman or cyberpunk or technoculture studies[1]) takes up this topic of the fractured online identity, and employs post-structural methods (genealogies, power-geometries, discourse analyses) to interrogate the "cyborg" as a particular politicized figure of postmodern, technicized society. The cyborg, as theorized by Donna Haraway (1991) and further extended by feminists and others in science (and science fiction) studies, is the figure of fragmented embodiment—a blurring of human and technology, where "mind, body, and tool are on very intimate terms" (p. 165), in some cases a literal merger of the body with various prostheses and other techno(bio)logical enhancements. Tom Foster (2005) describes this blurring as indicative of a posthuman world, where:

technology does in fact "become me" not by being incorporated into my organic unity and integrity, but instead by interrupting that unity *and opening the boundary between self and world. The point ... is not to reject the value of embodiment, however, but to make it possible to rearticulate the relationship between mind and body, "inner being" and external form, in more complex and diverse ways, by revealing the ways in which that relationship was always mediated socially.* (p. 10, emphasis mine)

Foster's argument extends Haraway's post-gender cyborg as a subject position that interfaces through communication prostheses—especially that found through the Internet. Interfaces support these moments of "interrupted unity", and thereby beg to be problematized to uncover the power operations that constitute certain identities in particular (virtual) spaces. The following section, proposes future research questions which are informed by both post-structural and (post)modern perspectives.

(Post-)modern and post-structural perspectives provide the theoretical and methodological framings for studying political and personal expression on the Web. These perspectives are not necessarily oppositional, nor incongruent. Instead, continued research on the Web will draw from a diversity of perspectives; this article has hopefully served to articulate two such framings.

FUTURE TRENDS

As disciplines find research about the Web to be relevant to studies of human behavior and interaction, there shall be growing interest in how to frame these explorations. Interactions on the Web are insistently political even as they are coded personal. This political-ness has been categorized as being distributive, antagonistic, and constitutive (Brown & Staeheli, 2003). As such, future research questions are offered below, categorized by these three moments of the political:

1. **Distributive.**
   - How does *Web 2.0* Internet design influence accessibility for underrepresented groups?
   - Which online community designs promote inclusive versus exclusive membership guidelines? How are these norms and regulations enforced?
   - How might collaborative tagging systems enable or constrain online interaction?
   - How are coalition-building Web sites able to affect policy formation?
2. **Antagonistic.**
   - How do "government and politics" discussion forums construct an immediate other? For what purpose?
   - To what extent are discussion forums largely homogenous in affiliation or commentary?
   - Is 'community' really the appropriate theoretical metaphor for online discussion and coalition-building Web sites?
3. **Constitutive.**
   - How might the purpose of an identity politics discussion forum be multiple? How do members of this discussion forum negotiate the political potential of such a Web site?
   - How might collaborative tagging systems or folksonomies contribute to the shared ontologies of Web site content?
   - How do users perceive their interactions within discussion forums as (un)useful to other users?
   - What emerges from online interaction studies? How do these studies in turn enact new forms of online interaction or interfaces?

CONCLUSION

The study of political and personal expression is dependent on how one understands "the political". This entry has reviewed how "the political" has been problematized, and has proposed two framings for expression on the Web: (post-)modern and post-structural approaches. Students and researchers should make use of this entry as a re-mapping of the topic—to push the boundaries of what is potentially meant by expression over the Internet. Indeed, there are new technological concepts, such as *Web 2.0*, that structure the online interaction between users, and certainly "change" is the status quo for

the Web. However, such a dynamic environment should simply enrich the various studies of interaction from diverse disciplinary and theoretical perspectives—some of which touched on previously (if a bit prescriptive). To conclude, I present some final thoughts which expand upon the topics and problematics from the previous sections.

Why is it interesting to study online interaction? The answer to this question is (of course) multiple. Depending on your perspective (a few of which are discussed earlier), online expression is interesting because it tells us something general about human behavior, as well as something about our specific, online selves; or maybe, online expression is interesting precisely because it has grown as a site of inquiry across various disciplines, drawing attention from the sciences and the humanities, not to mention private industry. Online expression can be approached as a culture, a technical achievement, a public sphere, a site of resistance or discrimination, or a virtual community. Due to the various positionings of this topical area from multiple disciplines, we must be more explicit about our politics in conducting this research—as the subjects of our research continue to virtually express themselves politically and personally.

KEY TERMS

Cyborg: The cyborg is a figure deployed most popularly by Donna Haraway to depict the partial subjects of post-modern technoculture. The cyborg is a method of critique, allowing theorists to challenge nature/human, mind/body, virtual/material dualisms.

Epistemology: Epistemology is the study of how we are able to know what we know. As a way to study knowledge, epistemological critique challenges assumptions about truth, causal relationships, and evidence.

Foucaultian Perspective: Foucaultian perspectives are post-structuralist critique specific to Michel Foucault, a French political theorist. Foucault's writings have been used in various academic disciplines and political projects. His interest in power is well cited as a methodology exploring processes of subject formation through normalization.

Postmodernism: Postmodernism is a category of thought within literature, architecture, and the arts, emphasizing complexity, chaos, and indeterminacy as a response to the modern tradition which emphasizes progress, determinism, and singular narratives. Within investigations of interaction on the Web, postmodernism informs the notion that data are always framed and relational. Postmodern perspectives advocate that there is no observational, transferable, or generalizable truth inherent to human behavior.

Post-structuralism: Post-structuralism is a response to foundationalism, concerned particularly with the work that language performs. Similar to postmodernism, post-structuralism challenges singular narratives and objectivity, but focuses on the processes of subjectification and identity formation through language.

Social Construction: Social construction is a perspective in research that argues all experience (including language, information, and knowledge) is premised on social relationships.

Web 2.0: A movement in Internet development and design, focusing on interaction and complementarity. Jesse James Garrett is a well-known advocate/critic of Web 2.0 approaches. Web sites that deploy Web 2.0 concepts usually build interactions with the "look and feel" of a computer application, using XML and Javascript (AJAX) to allow for greater responsiveness.

Free and Open Source Software

Mohammad AlMarzouq

INTRODUCTION

Free and open source software (F/OSS) is emerging as a promising alternative to proprietary software. The interest in F/OSS solutions is growing as firms realize that it could help reduce IT expenditures. Unfortunately, despite the heightened interest, F/OSS solutions remain misunderstood, and a number of myths regarding this approach still prevail.

F/OSS has been described as simply software, or even software specific for the Linux operating system, with hardly any reliable support available. Some have considered it a silver bullet solution that will always create superior quality software at lower or no cost (Wheatley, 2004).

The purpose of this article is to demystify these misconceptions surrounding F/OSS and provide an understanding of its basic concepts. Then, based on these concepts, we try to illustrate how companies can benefit from F/OSS. Our hope is that this article would assist interested observers to better understand F/OSS and help managers make more informed decisions regarding F/OSS solutions.

BACKGROUND

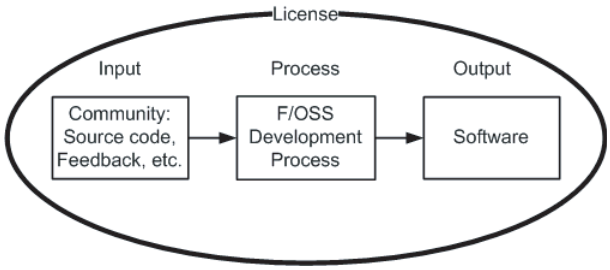
When computers first originated, the norm in most academic and corporate labs was to freely exchange programs and ideas between programmers. This was the early form of F/OSS. This norm changed when IBM unbundled its software and hardware in the 1970s. This move created a market and value for software. In order to preserve this newly found software value, software producers restricted user access to human readable source code in order to protect software secrets (Glass, 2004). This meant that users could not modify the software that they owned and more importantly, restricted the free flow of ideas. This did not fit well with many programmers, most notable was Richard Stallman from MIT's Artificial Intelligence Lab. Stallman believed strongly in the freedom of the user to use his software and created the Free Software Foundation (FSF) in 1985 to promote the development and use of free software. The following success of projects using the free software development model, such as Apache and Linux, inspired Eric Raymond to write his seminal piece *The Cathedral and the Bazaar* in 1997 that brought the attention of the corporate world to the free software development model (Raymond, 1999a). In a brain storming session on February 3, 1998 Todd Anderson, Christine Peterson (of the Foresight Institute), John "maddog" Hall and Larry Augustin (both of Linux International), Sam Ockman (of the Silicon Valley Linux User's Group), and Eric Raymond, agreed on the need for a marketing campaign to win the support of fortune 500 companies to ensure the long-term survival of the movement. The participants saw the need to use a term other than "free" which they figured would hurt the movement's chances of gaining support from the corporate world because of its ambiguous meaning. As a result of this session, the term *open-source* was coined by Christine Peterson and the Open Source Initiative Organization (OSI) was established ("History of the OSI," n.d.).

Richard Stallman of the FSF opposed this movement because in his opinion the term open-source was not pure enough. So the FSF and OSI remained separate movements promoting similar practical principles, but with different philosophies and beliefs. FSF decided to be vocal about its beliefs and maintained the *free* software label. They believed that the user's "freedom" is a priority, an end of itself, and they should be able to do whatever they want with their software. OSI on the other hand did not explicitly express the user's right for software freedom, but promoted it as a means of producing better software. The end is to get the corporate world to buy into this concept. Because of the coexistence of both philosophies, we refer to the group of software that adheres to the OSI or FSF principles as free and open source software (F/OSS). [1]

F/OSS IPO MODEL

The F/OSS development system can be conceptualized as an input-process-output (IPO) system, with the license as the boundary, the community as the input provider, the F/OSS

Figure 1. F/OSS IPO system



development methodologies as the process, and the software as the output (see Figure 1). So we would expect that all four components to have implications on the quality of the final product (software).

The License

The F/OSS license acts as the boundary that identifies the system as an F/OSS system. It specifies the terms by which the software is to be used and distributed. It serves as a governing mechanism that enforces the norms of the F/OSS community and provides motivation for programmers by protecting their efforts from appropriation (Bonaccorsi & Rossi, 2003).

There are numerous F/OSS licenses available that all maintain the openness and free redistribution of the source code.[2] The difference between the licenses reflects the philosophical differences between the FSF and OSI on how to advance the F/OSS projects. There are two principles that observers should be aware of (Lee, 1999):

- **The copyleft principle:** Software derived/revised from original F/OSS source code must remain F/OSS, and privatization of any part or whole of the program is prohibited.
- **The GPL compatibility principle:**[3] Licensed F/OSS cannot be mixed with proprietary source code.

Both the FSF and OSI have very similar criteria in qualifying licenses and there is a great deal of overlap between the approved licenses of both organizations. The fundamental difference between the two lies in the underlying philosophy. FSF recommends more open licenses that enforce both the GPL compatibility and copyleft principles, while the OSI is less stringent on this matter. Generally, an F/OSS license must allow programmers to access, modify, and redistribute the source code. F/OSS licenses do not prevent a software producer from demanding a distribution fee for his product. F/OSS licenses however prevent the software producer from placing restrictions on how the software should be used or redistributed after it is in the hands of the users ("*Selling Free Software,*" n.d.).

The Community

The community consists of all the developers and users of the F/OSS. The community and all their contributions are conceptualized as the input to the IPO system, which includes source code, documentation, and feedback (i.e., bug reports, support requests, and feature requests) (Raymond, 1999b).

The growth of the community ensures the ongoing survival of the F/OSS project and further improvement of the product. The advancement of the projects and community is dependent on the members who have the motivation and the ability to contribute. The most active of the community contributors are known as the *core*. The core is responsible for the majority of source code development. They also have the most control over the features and design of the software product. Occasional source code contributors are known as *co-developers*. They contribute by modifying or reviewing code or submitting bug fixes in addition to feedback. But the majority of the community members are the *users* who do not contribute with code submissions. Depending on the level of feedback, users can be active by providing some feedback, or passive, by providing none (Crowston & Howison, 2005).

THE DEVELOPMENT PROCESS

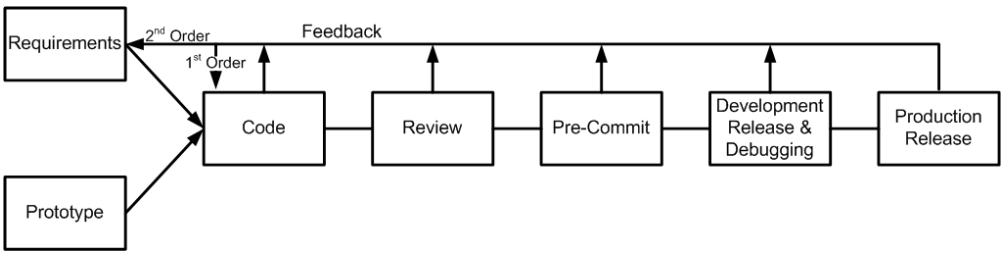
F/OSS development communities do not seem to adopt or practice traditional software development processes (e.g., the waterfall model). Many F/OSS projects begin with a prototype with predefined requirements developed from scratch or based on existent older product (Scacchi, 2002). Then, this early version incrementally evolves through rapid development iterations from the community, while concurrently managing as many designing, building, and testing activities as possible. Five main steps were identified for this approach: (1) code submission, (2) peer review, (3) precommit test, (4) development release and parallel debugging, and (5) production release (Jorgensen, 2001).

The F/OSS development process is an iterative process with feedback loops in every stage. The source code is constantly updated to meet the dynamic requirements that change along with the needs of the users (see Figure 2). These requirements are updated based on user feedback.

The Software

A continuous output of the F/OSS system is the software, which demonstrates some unique benefits when compared to proprietary software, such as:

Figure 2. The F/OSS development process



- **Reliability:** The reliability of F/OSS can be best reflected in Linus' Law, "Given enough eyeballs, all bugs are shallow." (Raymond, 1999b, p. 41). Due to a virtually unlimited number of contributors, software bugs are more likely to get uncovered. Short feedback and revision cycles also mean that improvements are incorporated quickly (Williams, Clegg, & Dulaney, 2005).
- **Security*:*** In a similar vein, community access to the source code makes it more likely to uncover and solve security problems. In contrast, securing the software by restricting access to the source code will only create a false sense of security, as it might take extended periods of time to locate and fix security holes (Raymond, 1999b).
- **Low Cost*:*** Software operation costs are drastically reduced due to the elimination of multiple licensing fees and the availability of support and updates from the community. However, when considering the total cost of ownership (TCO), training and customizing cost should also be accounted, which may vary by company (Stevenson, 2005).

All four components of F/OSS will have different implications on the quality of the software. The development process and community have a direct impact on the quality of the software. A large community will be worthless if the members are not motivated to contribute source code and feedback to the development process. The restrictions of the license will mean that only those who can accept these restrictions can contribute—essentially affecting the level and quality of contributions. Even the software design will have an effect on not only the quality of the software, but also how the community will organize around it (Crowston, Annabi, & Heckman, 2004).

SUCCESS WITH F/OSS

With a better understanding of F/OSS, we now discuss how companies can maximize the benefits gained from F/OSS depending on their specific needs. We have identified three distinct approaches centered on three components: software, community, and license. With these approaches on a rough continuum, companies can choose to have no involvement in the community or to be part of the F/OSS community core. Regardless of approach chosen, all four components of the F/OSS system should be evaluated (AlMarzouq, Zheng, Rong, & Grover, 2005).

Software-Centered Approach

The software-centered approach is about the autonomous use of the final product of the system (software). The software could be directly obtained from the community or provided by a vendor (who is usually part of the F/OSS community). It is most appropriate for companies with static and clear requirements that need well-developed software with a strict budget or time line. It focuses on utilizing the product and follows the same selection criteria as proprietary software.

In addition to reduction in time and costs in obtaining the desired software, companies can enjoy the improved reliability and security of F/OSS. However, less involvement and less input mean that the companies would have no influence on the features of the software. As passive users, companies have to accept the restrictions set up by the software and license.

Technical support or minor customization requirements also posit potential concern. Since technical support for F/OSS is dependent on the community, the evaluation should include an assessment of how responsive and supportive the community is or the availability of support vendors.

Community-Centered Approach

For the community-centered approach, the companies become more involved into the F/OSS community, and therefore are entitled to some influence on the features of the software. It is more suited when the desired software product or the requirements of the company are evolving.

The companies could get involved through this approach in two ways depending on the capabilities of the company.

They can either be active users providing feedback and feature requests on the product. Or they can, as co-developer, further contribute by providing source code contributions that would help enhance the software and make it more suitable for their use.

Becoming a co-developer has its benefits over being an active user. By participating in the development process, companies can improve the software development skills of their employees as the training process is embedded into the participation process (Lussier, 2004). Such valuable learning experience could enhance a companies' technical capability and facilitate the in-house application or customization of the software or even build competencies associated with the software that can be leveraged so the company could act as a support vendor for the F/OSS. The challenge with this approach is that companies have to devote more time and effort and possess certain technical capabilities to be able to act as an active player or co-developer in the community. Meanwhile, as players but not initiators, they still have to follow the restrictions of the licenses. Furthermore, the desired level of control over the software is not guaranteed since the company is part of a community. A potential challenge specific to becoming a co-developer with this approach is that in some cases companies have to adjust their own routines and structures to fit in the F/OSS development process. Such adaptation might introduce further costs and conflict within the company.

License-Centered Approach

The idea from this approach is to initiate an F/OSS community. As a result, the initiator has control over the choice of the terms of the license and becomes part of the core of the community, hence the term *license-centered*. An initiator can either release existing code, or embark on creating the initial prototype of the F/OSS.

Since users of the software can potentially be active members and developers within the F/OSS community, the initiating company can tighten the relationship with its customers should they get involved with the community. The customers can then be leveraged as a resource for innovative ideas, feedback, and developmental assistance to improve user satisfaction and prolong the product life cycle (Scacchi, 2004). This approach is most suited for companies seeking to improve their competitive position, especially with the existence of network effects working against the company. But given the long-term nature of the community building process, the benefits from this approach will be realized in the long run (West, 2003).

The biggest issue with having a company release software as F/OSS is that it might relinquish any competitive advantage associated with the software as the secrets of the software can be easily obtained by competitors. One solution is to "open parts," which is to release commoditized layers that are not a source of competitive advantage and retain full control of the layers that can be a source of competitive advantage. Another solution is to "partly open" the source code through using licenses to put legal restrictions that can provide value for the customer but prevent competitors from using the technology (West, 2003).

The biggest challenge that remains after releasing the software is getting the community to participate. Having the project develop into a self-sustaining one will require foresight from the company that initiated the effort in setting up the control structures and a willingness to hand off that control to the community (West & O'Mahony, 2005). The initiating company has to make a trade-off between its own interest and the growth of the community.

Another challenge is to align the company's internal development process with an F/OSS development process that enables community contributions. This may require some change management on the part of the initiating company.

Overall, the benefits and challenges of the three approaches are summarized in Table 1.

FUTURE TRENDS

As chief information officers (CIOs) get pressured to further reduce IT expenditures, we expect to see increased adoption and improved understanding of the benefits and utilization of the F/OSS system as a whole. We will not only see the success and influence of F/OSS on infrastructure-type software such as operating systems and database system (e.g., Linux and MySQL), but more complex applications. This move has already started with systems such as Compiere which is an F/OSS ERP system.

While research will continue to advance our understanding of the structure, efficacy, and strategic implications of F/OSS, there will clearly be regulatory issues (e.g., software patents) that will need resolution. It will be interesting to see how the change in legal environment will affect the F/OSS movement and whether F/OSS licenses can be effectively enforced.

CONCLUSION

Given the increasing pervasiveness of F/OSS, it is important that business managers evaluate alternatives to proprietary software and explore potential opportunities F/OSS may bring to their business. In doing this, they should understand and evaluate all the components of F/OSS that will impact the quality of the software. F/OSS is not software that is specific to an operating system, nor is it simply just software, but it is a complete system that includes the license, the community, the development process, in addition to the software.

Table 1. Summary of F/OSS benefiting approaches

Approach	Level of involvement in the community	Potential benefits	Potential challenges
Software-centered approach	None	• Reliable and secure F/OSS • Customizable software depending on the degree of competence of the user	• No influence on features developed by the community • Subject to license restrictions
Community-centered approach	Low to medium	• Reliable and secure F/OSS • Some influence on features • Learning/training through participating	• More time and effort required • Subject to license restrictions • Organizational changes required
License-centered approach	High	• Reliable and secure F/OSS • Influence on features • Learning/training through participating • Control over licenses • Improved customer relationship management	• Lose of competitive advantage • Motivate participation • Organizational changes required

Cost saving has been the main driver for F/OSS adoption, but even these savings might not be realized when the total cost of ownership is factored in. However, managers can maximize the benefits they could gain from F/OSS should they understand the whole system and learn to leverage all of its components. We have identified three different approaches companies could use to benefit from F/OSS. In addition to software cost saving, these different approaches (summarized in Table 1) could reduce development costs, increase innovation, improve technical training, and improve competitive position. Each approach provides a different set of benefits and challenges.

Functional and Object–Oriented Methodology for Analysis and Design

Peretz Shoval
Ben-Gurion University, Israel

Judith Kabeli
Ben-Gurion University, Israel

INTRODUCTION

The chapter provides an overview of FOOM–Functional and Object-oriented Methodology–for analysis and design of information systems. FOOM integrates the functional and object-oriented approaches. In the analysis phase, two main models are created: a) a conceptual data model, in the form of an initial class diagram; and b) a functional model, in the form of OO-DFDs (object-oriented data-flow diagram). In the design phase, the above models are used to design the following products: a) a complete class diagram, including Data, Menus, Forms, Reports and Transactions classes, including their attributes, relationships and methods; b) the user interface–a menus tree; c) the input and output form and report; and d) detailed descriptions of the class methods, expressed in pseudo-code or message charts.

BACKGROUND

Background on Traditional Approach to Information System Development

Many paradigms for system analysis and design have been proposed over the years. Early approaches have advocated the functional approach. Common methodologies that support this approach are SSA and SSD (DeMarco, 1978; Yourdon & Constantine, 1979). SSA is based on the use of data flow diagrams (DFDs), which define the functions of the system, the data stores within the system, the external entities, and the data flows among the above components. Early SSA and similar methodologies emphasized the functional aspects of system analysis, neglecting somehow the structural aspects, namely the data model. This was remedied by enhancing those methodologies with a conceptual data model, usually the entity-relationship (ER) model (Chen, 1976), that is used to create a diagram of the data model, which is later mapped to a relational database schema.

SSD is based on the use of structure charts, which describe the division of the system to program modules as well as the hierarchy of the different modules and their interfaces. Certain techniques have been proposed to create structure charts from DFDs (Yourdon & Constantine, 1979). The main difficulty of an approach where functional analysis is followed by structured design lies in the transition from DFDs to structure charts. In spite of various guidelines and rules for conversion from one structure to the other, the problem has not been resolved by those methodologies (Coad & Yourdon, 1990).

Shoval (1988, 1991) developed the ADISSA methodology that solved this problem. It uses hierarchical DFDs during the analysis stage (similar to other functional analysis methodologies), but the design centers on ***transactions***. A transaction is a process that supports a user who performs a business function, and is triggered as a result of an event. Transactions will eventually become the application programs. Transactions are identified and derived from DFDs: A transaction consists of elementary functions (namely, functions which are not decomposed into subfunctions) that are chained through data flows, and of data-stores and external-entities that are connected to those functions. A transaction includes at least one external-entity, which serve as its trigger. The process logic of each transaction is defined by means of structured programming techniques, for example, pseudo-code.

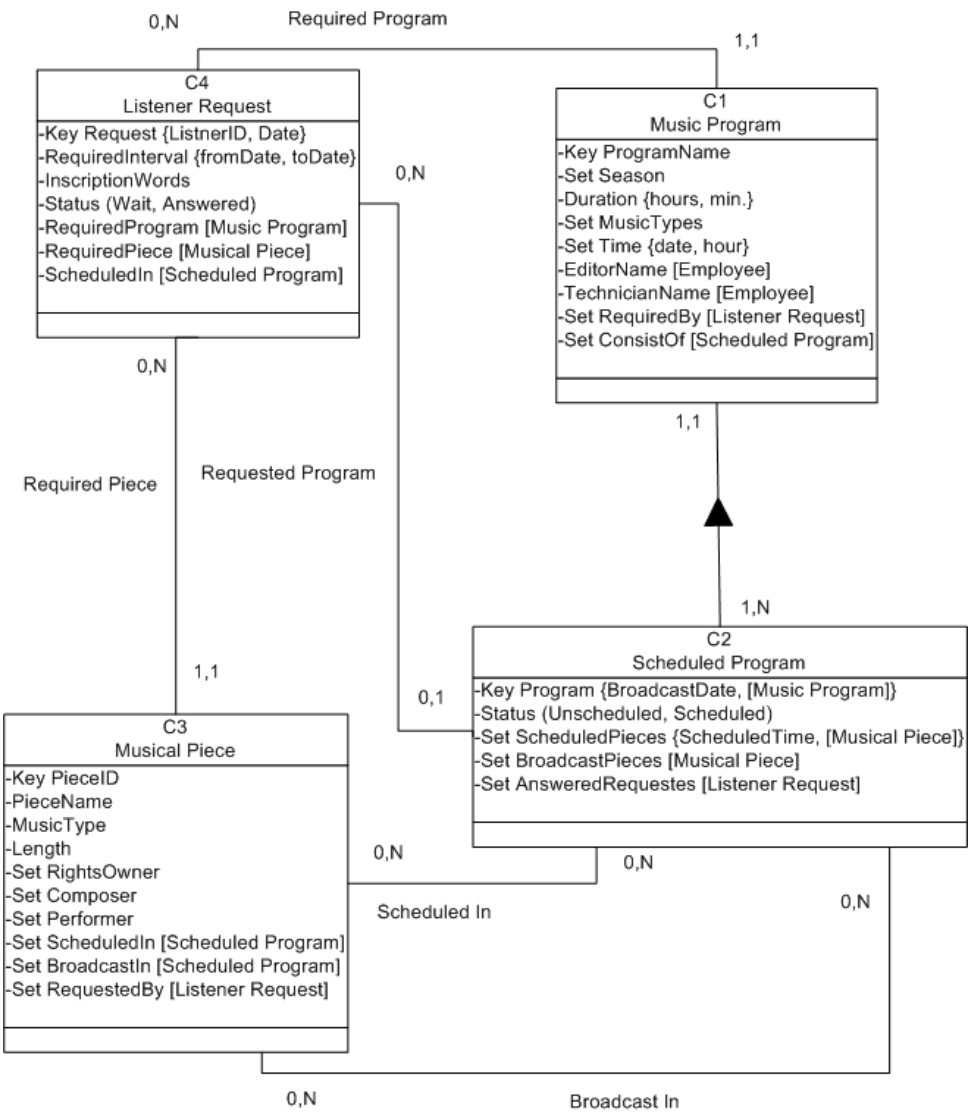
Based on the hierarchical DFDs and the transactions, ADISSA provides structured techniques to design the user-system interface (a menus-tree), the inputs and outputs (forms and reports), the database schema, and detailed descriptions of the transactions, which will eventually become the application programs. The menus-tree is derived from the hierarchy of DFDs in a semi-algorithmic fashion, based on functions that are connected to user-entities. The design of the forms and reports is based on data flows from user-entities to elementary functions and from elementary functions to user-entities. The design of the relational database schema is based on the analysis of dependencies among the data elements within the data-stores. The data flows from elementary functions to data-stores and from data-stores to elementary functions serve as a basis for defining access-steps, namely update and retrieval operations on the relations. Access-steps are expressed as SQL statements that will be embedded in the program code of the respective transactions. The products of the design stages can be easily implemented using various programming environments.

Background on the Object-Oriented Approach to Information System Development

The development of object-oriented (OO) programming languages gave rise to the OO approach and its penetration into system analysis and design. Many OO methodologies have been developed in the early 1990s (e.g., Booch, 1991; Coad & Yourdon, 1990, 1991; Jacobson, 1992; Rumbaugh, Blaha, Premerlani, Eddy, & Lorensen, 1991; Shlaer & Mellor, 1992; Wirfs-Brock, Wilkerson, & Wiener, 1990). In the OO approach, the world is composed of objects with attributes (defining its state) and behavior (methods), which constitute the only way by which the data included in the object can be accessed. When using the OO approach, a model of the system is usually created in the form of a class diagram consisting of data classes with structural relationships between them (e.g., generalization-specialization), and each class having its attributes and methods.

The early OO methodologies tended to neglect the functionality aspect of system analysis, and did not show clearly how to integrate the application functions (transactions) with the class diagram. Another difficulty with those methodologies was that they involved many types of non-standard diagrams and notations. The multiplicity of diagram types in the OO approach has been a major motivation for developing the UML (Booch, Rumbaugh, Jacobson, 1999;

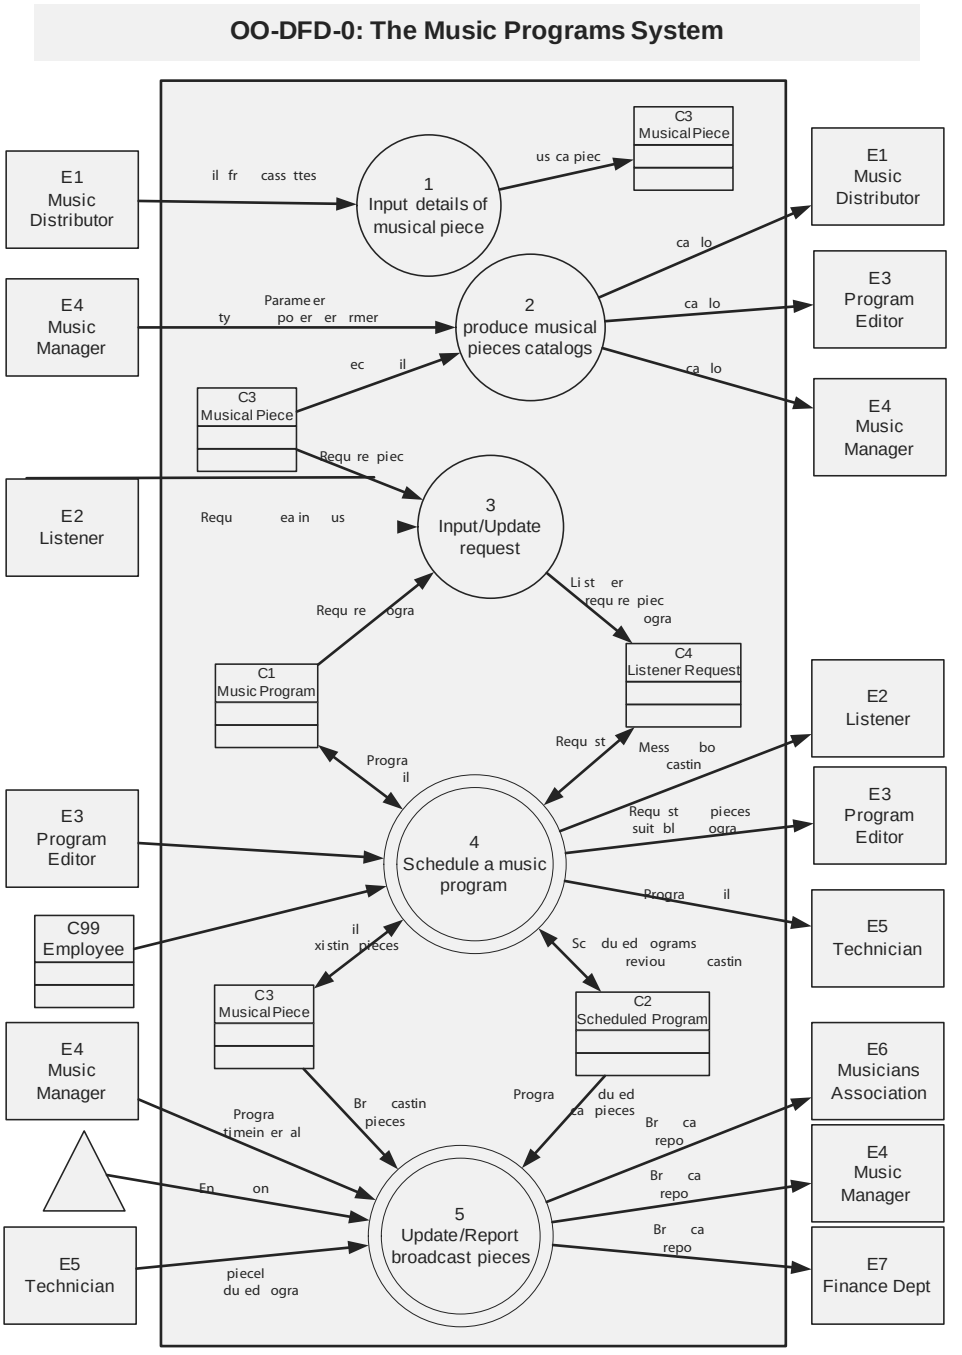
Figure 1. The initial class diagram of Music Program system



Fowler, 2004; Larman, 1998; UML, 2007). UML provides a standard ("unified") modeling language. It consists of several types of diagrams with well-defined semantics and syntax, which enable a system to be presented from different points of views. But UML in itself is not a development methodology that guides the developer how to do and which techniques to use. Moreover, some of the diagram types are redundant, and it is not always clear if and when they should be used in system development (e.g., sequence diagrams vs. collaboration diagrams).

Our approach is to integrate the two paradigms of system development. In our view, functions are as fundamental

Figure 2. The top-level OO-DFD of Music Programs system



as objects, complementing each other, and a development methodology should combine the functional and the object-oriented approaches. FOOM is a system analysis and design methodology that presents this combination.

ESSENTIALS OF FOOM METHODOLOGY

The essential steps of FOOM are described below. For more details see the initial paper, Shoval and Kabeli (2001), and the textbook, Shoval (2007).

The Analysis Phase

The analysis phase consists of two main activities: data analysis and functional analysis. The products of this stage are a conceptual data model, in the form of an **initial class diagram**, and a functional model, in the form of hierarchical **OO-DFDs**.

The **initial class diagram** consists of data (entity) classes, namely classes that are derived from the application/user requirements and contain real-world data. Each class includes attributes of various types (e.g., atomic, multivalued, sets, and reference attributes). Association types between classes include "ordinary" (1:1, 1:n and n:n) relationships, generalization-specialization (inheritance) links between super and subclasses, and aggregation-participation (part-of) links. Relationships are signified by links between respective classes, and by reference attributes to those classes. The initial class diagram does **not** include methods; these will be added at the design phase. An example of an initial class diagram is shown in Figure 1.

The **OO-DFDs** specify the functional requirements of the system. Each OO-DFD consists of general or elementary functions, external entities—mostly user-entities—but also time and real-time entities, data-classes (instead of the traditional data-stores), and data flows among them. An example of an OO-DFD is shown in Figure 2; it is the top-level (root) OO-DFD. For each general function, signified by a double circle, there is a separate OO-DFD which details its subfunctions and related entities and classes (not shown).

Data analysis and functional analysis may be performed in any order. When starting with functional analysis, the analyst elicits the user requirements and based on that creates the OO-DFDs, which include (besides other components) data-class rather than data-stores. Then, the analyst can create an initial class diagram, using the classes already appearing in the OO-DFDs. This means mainly defining proper class associations and attributes. Alternatively, the analyst can first create an initial class diagram (based on user requirements), and then create OO-DFDs, using the already defined classes. We investigated the pros and cons of the two alternative orders in an experimental setting, and found out that an analysis process which starts with data analysis provides better products and is preferred by analysts (Shoval & Kabeli, 2005). At any rate, the methodology provides rules for synchronizing the two analysis products, so that all classes appearing in the class diagram appear also in the OO-DFDs, and vise versa. This is done with the assistance of a data dictionary which is also created as part of the analysis stage and then keeps being updated in the following stages.

THE DESIGN PHASE

Top-Level Design of Transactions

This stage is performed according to ADISSA methodology, where the application transactions are derived from DFDs. The products of this stage include transactions diagrams, as extracted from the OO-DFDs, and top-level descriptions of the transactions. In addition, a new class—Transactions class—is added to the class diagram. This class will contain transaction methods that will be designed from the transactions' descriptions, as will be described later. Figure 3 shows an example of a "simple" transaction, consisting of an elementary-function, a class and a user-entity; this transaction is derived from OO-DFD (Figure 2).

Figure 3. A "simple" transaction diagram

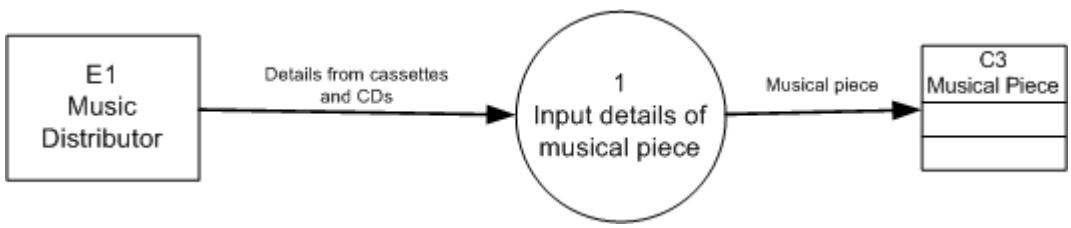


Figure 4. Top-level description of the transaction

```
Begin Transaction_1

  Repeat

    Piece=Forms.Input_Musical_Piece.Display (cassettes and CDs)

      /* Input_Musical_Piece is a form, which enable the user to fills in details of a musical piece. When
                                        the user completes the form it returns the filled piece object */

    If Piece <> NULL then        /* if the user selects to add a piece*/
            Musical_Piece.Construct(Piece)    /*Construct an object of Musical Piece*/
```

A top-level transaction description is provided in Structured-English (pseudo-code), and it refers to all components of the transaction: every data-flow from or to an external entity is translated to an "Input from entity..." or "Output to entity..." command; every data-flow from or to a class is translated to a "Read from class..." or "Write to class..." command; every data flow between two functions is translated to a "Move from... to..." command; and every function in the transaction is translated into an "Execute function…" command. The process logic of the transaction is expressed by standard structured-logic patters (e.g., if... then... else...; do-while...). The analyst and the user, who presents the requirements, determine the process logic of each transaction. This cannot be deducted automatically from the transaction diagram alone, because a given diagram can be interpreted in different ways, and it is up to the user to determine its proper semantics. The top-level description of the above transaction is shown in Figure 4. This description will be used in further stages of design, namely input/output design, and behavior (methods) design, to provide detailed descriptions of the application-specific class methods.

Design of the Interface: The Menus Class

As in ADISSA methodology, the menus-tree is derived in a semi algorithmic way from the hierarchy of OO-DFDs (Shoval, 1990). An example of a menus-tree that is derived from our example is shown in Figure 5. The main menu contains five lines/items; three marked by "T" (for "trigger"), indicating lines that trigger transactions; and two marked by "S" (for "selection") indicating lines that call other menus. (The numbers next to each line indicate the functions included in the transaction being triggered by the respective menu line). The menus-tree is translated into a new class, Menus; the instances (objects) of this class are the individual menus. Note that at run time, a user who interacts with the menu of the system actually works with a certain menu object. He/she may select a menu line that will cause the presentation of another menu object, or invoke a transaction, which is a method of the Transactions class.

Design of the Inputs and Outputs: The Forms and Reports Classes

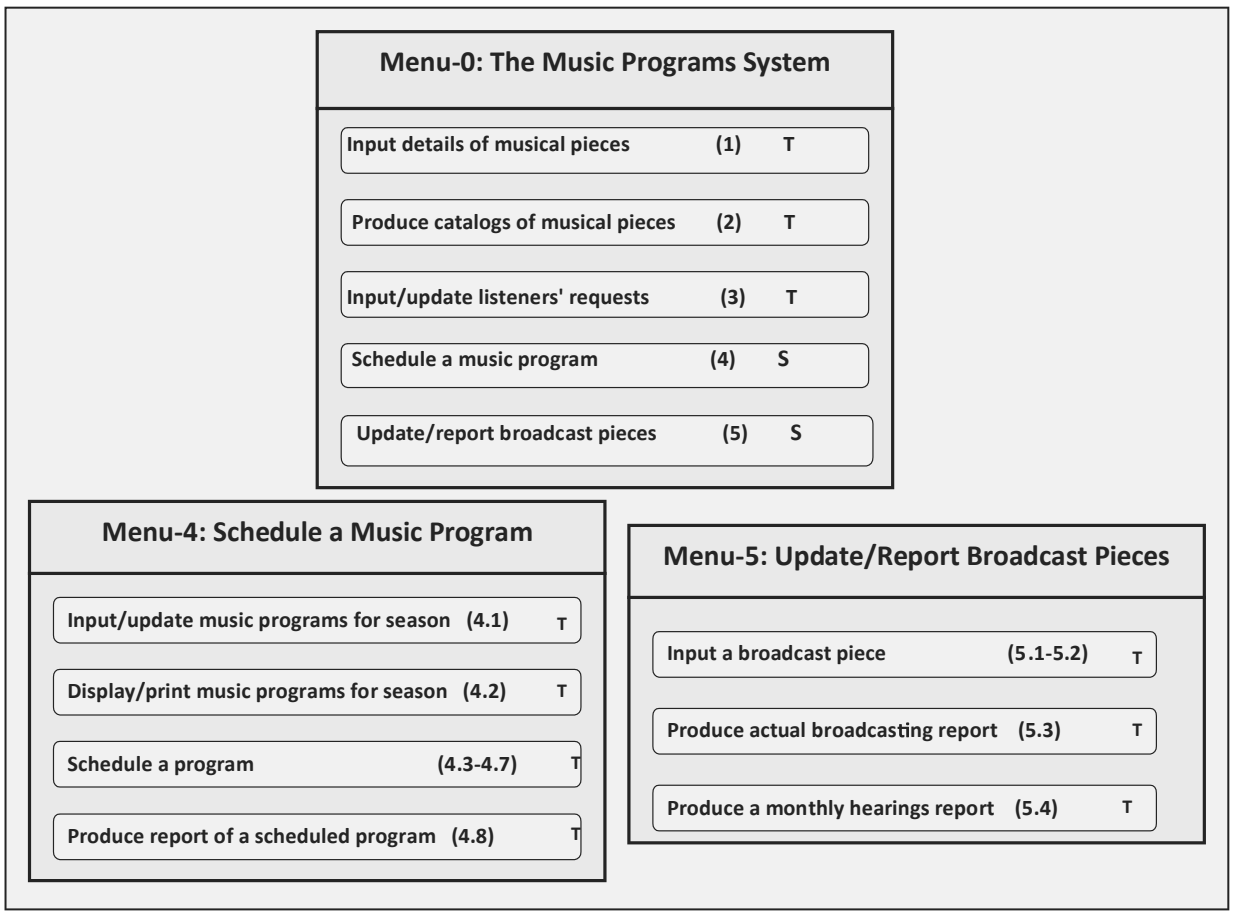
This stage is also performed according to ADISSA and is based on the input and output commands appearing in each of the transaction descriptions. For each "Input from..." command, an input screen/form will be designed, and for each "Output to..." command an output screen/report will be designed. Depending on the process logic of each transaction, some input or output screens may be combined. Eventually, two new classes are added to the class diagram: Forms, for the inputs; and Reports, for the outputs. Obviously, the instances (objects) of each of these classes are the input screens and output screens/reports, respectively.

Design of the System Behavior (Class Methods)

In this stage, the top-level descriptions of the transactions are converted into detailed descriptions of application programs and then into class methods. The transition from a top-level description of a transaction to detailed descriptions of the class methods is done as follows: Every "Input from entity..." and "Output to entity..." command in the top-level description is translated to a message calling an appropriate Display method of the Forms or Reports class, which will display the proper input or output screen or report. Every "Read from class..." or "Write to class..." command is translated to a message calling a "basic" method of the appropriate class. Basic methods include Create, Read, Update and Delete (CRUD methods), which are assumed to exist for every data class.

Every "Execute-Function..." command can be translated to a "basic" method of certain classes, or to an "application-specific" method, which will be attached to a proper class. An application-specific method may be one that performs a procedure/function that is specific to the application/transaction, beyond what is done by any "basic" method; for example, a procedure that performs some computations on values of attributes, and so forth. Each procedure/function

Figure 5. Interface design: The Menus tree



within the transaction description that is identified as a "basic" method or defined as an "application-specific" method of some class, is removed from the transaction's description and replaced by a message to that class-method. But a procedure/function that involves several classes, or performs some general computations, is not defined as an "ordinary" class method and is not attached to a specific class; rather, it remains within the transaction. The remaining parts of the transaction's description are defined as "transaction method." This method is actually the "main" part of the transaction's program, and belongs to the Transactions class. Hence, when users ask the system (via proper menu selections) to perform some activity/transaction, they actually trigger the "main" method of the transaction; that method executes, and while executing it may call (send messages to) other methods ("basic" or "application-specific") of respective classes, according to the process logic of the transaction.

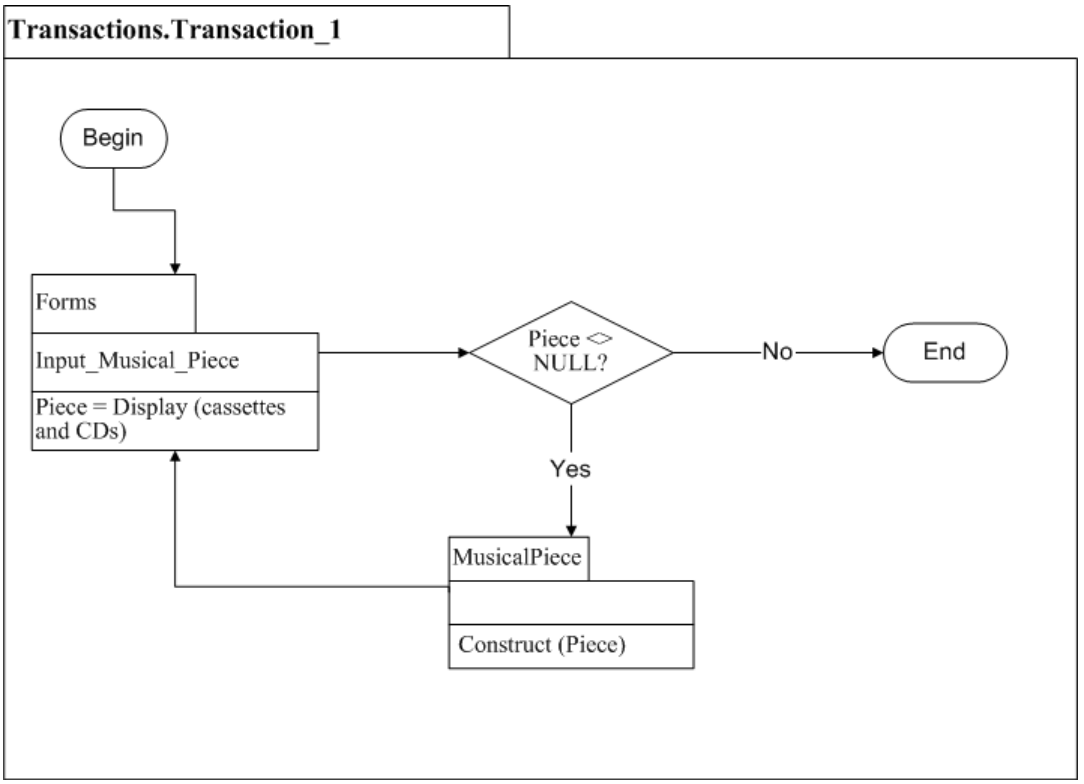
Each "transaction method" or "application-specific" method can be described in two complementing forms: pseudo-code and message chart. Figure 6 is an example of pseudo-code of the transaction. This description must not be too "formal;" it should include comments and explanations that will clarify the meaning of the transaction to the programmer who will implement it in the proper programming language. An equivalent way to describe a method is message chart (see example in Figure 7) which shows the classes, methods and messages included in a method, and the order/process logic of their execution. A message chart is actually an enhanced program flowchart which includes also the classes involved in the method and the messages to proper methods of those classes. As said, message charts are equivalent to pseudo-code and can be used interchangeably.

To summarize, the products of the design phase are: a) a complete class diagram, including Data, Menus, Forms, Reports and Transactions classes, each with various attribute types and method names, and various associations among the classes; b) detailed menu objects of the Menus class; c) detailed form and report objects of the Forms and Reports classes; d) detailed descriptions of the "transaction methods" and the "application-specific" methods, expressed in pseudo-code or in message charts. At the implementation

Figure 6. Pseudo-code of the transaction

```
Begin Transaction_1
   Repeat
      Piece=Forms.Input_Musical_Piece.Display (cassettes and CDs)
         /* Input_Musical_Piece is a form, which enable the user to fills in details of a musical piece. When the
                                    user completes the form it returns the filled piece object */
      If Piece <> NULL then        /* if the user selects to add a piece*/
               Musical_Piece.Construct(Piece)    /*Construct an object of Musical Piece*/
      End if
   Until Piece = NULL                          /* the user selects to stop adding pieces
End
```

Figure 7. Message chart of the transaction



stage, the programmers will use the above design products to create the software with any common OO programming language.

FUTURE DEVELOPMENTS

FOOM methodology is currently not supported by specific CASE tools. Any drawing tool, for example, MS-Visio, can be used to draw the class diagram, the OO-DFDs and the message charts. This has advantages and disadvantages: among the advantages are simplicity (of using any general-purpose tool) and flexibility (the possibility to adopt changes, if needed). The disadvantages are that a simple drawing tool does not provide for checking the syntactic correctness of the diagrams and for transformations from one product to the other.

In the future, we plan to develop a set of specialized CASE tools that will overcome the above limitations. More specifically, the set will include: a tool for drawing a

class diagram and hierarchical OO-DFDs, which will also enable checking the synchronization between them; a tool for deriving transactions diagrams from the OO-DFDs and specifying their process logic; a tool for designing the user interface (i.e., menus); a tool for designing the input and output forms and reports; a tool for mapping the class diagram to a relational database schema; and a tool for creating pseudo-code and message charts of the methods, based on the transactions.

CONCLUSION

The advantages of the FOOM methodology are: (a) in the analysis phase two complementary and synchronized models which represent the users' requirements are created: a conceptual data model, in the form of an initial class diagram, and a functional model, in the form of hierarchical OO-DFDs; (b) the design phase uses these products to create the various design artifacts: The class diagram is augmented with a Menus class which is derived from the menus designed earlier from the OO-DFDs. Inputs and Outputs classes are also derived from the input forms and the outputs of the system (earlier products of the design stage). The transactions are defined as "basic" methods, "application-specific" methods and "transaction methods;" and (c) the end products of the design phase can be easily implemented with any OO programming environment.

KEY TERMS

ADISSA – Architectural Design of Information Systems based on Structured Analysis: A systems analysis and design methodology which follows the functional- (process) oriented approach (Shoval, 1988). In the analysis phase of development it utilizes hierarchical DFDs. In the design phase the DFDs are used to design the various components of the system. These include: a) top-level descriptions of the transactions, which eventually become detailed descriptions

of the applications programs; b) the user interfaces (menus); c) the input and output screens and reports; and d) the database schema, or normalized relations, and SQL commands for retrieving and updating the database.

DFD - Data Flow Diagram: A diagram used in functional analysis which specifies the functions of the system, the inputs/outputs from/to external (user) entities, and the data being retrieved from or updating data stores. There are well-defined rules for specifying correct DFDs, as well as for creating hierarchies of interrelated DFDs.

ER - Entity-Relationship: A conceptual data model which defines the domain in terms of entities, attributes and relationships (Chen, 1976). ERD is an ER diagram, in which entities are represented as rectangles, attributes as ellipses and relationships between entities as diamonds.

FOOM – Functional and Object-Oriented Methodology: A systems analysis and design methodology which integrates these two approaches, as described in this chapter (Shoval, 2007; Shoval & Kabeli, 2001).

OO-DFD – Object-Oriented DFD: A variant of DFDs introduced in FOOM methodology, which include object (data) classes rather than data stores.

SSA - Structured System Analysis: A traditional, functional-oriented methodology for analyzing information systems, which utilized data flow diagrams.

SSD - Structured System Design: A traditional methodology for designing information systems, which utilized structure charts.

SQL – Structured Query Language: A standard language for querying and updating a relational database.

UML – Unified Modeling Language: An "industrial standard" notation for object-oriented development. It consists of a several types of (mostly) diagrams that enable describing systems from different perspectives, including structural, behavioral (functional) and managerial.

Fundamentals of Multirate Systems

Gordana Jovanovic Dolecek
INSTITUTE INAOE, Puebla, Mexico

INTRODUCTION

Digital signal processing (DSP) is an area of science and engineering that has been rapidly developed over the past years. This rapid development is a result of significant advances in digital computers technology and integrated circuits fabrication (Mitra, 2005; Smith, 2002).

Classical digital signal processing structures belong to the class of single-rate systems since the sampling rates at all points of the system are the same.

The process of converting a signal from a given rate to a different rate is called sampling rate conversion. Systems that employ multiple sampling rates in the processing of digital signals are called multirate digital signal processing systems. Sample rate conversion is one of the main operations in a multirate system (Harris, 2004; Stearns, 2002).

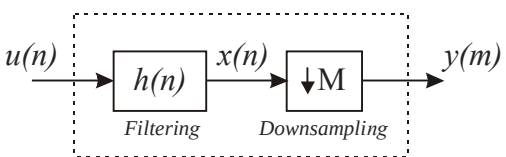
BACKGROUND

Decimation

The reduction of a sampling rate is called decimation, because the original sample set is reduced (decimated). Decimation consists of two stages: filtering and downsampling, as shown in Figure 1. The discrete input signal is $u(n)$ and the signal after filtering is $x(n)$. Both signals have the same input sampling rate f_i.

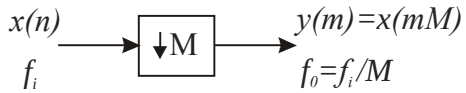
Downsampling reduces the input sampling rate f_i by an integer factor M, which is known as a downsampling factor. Thus, the output discrete signal $y(m)$ has the sampling rate f_i/M. It is customary to use a box with a down-pointing arrow, followed by a downsampling factor as a symbol to represent downsampling, as shown in Figure 2.

Figure 1. Decimation



DECIMATION

Figure 2. Downsampling



The output signal $y(m)$ is called a downsampled signal and is obtained by taking only every M-th sample of the input signal and discarding all others,

$$y(m) = x(mM). \tag{1}$$

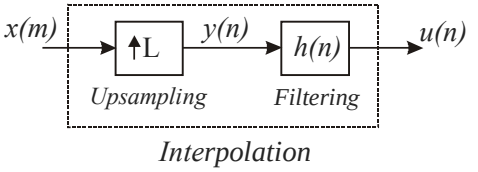
The operation of downsampling is not invertible because it requires setting some of the samples to zero. In other words, we can not recover $x(n)$ from $y(m)$ exactly, but can only compute an approximate value.

In spectral domain downsampling introduces the repeated replicas of the original spectrum at every $2\pi/M$. If the original signal is not bandlimited to π/M, the replicas will overlap. This overlapping effect is called aliasing. In order to avoid aliasing, it is necessary to limit the spectrum of the signal before downsampling to below π/M. This is why a lowpass digital filter (from Figure 1) precedes the downsampler. This filter is called a decimation or antialiasing filter.

Three useful identities summarize the important properties associated with downsampling (Jovanovic Dolecek, 2002). The First identity states that the sum of the scaled, individually downsampled signals is the same as the downsampled sum of these signals. This property follows directly from the principle of the superposition (linearity of operation). The Second identity establishes that a delay of M samples before the downsampler is equivalent to a delay of one sample after the downsampler, where M is the downsampling factor. The Third identity states that the filtering by the expanded filter followed by downsampling, is equivalent to having downsampling first, followed by the filtering with the original filter, where the expanded filter is obtained by replacing each delay of the original filter with M delays. In the time domain this is equivalent to inserting M-1 zeros between the consecutive samples of the impulse response.

The polyphase decimation, which utilizes polyphase components of a decimation filter, is a preferred structure for decimation, because it enables filtering to be performed at a lower sampling rate (Diniz, da Silva & Netto, 2002).

Figure 3. Interpolation



Interpolation

The procedure of increasing the sampling rate is called interpolation, and it consists of two stages: upsampling and filtering (shown in Figure 3).

The upsampler increases the sampling rate by an integer factor *L*, by inserting *L*-1 equally spaced zeros between each pair of samples of the input signal *x(n)* as shown by

$$y(n) = \begin{cases} x(n/L) & for\ \ n = mL \\ 0 & otherwise \end{cases} \qquad (2)$$

where *L* is called interpolation factor.

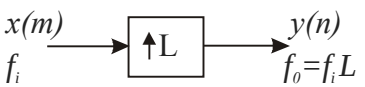
As Figure 4 illustrates, the symbol for this operation is a box with an upward-pointing arrow, followed by the interpolation factor. We can notice that the input sampling rate f_i is increased *L* times.

The process of upsampling does not change the content of the input signal, and it only introduces the scaling of the time axis by a factor *L*. Consequently, the operation of upsampling (unlike downsampling) is invertible, or in other words, it is possible to recover the input signal *x(m)* from samples of *y(n)* exactly.

The process of upsampling introduces the replicas of the main spectra at every $2\pi/L$. This is called imaging, since there are *L*-1 replicas (images) in 2π. In order to remove the unwanted image spectra, a lowpass filter must be placed immediately after upsampling (Figure 3). This filter is called an anti-imaging filter. In the time domain, the effect is that the zero-valued samples introduced by upsampler are filled with "interpolated" values. Because of this property, the filter is also called an interpolation filter.

We have already seen three useful identities of the downsampled signals, and now we will state the identities associated with upsampling. The Fourth identity asserts that the output signal obtained by upsampling followed by scaling of the input signal will give the same result as if the signal is first scaled and then upsampled. The Fifth identity states that a delay of one sample before upsampling is equivalent to the delay of *L* samples after upsampling. The Sixth identity, which is a more general version of the Fifth identity, states that filtering followed by upsampling is equivalent to having upsampling first followed by expanded filtering (Jovanovic Dolecek, 2002; Mitra, 2005; Diniz, da Silva & Netto, 2002).

Figure 4. Upsampling



Cascade of Sampling Converters

An interchange of cascaded sampling converters can often lead to a computationally more efficient realization (Fliedge, 2000; Vaidyanathan, 1993). If upsampling precedes downsampling, where both operations have the same factor, the signal is not changed. However, if downsampling is performed before upsampling, and both operations have the same factor, the resulting signal will be different from the input signal. Rational sampling conversion, that is, changing the sampling rate by a ratio of two integers, *L*/*M* can be efficiently performed as a cascade of upsampling and downsampling, where the interpolation and decimation filters are combined into one filter.

FUTURE TRENDS

Multirate systems have applications in digital radio, speech processing, telecommunications, wavelet transform, digital filtering, A/D converters, spectrum estimation, and so forth.

There are many applications where the signal of a given sampling rate needs to be converted into an equivalent signal with a different sampling rate. For example, in digital radio, three different sampling rates are used: 32 kHz in broadcasting, 44.1 kHz in digital compact disc (CD), and 48 kHz in digital audiotape (DAT), (Fliedge, 2000; Mitra, 2005). Conversion of the sampling rate of audio signals between these three different rates is often necessary. For example, if we wish to play CD music which has a rate of 44.1 kHz in a studio which operates at a 48 kHz rate, then the CD data rate must be increased to 48 kHz using a multirate technique.

In speech processing, multirate techniques are used to reduce the storage space or the transmission rate of speech data (Damiani, Dipanda, Yetongnon, Legrand, Schelkens & Chbeir, 2007; Meana, 2007). In the past years, multirate speech and audio signal processing has been a research topic that has produced several efficient algorithms for echo and noise cancellation, active noise cancellation, speech enhancement, and so forth. (Diniz, da Silva & Netto, 2002; Jovanovic Dolecek, 2002; Meana, 2007).

An example of an application of multirate signal processing in telecommunications is the translation between two multiplexing formats, time division multiplexing (TDM)

and frequency division multiplexing (FDM), (Fliedge 2000; Harris, 2004; Smith, 2001). The filter banks are used to separate a signal into two or more signals (Analysis filter bank) or to compose two or more signals into a single signal (Synthesis filter bank). Multirate systems and filter banks have found many applications in source and channel coding, thereby providing a bridge between communication system design/analysis and signal processing tools (Vaidyanathan, 1993).

The application of multirate techniques to a software radio (SWR) considerably increases the efficiency of the design, (Arslan, 2007; Harada & Prasad, 2002; Reed, 2002). It enhances flexibility and lowers the costs of constructing and operating wireless infrastructure (Bard & Kovarik, 2007). Software radio is one of the key enabling technologies for the wireless revolution and is considered as one of the more important emerging technologies for the future wireless communications (Burachini, 2000; Johnson & Sethares; Kenington, 2005.) Nowadays the term "software radio" generally refers to a radio that derives its flexibility through software while using the same piece of hardware, that is, the same piece of hardware can perform different functions at different times. In that way a completely reconfigurable physical hardware is obtained by programming in software. As a difference, the traditional radio architecture is primarily determined by hardware and so any upgrading means completely abandoning the old design and start with a new design. Software radio terminals must be able to process many various communication standards. These standards are generally based on different master clock rates and thus employ different bit/chip rates. The most obvious solution to cope with the diversity of master clock rates in one terminal is to provide a dedicated master clock for each standard of operation (Hentschel & Fettweis, 2000). However, this approach is too costly and limits the applicability of a realized terminal. Hence, it is much more elegant to run the terminal on a fixed clock rate, and perform digital sample rate conversion controlled by software (Babic & Renfors, 2005; Johansson & Gustafsson, 2005; Saud and Stuber, 2006; Tkacenko, 2007).

One of the most fascinating developments in the field of multirate signal processing has been the establishment of its link to the discrete wavelet transform (Diniz, da Silva & Netto, 2002; Rao, 2002). This link has been responsible for the rapid application of wavelets in fields such as image compression.

Multirate processing has found important application in the efficient implementation of DSP functions (Sheng, Chen & Shan, 2005). The multirate approach increases the computational speed, decreases the overall filter order, reduces word-length effects, and decreases power consumption, making it vital for efficient filtering. Basic multirate techniques used to satisfy the filter requirements are the polyphase decomposition, multistage filtering and frequency masking approach (Mitra, 2005; White, 2000).

The need for inexpensive, high resolution analog/digital (A/D) converters has led to the use of oversampling techniques in the design of such converters, that is, to sample the analog signal at a rate much higher than the Nyquist rate, one uses a fast low-resolution A/D converter, and then decimates the digital output of the converter to the Nyquist rate. Such A/D converter relaxes the sharp cutoff requirements of the analog antialiasing filter, resulting in a more efficient structure (Harris, 2004; Jovanovic Dolecek, 2002; Mitra, 2005).

Another application of multirate signal processing is in the area of spectrum estimation. By using the sampling rate conversion, the computational requirements for narrowband spectrum estimation based on discrete Fourier transform can be significantly reduced (Vaidyanathan, 1993).

Multirate systems also become an active research area in systems and control (Ding & Chen, 2005).

It is expected that in future the applications of multirate systems will play a very important role for resolving problems in communications, control, wavelet analysis, analog/digital converters etc. From the other side, the different applications will give an impulse to develop new algorithms and design methods for multirate systems.

CONCLUSION

There are many applications where the signal of a given sampling rate needs to be converted into an equivalent signal with a different sampling rate. The main reasons could be to increase efficiency or simply to match digital signals that have different rates. During the past several years the multirate processing of digital signals has been attracted by many researchers and the utilization of multirate techniques is becoming an indispensable tool of the electrical engineering profession.

Changing the sampling rate can reduce the computation necessary to complete some DSP operations, and thus reduce the overall system cost. Consequently, the main advantage of multirate systems lies in their high computational efficiency.

KEY TERMS

Analysis Filter Bank: Decomposes the input signal into a set of subband signals with each subband signal occupying a portion of the original frequency band.

Continuous-Time Signals: Continuous signals are defined along a continuum of time *t* and thus are represented by continuous independent variables, for example $x_c(t)$. Continuous-time signals are often referred to as analog signals.

Decimation: The process of decreasing the sampling rate. It consists of filtering and downsampling.

Decimation Filter: The filter used in decimation to avoid aliasing caused by downsampling.

Digital Filter: The filter is a discrete-time system, which changes the characteristics of the input discrete signal in a desired manner to obtain the discrete output signal.

Digital Filter Bank: Set of digital bandpass filters with the common input or a common output.

Discrete-Time Signals: Discrete-time signals are defined at discrete time values and thus the independent variable has discrete values *n*, as for example *x(n).*

Interpolation: The process of increasing the sampling rate. It consists of upsampling and filtering.

Interpolation Filter: The filter used in interpolation to remove the unwanted images in the spectra of the upsampled signal.

Multirate System: Discrete–time systems with unequal sampling rates at various parts of the system.

Sampling: The generation of a discrete-time signal $x(n)$ from a continuous signal $x_c(t)$ is called sampling, where $x(n) = x_c(nT)$. T is called the sampling period and its inverse $1/T$ is the sampling frequency or the sampling rate.

Software Radio: The term software radio generally refers to a radio that derives its flexibility through software while using the same piece of hardware, that is, the same piece of hardware can perform different functions at different times. In that way a completely reconfigurable physical hardware is obtained by programming in software.

Subband Coding (SBC) Filter Bank: Consists of an analysis filter bank followed by synthesis filter bank. This type of filter bank is used for partitioning signals into subbands for coding purposes, and vice versa.

Synthesis Filter Bank: Combines subband signals into one signal.

Transmultiplexer Filter Bank (TMUX): Consists of a synthesis filter bank followed by an analysis filter bank. This type of filter bank is used for converting time-multiplexed signals (TDM) into frequency-multiplexed signals (FDM), and vice versa.

INTRODUCTION

For modeling real-world problems and constructing intelligent systems, integration of different methodologies and techniques has been the quest and focus of significant interdisciplinary research effort. The advantages of such a hybrid system are that the strengths of its partners are combined and complementary to each other's weakness.

In particular, object orientation provides a hierarchical data abstraction scheme and a mechanism for information hiding and inheritance. However, the classical object-oriented data model cannot deal with uncertainty and imprecision pervasive in real world problems. Meanwhile, probability theory and fuzzy logic provide measures and rules for representing and reasoning with uncertainty and imprecision. That has led to intensive research and development of fuzzy and probabilistic object-oriented databases, as collectively reported in De Caluwe (1997), Ma (2005), and Marín & Vila (2007).

BACKGROUND

The key issues in research on extending the classical object-oriented data models to deal with uncertainty and imprecision are:

1. Modeling partial subclass relationship.
2. Definition of partial class membership.
3. Representation of uncertain and/or imprecise attribute values.
4. Representation and execution of class methods.
5. Expression of partial applicability of class properties.
6. Mechanism for inheritance under uncertainty and imprecision.

In the classical object-oriented data model, a class hierarchy defines the subclass/super-class relation on classes. A class *A* is derived as a subclass of a class *B*, which is then called *A*'s super-class, either by narrowing the crisp value ranges of *B*'s attributes or by adding new properties to *B*'s ones. In the probabilistic and fuzzy case, due to the uncertain applicability of class properties or the imprecision of attribute value ranges, the inclusion between classes naturally becomes graded, which could be computed on the basis of the value ranges of their common attributes (George & Buckles & Petry, 1993, Rossazza & Dubois & Prade, 1997).

As discussed in Baldwin, Cao, Martin, and Rossiter (2000), a set of classes with a graded inclusion or inheritance relation actually forms a network rather than a hierarchy, because if a class *A* has some inclusion degree into a class *B* based on a fuzzy matching of their descriptions, then *B* usually also has some inclusion degree into *A*. Moreover, naturally, a concept is usually classified into sub-concepts that are totally subsumed by it, though the sub-concepts can overlap each other, as assumed in Dubitzky, Büchner, Hughes, and Bell (1999) for instance.

Uncertain and imprecise attribute values lead to partial membership of an object into a class, and there are different measures proposed. Yazici and George (1999), for instance, defined for each class a membership function on a set of objects. Bordogna, Pasi, and Lucarella (1999) used linguistic labels to express the strength of the link of an object to a class. Dubitzky et al. (1999) defined membership as similarity degrees between objects and classes. Blanco, Marín, Pons, and Vila (2001) mentioned different measures, including probabilistic one, to be used for membership degrees. Nevertheless, it is to be answered how measures of different meanings, such as possibility and probability, on various levels of a model are integrated coherently.

Most of the works on fuzzy object-oriented data models, which are referred in this paper, were mainly based on fuzzy set and possibility theories, and used fuzzy sets or possibility distributions to represent imprecise attribute values. Bordogna, Pasi, and Lucarella (1999) and Blanco et al. (2001) also modeled uncertainty about an attribute having a particular value. However, much less concern was given for uncertainty over a set of values of an attribute and a foundation to combine probability degrees and fuzzy sets in the same model.

While class attributes were paid much attention and treatment, class methods, as common in object-oriented systems for modeling object behaviors and parameterized properties, were often neglected. In Dubitzky et al. (1999) and Blanco et al. (2001) methods were not considered.

Bordogna, Pasi, and Lucarella (1999) mentioned about methods but did not provide formal representation and explicit manipulation in their model. In Yazici (1999) and Cao and Rossiter (2003) methods were formally defined as Horn clauses and executed as a reasoning process, which were thus for declarative and deductive in contrast to imperative and procedural models.

In the classical object-oriented data model, the properties that represent a class are necessary and sufficient to define the class. However, there is no commonly agreed set of defining properties for many natural, scientific, artificial, and ontological concepts. Arguing for flexible modeling, Van Gyseghem and De Caluwe (1997) introduced the notion of *fuzzy property* as an intermediate between the two extreme notions of required property and optional property, each of which was associated with a possibility degree of applicability of the property to the class. Meanwhile, Dubitzky et al. (1999) addressed the issue by contrasting the prototype concept model with the classical one, assuming each property of a concept to have a probability degree for it occurring in exemplars of that concept.

We note the distinction between the notion of uncertain property values and that of uncertain property applicability. In the former case, an object surely has a particular property but it is not sure which one among a given set of values the property takes. Meanwhile, in the latter, it is even not sure if the object has that property. For example, "John owns a car whose brand is probably BMW" and "It is likely that John owns a car" express different levels of uncertainty. In Bordogna, Pasi, and Lucarella (1999), Blanco et al. (2001), and Cao and Rossiter (2003), the two levels were mixed.

Uncertain class membership and uncertain property applicability naturally result in *uncertain inheritance* of class properties. This was not considered in Bordogna, Pasi, and Lucarella (1999), Dubitzky et al. (1999), and Yazici and George (1999). In Blanco et al. (2001), class membership degrees were used as thresholds to determine what part of the properties in a class would be inherited. In Cao and Rossiter (2003), both membership of an object into a class and applicability of a property to the class were represented by support pairs (Baldwin, Lawry & Martin, 1996) and combined into the support pair for the object to inherit the property.

Recently, Cross (2003) reviewed existing proposals and presented recommendations for the application of fuzzy set theory in a flexible generalized object model. Furthermore, De Tré and De Caluwe (2005) focused on representing data as constraints on object attributes and query answering as constraint satisfaction. For realization of fuzzy object-oriented data models, Berzal et al. (2005) were concerned with implementation of their model on an existing platform. Meanwhile, Fril++, a fuzzy object-oriented logic programming language, was also developed in Rossiter and Cao (2005).

While the fuzzy object-oriented data models referred in this paper were mainly based on fuzzy set and possibility theories, Eiter, Lu, Lukasiewicz, and Subrahmanian (2001) introduced a probabilistic model to handle object bases with uncertainty, called POB (Probabilistic Object Base). For a POB class hierarchy, although a class was assumed to be fully included in its super-classes, the model specified the conditional probability for an object of a class belonging to each of its subclasses. Intuitively, it specified how likely an object of a class belonged to a subclass of that class. Accordingly, the partial class membership was measured by probability degrees. For each attribute of an object, uncertainty about its value was represented by lower bound and upper bound probability distributions on a set of values. The authors also developed a full-fledged algebra to query and operate on object bases.

However, the two major shortcomings of the POB model are: (1) it does not allow imprecise attribute values; and (2) it does not consider class methods. For instance, in the Plant example therein, the values of the attribute *sun light* are chosen to be only enumerated symbols such as *mild*, *medium*, and *heavy* without any interpretation. Meanwhile, in practice, those linguistic values are inherently vague and imprecise over degrees of sun light. Moreover, without an interpretation, they cannot be measured and their probability distributions cannot be calculated.

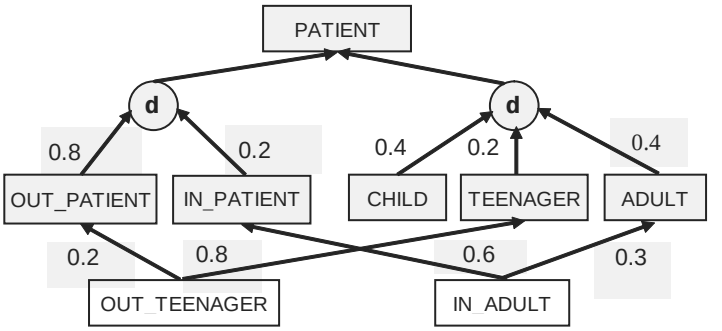
A HYBRID MODEL

In Cao and Nguyen (2007) and Nguyen and Cao (2007), POB is extended with fuzzy attribute values, class methods, and uncertain applicability of class properties. Here, the term *property* is used to subsume both the terms *attribute* and *method*. This hybrid model is called FPOB (Fuzzy-Probabilistic Object Base).

Figure 1 is an FPOB hierarchy of patients, who are classified as being children, teenagers or adults and, alternatively, as being out-patients, or in-patients. Those subclasses of a class that are connected to a **d** node are mutually disjoint, and they form a cluster of that class. The value in [0, 1] associated with the link between a class and one of its immediate subclasses represents the probability for an object of the class belonging to that subclass. For instance, the hierarchy says 80% of patients are non-resident, while the rest 20% are resident. As such, each object could be a member of a class with some probability.

Basically, imprecise and uncertain values of an attribute is expressed by a *fuzzy-probabilistic triple* of the form $\langle V, \alpha, \beta \rangle$, where V is a set of *fuzzy values*, that is,, those defined by fuzzy sets, and α and β are lower and upper bound probability distributions on V. For example, $\langle \{young, middle\_aged\}, .8u, 1.2u \rangle$, represents that the probability for the age of a patient is *young* or *middle-aged* is between 0.4 and 0.6, where *young* and *middle-aged* are linguistic labels of fuzzy sets, and u denotes the uniform distribution.

Figure 1. An example FPOB class hierarchy



For a unified treatment of class attributes and methods, an attribute could be considered as a special method with a fixed output, having no input argument. Alternatively, a method could be considered as a parameterized attribute, whose value depends on its input arguments. In other words, a method is a function from products of fuzzy-probabilistic triples to fuzzy-probabilistic triples. For example, a method could be define for the class PATIENT to compute the total treatment cost of a patient, depending on the daily treatment cost, the patient's treatment duration, and insurance cover.

Uncertain applicability of a class property in FPOB is expressed by a probability interval. For example, since not all patients may have a medical history recorded, that property might be defined with the interval [.8, 1] saying that at least 80% of patients have medical histories. For computation, a property value $\langle V, \alpha, \beta\rangle$ associated with a probability interval $[l, u]$ is assumed to be equivalent to the fuzzy-probabilistic triple $\langle V, \alpha\otimes l, \beta\otimes u\rangle$, where $\otimes$ denotes a probabilistic conjunction operator (Lakshmanan et al., 1997, Ross & Subrahmanian, 2005).

Let $[l, u]$ be the applicability probability interval of a property P to a class c, and $[x, y]$ be the membership probability interval of an object o into c. Then the applicability probability interval of P to o is defined to be $[l, u] \otimes [x, y]$. For multiple uncertain inheritance, in the logic-based fuzzy and probabilistic object-oriented model in Cao (2001), each uncertainly applicable property was considered as a defeasible probabilistic logic rule, and then uncertain inheritance was resolved by probabilistic default reasoning.

In FPOB, complex object structures, or types, can be recursively defined to be of the form $\tau = [P_1(\tau_{11},\ldots, \tau_{1n_1}): \tau_1[l_1, u_1],\ldots, P_k(\tau_{k1},\ldots, \tau_{kn_k}): \tau_k[l_k, u_k]]$. For each property P_i, τ_i and τ_{ij}'s (j from 1 to n_i) are respectively the types of its output and input parameters, and $[l_i, u_i]$ is the applicability probability interval of the property to the class in which it is defined. Simple types are atomic types like real numbers and strings, or fuzzy sets on atomic types.

Since complex object types can be so nested, one has the notion of *path expressions*. In particular, P_i is a path expression for the type τ aforementioned, and $[l_i, u_i]$ is its associated probability interval. $P_i[l_i, u_i]$ is called an *uncertain path expression*. Inductively, if λ_i is a path expression for τ_i with associated probability interval $[l_{\lambda_i}, u_{\lambda_i}]$, then $P_i.\lambda_i$ is a path expression for τ, and $[l_i, u_i] \otimes [l_{\lambda_i}, u_{\lambda_i}]$ is its associated probability interval.

For a particular object, a *fuzzy-probabilistic tuple value* of the type τ is $[P_1(\langle V_{11}, \alpha_{11}, \beta_{11}\rangle, \ldots, \langle V_{1n_1}, \alpha_{1n_1}, \beta_{1n_1}\rangle)$: $\langle V_1, \alpha_1, \beta_1\rangle[l'_1, u'_1], \ldots, P_k(\langle V_{k1}, \alpha_{k1}, \beta_{k1}\rangle, \ldots, \langle V_{kn_k}, \alpha_{kn_k}, \beta_{kn_k}\rangle)$: $\langle V_k, \alpha_k, \beta_k\rangle[l'_k, u'_k]]$, where $\langle V_i, \alpha_i, \beta_i\rangle$ and $\langle V_{ij}, \alpha_{ij}, \beta_{ij}\rangle$ are fuzzy-probabilistic triples of types τ_i and τ_{ij}, (i from 1 to k and j from 1 to n_i). Here, $[l'_i, u'_i]$ specifies the uncertain applicability of P_i to that particular object, which is not necessarily the same as the default value $[l_i, u_i]$ for a generic object of the type τ.

The most important database operation is selection. For FPOB, a *fuzzy-probabilistic selection expression* is inductively defined to be in one of the following forms:

1. $x \in c$, where x is an object variable and c is a class.
   This is to select those objects that belong to the class c.
2. $x.\lambda$, where x is an object variable and λ is a path expression.
   This is to select those objects to which the path expression λ is applicable.
3. $x.\lambda\ \theta\ v$, where x is an object variable, λ is a path expression, θ is a binary relation from $\{=, \neq, \leq, <, \subseteq, \in, \rightarrow\}$, and v is a value.
   This is to select those objects for which the values of the property defined by the path expression λ satisfy the relation θ with the value v.
4. $x.\lambda_1 =_{\otimes} x.\lambda_2$, where x is an object variable, λ_1 and λ_2 are path expressions, and $\otimes$ is a probabilistic conjunction strategy of combining the probabilities for $x.\lambda_1 = v_1$, $x.\lambda_2 = v_2$, and $v_1 = v_2$.

This is to select those objects for which the values of the properties defined by the path expressions λ_1 and λ_2 are equal.

5. $E_1 \otimes E_2$, where E_1 and E_2 are selection expressions over the same object variable and $\otimes$ is a probabilistic conjunction strategy of combining the probabilities for E_1 and E_2 being true.
   This is to select those objects for which both the selection expressions E_1 and E_2 are satisfied.
6. $E_1 \oplus E_2$, where E_1 and E_2 are selection expressions over the same object variable and $\oplus$ is a probabilistic disjunction strategy of combining the probabilities for E_1 and E_2 being true.

This is to select those objects for which either the selection expression E_1 or the selection expression E_2 is satisfied.

The *probabilistic interpretation* of a selection expression for an object gives the probabilistic interval for that object to satisfy the expression.

A *fuzzy-probabilistic selection condition* is then inductively defined as a selection expression to be satisfied with a probability in an interval as follows:

1. If E is a selection expression and $[l, u]$ is a subinterval of [0, 1], then $(E)[l, u]$ is a selection condition.
2. If ϕ and ψ are selection conditions, then $\neg\phi$, $(\phi \wedge \psi)$ and $(\phi \vee \psi)$ are selection conditions.

For example, selection of those patients who is young and likely have medical history records with a probability of at least .8 can be posed by the condition:

$(x.\text{age} \rightarrow \textit{young})[1, 1] \wedge (x.\text{medical\_history})[.8, 1]$

where *young* is a linguistic label of a fuzzy set.

An algebra has been developed to compute with fuzzy-probabilistic triples. Meanwhile, the basis for matching a selection expression to an object is the definition of probabilistic interpretation of binary relations on fuzzy sets. The probabilistic interpretation $prob(A\ \theta\ B)$ of a relation $A\ \theta\ B$, where A and B are respectively fuzzy sets on domains U and V, $\theta \in \{=, \neq, \leq, <, \subseteq, \in\}$, is a value in [0, 1] defined by:

$$\sum_{S\subseteq U,\ T\subseteq V} \Pr(u\ \theta\ v \mid u\in S,\ v\in T).m_A(S).m_B(T)$$

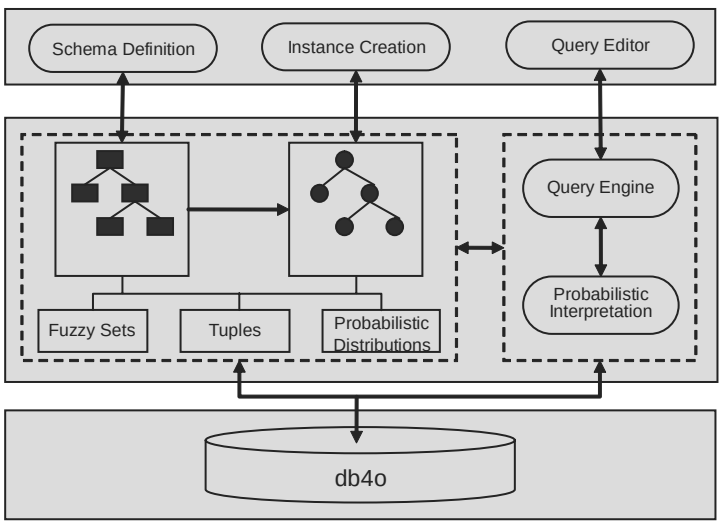
where $m_A(S)$ and $m_B(T)$ are the mass assignments of S and T with respect to A and B (Baldwin, Lawry & Martin, 1996). Intuitively, given fuzzy propositions $x\in A$ and $y\in B$, $prob(A\ \theta\ B)$ is the probability for $x\ \theta\ y$ being true. Especially, the probabilistic interpretation $prob(A \rightarrow B)$ of the relation $A \rightarrow B$, where A and B are fuzzy sets on the same domain U, is a value in [0, 1] defined by:

$$\sum_{S,T\subseteq U} \Pr(u\in T \mid u\in S).m_A(S).m_B(T).$$

The intuitive meaning of $prob(A \rightarrow B)$ is that it is the probability for $x\in B$ being true given $x\in A$ being true. These definitions are the foundation to combine probabilities and fuzzy sets into the coherent framework of FPOB.

Other basic algebraic operations on databases are Cartesian product, join, intersection, union, difference have also been defined for FPOB. For applications of FPOB, Nam et al. (2007) implement an FPOB management system called

Figure 2. FPDB4O architecture



FPDB4O, whose architecture comprises three layers as illustrated in Figure 2:

1. GUI Layer: this is for user interface, allowing users to draw an FPOB class hierarchy and define attributes for classes (Schema Definition), to create a new FPOB instance by creating and modifying data objects (Instance Creation), and to query on an FPOB (Query Editor).
2. Core Layer: this is the main component of the architecture. It includes two main blocks, one for representing the FPOB model, and one for executing queries. In more detail, the former determines the structure for representing schemas, data objects, probabilistic distributions of attribute values, and fuzzy sets. The latter parses queries, performs probabilistic interpretations, and gives answers.
3. Data Layer: this provides functions for storing and retrieving FPOB data objects, employing related functions of DB4O (Grehan, 2005).

FUTURE TRENDS

Research on fuzzy and probabilistic object-oriented databases has been extensive and mature. Due to complexities of theoretical foundation and practical implementation, no model would be so universal that could include all measures and tackle all aspects of uncertainty and imprecision. Different models are thus to complement each other to deal with certain facets of the complex real world. In the coming years, besides continuing work on development of new hybrid models, application tools, languages, and systems are expected to emerge.

CONCLUSION

Various fuzzy and probabilistic object-oriented database models have been developed during the last 15 years, introducing basic concepts and proposing solutions for key issues of fuzzy and probabilistic object-oriented modeling. They are truly extension of the classical object-oriented models with imprecise and/or uncertain class properties. FPOB, a state-of-the-art model, combines fuzzy set and probability theories into a coherent framework for modeling classes and objects and computing with their attributes and methods.

Currently, only natural join operation is defined in FPOB. To support general join operation, probabilistic interpretation of relations on fuzzy-probabilistic triples has to be defined. Also, developed fuzzy and probabilistic object-oriented database languages and systems are to be applied to real world problems.

F

KEY TERMS

Fuzzy Class Hierarchy: An extended conventional class hierarchy where each link between a class and one of its subclasses is associated with an inclusion degree in [0, 1].

Fuzzy Class Membership: A class is considered as a fuzzy set on a set of objects, for which each object is a member of a class to a certain degree.

Fuzzy Property: A property that is applicable to a class with a certain possibility degree.

Fuzzy-Probabilistic Selection Condition: A condition of a selection operation on a fuzzy-probabilistic object-oriented database, which is a selection expression associated with a probability interval.

Fuzzy-Probabilistic Selection Expression: An expression of a selection operation on a fuzzy-probabilistic object-oriented database, which includes constraints on uncertain path expressions and fuzzy-probabilistic triple values.

Fuzzy-Probabilistic Triple Value: An imprecise and uncertain value expressed by lower and upper bound probability distributions on a set of fuzzy set values.

Probabilistic Class Hierarchy: An extended conventional class hierarchy where each link between a class and one of its subclasses is associated with a conditional probability for an object of the class belonging to that subclass.

Probabilistic Class Membership: There is a probability for an object belonging to a class.

Probabilistic Interpretation of Selection Expression: A probability interval for an object satisfying a selection expression.

Probabilistic Property: A property that is applicable to a class with a certain probability.

Uncertain Inheritance: An object may inherit a property of a class to a certain degree only.

Uncertain Path Expression: A sequence of nested properties associated with a probability interval expressing the uncertainty of its applicability to a class or object.

Gender and Computer Anxiety

INTRODUCTION

Because of their ability to enhance productivity, computers have become ubiquitous in the workplace. By the early 1990s the use of computers in the workplace reached a per capita penetration that the telephone took 75 years to achieve (Webster & Martocchio, 1992). During the past several decades, there has been both speculation and hard research related to the psychological effects of computer technology. More recently the role of attitudes towards computers in influencing the acceptance and use of computer-based management information systems (MIS) has been highlighted by a growing number of MIS researchers. Generally, these studies focus on the negative attitudes towards computers and concerns about the impact of MIS on individual performance in the workplace.

Computer anxiety has been reported to be associated with negative attitudes towards computers. As computers play a pervasive role in MIS and decision support systems, these findings emphasize the need for additional empirical research on the determinants of computer anxiety and attitudes towards computers. Furthermore, with the increasing participation of women in information technology professions, important questions are whether men and women differ with regard to computer anxiety and attitudes towards computers, and what factors explain such differences where they exist, and how to ameliorate anxiety where it occurs.

The Concept and Correlates of Computer Anxiety

Much has been speculated about computer anxiety, both what it is and what to do about it. Computer anxiety is context specific and covers a wide variety of situations in which people interact with computers. Context-specific anxiety tests ask the question: "How do you feel when a specific type of situation occurs?" Commonly, the relationship between a measure of computer anxiety and other variables is examined. For example, the relationship of computer anxiety to computer-related experience has historically been a hotly contested question in MIS research, human-computer interaction (HCI), and educational psychology. Demographic variables posited or found to be related to computer anxiety include gender, age, organizational level, and academic major (Dambrot, Watkins-Malek, Silling, Marshall & Garver, 1985; Gutek & Bikson, 1985; Zmud, 1979). Personality variables examined as potential determinants of computer anxiety include trait anxiety, math anxiety, cognitive style, and locus of control (Howard & Smith, 1986; Igbaria & Parasuraman, 1989; Morrow, Prell & McElroy, 1986). Additionally, several studies have examined the relationship between computer anxiety and academic achievement. For example, Hayek and Stephens (1989) and Marcoulides (1988) reported significantly lower computer anxiety being associated with higher academic achievement.

BACKGROUND

Initially, computer anxiety became of interest during the technological revolution. In 1963 a social psychologist at IBM completed a nationwide study to examine popular beliefs and attitudes about one of the prime symbols of our rapidly changing technology—the electronic computer. Lee's (1970) findings concluded that the American public viewed computers on two independent dimensions. The first dimension, the "Beneficial Tool of Mankind Perspective," described a positively toned set of beliefs that computers are beneficial in science, industry, and business. The second dimension, the "Awesome Thinking Machine Perspective," connoted fear of an incomprehensibly complex machine with capabilities far exceeding those of a human. This perspective, which reflects ignorance about the capabilities and limitations of computers, is one of the generic origins of computer anxiety.

Later, during the 1980s, much of the writing about computer anxiety and attitudes towards computers was concentrated in trade and business publications (e.g., Howard, 1986; Igbaria & Parasuraman, 1989). During this time period uncertainty was often considered the primary predictor of computer anxiety. This uncertainty referred to an individual's ability to learn to use the computer or to the potential the machine had to rearrange traditional office functions and power structures. Sabotage and hostility were sometimes responses to these uncertainties, especially when they were

accompanied by fear of replacement by the machine. This particular concern was often voiced by middle managers who viewed their jobs as information conduits or as a mosaic of clerical tasks, all of which could be performed more efficiently by a computer. Managers with longer tenure with a company and those who felt they were currently utilizing their time quite effectively were likely to resist computer adoption and use. Additionally, computer usage required typing skills. Those persons who did not know how to type or considered typing a low-status skill were reluctant to adapt to the new technology.

Collectively two groups displayed the most susceptibility to computer anxiety: individuals without computer experience overestimated the difficulties involved in learning and interacting with computers; and individuals whose jobs appeared threatened resisted adaptation to technological improvements (Gilroy & Desai, 1986). It has been well documented that among individuals demonstrating computer anxiety are significant numbers of women, as examined in the next section.

The Role of Gender in Computer Anxiety

According to feminist technology studies, computers are widely perceived as belonging to the "male domain" of mathematics, science, electronics, and machinery (Beyer, 1999; Cockburn & Ormrod, 1993; Faulkner, 2001). This, coupled with reports of greater prevalence of math anxiety among women than men (e.g., Brown & Josephs, 1999; Chipman, Krantz & Silver, 1992), suggests that women are likely to have a more negative view of computer use than men. It is not surprising that men have been found to display lower computer anxiety, higher computer aptitude, and more positive attitudes towards computers in general than women (Chua, Chen & Wong, 1999; Coffin & Machintyre, 2000; Colley, Gale & Harris, 1994; Whitely, 1997).

The limited empirical research on gender differences in computer anxiety, attitudes towards computers, and computer experiences among working adults reveals conflicting results, however. By the early 1990s, only 25 studies presented sufficient statistical information that could be converted to correlations, and an additional 13 qualitative research reports supported only slight differences between men and women in computer anxiety (Rosen & Maguire, 1990). In contrast, other studies reported no gender differences associated with computer use in the workplace.

More specific studies found stronger correlations and gender differences. One of the most frequently cited studies on computer anxiety is by Rosen, Sears, and Weil (1987). They examined the relationship between computer anxiety and gender role as measured by the Bem Sex Role Inventory (Bem, 1974). This instrument identified individuals as belonging to one of four identity groups: masculine, feminine, androgynous, or undifferentiated. They found that feminine-identity individuals had more computer anxiety and more negative computer attitudes than did masculine-identity individuals, regardless of gender. Another influential instrument employed extensively in early studies on microcomputer anxiety in management is the Computer Anxiety Rating Scale (CARS) developed by Raub (1981). Raub investigated math anxiety, gender, age, trait anxiety, and knowledge of computers as possible correlates of computer anxiety. She suspected a gender effect based on the negative socialization of women toward mathematics, science, and technology and on the resulting production of anxieties. Raub found the relationship between computer anxiety and gender so strong that she ran separate regressions for males and females.

CARS has been used in more recent research as well. Anderson (1996) utilized CARS to determine whether or not perceived knowledge of software, computer experience, overall knowledge of computers, programming experience, and gender were predictors of computer anxiety. Table 1 displays the CARS portion of the Anderson questionnaire. Collaborating Raub's results, Anderson's study showed higher computer anxiety is accompanied by less experience and less perceived knowledge of computers, and that at higher levels of computer anxiety, women are over-represented.

Indirectly, the use of CARS led to the introduction of statistical modeling as a more formal investigation of the psychological mechanisms that trigger computer anxiety and the remedies for it. For example, the work of Howard (1986) is distinctive during the 1980s in its similarity to more recent research on computer anxiety. Howard developed a sequence of models addressing the predictors of computer anxiety and the use of computers in management. In schematic form, Figure 1 shows the possible relationships between psychological variables and the attitudes of managers toward the usefulness of microcomputers as management tools. Howard's study confirmed that computer anxiety is a significant inverse correlate of managers' positive attitudes toward microcomputers.

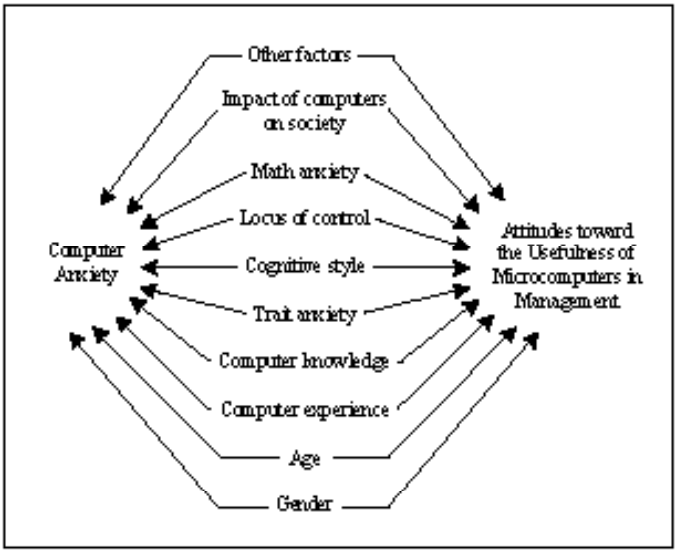
Similar to Raub, Howard speculated that gender may correlate with math anxiety and possibly with computer anxiety. Gender as a math anxiety correlate reflects psychological differences between men and women with regard to mathematics that may result from early socialization of females away from scientific and technical endeavors. If math anxiety and computer anxiety are similar phenomena, then they are likely to have common psychological roots. Thus, for both Raub and Howard, the prime psychological root of computer anxiety appeared to be that certain people simply did not see themselves as technological types. Math anxious types see mathematics and computers and all the paraphernalia of technology as for someone else and when required to use it experience stress.

A current perspective of Howard's usefulness of microcomputers research is several recent studies examining the

Table 1. The Computer Anxiety Rating Scale (CARS) is based on research by Raub (1981)

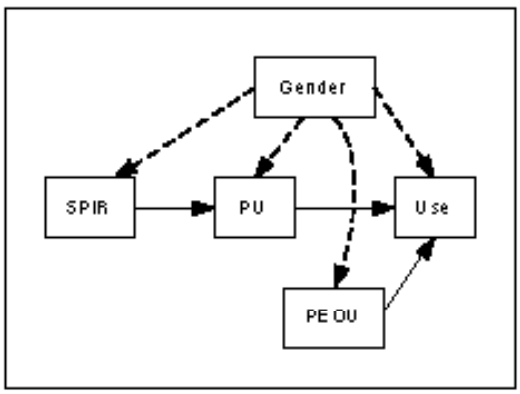
The responses are scaled as follows: 1 = Strongly Agree 2 = Agree 3 = Unsure 4 = Disagree 5 = Strongly Disagree
Items 2 through 10 are reverse scored so that high scores indicate high levels of computer anxiety. 1. I am confident that I could learn computer skills. 2. I am unsure of my ability to learn a computer programming language. 3. I will be able to keep up with the important technological advances of computers. 4. I feel apprehensive about using the computer. 5. If given the opportunity to use a computer, I'm afraid that I might damage it in some way. 6. I have avoided computers because they are unfamiliar to me. 7. I hesitate to use the computer for fear of making mistakes that I cannot correct. 8. I am unsure of my ability to interpret a computer printout. 9. I have difficulty understanding most technological matters. 10. Computer terminology sounds like confusing jargon to me.

Figure 1. Computer anxiety and other possible correlates of managers' attitudes towards microcomputers adapted from Howard (1986)



diffusion of information technology (IT) in the workplace. Many of these studies have demonstrated a strong link between self-efficacy and individual reactions to computing technology, both in terms of adoption and use of computers, and in terms of learning to use computer systems and applications. Beliefs about our capabilities to use technology successfully are related to our decisions about whether and how much to use technology, and the degree to which we are able to learn from training (Compeau, Higgins & Huff, 1999). While inconsistencies in group differences exist, overall findings of IT diffusion research suggest that women and men exhibit different perceptual tendencies and usage patterns in computer-related circumstances (Chou, 2001; Gefen & Straub, 1997; Hackbarth, Grover & Yi, 2003; Venkatesh, Morris & Ackerman, 2000).

Figure 2. Gender effects on TAM variables (Gefen & Straub, 1997)



Gefen and Straub (1997), and Venkatesh, Morris, and Ackerman (2000) are two prevalent examples of IT diffusion research predicated on influential theories evaluating information technology perception and use: the Technology Acceptance Model (TAM) and the Theory of Planned Behavior (TPB). Gefen and Straub (1997) modeled IT diffusion by extending TAM and the Social Presence/Information Richness (SPIR) factor addendum to include gender in the context of e-mail system usage. Figure 2 shows the effects of gender on TAM and cultural extensions, specifically the perceived attributes of SPIR, perceived ease of use (PEOU), and perceived usefulness (PU). Gefen and Straub sampled 392 female and male knowledge workers using e-mail systems in the airline industry in North America, Asia, and Europe. Study findings indicated that women's perceptions of e-mail are different from male co-workers. Covariates gender and culture accounted for 37% of the variance in SPIR, 53% of the variance in PEOU, and 59% of the variance in SPIR, culture, and PU combined. In this study gender definitely had an impact on the IT diffusion process.

Using TPB as a framework, Venkatesh, Morris, and Ackerman (2000) investigated gender differences in the context of adoption and sustained usage of technology in the workplace. User reactions and technology usage behavior were studied over a five-month period among 355 workers being introduced to a new software application. Men's attitude toward using the new technology was strongly motivated by achievement needs and task-oriented or instrumental behavior. In contrast, women's attitude toward using the new technology was more strongly influenced by subjective norm and perceived behavioral control. Sustained technology usage behavior in both men and women was driven by early usage behavior, emphasizing the importance of gender-based early evaluations of a new technology.

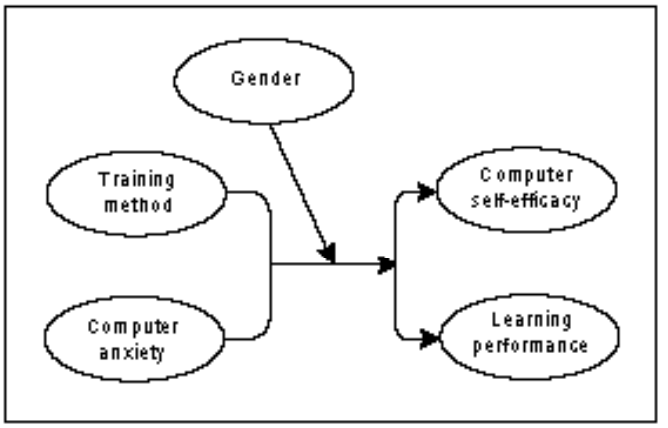
The above studies suggest several implications: when marketing IT and considering its effects, the gender of the users should be considered; and when training users on particular information technology such as e-mail systems, groups composed primarily of women should be addressed in a different manner than mixed or mainly masculine groups. When training mostly female groups, user friendliness and the ability of the system to convey the presence of the communicator should be emphasized.

Computer training has been widely researched and considered an essential contributor to the success of organizational computing. Computer anxiety and attitudes toward computers have often been identified as the critical factors influencing computer learning performance and training methodology. From the late 1980s up to today, the relationship of training techniques and personal characteristics has played a key role in training end users of information systems.

Characteristic of such training studies, Chou (2001) developed a conceptual model to evaluate how training method, an individual's gender, and computer anxiety level affect learning performance and computer self-efficacy. Chou used two types of training methods: an instruction-based method and a behavior-modeling method. The instruction-based method is a traditional approach that teaches primarily by lecture and follows a deductive way to learning, where learners proceed from general rules to specific examples (Davis & Davis, 1990; Simon, Grover, Teng & Witcomb, 1996). On the other hand, the behavior-modeling approach is a task-focused method involving a visual observation of the behaviors of a user performing a task. Learners then imitate and extend the demonstrated behavior in practice and experimentation to master the task. The behavior-modeling method employs an inductive approach that teaches by hands-on demonstrations first, followed by complimentary lectures (Compeau & Higgins, 1995; Gist, Schwoerer & Rosen, 1989). Figure 3 shows Chou's research model. In this model, gender was proposed as a moderating variable that moderates the effects of training method and computer anxiety on both learning performance and computer self-efficacy. When the training methods were tested on students, gender effects in general were found to be significant: male subjects performed better then female subjects. Male students had better learning performance, higher computer self-efficacy, and lower computer anxiety. Female students had significantly lower self-efficacy and a lower self-image about their computer learning capabilities. The behavior-modeling method appeared to enhance the computer self-efficacy of male students, whereas the instruction-based method benefited female students, suggesting that instruction technique preference varies with gender.

Studies on the relationships between computer anxiety, learning performance, and gender contribute solid knowledge about end-user training potential. This knowledge aids educators and trainers in the development of more personalized

Figure 3. Moderating effects of gender on computer self-efficacy and learning performance (Chou, 2001)



and therefore effective training programs for groups and individuals (Bostrom, 1998; Chou, 2001; Davis & Davis, 1990; Santhanam & Sein, 1994).

FUTURE TRENDS

In the developing research area of profiling Internet users, extrapolation of the computer anxiety literature offers parallels between gender differences in Internet use and differences in expertise and attitudes towards computers. It is widely assumed that women's participation in the Internet is hampered by their attitudes towards computers, which in turn is reflective of their attitudes towards new technology (Durndell & Haag, 2002; Gackenback, 1998; Jackson, Ervin, Gardner & Schmitt, 2001; Kraut et al., 1998; Schumacher & Morahan-Martin, 2001; Weiser, 2000).

Supporting this claim, Durndell and Haag (2002) utilized a Computer Self-Efficacy Scale, a Computer Anxiety Scale, and an Attitude to the Internet Scale in obtaining information from 74 female and 76 male university students on their Internet usage. Durndell and Haag found significant gender effects throughout, with males tending to report greater computer self-efficacy, lower computer anxiety, more positive attitudes towards the Internet, and longer use of the Internet than females. Similarly, Schumacher and Morahan-Martin (2001) reported males feeling more comfortable and competent with computers and the Internet. One explanation is that males, from childhood on, have more experience with computers than females, especially with games and programming that enhance technological sophistication and increase overall levels of competence and comfort with computers. Sussman and Tyson (2000) suggested the nature of communication on the Internet may vary by gender, and Balka and Smith (2000) proposed gender differences in Web navigation strategies.

Employing psychological methodology, DeYoung and Spence (2004) designed an instrument, the Technology Profile Inventory (TPI), to profile information technology users for dynamic personalization of software interfaces. Their approach was to generate a broad range of items for assessing responses to information technology, to examine their factor structure in a normal population, and to investigate potential associations between the emergent factors and variables that have, in the past, been associated with responses to computers, including gender, age, experience with information technology, and use of information technology. In application, a Web page could conform itself to suit the technology profile of each user who encounters it, for instance, a program could display all of its options for someone high in "computer interest" while displaying only the most functional options for someone who just wants to accomplish a task as simply as possible.

CONCLUSION

Computers are a vital asset in today's business and education world. The emergence of computers and information systems has been perhaps the single largest factor influencing organizations during the past three decades. Despite the increasing dispersal of computers, there is significant evidence that individual computer usage is affected by the computer anxiety or fear of computers that is widespread, and negative attitudes towards computers in general. This suggests that the potential benefits of computers as aids to professionals may not be fully realized, and the success of using a computer is dependent on the user's acceptance and commitment. The presence of computer anxious individuals in the workplace can lead to performance problems, decline in motivation, work quality, and moral, and can increase errors,

absenteeism, interpersonal conflicts, and turnover (Brosnan, 1998; Mikkelsen, Ogaard, Lindoe & Olsen, 2002).

Historically, a commonly held stereotype of computer anxiety is that of a frightened female secretary, struggling to learn the new word processor that her (male) boss is making her use as a replacement for her old, trusty IBM Selectric typewriter. The majority of gender and computer anxiety research does not support this description—both the secretary and the boss in this story may be anxious, but for different reasons and with different implications. In this particular case role has a greater effect than gender. However, the confusing continuum of disagreement characterizing the role of gender as it relates to attitudes toward computers, and by extension, IT diffusion and learning performance in the workplace, carries on today. While men may still represent a majority of the IT workforce, the number of women in technology-oriented areas continues to rise. As a result, the implementation of new technology requires an understanding of the factors that are likely to lead to user acceptance and sustained usage across gender and experience levels.

Does gender matter when examining attitudes and anxiety toward computers? The only valid conclusion that can be drawn from the existing body of literature is: it is important, but we do not fully understand gender as a moderating variable in the context of computer anxiety. One standard recommendation is to do more research and bring to the forefront the need to be cognizant of sex differences. The hypothesis that some users will have less overall experience with computers and are therefore more likely to have negative attitudes towards computers should be kept in mind when creating, adopting, and using information technology systems. Also, if cognitive style is distributed differently across genders, which it currently appears to be, it too may be a relevant factor in IT diffusion. One way to ameliorate these differences is for new technology introductions to be accompanied by user involvement, training, and active practical use. Special attention should be paid to the user's sex and their experience level. Because of the ramifications in society, education, and the workplace, educators and managers need to know how to recognize computer anxiety and the strategies to help alleviate or eliminate it. It is important that future research has focus and direction, and answers larger questions, such as: understanding how high levels of computer anxiety develop; what role such anxiety plays in career choices; and constructing methods to reduce computer anxiety within technological environments.

KEY TERMS

Cognitive Style: Information processing habits that represent an individual's typical modes of perceiving, thinking, remembering, and problem solving. Various cognitive styles have been identified, measured, and shown to affect the manner in which individuals perceive their environments. As just one example, two such styles are field-independence and field-dependence. Field-independent individuals perceive objects as separate from the field, impose personal structures on the environment, set self-defined goals, work alone, choose to deal with abstract subject matter, are socially detached and rely on their own values, and are self-reinforcing. In contrast, field-dependent individuals tend to rely on the environment for clues about an object, prefer a structure provided by the environment, experience the environment more globally, are interested in people, use externally defined goals, receive reinforcement from others, focus on socially oriented subject matter, and prefer to work with others (Riding & Rayner, 1998; Witkin, Moore, Goodenough & Cox, 1977).

Computer Anxiety: The tendency of a particular individual to experience a level of uneasiness over his or her impending use of a computer, which is disproportionate to the actual threat presented by the computer. Computer anxiety, defined by Raub (1981), is "the complex emotional reactions that are evoked in individuals who interpret computers as personally threatening."

Computer Anxiety Rating Scale (CARS): A self-report inventory consisting of 10 statements designed to measure computer anxiety. The scale comprises a mix of anxiety-specific statements (e.g., "I feel apprehensive about using the computer") and positive statements (e.g., "I am confident that I could learn computer skills") (Raub, 1981).

Computer Self-Efficacy: Computer self-confidence or perceptions of ability. Beliefs about one's ability to perform a specific behavior or task on a computer.

Locus of Control: Individuals' perceptions of whether they themselves influence events and outcomes in their lives (internal control), or that events and outcomes are influenced by factors such as luck, fate, chance, or powerful others (external control). Locus of control is considered a trait characteristic that is unlikely to change significantly in an individual's lifetime.

Math Anxiety: The psychological fear or anxiety associated with engaging in mathematical activity. Characteristics of math anxiety are an above-average number of negative attitudes (e.g., nervousness, solitude, uneasiness, and low confidence) and/or intense emotional reactions to math based on past experiences. Math anxiety and test anxiety are generally significant correlates and somewhat resemble computer anxiety as a situational manifestation of a general anxiety construct.

Perceived Ease of Use (PEOU): The degree to which an individual believes that using a particular information technology system would be free of effort. An application perceived to be easier to use than another is more likely to be accepted by users (Davis, 1989).

Perceived Usefulness (PU): The degree to which an individual believes that using a particular information technology system would enhance his or her job performance. A system high in perceived usefulness is one that a user believes has a positive usage to performance relationship (Davis, 1989).

Social Presence/Information Richness Factor (SPIR): A factor appended to TAM derived from Hofstede's (1980) work on dimensions of cultural differences among countries

that include a disposition toward masculine attitudes and other behavioral indexes. The extension combines perceived social presence and the sense of human contact embodied in a medium with the information richness of the medium (Straub**,** 1994).

Technology Acceptance Model (TAM): A causal model hypothesizing that actual information technology system use is affected by behavioral intentions that themselves are affected by attitudes toward use. Beliefs about the system, perceived usefulness, and perceived ease of use in TAM directly affect attitudes toward use (Davis, 1989).

Technology Profile Inventory (TPI): A psychological instrument that generates technology profiles to predict how individuals are likely to respond to various aspects of information technology. The ability to profile information technology users facilitates the design of software capable of dynamic personalization (DeYoung & Spence, 2004).

Theory of Planned Behavior (TPB): Defines relationships among beliefs, attitude toward a behavior, subjective norm, perceived behavioral control, behavioral intention, and behavior. The theory has been widely applied across a range of disciplines such as marketing, consumer and leisure behavior, medicine, and information technology. When applied in technology adoption and usage contexts, TPB explains an individual's adoption of new technologies (Ajzen**,** 1991).

Trait Anxiety: Traits are properties of individuals that dispose them to react in certain ways in given classes of situations. Trait anxiety is a chronic predisposition to be anxious and nervous that may be based on feelings of inadequacy, usually due to poor past performances, low-self image, or low-self esteem.

Genetic Algorithms in Multimodal Search Space

Marcos Gestal
University of A Coruña, Spain

Julián Dorado
University of A Coruña, Spain

INTRODUCTION

Genetic algorithms (GAs) (Holland, 1975; Goldberg, 1989) try to find the solution for a problem using an initial group of individuals—the population—where each one represents a potential solution.

Actually they are successfully applied in very different and actual fields (Yang, Shan, & Bui, 2008; Yu, Davis, Baydar, & Roy, 2008); nevertheless, GAs have some restrictions on a search space with more than a global solution or a unique global solution, together with multiple local optima. A classical GA faced with such a situation tends to focus the search on the surroundings of the global solution; however, it would be interesting to know a higher number of possible solutions for several reasons: precise information about the search space, easy implementation of the local solutions compared with the global one, simple interpretation of certain solutions compared with others, and so forth. To achieve that knowledge, an iterative process will be executed until reaching the desired goals. Such process will start with the grouping of the individuals into species that will independently search a solution in their environments; following, the crossover operation will involve individuals from different species in order not to leave unexplored any search space area. The process will be repeated according to the goals achieved.

BACKGROUND

Multimodal Problems

There are problems that do not exclusively have a unique global solution, but they have multiple optima, either global or local: the multimodal problems (Ehrgott, 2005).

For dealing with such type of problems, it is interesting to know the higher possible number of solutions. On one hand, the knowledge about the problem might not be complete; this fact leads to the uncertainty about the goodness of the obtained solution, as it cannot be guaranteed that no better solutions might be found at the unexplored search space. On the other hand, and even achieving the best solution, there might be other possible solutions that, due to different reasons (economy, simplicity), might be preferable.

BRIEF INTRODUCTION TO GENETIC ALGORITHMS

GAs are adaptive methods, generally used in problems of search and of parameter optimization, based on sexual reproduction and on the "survival of the fittest" theory (Tomassini, 1995; Beasley, Bull, & Martin, 1993; De Jong, 2002).

A population, a group of individuals where each one represents a potential solution that will evolve through different generations, is initially created. The best individual would tend to be kept after several evolutions, but other less-fitted individuals will be also kept in order to keep diversity. The diversity will enable that there might be individuals with different characteristics that could, some of them, be suitably adapted to the eventual changes on the environment.

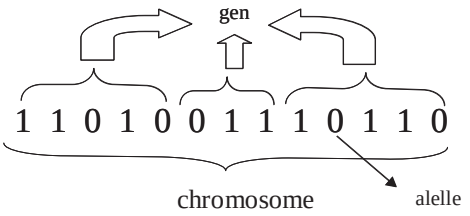
The best-fitted natural individuals are those that have more possibilities of having descendants, following the natural selection principles proposed of Darwin (1859).

In nature, individuals usually establish different groups, each of them specialized in different tasks: hunting, harvesting, and so forth. But the traditional GAs do not envisage this possibility for reaching several solutions; the present work will study an extension that will bear this in mind.

Problems Encoding

Any potential solution to a problem can be represented by providing values for a series of parameters. The whole of these parameters (or genes) is codified by a strand of values: the chromosome. The encoding is usually done by means of binary values, although other representations can also be used (see Figure 1).

Figure 1. Genetic individual



Main Algorithm

The generic functioning of a classic GA can be observed in Figure 2. A generation is obtained from a previous one by means of the reproduction operators. There are two types: the crossover and the copy. The crossover is a sexual reproduction that originates new descendants after the exchange of the genetic information of the parents. In the second case, a given number of individuals pass, with no variation, to the following population. Once the new individuals have been generated, the mutation is carried out with a P_m probability in such way that the transcription failures, which occurred in the copy of the genetic material during the sexual reproduction, are mimicked.

The GA run finishes when there are solutions good enough shaped as best individuals, when they all concur on a similar value, or when a prefixed generation's maximum number is reached.

For the GA to work correctly, a method should also exist that might indicate whether the population individuals represent or not, and to what extent, good solutions for the problem put forward. The later task would be carried out by the evaluation function, which establishes a numerical measurement (fitness) of the solution goodness (Koza, 1992).

EVOLUTIONARY APPROACHES TO MULTIMODAL PROBLEMS

Several approaches related to evolutionary techniques have been tried. A brief summary is shown in this section.

The modification proposed here is based on niching techniques. These are techniques that try to make and maintain stable subpopulations in GAs. This idea comes from nature, where individuals have different roles that allow them to survive in their natural ecosystems. These roles are called "ecological niches." Given some maximums, and given a limited capacity to locate them, the best niching algorithm will choose the global maximum. In addition, since they are not selective, they will keep both global and local maximums.

Different niching techniques have emerged throughout time. Some of the most important are:

- *Fitness Sharing:* This was first implemented by Goldberg and Richardson (1987) for its use with multimodal functions. This technique uses the concept of similarity

Figure 2: GA pseudocode

```
initialise current population randomly
WHILE the termination criterion is not fulfilled
 create temporal empty population
 WHILE temporal population don not fill
    select parents
    cross parents with Pc probability
   IF the crossover has occurred
               mutate one of the descendants with Pm probability
         assess descendants
        add descendants to the temporal population
   ELSE
      add parents to the temporal population
   END IF
END WHILE
increase generation counter
establish the temporal population as current new population
END WHILE
```

to determine the level of sharing between individuals of the same population. The fitness is scaled according to the similarity level with other individuals of the same population. It has two components: distance function (which measures the overlapping between individuals) and sharing function (returns "1" if the individuals are identical, or values closer to "0" as the difference between individuals increases). Based on this technique, Miller and Shawn (1995) propose a variant using a dynamic variation of the fitness.

- *Cavicchio's Pre-Selection:* This pre-selection is applied in Cavicchio (1970) so the good descendants replace one of their parents to maintain diversity. Therefore, the good individuals are favored respect by their neighbors, being later affected by crossovers and mutations. This is required by the complexity of the used chromosomes.
- *De Jong's Crowding:* The replacement of the existing individuals with the descendants is based on their similarity. The new individual is compared with a random subset of the population. The individual of this subset that presents more similarity with the new one is replaced. This technique is based on the natural effect produced when two similar individuals compete for the same resources in natural populations(De Jong, 1975). There are other variants of crowding. Among them, one of the most important is Mahfoud's (1992). An example of a more recent approach is found in Thomsem (2004).

These techniques have several limitations, some of them very common, like the necessity of calibrating the functions that control the niching process. This requires an a priori knowledge of the problem environment. A more important problem is that it is necessary to have a definition of similarity between individuals, but if the problem is not well understood, it will be complicated to specify a good function. As will be shown below, a grouping algorithm has been adopted here, independently of the problem domain.

Another type of technique used for the resolution of multimodal problems is *particle swarm optimization* (PSO) (Kennedy & Eberhart, 1995, 2001; Clerc, 2004; Iwamatsu, 2005). This technique is based in the social behavior of several organisms, like bird flocking or fish schooling. The search procedure is based in the changes of the positions of the individuals, named particles, through the multidimensional search space. During its movement, each particle updates its position according to its experience and to the experience of a neighbor particle, making use of the best position found by it and its neighbor. Therefore, it combines local and global search methods, trying to find a balance between exploration and exploitation.

GENETIC ALGORITHMS WITH DIVISION INTO SPECIES

During the course of evolution, the individuals tend to gather themselves into different species that will be adapted to a given environment and will evolve differently. It would be as much optimal individuals as species. Besides, sometimes the individuals, due to different reasons, will split from the initial group for them to experience crossover with individuals belonging to other groups from different places.

When a multimodal problem is intended to be solved, it is interesting to find several solutions. The use of traditional GA is not optimum for that scenario because, as generations advance, they tend to focus the search near the best solution. However, there are several options for at least minimizing this problem.

The simpler and most immediate (but inefficient) option would be the execution of the GA several times. This alternative randomizes the management of the problem to a great extent; other disadvantages are the repetition of solutions or the time-consuming execution until reaching the goal.

A more efficient technique, from the computational and solution quality viewpoint, implies the grouping of individuals of the genetic population into species; in such way, each of these species will carry out the search of a different solution.

Broadly speaking, the grouping technique into species entails gathering the initial population into groups of similar individuals. It is hoped that every group could specialize in a given search space area. Each species will search a solution existing in its surroundings that will be different from the ones provided by the rest of species.

The natural distribution of individuals into species and their separate evolution is tried to be mimicked. In nature, there are individuals adapted to cold, dry, or hot environments; each group keeps its life in a given environment by means of adapting specific characteristics that distinguish it from other groups.

Nevertheless, this technique is not free of disadvantages; certain requirements are needed for a good functioning, and they are not directly achieved during the initial arrangement of the problem. For instance, it should be desirable that the population could be perfectly distributed throughout the whole search space, as well as that the groups were fairly distributed along that space and in a quantity in accordance with the number of total solutions of the problem. Unexplored areas might exist if these characteristics were not present; in contrast, there might be another area highly explored where, depending on the grouping procedure, several species might coexist. Most of these problems can be avoided by means of an automated mechanism for the number of existing species. It seems clear that if the number of solutions is different for

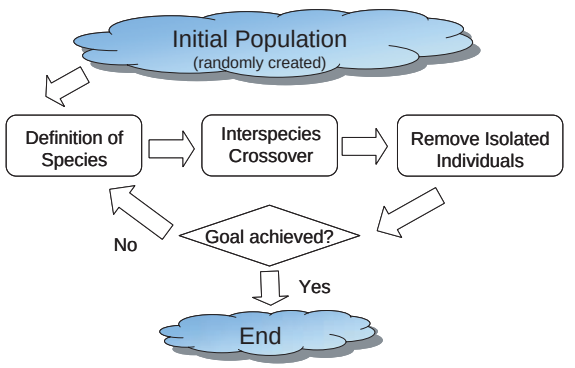
different problems, the GA should be the one who manages the number of evolved species in each generation.

In order to do this, the GA will be allowed to expand the starting number of species as generations advance. The increase of the species number will be achieved by performing crossover on individuals from different species throughout several generations. As the resulting descendants mix the knowledge from the species of their ancestors, a new species can be created in a different location from the ones of their progenitors. In this way, the species stagnation can be avoided and the exploration of new areas, together with the appearance of new knowledge, may be obtained; in short, environment diversity is achieved. As individuals might migrate or be expelled and afterwards create new, the performance of individuals is again modeled in their natural environment.

From an initial population generated for these techniques to be implemented, some following steps take place (see Figure 3):

1. random creation of the genetic population,
2. organization into species with similar characteristics,
3. application of the GA on every species,
4. introduction of new individuals coming from the crossover on different species (These individuals are located in another area of the search space. A variant of the functioning implies the elimination of the individuals that, after several generations, do not create a species large enough.); and
5. verifying whether the number of evolutions reaches the maximum allowed or if the population reaches a top level of individuals (defined at the beginning of the execution).

Figure 3. Overview of the proposed system



If some of these conditions are not fulfilled, the algorithm execution finishes; if they are, the individuals of the existing population will again be arranged into species (step 2).

As Figure 3 shows, the process is quite similar to standard parallel GAs. The main difference resides in points 3 and 4. Usually parallel GA involves different populations in isolated ways. After a predefined iteration count, an interchange of individuals is produced between populations. Here, there is only one population where GA differences between species instead of multiple populations are usual. So, crossover operations are able to produce individuals that will be inserted in the according population (different form original) when the grouping algorithm will be re-executed. So, species are really a mechanism to allow the execution of a set of iterations of an internal GA which involves only the individuals of that species. It allows improving the task of reaching the local optima.

Furthermore, as grouping algorithm is executed before each iteration, it allows that population size not be fixed; even the individuals within each population vary between iterations.

Grouping Algorithms

The grouping process of the genetic individuals into species is a key value in the proposed solution. Non-supervised grouping techniques have been chosen for carrying this grouping out. The classification is done according to concrete parameters that are specific for each type of grouping algorithm and that will later be discussed.

The most relevant of these heuristic methods are the *adaptive method* and the *algorithm of Batchelor and Wilkins,* also known as the *maximum distance algorithm* (Batchelor & Wilkings, 1969).

The adaptive method is a heuristic method that uses two intimately related parameters: τ, acting as the distance threshold for creating the groups, and θ, τ fraction that indicates up to what extent two individuals should have similarities for belonging to the same species. The basic functioning of the algorithm involves the incremental creation of groups; every one of the samples and a portion of the whole of patterns to be grouped will be individually processed. According to the distance threshold, it can be established whether they belong to an existing group or if a new group should be created.

The main advantage to be highlighted is its simplicity, as it is an algorithm that bases the grouping on simple comparisons and it does not additionally need the predetermination of the number of groupings. However, it has some disadvantages, the main one being that the grouping is biased by the patterns first used for the learning, meaning that it depends on the sequence of presentation.

The algorithm of Batchelor and Wilkins is also an incremental heuristic method that only uses a unique parameter, θ, which determines the mean distance among the existing

groups. It is used for calculating a distance threshold useful for deciding whether a new grouping should be created. As in the adaptive algorithm, θ value ranges as follows: $0 \leq \theta \leq 1$.

Basically, the algorithm creates a group if the distance from a given pattern to the nearest group exceeds the threshold value. Different from the adaptive algorithm, the distance threshold is not fixed and it is calculated according to the θ parameter and the mean distance among the existing groups.

Figures 4 and 5 show grouping examples of the use of grouping algorithms on the same initial sample set. It can be observed that, although both groups are not identical, they are quite similar.

The yellow area of Figure 4 is the acceptance area. The intermediate area is the uncertainty area. Despite that the figure represents the final stage, these mentioned areas are used as acceptance criteria throughout. In this way, it is considered that the individuals within the yellow area belong to that class and they have influence on its center. On the contrary, the individuals within the uncertainty area will induce the execution of the algorithm until the stabilization, until they cannot belong to any other group.

Tests

Once the approach for obtaining multiple solutions has been defined, it should be tested on different examples. The first

Figure 4. Adaptive method example

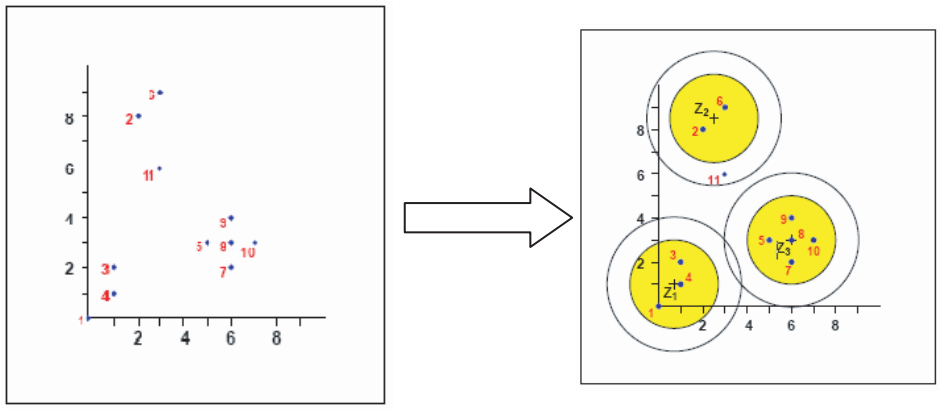


Figure 5. Batchelor & Wilkins algorithm example

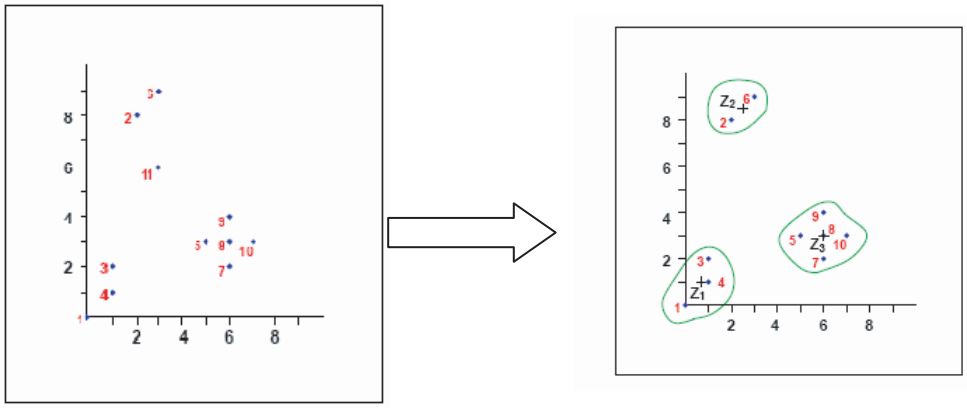

of them will include an undetermined number of equations that, therefore, would have infinite possible solutions. This simpler example will facilitate the adjustment of the configuration to the different parameters that are involved in the process.

Resolution of an Undetermined Equation System

As has been mentioned, the proposed approach will be applied on an undetermined equation system (see Figure 6). The solution to such a system is the straight line that crosses the two planes, so the solutions will be infinite; it might be then considered a multimodal system.

The individuals ought to have (m-1) genes. Each one will represent the value designated for each unknown factor in order to solve the equation system.

The fitness value will be the addition of the absolute values of the differences between each of the independent terms specified in the system and the independent terms obtained after replacing the genotype values in the subsequent equation.

Several steps of the evolution are graphically represented in Figure 7. Each subfigure represents up until what extent the solutions provided by the GA are close to the straight line that represents the solution of the undetermined equation system. Every one of the red spots represents the place where the best individual is after all the foreseen generations. On the other hand, the appearance of a line indicates the movement of a species along that generation. If no line is present, it means that the change of location of the best individual along evolution is small. Figure 7 seems to show that the proposed solution is valid for providing multiple solutions to a problem.

The same example has been used for approximately determining the optimum GA execution parameters. Obviously, the final configuration will depend on the specific problem, but the values in Figure 8 could be perfectly used as a starting point. The validity of a given parameter-value partnership is tested by executing the application and checking not only the number of found solutions, but also the additive error of all the solutions.

Figure 6. System representation

$$\begin{aligned} 2*x + 2*y + 6*z &= 0 \\ x - y + 25*z &= -22 \\ 2*x + 2*y + 6*z &= 0 \end{aligned}$$

Rastrigin Function

The Rastrigin function is a good example of a multimodal problem. The GA has been applied with the proposed modifications on a Rastrigin function with two variables, and it

Figure 7. Example of execution

Figure 9. Rastrigin function: Example of execution

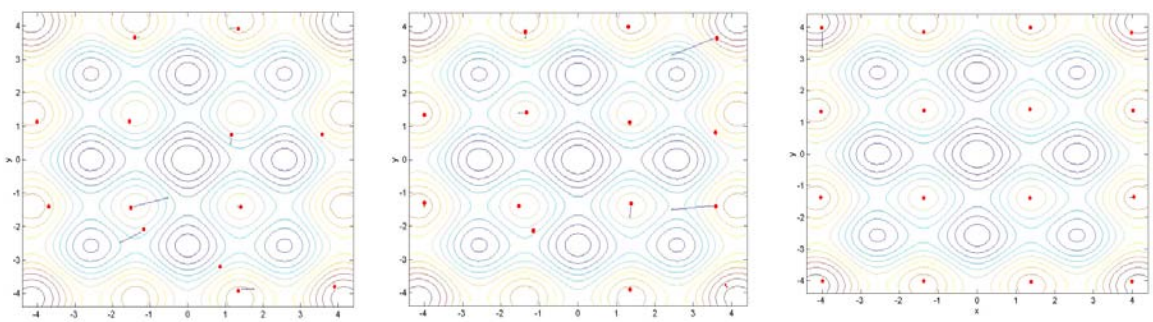

Figure 10. Rastrigin function: Evolution of the number of individuals

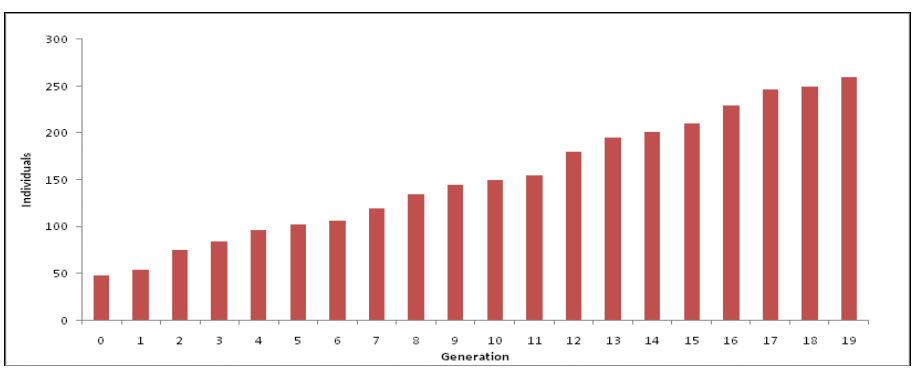

can be observed in the following example, where the results are clearly and legibly represented with graphs. In this case, the explored space is between X = [-4..4] and Y = [-4..4], where there are 16 maximums clearly identifiable.

Figure 9 shows that almost all the existing optimums of the specified search space are obtained after less than 20 generations. In this example is also interesting to see that the number of individuals increase as generations advance (see Figure 10). This increment is due to the fact that the inter-species crossovers create new individuals in unexplored areas of the search space and therefore originate new species as generations advance.

FUTURE TRENDS

The mutation operator is currently applied on the crossover-generated individuals. However, it should be desirable that it could be applicable on any randomly chosen individual in order to increase the diversity of the global population. This variant, and some others, should be implemented for providing the user with the option of choosing among them according to a specific problem.

Another aspect to be improved is the response time. In problems where the evolution of the individuals has high computational cost, it should be desirable to distribute the application execution among different machines in order to achieve a considerable reduction of time.

CONCLUSION

Due to the Gas' traditional trend of returning a unique solution for a given problem, they are not an optimal option for the search of solutions to multimodal problems. The present work has proposed the division of the population into species for them to individually search a solution in their own development areas. In this way, the solutions are found in a more organized way, not having to execute the GA with the whole of the population, but within each species.

Nevertheless, a problem arises when dividing the problem into species and applying the GA to them. If the species finds a solution in its area, it tends to remain there, as the exploration of its boundaries does not achieve anything better. After several evolutions, there would be species fixed on a solution, but others would not find any because there are no solutions in their surroundings. The crossover between different species avoids the stagnation. The resulting individuals will not strictly belong to the species of their progenitors, but they will belong to a different species. Therefore, new species will appear in order to increasingly cover, as much as possible, the complete search space. The validity of such approaches can be observed in the examples.

KEY TERMS

Diversity: Measure of the genotypic difference between different individuals. It is necessary to keep a high ratio of diversity to explore in depth the search space and avoid a premature gene convergence due to the genetic drift.

Evolutionary Technique: Technique that tries to provide valid solutions for a specific problem using concepts taken from nature or biology, such as survival of fittest.

Fitness: Value derived from the evaluation of an individual with respect to its reproduction capability. This measure determines the goodness of the solution encoded by an individual. Usually, selection in evolutionary algorithms depends on the fitness.

Genetic Algorithm: A special type of evolutionary technique where the potential solutions are represented by means of chromosomes (usually either binary or real sets of values). Each gene (or set of genes) represents a variable or parameter within the global solution.

Genotype: Set of values (real, binary, …) that codifies the internal solution representation to which the crossover and mutation operators are applied.

Multimodal Problem: Special kind of problem with several global solutions or one global solution with several local peaks instead of a unique global optimum.

Niching: Separation of individuals according to their states in the search space or maintenance of diversity by appropriate techniques, for example, local population models, fitness sharing, or distributed evolutionary algorithms.

Phenotype: Expression of the properties coded by the individual's genotype. The precise definition of phenotypes is mostly problem dependent. For parameter optimization the phenotype is usually identical with the object parameters, whereas for structure optimization (e.g., of neural networks) the phenotype represents a specific structure (in this case, the genotype represents the value parameters of the structure).

Search Space: Set of all possible situations of the problem that want to be solved. Combination of all the possible values for all the variables involved with the problem.

Species: Within the context of genetic algorithms, subset of genetic individuals with similar genotypes (genetic values) that explores a similar area in the search space.

Geographic Information Systems as Decision Tools

Martin D. Crossland
Oklahoma State University, USA

INTRODUCTION

Geographic information systems (GISs) as a technology have been studied and reported extensively and, not unexpectedly, in the field of geography. The various ways of capturing spatial data, arranging attribute data into appropriate database structures, and making the resulting large data sets efficient to store and query have been extensively researched and reported (Densham, 1991). However, the geographic research community has only recently noted the need to study how GISs are used as decision tools, especially with regard to how such decision making might be related to a decision maker's cognitive style (Mennecke, Crossland, et al., 2000). As an example, the University Consortium for Geographic Information Science called for research examining how geographic knowledge is acquired through different media and by users with different levels of experience and training (University Consortium for Geographic Information Science, 1996).

Researchers in the fields of decision sciences and information systems have more recently begun to make contributions in the area of decision making with GISs. When a GIS is employed as a decision support system, in these studies the resultant system is often referred to as a *spatial decision support system,* or *SDSS* (see Crossland, 1992; Crossland, Perkins, et al., 1995; Mennecke et al., 2000).

A *geographic information system* in its simplest form is a marriage of accurately scaled digital maps with a database. The digital maps comprise spatially referenced details such as natural elements (lakes, rivers, topographic elevation contours, etc.), manmade objects (buildings, roads, pipelines, etc.), and political boundaries (city limits, state and county lines, international boundaries, etc.). These natural elements are typically referenced, with varying degrees of precision, to latitude/longitude coordinates on the earth's surface. It must be noted here that the degree of precision and, more importantly, differences in degrees of precision for the various elements are the subjects of much research and user consternation in applications of GISs to solving problems. The database, in turn, catalogs information about the various spatial elements (e.g., the names of rivers, names of buildings, building owner, operator of a pipeline, etc.). These descriptive entries in the database are often referred to as *attributes* of the various spatial elements.

A GIS may be paired with the *global positioning system* (*GPS*), from which real-time, satellite-derived location information may be derived, as provided by an appropriate GPS receiver.

BACKGROUND

With regard to the effectiveness of decision making when using information tools, there is a relatively long history of researchers emphasizing that tools which provide graphical presentations and graphical representations of information are deserving of special note and study. For example, Ives (1982) discussed at great length the role of graphics in business information systems. He even went so far as to state, "The map, perhaps more than any other chart form, gains the most from the availability of computer graphics" (p. 16).

Several more recent studies have drawn from Image theory (Bertin, 1983) to help explain why decision makers using GISs may experience greater effectiveness in decision making. Image theory states that one graphical representation of information may be considered more efficient than another for a particular question, if that question can be answered in the mind of the decision maker in a lesser amount of time. In his *Semiology of Graphics*, Bertin defined image theory and put forth the constructs of images and figurations. An *image* is a meaningful visual form, perceptible in a minimum instant of vision. A *figuration* is a more complex construction comprising multiple images. Figurations are inherently less efficient than images, according to image theory. This is because the viewer is able to grasp the full informational content of an image in a brief moment of viewing it. Figurations, on the other hand, comprise multiple images which must be mentally extracted, processed, and related in the viewer's perception. Although the informational content may be richer in a figuration, it is inherently less efficient for quick extraction of specific information.

The more recent studies propose that one role of GISs is to collapse more complex figurations into simpler figurations or even to simple images. This has the net effect of increasing a decision maker's efficiency in extracting relevant information for the purpose of evaluating and making a decision. For examples the reader is encouraged to review Crossland

(1992), Crossland, Herschel, et al. (2000), Crossland et al. (1995), and Mennecke et al. (2000).

Although there seems to be a common assumption that GISs improve decision making (Morrison, 1994), only a few studies to date have performed controlled experiments to actually test this assumption. Those that have been accomplished typically used dependent variables of decision time and decision accuracy to measure decision-making effectiveness. These include Crossland (1992), Dennis and Carte (1998), Mennecke et al. (2000), Smelcer and Carmel (1997), and Swink and Speier (1999). All of these studies found that the addition of a GIS to a spatially referenced decision-making task had a positive effect on decision outcomes.

THE ROLE OF COGNITIVE STYLE IN DECISION MAKING WITH GISS

With respect to decision making, the term *cognitive style* has been used to refer to enduring patterns of an individual's cognitive functioning that remain stable across varied situations. Various elements of cognitive style have been speculated upon and studied in various disciplines. With respect to decision making using GISs, two elements have been studied in some depth, *field dependence* and *need for cognition*.

Field dependence (FD) measures a person's ability to separate an item from an organized field or to overcome an embedded context (Witkin, Lewis, et al., 1954). Zmud and Moffie (1983) proposed that people with lower field dependence tend to outperform those with higher field dependence in structured decision tasks and that they tend to make more effective use of transformed information (e.g., aggregated values and graphical formats, such as are typically found in a GIS). FD can be measured using commercially available testing instruments. Because making decisions using a GIS, by its nature, involves mentally extracting relevant information from a potentially complex field of information, studies have hypothesized that low field dependence should predict better decision making with a GIS or other spatially referenced tool. In particular, field dependence is seen as an inverse proxy for an individual's level of spatial cognition—the ability of an individual to grasp and analyze information within a spatial context.

Need for cognition (NFC) was proposed by Caccioppo and Petty (1982) as a measure of a person's internal motivation to pursue and enjoy cognitive tasks and activities. They developed a questionnaire which can be used to measure this cognitive-style attribute. People who score high on the need for cognition scale tend to enjoy the engagement of thought activity in a task as much or more than even the result of a task. The studies named below hypothesized that this tendency to engage more fully in a task should lead to more effective decision making, as measured by the dependent variables of decision time and decision accuracy.

Studies that looked at FD, NFC, or both as independent variables of decision-making performance using GISs include Crossland (1992), Crossland et al. (1995), and Mennecke et al. (2000). In general, the findings may be summarized as follows:

- Field dependence exhibits an inverse main effect on decision time, but not on decision accuracy. That is, subjects with lower field dependence tend to solve spatially referenced problems more quickly, but not more accurately. It may be that the efficiency predicted by image theory does contribute to faster decision making, but not to more accurate decisions.
- Need for cognition exhibits a positive main effect on decision accuracy, but not on decision time. That is, higher-NFC subjects tend to solve spatially referenced problems more accurately, but not more quickly. This last finding was noted as unexpected by Crossland (1992). He speculated that perhaps an individual with a high NFC might tend to spend longer in thinking about the problem and its solution, thereby extending the decision time. It would seem, however, that this extra thinking effort may have contributed to a more accurate solution.

FUTURE TRENDS

Some questions and issues in this area of research that remain to be addressed include:

- How do other important measures of cognitive style affect a decision maker's ability to solve spatially referenced problems accurately and quickly?
- How does problem complexity factor in or even interact with the decision maker's task? Several studies also examined problem complexity as an independent variable (Crossland, 1992; Crossland et al., 1995; Mennecke et al., 2000). Crossland et al. (1995) reported an observed interaction of field dependence with problem complexity that would be interesting to explore further.
- To what extent are SDSSs/GISs effective in collapsing figurations (as defined by image theory) into images or into simpler figurations? Are there certain levels of complexity beyond which it becomes impractical or ineffective to combine or collapse displays into simpler decision tools? How does the cognitive style of the decision maker factor into this consideration?
- Are SDSSs/GISs even necessary for certain types of problems? Perhaps a series of static, hard-copy outputs are sufficient for some decisions by some decision makers, and the combined or flattened displays are not

necessary. The cognitive style of the decision maker may be an important factor in this.

- Studies in this area may be useful in understanding more generally how technology is useful in supporting decision makers in other contexts. For example, Vessey (1991) and Vessey and Galletta (1991) suggested that three variables would influence the mental representation that the decision maker develops: (1) the problem representation, (2) the problem-solving task, and (3) the decision maker's problem-solving skills.
- It may be useful to apply cognitive fit theory to these types of problem-solving tasks, as proposed by Mennecke et al. (2000), to better understand the factors that appear to be important in influencing a user's formation of a mental representation of spatial tasks.

CONCLUSION

The roles of components of cognitive style of a decision maker are important factors in how well he can solve problems and carry out spatially referenced tasks when using a GIS. Although current research has shown that simply using a GIS can enhance decision-making effectiveness, the cognitive style of the subject is a less well understood element of the process. More research is needed in this area to better define and understand it.

KEY TERMS

Attributes: are the pieces of information contained in a GIS database that describe or detail a spatially referenced element.

Cognitive Style: refers to enduring patterns of an individual's cognitive functioning that remain stable across varied situations.

Digital Map: any form of geographic boundaries or spatially referenced drawings that have been captured, or "digitized," into an electronic form. Each element of the map is or may be linked to various descriptive or identifying types of information in a database.

Field Dependence (FD): measures a person's ability to separate an item from an organized field or to overcome an embedded context.

Figuration: as defined in image theory, is a complex construction comprising multiple images. Figurations are inherently less efficient for extracting information than images, according to image theory.

Geographic Information System (GIS): a marriage of accurately scaled digital maps with a database. The digital maps comprise spatially referenced details such as natural elements (lakes, rivers, topographic elevation contours, etc.), manmade objects (buildings, roads, pipelines, etc.), and political boundaries (city limits, state and county lines, international boundaries, etc.). These natural elements are typically referenced, with varying degrees of precision, to latitude/longitude coordinates on the earth's surface.

Global Positioning System (GPS): provides real-time, satellite-derived location information based on information received by an appropriate GPS receiver. GPS is funded by and controlled by the U.S. Department of Defense (DOD). While there are many thousands of civil users of GPS worldwide, the system was designed for and is operated by the U.S. military. A GPS may be employed in the original construction of the digital map information to be stored in a GIS. Or, if the GIS is already constructed, the GPS may be employed to accurately render the position of new elements to be added to the GIS or the current position of a mobile element to be referenced against the information stored in the GIS. A good example might be a freight truck moving on a highway. The GPS receiver on the truck can derive its current latitude and longitude and then send that information to the GIS system in the truck cab, to a GIS in a central control center via radio, or to both for subsequent reporting and analysis.

Image: as defined in image theory, is a meaningful visual form, perceptible in a minimum instant of vision.

Need for Cognition (NFC): a measure of a person's internal motivation to pursue and enjoy cognitive tasks and activities.

Spatial Decision Support System (SDSS): typically, a geographic information system (GIS) that has been extended to provide knowledge workers with decision-making tools and support data.

Spatially Referenced Data: entities, typically recorded as records in a database, which have some notion of a definite location in space.

INTRODUCTION

From John Snow's pioneering work on cholera in the 19th century until the present day, placing illness and disease within the context of a geographic framework has been an integral, if understated, part of the practice of public health. Indeed, geographical/spatial methods are an increasingly important tool in understanding public health issues. Spatial analysis addresses a seemingly obvious yet relatively misunderstood aspect of public health, namely, studying the dynamics of people in places. As advances in computer technology increase almost exponentially, computer intensive spatial methods (including mapping) have become an appealing way to understand the manner in which the individual relates to larger frameworks that compose the human community and the physical nature of human environments (streets with intersections, dense vs. sparse neighborhoods, high or low densities of liquor stores or restaurants, etc.). Spatial methods are extremely data intensive, often pulling together information from disparate sources that have been collected for other purposes such as research, business practice, governmental policy, and law enforcement. Although initially more demanding in regard to data manipulation compared to typical population level methods, the ability to compile and compare data in a spatial framework provides information about human populations that lies beyond typical survey or census research. We will discuss general methods of spatial analysis and mapping that will help to elucidate when and how spatial analysis might be used in a public health setting. This discussion will include a method for transforming arbitrary administrative units, such as zip codes, into a more useable uniform grid structure. In addition, a practical research example will be discussed focusing on the relationship between alcohol and violence. A relatively new Bayesian spatial method will be part of this example.

BACKGROUND: GIS CAPABILITIES AND PREVENTION

A basic understanding of the capabilities of geographic information systems (GISs) is critical to the development of prevention activities because alcohol-related problems are not evenly distributed across space. GIS can be defined as a combination of computer hardware, software, spatial data (digital maps), and data with a geographic reference (e.g., alcohol outlets or crime locations) that facilitates spatial analysis. The key functions of GIS provide access to the broad spectrum of potential spatial analyses that can support the simple targeting of resources as well as the development of more complex models of spatial interactions. Both simple maps of problem rates or clusters and spatial interaction models may be useful for targeting traditional individual-based prevention programs or environmental interventions. Spatial interaction models, however, may be more appropriate for identifying the locations of events (e.g., assaults or crashes) that may be most amenable to environmental or regulatory prevention. In addition, GIS capabilities promote the development of a basic spatial/geographic epidemiology of alcohol use and related consequences, which is critical to the development of prevention programs (see Wieczorek, 2000, and Wieczorek and Hanson, 1997, for more details).

The key functions of GIS include geocoding, data overlays, reclassification functions, and distance/adjacency measures. Geocoding is a generic term used to describe the GIS function of providing a specific location to descriptive data. Geocoding applies to point data (e.g., alcohol outlet)

as well as to area data (e.g., number of assaults in a census tract). Sometimes geocoding is known as address matching because the process of matching points to addresses is very common. The advent of the Census Bureau's TIGER system has made geocoding a relatively low cost and widely available GIS function. However, professional geocoding services have developed to assist persons who are not comfortable in geocoding their own data or because of the high cost of updating digital maps based on TIGER in areas of changing population. Geocoding is the most basic of GIS functions because it transforms descriptive information into a format suitable for spatial analysis.

A GIS-based map may consist of multiple sources of data. The ability to combine multiple layers of information is known as the overlay function. An example of an overlay function is to place geographic boundaries (such as the outline of a town) on top of individual points (such as residences of DWI offenders). The points within each area can then be automatically counted to create rate-based maps such as those shown in Figure 1. To create rate-based maps from relevant point information, at least three layers of data are necessary (i.e., map of the points, a map with relevant boundaries, and Census data on population). The ability to perform an intersection between separate maps, to aggregate data into meaningful geographic areas, and to link data to standard sources, such as Census data, highlights some of the processing capabilities of GIS overlay functions, processes nearly impossible to accomplish by non-automated methods (see Wieczorek & Hanson, 2000, for an example using regions and mortality data).

One major contribution of GIS to prevention is its ability to provide useful visualizations of spatial data. The reclassification function of GIS allows the user to easily manipulate the number of categories or select specific information (e.g., crashes by time of day or day of the week) for display. Figure 1 shows how the reclassification function can assist in the targeting of prevention by reclassifying the same data to emphasize highest rate areas.

A second major contribution of GIS to prevention is that the technology enables the development of models of spatial patterns and interactions within and between populations and environments. These models require accurate information on the distance between individual objects (e.g., bars and traffic crashes) and their spatial relationships to one another. Distance and adjacency functions of GIS allow assessments of these relationships. Data generated from these assessments of spatial relationships can be exported from the GIS and used in spatial modeling software. Information about adjacencies of different geographic objects can be used to assess contributions of environmental features (e.g., bars) to problematic public health outcomes in surrounding areas (e.g., assaults) (Gruenewald et al., 1996; Lipton & Gruenewald, 2002). Other important GIS functions are based upon the assessment of distance relationships: neighborhood functions calculate the number of a specific characteristic (e.g., assaults) within a specific radial distance (e.g., 300 yards) of

Figure 1. Reclassification and targeting prevention

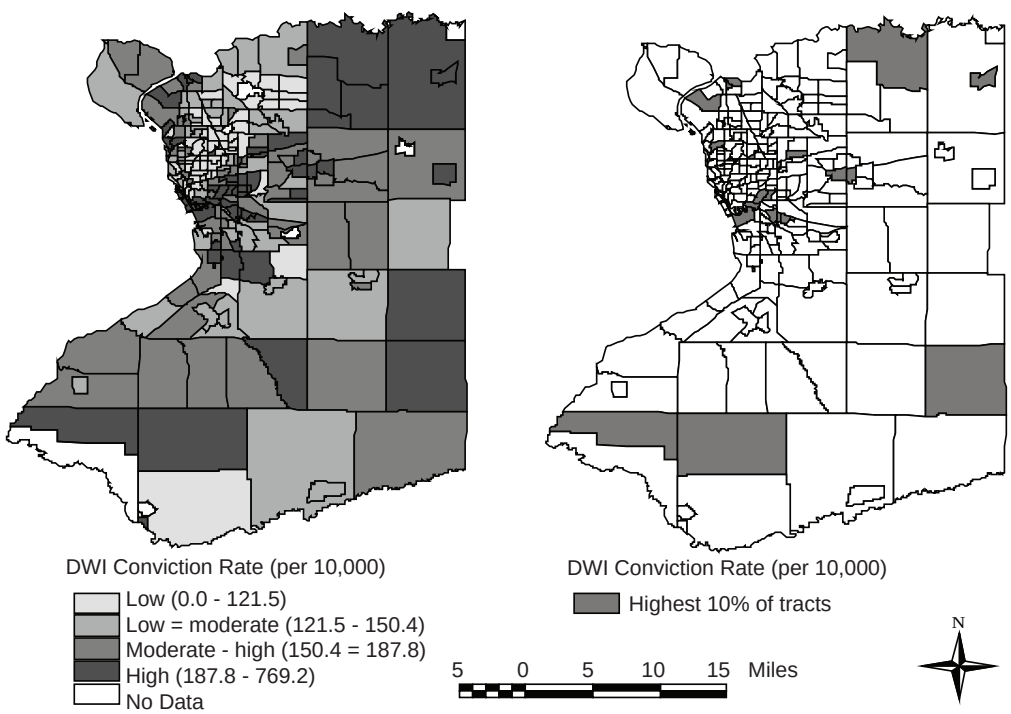

Figure 2. Significant spatial scan clusters of alcohol-explicit mortality

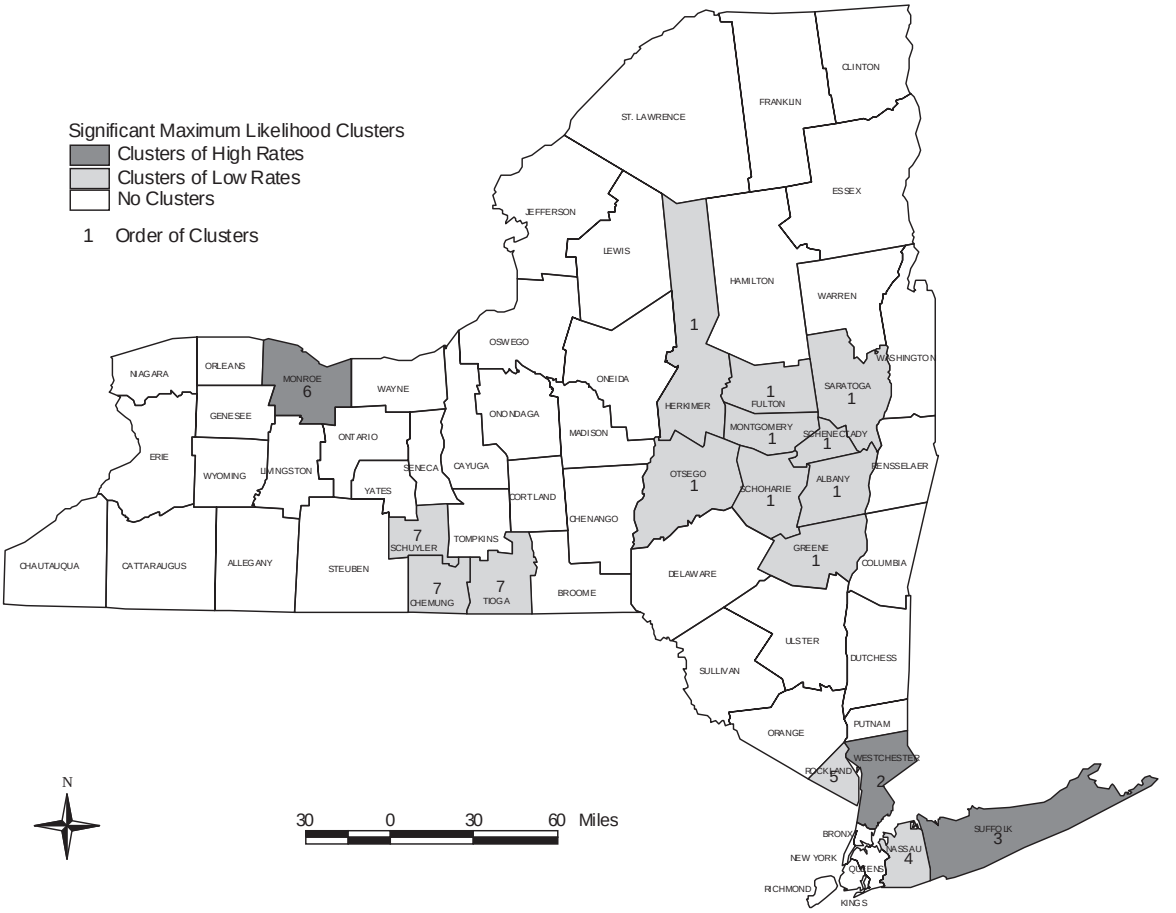


point features (e.g., bars). Buffer functions use the distance function on a complex feature, such as the road network, to identify points within a set distance of the feature (e.g., homes of DWI offenders within 400 yards of a bus line). These GIS functions can also be combined in complex ways to provide new insights for targeting prevention activities to areas with the greatest need (see Harding and Wittman, 1995, for additional applications in support of prevention).

Spatial Clusters

Spatial clusters are a greater than expected geographically close group of occurrences or events (e.g., deaths, crashes, alcohol outlets). Spatial clusters are a natural result of spatial dependencies in the data; by definition, spatially dependent data will have an uneven geographic distribution. The use of spatial cluster analysis was pioneered for finding cancer clusters, especially for rare cancers (Aldrich, 1990; Ricketts, Savitz, Gesler, & Osborne, 1994). Specific spatial clustering techniques can be used with point or geographic area data and may also be used for space-time cluster analysis to examine temporal trends (Jacquez, 1994). Spatial cluster analysis is useful for identifying areas with significantly high or low rates of alcohol problems where services can be targeted, to identify new research questions (e.g, why are rates highest in certain areas), to empirically identify the appropriate scale of analysis in small area studies, and to examine the impact of interventions on communities over time (e.g., do the clusters change or disappear in response to interventions).

It is important to note that low rate clusters are as important to identify for prevention purposes as high rate clusters. High rate clusters clearly have problems that require prevention/intervention; however, low rate clusters may be areas at high risk of developing problems, especially if the low rate area is embedded in surrounding high rate areas. Characteristics of low rate areas may also provide important insights into factors important for prevention application in high problem locations. Figure 2 shows a map of spatial scan clusters of alcohol-related mortality in New York. Note that both high and low rate clusters are identified. The analysis of county-level data also shows the potential for regional level prevention approaches.

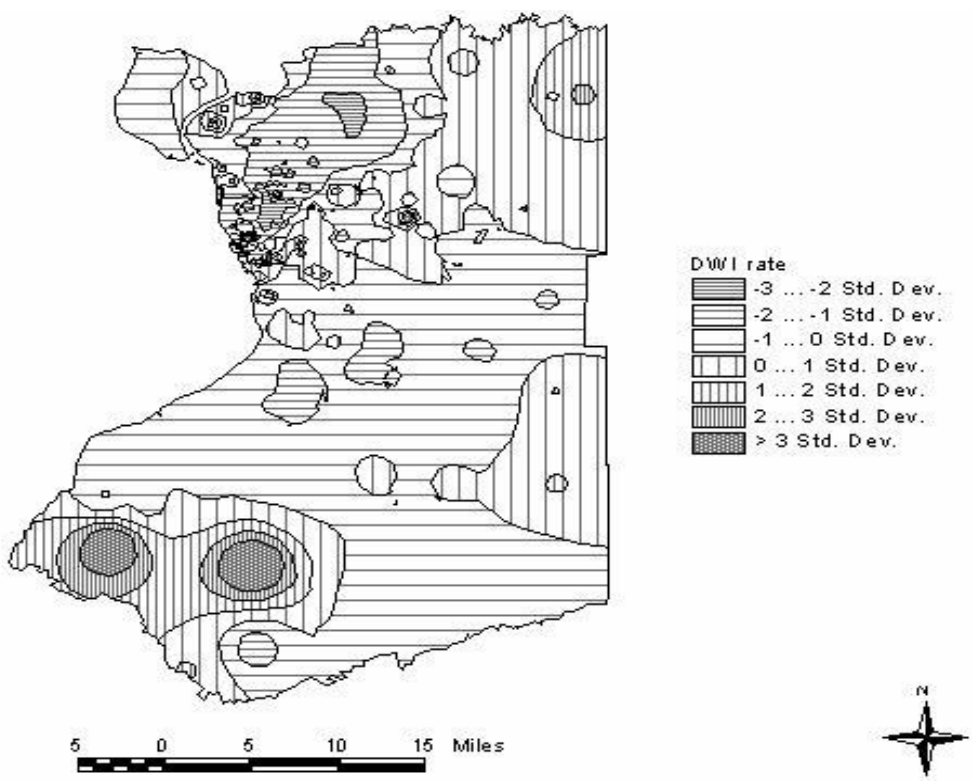
Other Spatial Analytic Techniques

Three additional approaches deserve mention in the context of spatial analysis for prevention. The first technique is a relatively simple method to control spatial autocorrelation in multiple regression analysis. Spatial autocorrelation, correlated measurement error between spatially adjacent units, is a substantial source of statistical bias in these analyses. The method is to use a GIS to calculate a generalized spatial potential for the dependent variable used in multiple regression of geographic area data (e.g., Census tracts or zip code areas). Wieczorek and Coyle (1998) provide an example of this technique in the context of targeting the neighborhoods of DWI offenders. A generalized spatial potential (GSP) for the DWI rate was calculated for each tract by summing the ratio of DWI rates (V) and distances (D) to every other tract ($GSP_i = V_1/D_1 + V_2/D_2 + \ldots V_n/D_n$). By including the GSP as an independent variable in multiple regressions, some aspects of biases due to spatial autocorrelation can be controlled (allowing more appropriate interpretations of model coefficients and statistical tests). This approach is not as statistically complete as direct methods for assessing and controlling spatial autocorrelation (see Gruenewald et al., 1996), but it is a substantial improvement that may be implemented relatively easily.

The second technique is the development of continuous surface models, or "kriging." Kriging is a modeling technique for spatial data that can be used to develop contour maps (e.g., maps that show lines of equal value such as DWI rates) from a limited number of assessment points or areas (Isaaks & Srivastava, 1989). These continuous surface models overcome a central limitation of area data: that actual rates within the geographic areas are unlikely to be as uniform as suggested in area maps. Kriging creates a continuous surface model by overlaying a grid of cells over the entire areas and calculating a weighted value for each cell based on the distance to surrounding centroids. The values calculated for the grid are then used to create a contour map. An example of kriging is provided in Wieczorek and Hanson (1997). Figure 3 shows a continuous surface model created by applying kriging to the specific tract rates used to generate Figure 1. A continuous surface model may provide a more realistic version of geographic variation that can be used to target prevention and assist in the overall planning of alcohol-related services.

The third technique allows for the transforming of zip code level data into a uniform geo-spatial Grid. Zip code information, due to its primarily administrative and political nature, is quite difficult to use for panel data analysis and public health purposes. Using irregular area units (like zip

Figure 3. DWI conviction rate continuous surface model

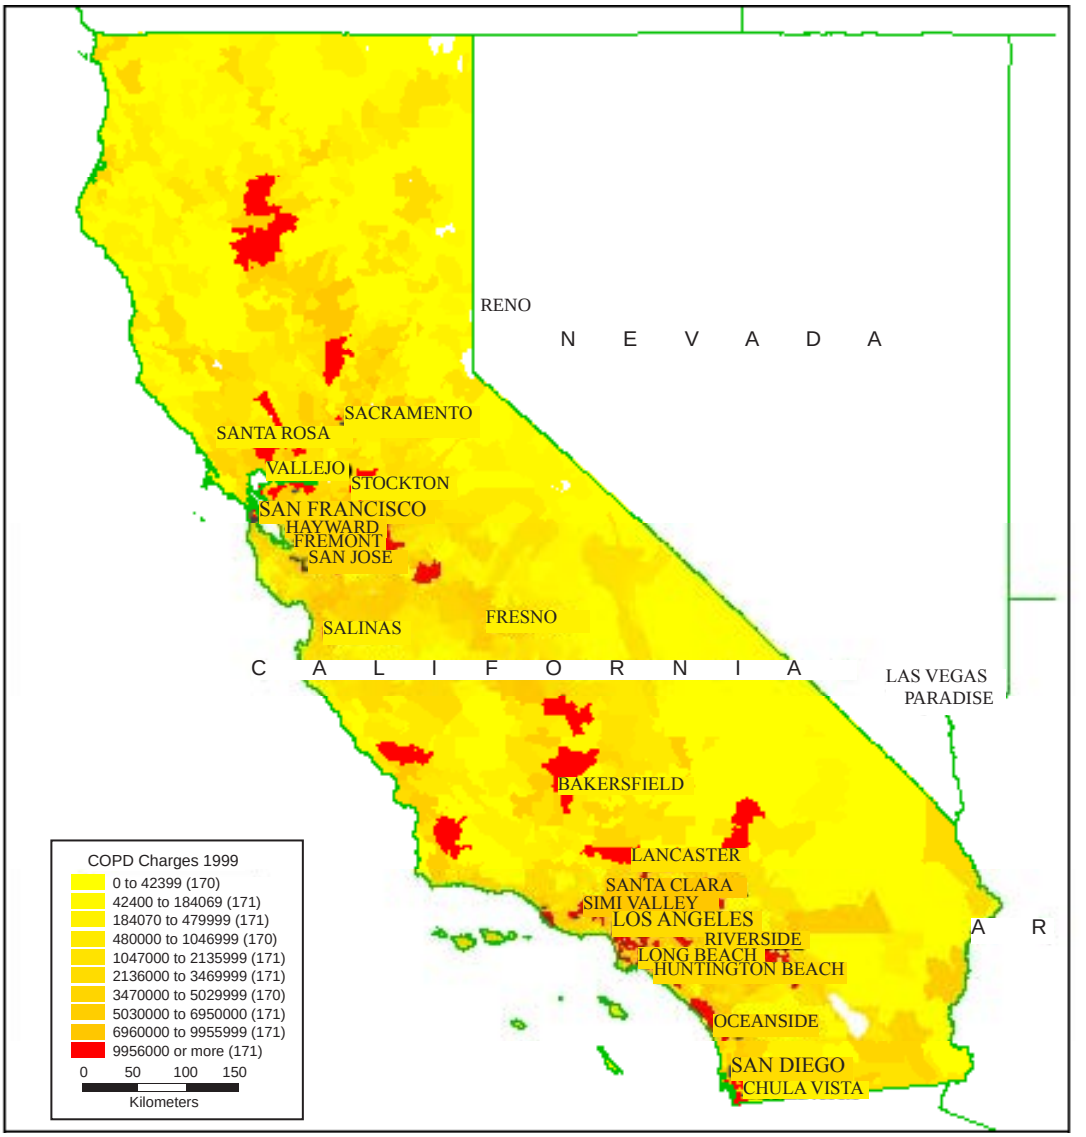


codes) for calculating disease risks poses problems of geo-statistical consistency. Changing the boundaries of collection units or grouping them differently produces different spatial patterns and gives rise to the Modifiable Areal Unit Problem or MAUP (Openshaw & Taylor, 1979). The ecological inference problem (or ecological fallacy) (Robinson, 1950), which refers to the failure to incorporate relevant, spatial information about individuals that changes the summary statistics, is a more generalized form of the MAUP.

According to Gotway and Young (2002), the MAUP and ecological fallacy are special cases of a mathematically well-defined problem known as the change of support problem (or COSP). COSP addresses the "specification bias" that can violate the properties of statistical inference and underpins the basis of probability theory (Hogg & Craig, 1995). Gotway and Young (2002) outline a combination of spatial smoothing and geo-statistical upscaling or aggregation of data with point support to avoid statistical pitfalls associated with the COSP. One way to minimize the effects of the COSP is to collect point addresses of health events so that they are not affected by scale changes. Flexible aggregation of these points with the help of a grid (as opposed to ZCTAs or census tracts) eliminates the effect of COSP. Although simple comparisons across time (panel data) are almost impossible with zip code analysis, they can be rendered in a straightforward fashion with this grid approach.

In one example examining chronic obstructive pulmonary disease (COPD) we employ a spatial overlay that applies a

Figure 4(a). COPD charges 1999 (ZCTA deciles)

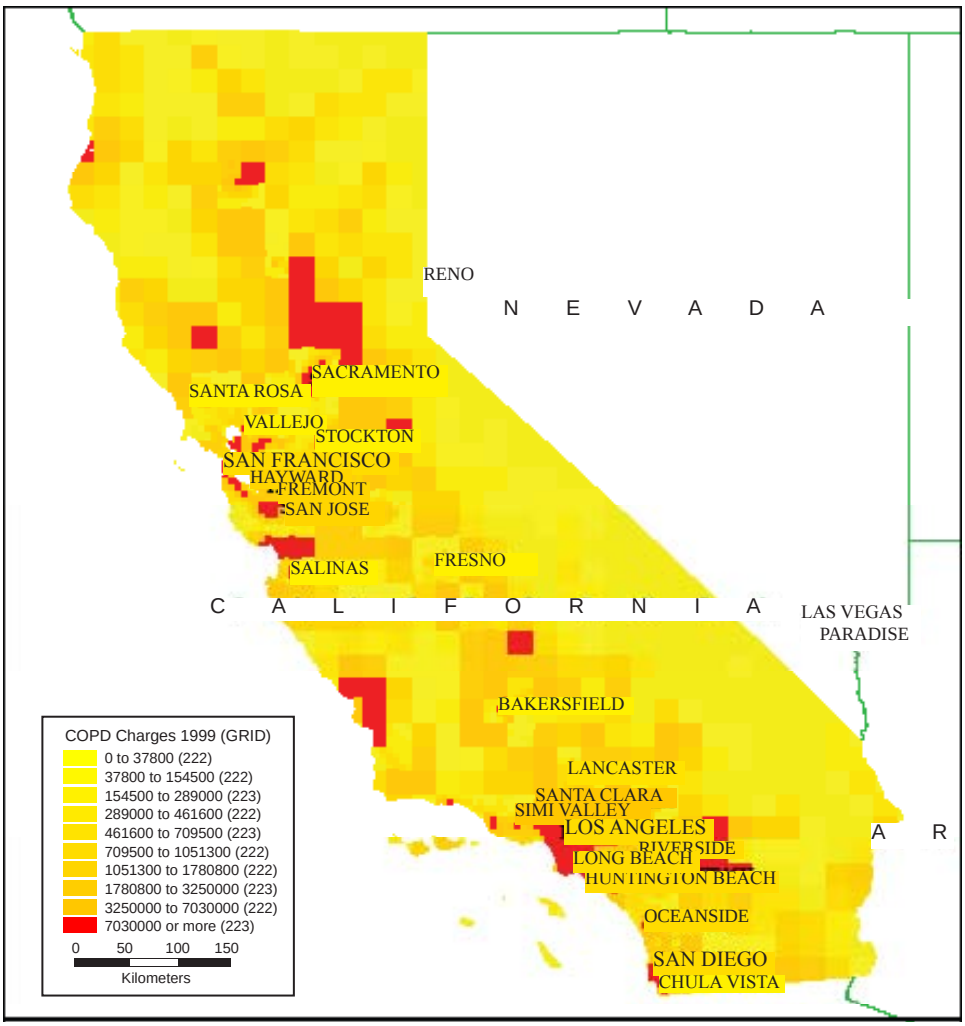


linear transformation of the zip code data to the grid, employing a "4 x 4" mile square grid for urban areas and a "16 x 16" mile grid for rural areas. This overlay procedure estimates the attributes of one or more features by superimposing them over other features and determining the extent to which there was overlap between the grid and a spatial unit—in this instance, the degree of overlap between a spatial unit and a zip code. Information for each zip code was then proportionally divided into their share of the grid by estimating the ratio of the area overlaid. Statistically, this equates to a transformation using a uniform probability density function from one area to another area of support (Goodchild & Lam, 1980). There were 1,527 zip code areas in 1993 and 1,707 zip code areas in 1999. After the spatial overlay procedure, both years had 2,224 grid units with exactly the same shape and size. In Figure 4a we show COPD hospital charges in 1999 by zip code, and in Figure 4b we show COPD charges using a uniform grid structure. While the two maps are similar in terms of showing differences across California for COPD charges, the uniform grid structure provides a much more consistent and manageable data source than the zip code map. Indeed, using a uniform grid structure for a temporal analysis eliminates differential statistical support thereby minimizing COSP (Gotway & Young, 2002). A possible disadvantage associated with this procedure is that some information will be lost when converting zip code areas into grid areas; however, the stability of the new units over time more than compensates for this by improving statistical support and minimizing statistical misspecification.

SPATIAL DECISION SUPPORT SYSTEMS (SDSS)

GIS can help us link traditional data analysis with good geo-spatial data. Traditional data analysis that deals with optimization, as in graph theory or network theory, can be

Figure 4(b). COPD charges 1999 (4&16 mile grid)



implemented in a geo-spatial context. For example, locating a new hospital where a certain outcome (like distance to patient population) can be minimized can be very helpful from a public health perspective.

Some of the applications of optimization (TransCAD, 2005) in a spatial and public health context are as follows:

- **Vehicle Routing:** Describes procedures used to provide efficient routes for making ambulance pick-up and deliveries, including restrictions on times at which stops are made and multiple vehicle dispatches during an emergency.
- **Partitioning:** Describes how districts (patient districts) can be created that optimize the hospital loads based on numbers served and minimized travel times for patients.
- **Facility Location Models:** Describes models that find efficient location for facilities (like new health centers in addition to old ones) that can optimize some objective (like improving level of service, cost of service, etc.).

These types of sophisticated analyses, can be viewed as a move (for spatial analysis) from mere data modeling to applying techniques of operations research—a highly developed field in applied and theoretical mathematics.

SPATIAL ANALYSIS: AN EXAMPLE FROM VIOLENCE PREVENTION

Knowing where problem events take place is different from knowing why they take place where they do. And understanding the etiology of public health problems in different geographic areas requires knowing all the spatial technologies discussed to this point and their suitable application in spatial statistical analysis, the use of spatial data for the purpose of explicating the etiological dynamics of public health problems. This section will provide an example of one such application, a first approach to understanding the environmental correlates of violence.

Much of the criminology and public health literature is concerned with the determinants of violence in different community areas. A particular focus has been upon the role of alcohol outlets in violence. Similar to the work of Morenoff, Sampson, and Raudenbush (2001) and Baller, Anselin, Messner, Deane, and Hawkins (2001), our analysis includes demographic and socio-economic data so as to capture violence related to population characteristics (i.e., high unemployment, low rates of high school graduates, etc.). These population characteristics are analyzed in relation to the moderating effects of alcohol outlets on the production of violence. Moderation can simply be thought of as interaction of outlets with people (with a mix of characteristics). This outlet interaction could serve to increase or decrease violence, depending on the composition of population characteristics and outlet presence and type. Further, we examine spatial components of these moderating effects. Rates of violence may be affected by characteristics of populations living in adjacent areas (Gorman, Speer, Gruenewald, & Labouvie, 2001).

Our analysis assesses whether such spatial relationships exist and controls for spatial autocorrelations that may obscure the relationship between population characteristics and the production of violence. The sample comprised 766 zip codes from four selected areas of California: Los Angeles, the Bay Area, Sacramento, and the northern section of the state. The first three areas are heavily urbanized, while the last is quite rural. The three urban areas are heterogeneous with regard to ethnic, age, and socio-economic composition, particularly in relation to the rural area that is more homogeneous in most population level measures. In this research, data are taken from three different sources: Census data (1990), using a three-item scale representing concentrated disadvantage, immigrant concentration, and residential stability, based on the work of Sampson, Raudenbush, and Earls (1997). Hospital discharge data for 1991, using patient home address, contained information on assaults. California state data on alcohol outlets (1991) gave type and address of outlet.

The graphic presented in Figure 5 outlines the general conceptual framework that guides the analysis. We hypothesize that populations of people produce assaults at a given rate that is moderated by population characteristics (e.g., greater in places where there are more young people) and environmental characteristics (e.g., where there are more alcohol outlets). This adjusted rate may be further modified by the numbers and characteristics of nearby populations (not shown). It is assumed that errors in estimation are not independent, but rather are spatially autocorrelated, r_s.

In Figure 6 assaults per roadway mile are presented for each of the four regions. The difference in concentrations of assaults is apparent in this map, with greater densities

Figure 5. Conceptual model and statistics for actual spatial regression

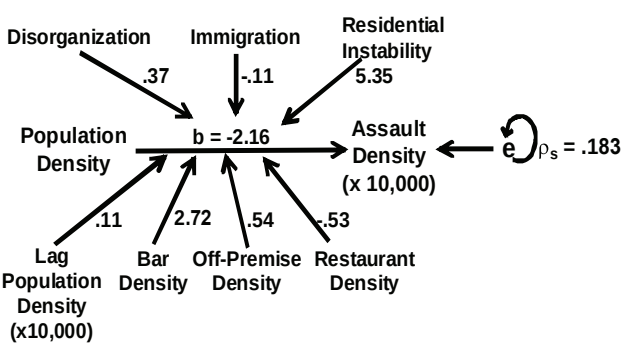


Figure 6. Assaults per mile of roadway

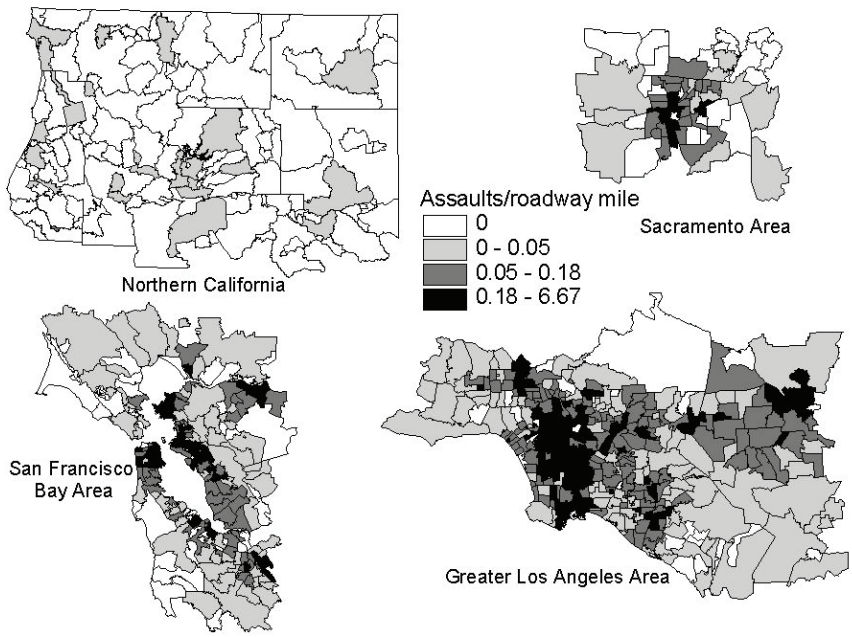


occurring where there are greater densities of population. This is not, however, universally the case. For example, the western region of the Los Angeles basin appears to exhibit relatively greater assaults than expected from the population distribution observed. Overlays of zip codes are represented on this particular map.

Table 1 and Figure 5 (note numbers in the figure) present the results of an analysis that includes the direct effects of population variables, alcohol outlets, and adjacent population density. Many, but not all, of the estimated coefficients from the model are significant. A direct interpretation of the coefficients of the model suggests that as population density increases, there is a reduction of approximately 2.16 assaults for every 10,000 persons in each zip code area. This rate, however, is that expected for an isolated population living in an area with no bars, restaurants, or off-premise alcohol establishments (and rather unrealistically, with values of zero for the measures of population characteristics). This rate is moderated, however, by the presence of large populations in adjacent areas, the densities of restaurants, bars, and off-premise establishments, and local population characteristics. This rate is greater in areas where bar densities are greater and restaurant densities are less. This rate is further greater in areas where social disadvantage is greater, immigrant presence less, and residential stability greater. Finally, the rate at which local population density produces assaults is greater in areas surrounded by larger populations.

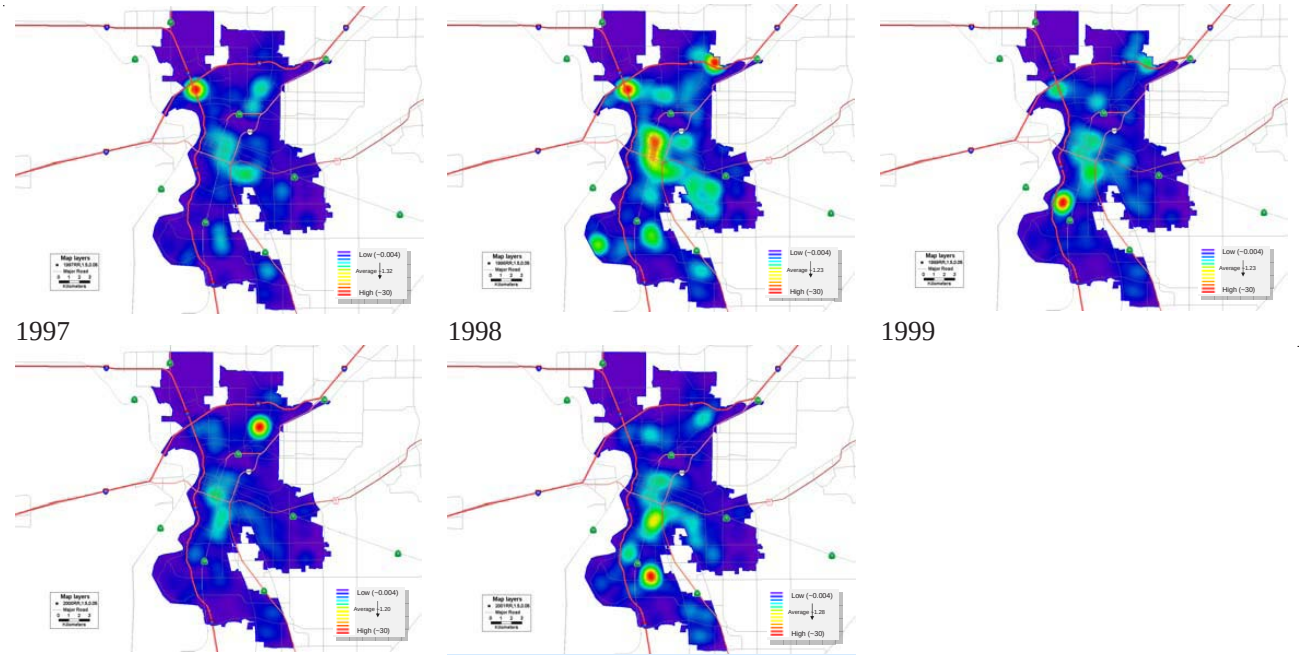
Table 1. Associations of outlet densities with rates of assault hospitalizations (x 10,000)

Variable Name	b:	t:	p:*
Population Density	-2.16	02.62	.009
Outlet Densities			
Bars	2.72	4.36	<.001
Off-Premise	.54	1.64	.101
Restaurants	-.53	-3.97	<.001
Population Characteristics			
Social Disadvantage	.37	32.74	<.001
Immigrant presence	-.11	-15.17	<.001
Resident Stability	5.35	2.41	.016
Adjacent (Lag) Population Density (x 10,000)	.11	2.21	.027
Model based estimate for spatial autocorrelation: $\rho_{s=}$ .183 ** Z = 3.51 P < .001			

**two-tailed significance*

*** a measure of spatial autocorrelation for the model*

Figure 7. Predicted changes in relative rates of assault using a Bayesian hierarchal modeling framework



The results of this analysis indicate that it is possible to construct a conceptually well-framed spatial analysis of assault rates that explains to a substantial degree variation in rates of assault between places in California. Shifting from a representation that suggests that outlets on their own create violence to one that presents outlets as providing contexts for violence, the usual pattern of relationships of violence to environmental densities of alcohol outlets continues to be observed. The current analysis suggests, however, that alcohol outlets moderate rates at which violence is produced within areas and that these effects persist when controlling for spatial effects and other covariates related to the production of violence in local populations (Table 1). Notably, positive relationships continue to exist between bar and off-premise outlet densities and assaults, with no relationship to densities found for restaurants (Table 1 and Figure 5). At the geographic scale of the current study (zip codes), greater rates of violence are observed in stable, non-immigrant areas with greater concentrated disadvantage. Bar densities, when controlling for other environmental or socio-demographic measures, are clearly connected to an increase in assaults. Thus, in this spatial example, beyond the obvious finding that denser populations have more assaults, we are able to observe important environmental effects that may be actionable in terms of prevention policy.

BAYESIAN MODELS

Before the advent of the Markov Chain Monte Carlo (MCMC) revolution in 1990 a small group of researchers, consisting of mathematical statisticians and theoretical probabilists, were involved with hierarchical Bayesian methods (Banerjee, Carlin, & Gelfand, 2004). MCMC made Bayesian methods popular due to its ability to translate the complex combination of theoretical random variables and random coefficients into numerical outputs for real world problems. Before MCMC, hierarchical Bayesian models were simple to construct but difficult to implement due to the lack of computing power to integrate hundreds and thousands of unknown parameters. Hierarchical Bayesian methods are suitable for spatial statistical applications. Modeling coefficients as random effects allows us to induce a specific correlation structure for the coefficients. Thus, a specified correlation structure such as spatial autocorrelation can be modeled within any multivariate study. For example, the relationship between violence and alcohol problems can be modeled at the local level using hierarchical Bayesian modeling. Gruenewald and Banerjee (2005) hypothesized that:

- **Hypothesis #1:** Drug activity will generally be related to levels of violence across neighborhood areas ("systemic" violence).

- **Hypothesis #2:** Drug activity will lead to explosive growth in related violence in areas where "core groups" form (core group subcultures).
- **Hypothesis #3:** Built environments in public areas (e.g., alcohol outlets) will tend to suppress violence associated with drug activities (surveillance, guardianship).

Analysis features:

- **City of Sacramento: Population 403,796 (1997) Years 1997-2001, 304 Census Block Groups (n * t = 1,520)**
- **Dependent Variable:** Number of Emergency Medical System (EMS) Assaults. At-site treatment for physical assaults by EMS.
- **Independent Variables:** Population size, percent population in poverty, number of Hispanics, number of African Americans, drug activities (police calls for service), number of bars, number of off-premise establishments.
- **Analysis Model:** Poisson space-time model with unit and time specific random effects and statistical controls for spatial heterogeneity (spatial autocorrelation) using Conditional Autoregressive Models implemented in a Bayesian framework. Asymmetric bootstrapped standard errors (Bernardinelli et al., 1995).

In Figure 7, we can see that when modeling the relative risk of assaults in Sacramento using Bayesian methods, over time, the loci of assaults shift. Such a result is only available using conditional hierarchal multivariate models. Although theoretically possible using traditional techniques, in reality, only Bayesian methods are currently practical. Further, the results described are in accord with the previous hypotheses, which provides a coherent dynamic spatial explanation for the production of violence.

FUTURE TRENDS

Spatial analysis in public health is in its infancy. This is due to the rapid increase in computing power that has only in the last few years allowed for a more comprehensive development of mapping and spatial statistical techniques. There are two general areas of development that are interrelated: (1) GIS will become more intuitive and popular with more data becoming accessible (e.g., through geo-coding techniques that will become more consistent and "industry standard" through time), and (2) spatial statistical methods will become more available and more user friendly with statistical software companies offering spatial statistical solutions. As the comfort level grows with both mapping and spatial statistics, there will be an increasing demand for data and software that more capably handle research needs. This trend will only accelerate. The ability to add a spatial component to typical population level data opens up an entirely new approach toward thinking about public health issues. The individual will no longer be considered the sole unit of analysis; place will start to constitute its own unit of analysis or as complexly interacting with the individual. Further, as spatial methods improve we will be able to model the dynamic relationship between a target area and areas around the target. The previous example is one of the first public health examples of such an approach. In the future this dynamic modeling will become much more routine and essential to characterizing people in places. In addition, with the introduction of Bayesian hierarchal spatial approaches, we have a readily available ability to see how such dynamic spatial systems change over time. There is no methodological or theoretical obstacle to being able to, for example, analyze how characteristics in one area, such as density of liquor stores, affects violence in an adjacent area and to see how this relationship changes through time.

SUMMARY AND CONCLUSIONS

In this article we have described how spatial methods may be applied in specific public health areas, namely alcohol and alcohol related problems and COPD. Although important areas of research, they are by no means unique in being amenable to spatial/ecological analysis. There are several important factors that should be considered when contemplating public health spatial analysis: (1) Are there specific environmental features (such as the presence of bars or liquor stores) that might help explain an outcome (such as violence)? (2) Is there a dynamic relationship between individual behavior and environmental (area) setting? (3) Do environmental factors, such as alcohol outlets, modify the relationship between socio-demographic factors and the outcome of interest (e.g., violence)? (4) Is there data available to support a spatial analysis? (5) Is the effect of adjacent areas likely to obscure relationships between exposures and outcomes (spatial autocorrelation)?

When studying alcohol related problems, spatial analysis allows for the integration of disparate types of information into a meaningful story from both a public health and criminological/sociological point of view. Further, being able to use a uniform grid structure as seen in the earlier COPD example, notwithstanding certain strong assumptions, is a method that can be used to overcome limitations of using typical administrative geographical units such as zip codes. Given that zip codes are perhaps the most common basic areal unit of analysis, novel approaches toward dealing with such data are necessary. Similarly, the Bayesian spatial method described allows for a more powerful and

efficient ability to handle spatial statistical models compared to other methods.

The ability to put people in places in more than a purely descriptive framework signals a new generation in research that transcends traditional proscriptions against the use of ecological data. Further, measures of community health such as social cohesion take on a more fully realized form in a spatial analytical context. Indeed, given that most public health and criminological data are collected at a population level, spatial analysis allows researchers to more clearly observe population level effects for whatever measures chosen. Ultimately, GIS and spatial methods will become an integral part of public health research and practice as will the concept of place. In the future, measures of place will be as essential to public health research as race and class are now.

KEY TERMS

Bayesian Spatial Analysis: Spatial probabilities are often conditional and hierarchical. Bayes's theorem provides a convenient way to compute such conditional probabilities. Because the computational impediments to computing posterior probabilities in a Bayesian setting are eliminated after the advent of Markov Chain Monte Carlo algorithms, this method is an efficient and flexible method for conducting spatial analysis.

Geocoding: A generic term used to describe the GIS function of providing a specific location to descriptive data. Geocoding applies to point data (e.g., alcohol outlet) as well as to areal data (e.g., assaults in a census tract).

Geographical Information Systems (GIS): The geographic uses of data to develop maps and statistical relationships that help describe processes like the relationship between alcohol outlets and violence or vehicle crashes and alcohol outlets.

GIS Distance and Adjacency Function: The distance between individual objects (e.g., bars and crashes) and whether areas are adjacent to one another.

Kriging: A technique that can be used to develop contour maps (e.g., maps that show lines of equal value such as DWI rates) from a limited number of points or areas (which can be given a value at the centroid).

Overlay Function: The ability to combine multiple layers of information.

Spatial Analysis: Using geographic data to mathematically model the relationship between measures such those mentioned previously, that is, alcohol outlets and violence.

Spatial Autocorrelation: The measure of similarity between values (for a given variable, for example, income) located in space. Similarity of values in spatial proximity may indicate some underlying mechanism that is spatial in nature and contributes to the spatial pattern of the predictor variable. Controlling for spatial autocorrelation reduces statistical bias in parametric modeling.

Spatial Clusters: A greater than expected geographically close group of occurrences or events (e.g., deaths, crashes, or alcohol outlets).

Spatial Decision Support Systems (SDSS): Decision algorithms and software developed for particular types of decision support that deal with geographic space. Developed with GIS technology, but without requiring programming skills or knowledge of GIS software, SDSS uses digital maps, tables, and charts that are intuitive and help reduce the amount of information processing needed to make complex decisions.

Uniform Grid Unit Transformation: A method for taking information from arbitrary administrative spatial units like zip codes and transforming the data into a uniform grid structure.

Geospatial Information Systems and Enterprise Collaboration

Nova Southeastern University, USA

INTRODUCTION

Organizations and teams are becoming increasingly more distributed as groups work to expand their global presence while rationalizing team members across skill sets and areas of expertise instead of geographies. With this expansion comes the need for a robust and comprehensive language for pinpointing locations of globally distributed information systems and knowledge workers. Geospatial information systems (GISs) provide a common framework for jointly visualizing the world. This shared understanding of the world provides a powerful mechanism for collaborative dialogue in describing an environment, its assets, and procedures. The collaborative framework that GIS provides can help facilitate productive dialogue while constraining impulses of extreme positions. Collaboration and GIS intersections take many forms. Under a collaborative work-flow model, individuals use GIS to perform their job and post data back to the central database (e.g., engineering designs and as-built construction).

This article addresses the increasing role of GIS in emerging architectures and information systems in a number of applications (e.g., land planning, military command and control, homeland security, utility-facilities management, etc.). Real-time applications, mobile access to data, GPS (global positioning satellite) tracking of assets, and other recent developments all play a role in extending the scope and utility of the GIS-enabled enterprise. The impact of new GIS Web services standards and open geospatial-data archives are also addressed as areas of increased potential for remote GIS collaboration in global organizations. The expansion of enterprise GIS within organizations increases the opportunity and necessity of using GIS collaboratively to improve business processes and efficiency, make better decisions, respond more quickly to customers and events, and so forth.

BACKGROUND

The term *geospatial* is increasingly used to describe digital data about the earth in GIS, image, or GPS formats. The related technologies of GIS, remote sensing image-processing systems, and GPS data collection are all components of geospatial information systems. Geospatial-technologies use continues to expand in a great variety of applications ranging from land planning to utility-engineering design and military command and control. Those applications, which were once relegated to discrete groups of specialists, have now begun to take a more prominent role in the enterprise. Duffy (2002) describes the transition of GIS from a specialist technology to a more mainstream environment in the industry information-systems department from the end of the last decade into 2002.

The essence of collaboration is people and organizations working together to accomplish a common goal. Information–technology- (IT) enabled collaboration has improved business processes in many organizations and contributed to more functional and profitable operations. Collaboration technologies are characterized by three major generic attributes: communication, information sharing, and coordination (Munkvold, 2003). These characteristics can be further refined into available channels such as synchronous or asynchronous, the medium of sharing information through repositories or real-time interaction, and work-flow management to coordinate steps in a decision process or protocol. Geospatial technologies and systems extend collaboration in unique ways for problems that are related to location.

GIS provides a geographic dimension to enterprise collaboration, which helps solve a variety of problems that are difficult to address by any other means. For example, vehicle-routing and dispatching applications make it possible for Sears to deliver goods to customers more efficiently within tighter time windows. As a result, Sears is more profitable and customers are more satisfied. This example of distributed-network optimization using efficient queuing mechanisms based on location information is a simple illustration of the impact that GIS data may have on existing

business processes. In fact, most aspects of business-process automation initiatives at present require some element of collaboration either between networked systems or dispersed individuals.

Collaboration utilizing GIS and geospatial frameworks continues to be a focus of research both in the United States and abroad (Boettcher, 2000; Songnian, 2004; Stasik, 2000).

EMERGING GEOSPATIAL INFORMATION-SYSTEMS ARCHITECTURES AND COLLABORATIVE ENTERPRISE APPLICATIONS

As organizations become more dispersed in an effort to rationalize across areas of expertise in lieu of geographies, complex infrastructures for location analysis and coordination may emerge (Munkvold, 2003). In recent years, GIS software companies have developed an expanding and increasingly capable enterprise suite of tools. Early generations of GIS were used by GIS specialists only; these systems were available in stand-alone or project-systems configurations. GIS product options have improved and now provide a sound basis for supporting casual users as well as specialists with desktop, distributed client-server, and Internet solutions.

Geospatial data standards and interoperability have greatly improved the ease of using data in different formats or geographic projections. Geospatial Web-services standards provide Internet access to geospatial data stored in geospatial-data archives. Federal-government initiatives (e.g., Geospatial One Stop, the National Map, Homeland Infrastructure Foundation Level Database, etc.) will increase data standardization and access, and reduce expensive, redundant data collection.

GIS-enabled collaboration can now involve a broad range of different types of users within and outside of a particular organization. These users can be expert or casual as well as stationary or mobile. Medeiros, de Souza, Strauch, and Pinto (2001) present an analysis of aspects of coordination in a collaborative system for spatial group-decision support that resulted in a prototype system for a distributed GIS.

Geospatial Information-Systems Products and Architectures

GIS-product vendors continue to innovate and expand the solution set available to the user (Atkinson & Martin, 2000).

Enterprise suites of GIS include the following different types of products.

- Desktop GIS with varying levels of functionality
- Spatial analysis extensions
- Internet GIS with limited functionality or full functionality
- Mobile GIS
- Geospatial-data middleware
- Software to embed geospatial functionality in business applications
- 3D GIS
- Geospatial-data visualization software
- GPS tracking software
- Remote sensing image-processing software
- Geospatial Web-services software
- Location services

GIS products are available to support stand-alone users, and distributed client-server and centralized Internet architectures. GPS tracking units and mobile GIS on Personal Digital Assistants (PDAs) and pocket PCs extend the range of the technology into the field. Wireless communication of data is improved through the use of data compression and area-of-interest extraction techniques.

Geospatial-data management functionality is improving but is less capable than business-data management functionality. While Oracle states that their products now provide equivalent data-management functionality for spatial and business data, experience is limited for enterprise replication of geospatial data. ESRI, the GIS-software market leader, promises to add geospatial-data replication to its ArcSDE product with the release of ArcSDE 9.1, which is projected for 2005. The large size of geospatial-data files means that substantial bandwidth is needed to move data through a communications network.

Location services refer to mobile geospatial services that will primarily be delivered to location-aware smart phones. The E-911 legislation mandates that cell phones must become location aware so emergency vehicles can locate 911 callers who use cell phones. Cell-phone operators and partners are and will offer an increasing array of location services to provide users with directions for driving, the nearest services of different types, and the location of buddies (i.e., those who have authorized sharing this information, etc.). An example system is presented in the location-based tourist-guide application of Simcock, Hillenbrand, and Thomas (2003). This tool combines a mobile PDA device and GPS technology to provide the user with location tours that are self-guided.

Collaborative Land-Use Planning

Geospatial data provides a common view or abstraction of an area. GIS has been used extensively in land-use planning. While GIS initially served and continues to serve as a tool for planners, it is increasingly used to facilitate collaboration with the public. The ability to show land and its characteristics to groups of people with divergent views provides a common

frame of reference, which can make it easier to develop consensus or agreement on difficult issues. The common GIS data framework serves to constrain more extreme positions, which are more likely to be presented without geospatial data. The implementation of the collaborative system in Medeiros et al. (2001) described earlier was targeted as a land-use and planning application for a distributed GIS.

The Urban and Regional Information Systems Association (URISA) is in the third year of hosting an annual conference on the topic of public participation in GIS (URISA, 2004b; Voss et. al., in press). A discussion of presentations at the second conference in the series mentioned that Internet GIS technology was used to present and solicit public comment regarding alternative proposed designs for the World Trade Center buildings and parks (URISA, 2004a). From the number of questions and issues that were identified in the conference, it is clear that there is not yet a commonly accepted model for how GIS should be used to facilitate public participation in planning. As the role and power of planners, politicians, GIS specialists, developers, and the public could potentially shift with more publicly available geospatial data and analytic capabilities, there is no simple answer to the question of how collaboration between government and the public should be enhanced using GIS. Clearly, the technology increases options for public participation in land planning.

The Orton Family Foundation, a Vermont-based nonprofit organization dedicated to better decision making by communities, has developed 2D and 3D GIS software to help people develop, visualize, and analyze the implications of alternative approaches to land- and growth-management planning (Orton Family Foundation, 2004). Their CommunityViz GIS software has been used extensively by smaller communities to help involve the public in land planning. In Eureka Township, Minnesota, GIS was used to help the Eureka Township Envisioning Project understand the impacts of alternative growth-management scenarios on septic-system placement and water quality (Orton Family Foundation).

Utilities-Engineering Design and Construction

Utilities use geospatial-information systems to plan and manage their assets and design new components of their outside plant infrastructure (e.g., poles, wires, transformers, pipes, etc.). While most of the collaboration occurs within the utility, collaboration occurs to some degree with developers and government officials. For example, a developer will submit their design for a new subdivision, usually in CAD (computer-aided design) format. Field surveys are often conducted at the site and these surveys are increasingly conducted using GPS technology. The utility designer will import this CAD into either a CAD or GIS tool, which will be used to design the utility infrastructure that is needed to support the proposed development. Typically, the proposed design is analyzed as if it were connected to the network, so a proposed version of the design is developed. Alternative designs may be developed and costs of the alternatives may be determined so that the most cost-effective option can be chosen. Designs may be reviewed by other designers or a design supervisor to select the preferred option, which may also be with the developer and government officials. When approved for construction, the design will be attached to a work order and assigned to a crew which will be dispatched to the construction site. The design may be modified in the field if logistical difficulties are encountered. Construction crews will record as-built conditions for the project, and this data will be reviewed and posted to the database, which represents the utility assets that are constructed.

This utility design and construction process occurs over an extended period of time, which makes it a long transaction. Engineers will typically extract a version of the database to use to develop their designs. Usually, a utility will use optimistic logic and not formally lock the portion of the database that is included in the versioned database. Conflicts between alternative designs in the same general area are flagged for resolution by an engineering supervisor.

This CAD- and GIS-based process represents a major increase in productivity in design and maintenance of utility maps and records. Utility GIS practitioners often network through an organization called the Geospatial Information & Technology Association (GITA, 2004).

C4ISR and Defense Geospatial Applications

Command, control, communications, computers, intelligence, surveillance, and reconnaissance (C4ISR) is a military application that makes extensive use of geospatial technologies. The National Geospatial-Intelligence Agency, the National Reconnaissance Office, and other agencies collect imagery and produce different types of geospatial data for military and intelligence purposes. For example, cruise missiles use topographic data as a model of the terrain. The terrain is sensed by the cruise missile and pattern-matching techniques are used to follow the landscape to reach a target. High-resolution imagery is interpreted to help select targets.

C4ISR provides the military forces with geospatially enabled command and control capabilities. Trends are to make C4ISR more widely available to help cut through the fog of war and provide a better coordinated understanding of the battle space. The Geo-Intel 2003 conference included discussions of the importance of geospatial data and technologies and the role played by them in the rapid and successful movement of U.S. troops in the Iraqi War.

In the future, geospatial intelligence and C4ISR will be more ubiquitous. Currently, the military is still in the process of adopting geospatial data for battle-space operations. The Commercial Joint Mapping Toolkit initiative could place GIS-enabled C4ISR in the hands of up to one million U.S. military forces.

Homeland-Security Command Centers

Homeland–security command centers are making effective use of GIS to provide planning and response capabilities. The emphasis on situational awareness and command and control is similar to DOD C4ISR applications. 3D GIS applications developed by IT Spatial are playing a major role in command centers in Washington, DC, and elsewhere. Plume modeling software combined with demographic data, 3D GIS data, and real-time weather data provide a capability to predict terrorist acts, like a dirty nuclear explosion, and their consequences. There is no shortage of investigation of 3D GIS technologies (Manoharan, Taylor, & Gardiner, 2002). The better the consequences are understood, the more effective the response can be from emergency first-responder forces. First responders in the field can access data and also feed back information regarding emergencies and events to provide command and control personnel and other responders with better understanding. This impact of geospatial information in emergency situations has been the subject of research by several in the wake of the attacks of September 11, 2001 (Kevany, 2003; Kwan & Lee, in press; Rauschert, Agrawal, Sharma, Fuhrmann, Brewer, & MacEachren, 2002), in addition to some early research examining this area prior to the attacks (Kumar, Bugacov, Coutinho, & Neches, 1999). GPS tracking can be used to understand the location of police cars, ambulances, and other emergency vehicles. Integration of GIS with live video data feeds also provides a useful real-time picture of ground conditions and events. There are some, however, that continue to point out the numerous impediments to effectively using GIS in disaster-control decision situations (Zerger & Smith, 2003).

GIS additionally continues to play an important role in the containment of medical outbreaks and the analysis of systems mapped to locations, such as in the work of Cockings, Dunn, Bhopal, and Walker (2004).

Presence Awareness in Instant Messaging and RFID-Based Asset Tracking

In an effort to better display the impact of emerging technologies such as radio-frequency identification (RFID), Web services on GIS, and collaboration for real-time presence management, AMS, through its Center for Advanced Technologies, customized the BuddySpace instant messaging (IM) product to allow IM users the ability to display the location of other users. This information was automatically captured through the implementation of a GIS Web service and an RFID network (Del Vecchio & Carter, 2004). This location or presence awareness adds an additional useful dimension to dialogue between IM users. There are alternative methods of collecting the location data and these options include

- entering and geocoding addresses,
- GPS data collection, and
- RFID-tag readings.

The RFID-tag approach is interesting due to future expectations for expansion in the use of this technology. RFID tags must be read by a stationary reading device, and the location of this reader can be determined by address geocoding or GPS. RFID tags that are read can be related to their location, and this could prove useful for supply chain applications. This experiment builds on the assertions of Mitchell (2003), which state that Web services will further propel GIS into the spotlight.

FUTURE TRENDS

Geospatial technologies have begun to play mission-critical roles on a large scale in a variety of different types of organizations. Early adopters of geospatial technologies included many organizations that traditionally have maintained maps and records to manage their assets and operations. Geospatial functionality will increasingly be embedded in various business applications (e.g., SAP ERP) that might support almost any organization with simple geospatial data visualization, queries, and analysis. In addition, spatial extensions to commercial RDBMS products will permit organizations to visualize the geospatial dimensions of their business data without a major investment.

The ability to deliver data in real time to mobile users extends GIS to the field. The number of mobile GIS users and the wireless communication of data to and from these mobile users will continue to expand. Location services will deliver focused geospatial-information services (e.g., directions, nearest services, etc.) to cell-phone users willing to pay for these supplemental options. According to Nellis (2004), these innovations are "…now at the heart of a vast array of real-time interactive mobile computing, geo-location applications and asset management, along with wireless geographic services that are revolutionizing the role of geography and geospatial information analysis in meeting the needs of everyday society."

The high cost of geospatial data has been a major impediment to its adoption. As geospatial data are increasingly available from geospatial Web-services-compliant sites, costs to access data will decline and users will be able to develop

and use applications more rapidly. There will continue to be some significant policy concerns and debate with regard to the privacy implications of GIS technology as outlined in Balough (2001).

CONCLUSION

Geospatial information systems provide unique capabilities for geospatial-data visualization and analysis. While the large data sizes associated with this technology make real-time and mobile uses more challenging, it is now possible, and increasingly practical and necessary, to use GIS across an enterprise for real-time, mobile geospatial applications. Military and homeland-security markets are currently driving the market for collaborative GIS enterprise applications. Other markets have also emerged and more will surely follow as the advantages of location awareness and geospatial analysis are better appreciated.

KEY TERMS

C4ISR: Command, control, communications, computers, intelligence, surveillance, and reconnaissance, a military application framework that makes extensive use of GIS technologies.

CAD: Computer-aided design.

Enterprise Collaboration: Application of systems and communications technologies at the enterprise level to foster the collaboration of people and organizations to overcome varying levels of dispersion to accomplish a common goal. This term, when applied to the use of technologies, is also known as e-collaboration or distributed collaboration.

Geospatial Information Systems (GISs): Systems that provide a common framework for jointly visualizing the world.

Global Positioning Satellite (GPS): A format of presenting geospatial data for tracking purposes used often in location-based services.

RFID: Radio-frequency identification. This technology uses the electromagnetic spectrum radio signals to transmit information from a transponder (tag) to a receiver for purposes of identifying items. This technology has been in development for a standard to replace the Universal Product Code (UPC) symbol with the Electronic Product Code (ePC) symbol through the Auto ID Center, formerly of MIT.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 1278-1283, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Geospatial Interoperability

Manoj Paul
Indian Institute of Technology, India

S.K. Ghosh
Indian Institute of Technology, India

INTRODUCTION

Spatial information is an essential component in almost all decision support system due to the capability it provides for analyzing anything that has reference to the location on earth. Spatial data generally provides thematic information of different aspects over a region. Geospatial information, a variant of spatial information, is generally collected on thematic basis, where individual organizations are involved on any particular theme. Geospatial thematic data is being collected from decades and huge amount of data is available in different organizations (Stoimenov, Dordevi´c, & Stojanovi´c 2000). Information communities find it difficult to locate and retrieve required geospatial information from other geospatial sources in reliable and acceptable form. The problem that has been incurred is the lack of standards in geospatial data formats and storage/access mechanism (Devogele, Parent, Spaccapietra, 1998). Heterogeneity in geospatial data formats and access methods poses a major challenge for geospatial information sharing among a larger user community.

With the growing need of geospatial information and widespread use of Internet has fostered the requirement of geospatial information sharing over the Web. The *Geo-Web* (Lake, Burggraf, Trninic, & Rae, 2005) is being envisioned to be a distributed network of interconnected geographic information sources and processing services that are:

- Globally accessible, that is, they live on the internet and are accessed through standard Open Geospatial Consortium (OGC) and W3C interfaces,
- Globally integrated data sources that make use of standard data representation for sharing and transporting geospatial data.

Unless a standard means for geospatial information sharing is developed, interoperability cannot be realized. Without successful interoperability approaches, the realization of Geo-Web is not possible. Geo-Web is being developed to address the need for access to current and accurate geospatial information from diverse geospatial sources around the world. The *National Spatial Data Infrastructure* (NSDI) initiative has been taken by many nations for providing integrated access of geospatial information (Budak, Sheth, & Ramakrishnan, 2004). Actual data will be kept under the jurisdiction of the organization producing that data. A user will be interested in availing geospatial services through well-defined interface. Without some internationally agreed upon standards for geospatial data and computational methodology, this cannot be made into existence. This chapter discusses several issues towards geospatial interoperability and adoption of *geography markup language* (GML) (Cox, Cuthbert, Lake, & Martell, 2001; Lake et al., 2005) as a common geospatial data format. The associated technologies that can be used for realizing geospatial interoperability have also been discussed.

BACKGROUND

The need for integrated and interoperable geospatial system has been felt for long time and several methods for information integration have been adopted into geospatial domain as well (Devogele et al., 1998; Guan et al., 2003). NSDI (Shekhar, Vatsavai, Sahay et al., 2001) attempts to bring the single point accessibility of geospatial information. But the heterogeneity in geospatial data formats and access mechanism immediately puts into concern about some standard way of sharing data.

The *Open Geospatial Consortium* (OGC) (2000) is an international voluntary consensus standards organization defining standards to bring geospatial computing into mainstream computing. In OGC, several organizations worldwide collaborate in an open consensus process encouraging development and implementation of standards for geospatial content and services, GIS data processing and exchange. The standards defined by OGC are popularly known as *open GIS standards*. These are being adopted by GIS vendors, which in turn increase the possibility of geospatial data sharing. The proposition of geography markup language (GML) (Cox et al., 2001; Lake et al., 2005) as standard data transformation format and service based sharing of geospatial interoperability is going to add new dimension in geospatial interoperability.

The proposition of GML has changed the concept of sharing geospatial information among large-scale users.

Being an XML-based encoding method, GML allows users to share the geospatial information irrespective of the platform or the system in which the data repositories are residing (Badard & Richard, 2001; Zaslavsky, Marciano, Gupta, & Baru, 2000). The advancement of Web service technology and service oriented architectures (Erl, 2004) has led the further progress in geospatial information domain. Geospatial data are now increasingly becoming available on the Web (Kim & Kim, 2002) as geospatial services. The advantage is that they are capable of providing geospatial data in GML-encoded format. Thus, anybody having the knowledge about the geospatial service interface can utilize the information in their application.

GEOSPATIAL INTEROPERABILITY

The main objective of the chapter is to discuss the support that GML and its associated technologies provide towards interoperability.

Geography Markup Language

XML technology today is extremely widespread. It is the "lingua franca" of emerging e-business frameworks, and it powers the generation of thousands of Web sites[1]. Due to its text format it is easily processable across different computing platform. XML has changed the way people thought about interoperability among large-scale disparate systems. GML is based on XML with added support for spatial geometries. In GML, geospatial entities are treated as features. Each feature should have its own properties, both spatial and non-spatial. It is proposed that data has to be shared to the user in GML encoded format irrespective of the heterogeneity of their data formats (Cox et al., 2001; Lake et al., 2005).

There are several base structures defined for modelling a geospatial domain in GML like geometry, features, and so forth. A sample GML instance depicting a geospatial feature *School* is shown in Figure 1. It assigns a feature-id (say, *fid*) for the feature. The polygon geometric element describes the spatial expansion of the feature. It is also geo-referenced by spatial reference system by the element *srsName*.

GML Geometry

Several basic primitive geometry elements have been described in GML for describing the geometric properties of real world objects like rivers, roads, states and so forth. Table 1 provides detailed description of different GML geometry elements. The base schema *geometry.xsd* provides the constructs and structure for geometries. There are a number of homogeneous geometry collections that are predefined in the geometry schema[2]. The fundamental geometry element is "co-ord." All other geometry elements are derived from this basic geometric element. Some of the composite geometry structures in the geometry core schema are as follows: a *multipoint* is a collection of *points*; a *MultiLineString* is a collection of *LineStrings*; and a *MultiPolygon* is a collection of *polygons*. Many new geometric elements have been added to the geometry schemas in GML 3.0, including *curve*, *surface*, *solid* and so forth.

GML Feature

GML defines features, which are different from the concept of geometry objects. A feature is an application object that represents a physical entity, for example, a road, a river, or a forest. A feature may or may not have geometric aspects. The distinction between features and geometry objects in GML contrasts with models used in other geographic information systems.

In GML, a feature can have various geometric properties that describe aspects or characteristics of the feature (e.g., the feature's *point* or *extent* properties). The feature structure

```
<Feature fid="142" featureType="school" Description="A middle school">
  <Polygon name="extent" srsName="epsg: 27354">
    <LineString name="extent" srsName="epsg: 27354">
      <CData>
        491888.99,5458045.99,491904.99,5458044.99 491908.99,
        5458064.99, 491924.99, 5458064.99 491925.99, 5458079.99,
        491977.99, 5458120.99 491953.999999466, 5458017.99963357
      </CData>
    </LineString>
  </Polygon>
</Feature>
```

Table 1. Geometric elements of GML base schemas with example

Point: Used to encode instances of the point geometry class.	<Point gid="P1" srsName="http://www. opengeospatial.org/gml/srs/epsg.xml#4326"> <coord> <X>56.1</X> <Y>0.45</Y> </coord> </Point>
LineString: A linear path defined by a list of coordinates that are assumed to be connected by straight line segments	<LineString srsName="http://www.opengeospatial.org/gml/srs/epsg.xml#4326"> <coordinates> 0.0,0.0 20.0,35.0 100.0,100.0 </coordinates> </LineString>
LinearRing: Closed, simple linear path which is defined by a list of coordinates that are assumed to be connected by straight line segments.	<LinearRing srsName="http://www.opengeospatial.org/gml/srs/epsg.xml#4326"> <coordinates> 0.0,0.0 100.0,0.0 100.0,100.0 0.0,100.0 0.0,0.0 </coordinates> </LinearRing>

of geospatial objects is defined in *feature.xsd*. GML also provides the ability for features to share a geometry property with one another by using a remote property reference on the shared geometry property. For example, a *building* feature in a particular GML application schema might have a position given by the primitive GML geometry object type *point*. However, the *building* is a separate entity from the *point* that defines its position. Any such property may share its geometry object with properties of other features. An *xlink: href* attribute on a GML geometry property means that the value of the property is the resource referenced in the link.

GML Application Schema

For modeling any geospatial domain, we need to identify the different features of the domain and their properties, relationships. A subset of the base schema, proposed by OGC, can be used for this purpose. A GML application schema is an XML schema written according to the GML rules for application schemas and defines a vocabulary of geographic objects for a particular domain of discourse (Cox et al., 2001; Lake et al., 2005).

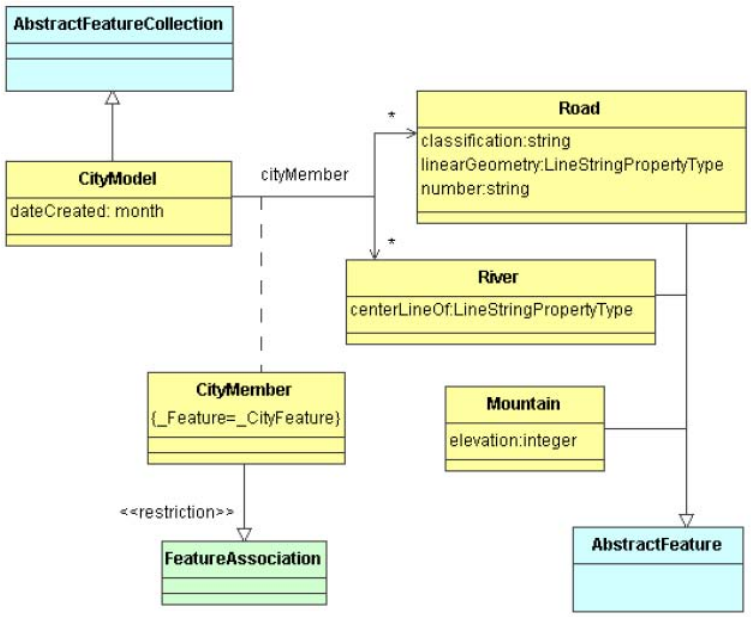
Application schemas are generally designed using ISO 19103 conformant unified modeling language (UML), and then the GML application schema created by following the rules given in ISO DIS 19136. Let us give an example for describing the overall process of application schema generation. For modelling a *city*, we need to incorporate features like *road, river,* and so forth. Each of these features will have several properties and relationships with other features. A UML model incorporating the base schemas can be generated to capture the *City* model precisely as shown in figure 2 (OGC, 2000). It shows different features, which are included for modeling the *city* feature, the relationships among them. Some rules can be applied to generate the application schema from the UML model. For ensuring interoperability, data providers have to publish their application schema. The data user can easily import them to their data repository if the schema is provided along with the actual data.

Advanced Features in GML

Several advanced concepts have been incorporated in GML 3.1.3[3]. New additions in GML 3.0 support complex geometries, spatial and temporal reference systems, topology, units of measure, metadata, gridded data, and default styles for feature and coverage visualization. The most important of these is the support for 3D geometry and topology definition. Topology is the branch of mathematics describing the properties of objects which are invariant under continuous deformation. For example, a circle is topologically equivalent to an ellipse because one can be transformed into the other by stretching. In geographic modelling, the foremost use of topology is in accelerating computational geometry. Topology, realized by the appropriate geometry, also allows a compact and unambiguous mechanism for expressing shared geometry among geographic features.

The GML temporal schemas extend the core elements of GML to include elements for describing the temporal characteristics of geographic data; their purpose is to provide a means of describing the history of a dynamic feature basic temporal schema. The underlying spatio-temporal model strives to accommodate both feature-level and attribute-level time stamping; basic support for tracking moving objects is also included. *gml:_TimeObject, gml:_TimePrimitive, gml: TimeInstant; gml:timePosition, gml:TimePeriod, gml:_dura-*

Figure 2. Sample application schema for a city

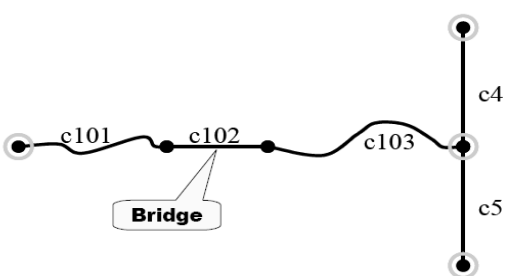


tion have been defined in GML 3 to capture the temporal behavior of dynamic objects.

GML 3.1.1 also supports the creation of complex geometry using simple geometry primitives. Figure 3 is an example of instances of two different feature types, a *road* and a *bridge*, sharing a *gml:LineString* geometry using an *XLink*. It also demonstrates a *gml:Composite* curve composed of *gml:curveMember* elements that are geometries with different interpolation.

GML supports geo-spatial interoperability in a number of ways. It provides a common schema framework for defining geo-spatial features. GML further supports interoperability by providing a common set of GML geometry types. While two different schema authors might for example model a road in different ways they can share the same mechanisms for geometry description and it is then very likely that one can interpret the correspondence between the two schemas. The overall scheme for interoperability can be as shown in Figure 4, which resemblence the service-based integration of geospatial repositories.

Figure 3. Composite geometry support in GML



Supporting Technology

GML alone cannot be sufficient towards achieving interoperable *Geo-Web*. It is just a data description language and there is the need for other associated technologies for its full-fledged use. This section provides some of these related technologies to make GML useful.

Visualization

GML represents the content of data without providing any information of how to visualize the data. Since GML is an XML standard, XSLT can be used to convert it into vector graphics format like SVG, VML, and so forth. SVG is ideal for displaying GML-encoded geospatial information in a Web browser. SVG provides support for 2D graphics including rectangles, circles, ellipses, lines, polylines, polygons, symbols and path elements. In order to visualize GML data, XSLT stylesheets are required. Stylesheets are used to convert and format GML into SVG and different style and symbols can be applied. The overall methodology fro GML visualization is shown in figure 5. Some works on GML visualization have been proposed by (Guo, Zhou, Zu, & Zhou, 2003; Shekhar et al., 2001).

Figure 4. GML and application schema for ensuring interoperability

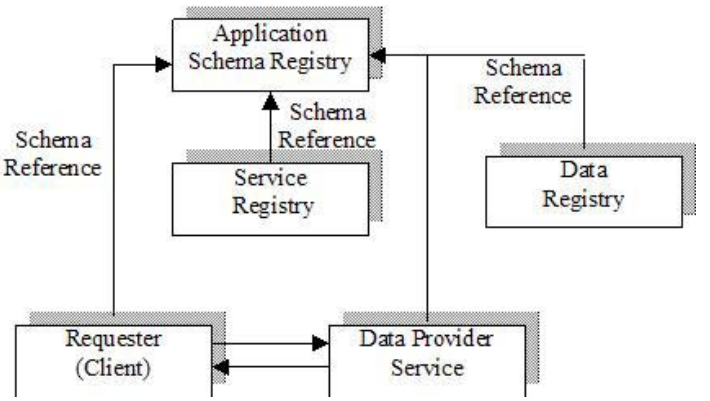


Figure 5. Relationship between GML and SVG

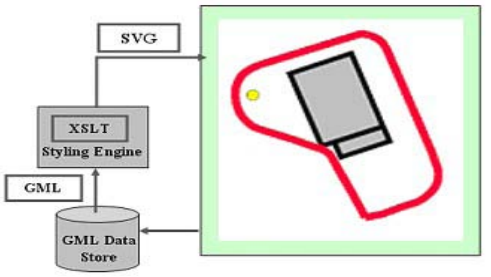

Geospatial Services

With Web service technology providing interoperability among disparate systems, more and more geospatial data are being provided as geospatial services. Similar to general Web service computing, where XML has been the backbone for data sharing and communication, geospatial services make use of GML for data and message transportation. OGC has come up with several specifications for service-based computations in geospatial domain (Doyle & Reed, 2001). These are mainly the following:

- **Web feature service:** Allows feature level access of geospatial data in GML format along with the feature schema
- **Web map service:** Provides geospatial features in the form of map/images
- **Web coverage service:** Allows access of data at the coverage level
- **Catalog service:** Standard registry for services for service discovery purpose

The service based geospatial computation methodology with the help of GML is perceived to be successful in interoperable geospatial data sharing. A framework for service-based geospatial information integration for achieving interoperability has been described in (Paul & Ghosh, 2006b).

GML APPLICATION

Some of recent works, primarily on geospatial infrastructure development, are making use of GML as the standard geospatial data formats. The integration framework proposed in (Boucelma, Garinet, & Lacroix, 2003; Paul & Ghosh, 2006a,2006b; Stoimenov et al., 2000) uses GML for achieving interoperability.

Boucelma et al. (2003) proposes an approach, which uses a WFS-based mediation with the help of *derived wrappers* for geospatial information integration. It proposes a multi-tier, client-server architecture and uses standard wrappers to access data, extended by derived wrappers that capture additional query capabilities. It uses GML as the geospatial data sharing format. The mediation architecture is composed of three main layers: a GIS mediator, *Web feature service (WFS)* and data sources. The GIS mediator is in charge of query processing. The WFS layer receives the query, executes them in the data sources and returns the result in GML format to the mediator. Service-based integration methods for geospatial information using GML have been proposed in (Erl, 2004; Guan et al., 2003; Paul & Ghosh, 2006b).

With increasing adoption of GML for geospatial information sharing, some query language for GML has also been

proposed. Corcoles and Gonzalez (2001) propose a spatial query language for GML. The data model and the algebra underlying the query language has been designed that support spatial features.

With increasing availability of geospatial information in GML-encoded format, the need has arisen for the efficient storage of it in standard DBMSs. Li, Li, and Zhou (2004) propose an approach in which a schema tree is generated from the GML application schema. The tree is subsequently mapped into the relational schema. Paul and Ghosh (2006a) proposed methodology uses a combination of *Element Level* mapping and *Feature Level* mapping for GML storage and utilizes the semantic concepts. Corcoles and Gonzalez(2002) analyse different methodologies for GML storage. They compare three approaches for GML storage: *LegoDB*, a structure-mapping approach, and two simple model-mapping approaches, *Monet* over Relational database and *XParent*. A performance study is conducted using different data sets.

FUTURE TRENDS

The requirement of using XML-based data exchange format for geospatial domain (Badard & Richard, 2001) has given rise to the concept of GML. The usability of GML is increasing day-by-day and thus providing several research issues on effective use of it in different application. There are several future scopes involving GML—GML querying, GML mining, and so forth. The research work on GML querying focuses on query optimization and query expansion involving composite geospatial features. GML mining, on the other hand, involves finding some pattern form a set of GML data. This has direct correspondence with information retrieval form GML document. Advancement in research with XML is being used for GML also.

CONCLUSION

With the increasing need of geospatial information among organizations and the heterogeneity in GIS has led to formalizing a standard way for geospatial data sharing. OGC proposed GML towards the realization of interoperable access of geospatial information. Application schema is aimed at providing interoperability to a significant extent. The adoption of Web service technology for providing geospatial services has brought a new era in geospatial integration paradigm. GML has found extensive use for service description, data transportation, and registry description. The NSDI approaches are increasingly focusing on the realization of service based geospatial information access portal with extensive use of GML.

KEY TERMS

Application Schema: A metadata structure describing the geospatial feature for the domain of interest. GML adheres to XML-based schema language for application schema design.

Geo-Web: A globally integrated and accessible spatial infrastructure that comprises a number of interconnected geospatial datasets and Web services.

Geospatial Data: Geographically referenced spatial data that provides some thematic information over a region.

Geospatial Web Services: A Web service that provides access to, or data processing on, geographic information. The OGC Web Feature Service (WFS), Web Map Service (WMS) are examples of geospatial Web service.

Geospatial Interoperability: Ability to access, share and manipulate of geospatial data stored in heterogeneous distributed repositories**.**

GIS: A system of computer hardware, software and data for collecting, storing, analyzing and disseminating information about areas of the earth.

Spatial Reference System: A co-ordinate system that defines the maximum possible extent of space that is referenced by a given range of coordinates with respect to a point on earth.

Spatial Geometry: Describes the structure of spatial objects in terms of points, lines, polygons, polylines, and so forth.

UML: UML is a language for specifying, constructing, visualizing, and documenting the artifacts of a software-intensive system.

XML: An open standard for exchanging structured documents and data over the Internet that was introduced by the World Wide Web Consortium (W3C)

GIS and Remote Sensing in Environmental Risk Assessment

X. Mara Chen
Salisbury University, USA

INTRODUCTION

The existence, well-being, and sustainable development of the global economy hinges upon the state of the earth's environment. Effective environmental risk assessment and management issues have become increasingly important. With the ever-growing global population and expanding economic development, we consume more natural resources, produce more waste, and develop more areas into the regions that are prone to environmental risks. Although humans have interacted with the environment for thousands of years, environmental risk assessment and management is only a recent research undertaking. As the industrialization has made the human-environment interactions more dynamic and complex, the increased environmental risks have propelled and compelled people to use technologies for identifying and solving problems. The earliest global environmental applications of remote sensing and GIS technologies began in the 1960s, particularly marked by the successful launch of the TIROS-1, the first meteorological satellite, and the development of computer-based geographic information systems (GIS). The story *Silent Spring* (Carson, 1962) awoke the public's environmental consciousness and promoted the public demands for governments to set up environmental protection policies and research priorities. The birth of the U.S. Environmental Protection Agency (EPA) in 1970 set the stage for modern environment risk assessment. The launch of the LANDSAT program in 1972 created a new way for monitoring global land use and land cover changes (Foley, 1999; Goward, Masek, Williams, Irons, & Thompson, 2001).

BACKGROUND

Environmental risks ranging from natural to human-induced hazards present growing threats to communities at local, national, regional, and global scales. Effective and timely environmental risk assessment and management has become a forefront issue in ensuring the health and functions of modern civilization. Information technologies offer a promising approach of integrating and processing information from various sources and formulating comprehensive solutions to complex environmental problems. In particular, GIS and remote sensing technologies together offer the abilities of rapidly collecting data, processing and integrating data and information, and displaying results in geographic-referenced maps and reports. Environmental professionals have increasingly utilized remote sensing and GIS to study human activities and the environment (Chen, Blong, & Jacobson, 2003; Turner, 2003). Multi-spectral and multi-resolution sensors mounted on different platforms (aircrafts or spacecrafts) have become our "eyes" in space, providing constant and consistent environmental surveillance. In the mean time, GIS has provided us with the extended brain-power to store, process, analyze, and display unprecedented vast amounts of complex data. The technological marriage of remote sensing and GIS created a powerhouse that allows remotely sensed data to be directly fed into GIS for integrated analysis and visualization. Satellite remote sensing provides a systematic and synoptic knowledge base about the earth's complex geophysical phenomena (Tralli, Blom, Zlotnicki, Donnellan, & Evans, 2005). A GIS-based integrated approach can be used for the risk management of natural hazards (Chen et al., 2003).

CURRENT STATE

Effective environmental risk assessment and management is a complex process (Figure 1). The success of the process depends upon the prerequisite steps of comprehensive data collection, data integration, and analysis. Remote sensing is very critical in capturing the dynamic and vicissitudinary nature of hazards. The essential environmental risk assessment database must encompass the measurements and information on hazard types, occurrence probability and frequency, intensity and magnitude, and their proximity to the human environment. Remote sensing technology offers spatial, spectral, and temporal monitoring functionalities to fully measure these environmental variables.

Multi-platform remote sensing allows the earth's environment to be monitored at different spatial scales (local, regional, and global), spatial resolution (fine, medium, and coarse), and from a variety of spectral ranges beyond human's visible spectral vision (see Table 1). High resolution imagery (of 5m or less pixel size) is used for precise topography mapping and complex ecosystem change detection in densely populated regions (Ehlers, Gähler, & Janowsky, 2002; Ellis et al., 2006; Morsdorf, Meier, Kotz, Itten, Dobbertin, & Allgower, 2004). Medium-resolution satellite imagery (5-100m) is utilized for diverse global environment monitoring and assessment. For example, data from many

Figure 1. Flowchart of GIS and remote sensing in environmental risk assessment and management

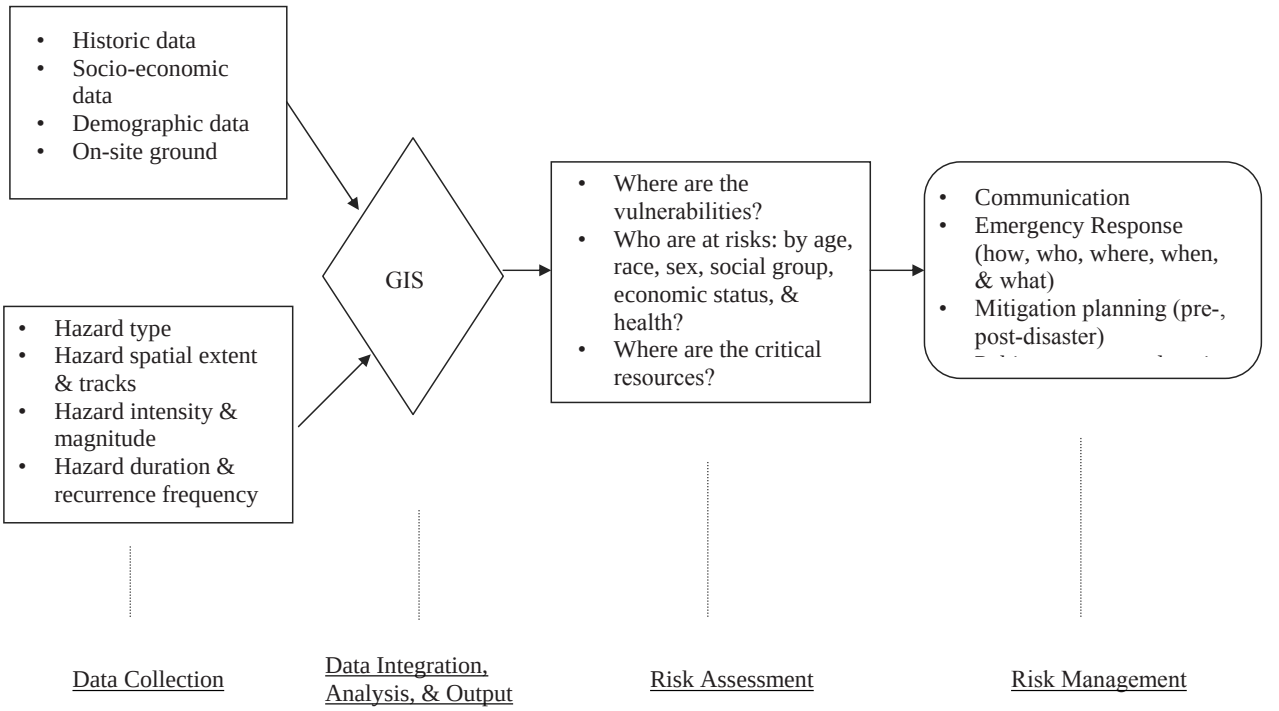

Table 1. Selected remote sensing application in environmental risk assessment

Remote Sensing Type		**Characteristics**	Environmental Risk **Assessment**
Platform	Aircraft	Local & regional coverage at certain time interval	A variety of environmental monitoring and assessment at relatively local levels
		low, medium, and high altitudes	
	Spacecraft (Shuttle & Satellite)	regional and global coverage	Monitoring the environment at regional or global levels in a long-term repetitive manner
		long term and repetitive surveillance	
		high & very high altitudes	
Sensor Spectral Range	Ultra violet (UV)	0.3–0.4 μm	Oil spills, wildlife inventory
	Visible	0.4–0.7 μm	Various land use and land cover assessment
	Near & mid infrared (NIR, MIR)	0.7–3 μm	Water and land boundary, vegetation differentiation
	Thermal infrared (TIR)	3–14 μm	Fire, volcanic activities, thermal pollution
	Microwave/RADAR	1 mm–1 m	Oil spill, deforestation, polar ice study
Sensor Spectral Resolution	Panchromatic mode	One broad band	Preliminary assessment
	Multispectral mode	Several to tens of broad bands with spectral range in μm	Comprehensive comparative study, feature discrimination
	Hyperspectral mode	Hundreds of narrow bands with spectral range in nm	Possible specific feature identification
Image Spatial Resolution	Fine resolution	Less than 5m	Precise and detailed study
	Medium resolution	5–100m	Local & regional study
	Coarse resolution	Greater than 100m, often in km	Sub-continental & global environment assessment

satellite imaging systems (e.g., Landsat, IRS, SPOT, MODIS) have created new ways of monitoring fundamental land use and land cover changes and a variety of natural hazardous phenomena. Landsat data provide systematic observation data for assessing human risks to earthquakes, volcanoes, floods, landslides, coastal inundation, and forest fires (Mbow, Goïta, & Bénié, 2004; Tralli et al., 2005). Coarse resolution satellite imagery is often used for tracking highly dynamic hazardous weather phenomena such as hurricanes/typhoons, tornadoes, and other types of severe storms.

In addition to precise and accurate observations and measurements of hazards, integrated data processing, and analysis is crucial for a complete and comprehensive risk assessment and management. Many hazards, however powerful, only become harmful when their dynamic spheres intersect with the spheres where people live and develop (Chen, Parrott, & Johnson, 2006). The analytical capacity of GIS ensconces its increasingly important role in environmental risk assessment and management. GIS assists environmental analysts and decision makers to better understand the spatial, socio-economic, and historic aspects of hazards and their associated risks to humans and the human environment.

Spatially, over half of the global population are concentrated along the coastal zones (Finkl, 2000), about half of the population are clustered in cities (Thouret, 1999), especially in coastal cities. Eleven of the world's 15 largest cities are on the coast (Cohen & Small, 1998). About 500 million people live close to active volcanoes (Thouret, 1999). GIS is used for delineating the spatial distribution of hazards, assisting community risk assessment, and emergency response planning (Chen et al., 2006; Mondschein, 1994; Wood & Good, 2004), documenting global offshore hazardous materials sites (Lindsay & Aguirre, 2004), supporting large area land use and land cover studies and sustainable land management (Foley, 1999; Groot, 1997; Lidrah, 2000). Socio-economically, people who are at the same level of exposure to hazards do not necessarily face the same degree of risk. Young children and old people who are of poor health and scarce resources and limited social supporting networks are the most vulnerable. GIS not only helps map exposure risks, but also highlights the importance of understanding environmental injustice and inequality problems (Dolinoy & Miranda, 2004; Fielding & Burningham, 2005). Historically, human activities have significant accumulative effects on transforming the environment. Historic data are often combined with the data of human settlement patterns, historic fire occurrences, and economic developments in the GIS for monitoring coastal evolution, land use changes, and wildfire recurrences (Foley, 1999; Mountford & Sheppard, 2000; Riva, Pérez-Cabello, Lana-Renault, & Koutsias, 2004). GIS is capable of processing data at a full gamut of temporal cycles, ranging from century, to decadal, to annual update cycles, and to even real time observations (Chen, Yang, & Chen, 2005). Historic data analyses help people reflect upon what has happened and what could have been done better in the past, observe what is happening in the present, and predict what potential risks would be and what can be done to better mitigate the risks in the future.

FUTURE TRENDS

With the continuous evolution of computing and information technologies, GIS and remote sensing will facilitate more effective and efficient environmental risk assessment and management. Remote sensing will continue to improve its spatial resolution, radiometric precision, spectral differentiation and coverage, and timely or real time imaging capability. It will become an indispensable tool in providing data for climate change detection and sustainable development study (Cihlar, 2000). In the mean time, GIS will provide more powerful analytical and visualization capabilities to process the increasingly complicated and comprehensive environmental databases. Together, GIS and remote sensing will not only able to estimate post-disaster impact risks, but also project and predict the potential risks and optimum management strategies. Hybrid knowledge-based GIS systems are explored for simulating exposure risks (Fedra & Winkelbauer, 2002; Swartz, Rudel, Kachajian, & Brody, 2003). Potential real time 3D GIS is examined for rapid urban emergency response and flood management (Al-Sabhan, Mulligan, & Blackburn, 2003; Kwan & Lee, 2005).

Despite the genuine utilities and potential promises, many challenges still exist in using GIS and remote sensing for environmental risk assessment and management. Major aspects include:

- No systematic methodology in using the technologies for different types of environmental risk assessment and management applications at different spatial scales (local, national, regional, and global context);
- Inadequate algorithms and procedures developed for integrating heterogeneous data that are acquired at different scales and resolutions, during different times, from different methods, and by different agencies;
- Large gaps between high-level research agendas and local-level practical actions due to a lack of financial resources and technical know-how in using GIS and remote sensing in many poor hazard-prone communities and regions;
- Growing needs for portable and mobile GIS. They can be used in a distributed computing environment simultaneously by multi-agency first responders and decision makers to facilitate optimal procedures for pre-, during-, and post-disaster risk assessment, response, and management. Finding suitable info in the distributed geographic information services is crucial in disaster management (Klien, Lutz, & Kuhn, 2006).

CONCLUSION

As the rapid growing global population and expanding industrialization place more pressure on the earth's environment, GIS and remote sensing will become increasingly critical for environment risk assessment and management. Remote sensing imagery of multi-spectral bands, multi-spatial resolutions, and multi-temporal cycles will provide accurate and timely fundamental data sources for measuring ever-changing environmental variables. GIS will help combine geo-spatial data, from remote sensing and other data sources, socio-economic data, and demographic data to formulate integrated solutions and strategies. More advanced image-processing algorithms and methods will streamline real time data update and dissemination, which will help develop a comprehensive global environment database. New developments in computing and information technologies will propel GIS to overcome current technical challenges for carrying out real time three-dimensional simulations in a distributed computing environment. Together, GIS and remote sensing will help environmental scientists and decision makers to optimize resources allocation, enable global data and information sharing, and promote effective and cost-efficient environmental risk assessment and management practices.

KEY TERMS

GIS: A digital-based data storage, data manipulation and analysis, and visualization system and science, consisting of hardware, software, and organization structure. The modern GIS began in the 1960s, and it has evolved into a maturing science discipline. GIS was an acronym for geographic information systems, but was first used to represent geographic information science in 1992 by Michael F. Goodchild.

Human Environment: The complete continuum of matter and conditions that surround human and human society. The state of the earth's environment dictates the existence, safety, and health conditions of human and is affected by the interactions between human and the natural environment.

Image Resolution: The quality of remote sensing imagery is controlled by its resolution, which includes spatial resolution, spectral differentiation, radiometric calibration, and temporal revisit cycle. Spatial resolution (image pixel size) is the minimum ground separations between adjacent objects that appear distinct on the image. Spectral resolution is the sensor's overall spectral range and the width of individual spectral band, with higher resolution having narrower bands and/or overall broader spectral range. Radiometric resolution is the sensor's calibration capability to detect the minimum spectral response differences of imaged objects. Temporal resolution is the time interval between two repetitive sensing cycles for a given region. A smaller time interval gives a better coverage to monitor changes or dynamic phenomena.

Remote Sensing: The technology of obtaining, analyzing, and displaying the information about an object or a phenomenon through remote detection of its reflected and emitted electromagnetic energy. The term "remote sensing" was first used in the United States in the 1950s by Ms. Evelyn Pruitt of the U.S. Office of Naval Research.

Risk & Vulnerability: Risk is the possibility for human to suffer the loss and/or injury (physical, social, economic, property) from hazards. Vulnerability is an area's susceptibility to damage and degradation. Risk and vulnerability often occur side by side.

Risk Assessment: A process to identify hazard types, their intensities/magnitudes, occurring probabilities, and the associated consequences of impact.

Risk Management: The responding practices to better mitigate hazards or recover from any associated adversary impact. Typically, effective risk management includes pre-disaster mitigation planning by means of insurance, land use regulation, and technology; rapid and effective emergency responses during the emergency; post-disaster recovery and rebuilding management; and increased public awareness education.

Global Digital Divide

Nir Kshetri

Nikhilesh Dholakia
University of Rhode Island, USA

INTRODUCTION

Despite rapidly falling costs of hardware, software and telecommunications services, a wide gap persists between rich and poor nations in terms of their capabilities of accessing, delivering, and exchanging information in digital forms (Carter and Grieco, 2000). According to a report published by the United Nations Conference on Trade and Development in 2006, a person in a high-income country was more than 22 times likely to use the Internet than someone in a low-income country (UNCTAD, 2006). The ratios were 29 times for mobile phones and 21 times for fixed phones.

An estimate suggested that more than 95% of e-commerce transactions in 2003 were industrialized countries (Tedeschi, 2003). Another estimate suggested that 99.9% of business-to-consumer e-commerce in 2003 took place in the developed regions of North America, Europe, and Asia Pacific (Computer Economics, 2000). This is a form of commercial divide (UN Chronicle, 2003). Another estimate suggests that 80 percent of the global trade in high technology products originates from Europe, the U.S., and Japan (Bowonder, 2001) and 92 % of the patents granted in the world are owned by the members of Organisation for Economic Co-operation and Development (Archibugi and Iammarino, 2000).

Whereas high-income countries have income 63 times that of low-income countries, the respective ratios are 97 for PCs, 133 for mobile phones, and over 2,100 for Internet hosts (Dholakia and Kshetri, 2003). While reliable data on e-commerce transactions are not available, the ratio is likely to be even higher for e-commerce transactions since e-commerce is virtually non-existent in many developing countries. The pattern indicates that the gap between developed and developing countries is wider for more recent technologies such as PC, mobile phone, and the Internet than for technologies which were introduced earlier.

This article provides an assessment of three computer networks that redefine the conventional definition of market value by allowing developing nations and communities (Brooks, 2001) reap the benefits of modern ICTs: Global Trade Point Network (GTPNet) and Little Intelligent Communities (LINCOS).

BACKGROUND

The "global digital divide" is the outcome of the complex interactions between information and communication technologies (ICT) and various economic, political, and social factors in the environment. The global digital divide arguably is one of the strongest non-tariff barriers to the world trade with potentially adverse social, economic and other consequences influencing a developing country's ability to take advantage of opportunities provided by modern ICTs (UN Chronicle, 2003). First, a large majority of potential users in developing countries are unable to afford a telephone line, a PC, and the telephone and Internet services provider (ISP) access charges. Whereas the cost of a PC is 5% of per capita GDP in high-income countries, it is as high as 289% in low-income countries (ITU, 2001). Furthermore, monthly Internet access charge as a proportion of per capita GDP in the world varies from 1.2% in the U.S. to 614% in Madagascar (UNDP, 2001).

Second, even if consumers are willing to pay for the connection of a telephone line, there is a big gap between demand and supply in developing countries. For instance, in 2001, 33 million people in the developing world were on the registered waiting lists for telephone connections, the average waiting periods being over 10 years in some countries.

A third problem is related to the lack of skills. A majority of potential users in developing countries lack English language and computer skills, prerequisites to the use of Internet. For instance, in 1998 about 85% of the text on the Internet was in English (Nunberg, 2000). This proportion was estimated at 80% in 1999. Another estimate suggested that about 70% of the world's Web sites were in English in 2003 (UN Chronicle (2003). Although a shift of Internet content to non-English languages is under way, some knowledge of English is still necessary to use the Internet as the bulk of software used in the Internet is in English (Hedley, 1999) and most of the human-computer interfaces favor English language users (Goodman, 1994).

A fourth problem is related to the lack of relevant content or the content divide (UN Chronicle, 2003). Although there are over 17 billion Web pages[1] in existence, the content remains largely geared to the needs of advanced nations. Most of the information available on the WWW is not relevant to

the needs of people in the developing world (UN Chronicl, 2003). Edejer (2000) observes the difficulty of finding reliable health related information relevant to developing countries online:

Few reports of health research from developing countries are published in journals indexed by Western services such as Medline. Western indexing services cover some 3,000 journals, of which 98% are from the developed world. The whole of Latin America accounted for 0.39% of the total number of articles referenced by Medline in 1996... Because only a small number of journals from developing countries are indexed by Medline, research from these countries is almost invisible.

CREATIVE WAYS TO BRIDGE THE DIGITAL DIVIDE: SOME EXAMPLES

The effectiveness of a network in bridging the global digital divide is thus a function of (1) the network's ability to identify priorities of digitally excluded populations, and (2) the network's ability to attack the major barriers to Internet and e-commerce adoption. In the following section, we examine three projects aimed to enable e-business systems for the global poor: DDD, GTPNet (Figure 1) and LINCOS (Figure 2).

Digital Divide Data (http://www.digitaldividedata.com/)

Digital Divide Data (DDD), a nonprofit organization, was started in 2001 by a group of North Americans. Canada's Jeremy Hockenstein and Jaeson Rosenfeld of the U.S. came up with the idea for DDD. When Hockenstein visited Cambodia in November, 2000, many Cambodians were in Internet cafes, but he realized that they were not using the technology to increase economic productivity (The Associated Press, 2001). Hockenstein felt that Cambodia should focus on attracting IT-related businesses, rather than factories that produce clothing or other manufacturing goods (Reed, 2001).

The two North Americans invested $25,000 of their own money and received a $25,000 grant. An Indian firm donated technical advice and software (Shih, 2003). In 2002, DDD received another $45,000 grant to support DDD's expansion[2].Its main office is located in Phnom Penh, Cambodia. Subsequently, DDD expanded its operations in Vietnam and Laos also (Fast Company, 2005).

DDD was started with 20 employees and the number grew to about 115 by 2003 (Tedeschi, 2003). By the spring of 2004, DDD had 140 people employed in the three countries (St. John, 2004). The employees digitize data from maps or documents and send them back to the country of origin (e.g., the U.S.). DDD's first project was a $50,000 contract to digitize 100 years of archives of the Harvard Crimson, Harvard University's student newspaper (Shih, 2003). Digital Divide Data generated $178,974 in 2003, a 67% increase over 2002, which covered the operating expenses, with some money left for further business development (St. John, 2004). In 2003, DDD workers earned $1,200 a year, which is four times the average Cambodian's income (Tedeschi, 2003).

Most of DDD's employees are women, polio and landmine victims, orphans and other categories of internally displaced people (Anderton, 2003). Whereas the wage offered at Phnom Penh garment factories exporting clothing to the U.S. was $11.25 for a 48-hour work week in 2003, DDD typists earned $16.25 a week working a 36-hour week (Shih 2003). DDD workers do data entry jobs for six hours a day and get English and computer training for another six hours (Helm and Kripalani, 2006). Thus, the work makes them employable in more challenging and better paying jobs. In addition, if employees set aside $20 per month for educational purposes, DDD matched with a $20 scholarship (St. John, 2004). The company awarded 80 such scholarships by the spring of 2004 (St. John, 2004).

In the beginning, DDD faced a number of problems. For instance, typists did not save their documents, which resulted in every new day's typing erasing the previous day's work, and workers were shy to ask questions and embarrassed to point out errors in their colleagues' works (Shih, 2003). Efficiency and quality were problems attributed to DDD's hiring practices which employed people with little IT experience and very limited English language skills. DDD utilizes a rigorous proofreading system and other quality-control processes such as specialized "double entry" software to minimize typographical errors (St.John, 2004). Accuracy rates gradually improved. Estimates suggest that U.S. companies can save 50-60% by outsourcing works to DDD (Anderton, 2003).

Global Trade Point Network (GTPNet) of the World Trade Point Federation (http://www.wtpfed.org/)

The United Nations Conference on Trade and Development (UNCTAD) launched the Global Trade Point Program in 1992 to facilitate the access to international markets for small and medium-sized enterprises (SMEs). The program was taken over by the World Trade Point Federation (WTPF) in November 2002. In mid-2003, GTPNet had a human network of 121 Trade Points in over 80 countries on the 5 continents[3].

In a trade point, participants in foreign trade transactions (e.g., customs authorities, foreign trade institutes, banks, chambers of commerce, freight forwarders, transport and

Figure 1. UNCTAD GTPN

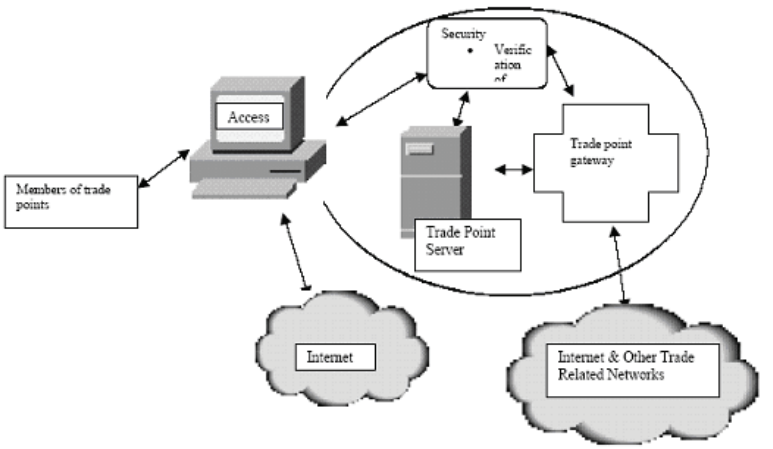

Figure 2. LINCOS network

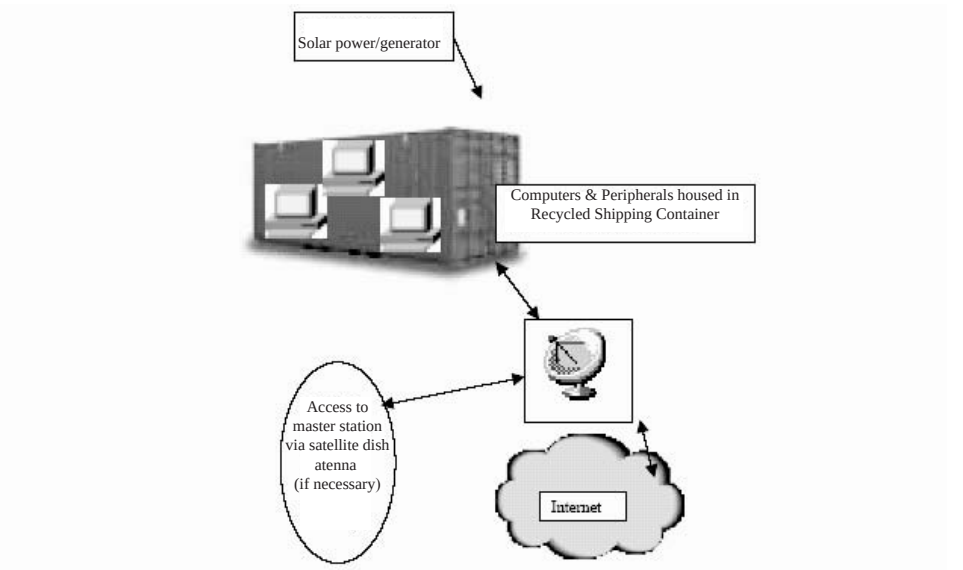

insurance companies) are grouped together under a single physical or virtual roof to provide all required services at a reasonable cost. It is a source of trade-related information providing actual and potential traders with data about business and market opportunities, potential clients and suppliers, trade regulations and requirements, etc. A survey found that 85.7% of trade point customers are SMEs and micro-enterprises (UNCTAD, 1997).

The ETO System is probably one of the most important aspects of the GTPNet. It was started by the UN Trade Point Development Center (TPDC) in June 1993 and is the world's largest Internet-based business opportunities system. ETOs are offers and demands for products, services, and investment and are distributed point-to-point and company-to-company. They are forwarded to the GTPNet system by Trade Points and third-party information providers. A random survey of ETO users conducted in 1998 revealed that 48% of the ETO users received 1-10 responses per posted ETO, an additional 14% received 10-30 responses, about 7% received over 100 reactions. About a third of respondents made business deals on the basis of ETOs.

Developing countries also have a much higher share in the ETOs than in the overall global e-commerce. A United Nations Trade Point Development Center's (UNTPDC) analysis of ETOs posted on the GTPNet during March 1- July 15, 1998 indicated that 20% of them were posted by U.S. based companies followed by companies in China (19%), South Korea (11%), and India (7%) (UNCTAD, 1998). It is interesting to note that the U.S. accounted for 74% of the global Internet commerce market in 1998 (Wang, 1999).

Password-restricted areas have been added to the GTPNet site which uses state-of-the-art tools for uploading, downloading, automatic updating, and searching for information. Only Trade Points and members of Trade Points can send electronic trading opportunities (ETOs) and see hot ETOs[4]. Java is used to control access, certify trading partners, and handle payments. The Java-based secure infrastructure ensures integrity and confidentiality of all trade information. Certification is the first step in secure trading. Prospective traders download the UNTPDC's 100% Pure Java-based applet and use it to provide the UN with reference data about their banking, trading, and services. After the UN certifies it, the company uses the Java applet residing in their standard Internet browser to access the network. Similarly, the smart card project of the UNCTAD is facilitating the payment flow in international trade. As discussed in the previous section, the first and second level smart cards allow secure ETO, confidentiality, payment information integrity, authentication, etc.

The Secure Electronic Authentication Link (SEAL) project and concept were developed by the United Nations Trade Point Development Center. Its smart card project facilitates payment flows in international trade. The first level smart card allows users to automatically authenticate their user profile to the SEAL and secure electronic trading opportunity (ETO) on the GTPN. The second level smart card allows confidentiality of information, payment information integrity, cardholder account authentication, merchant authentication, and interoperability with the ETO system on the Internet and the GTPN.

Most of the trade points are, however, located in big cities and many less developed countries are still deprived of the services of trade points. GTPNet sites are also vast and not well organized (Lehrer, 2003). A recent international forum on ways to improve the Trade Point programs for SMEs came up with many suggestions[5] including the necessity of encouraging and assisting non-exporting companies possibly by even creating special e-commerce programs open to "new exporters" only; providing guidance for the management; providing translation services so that import-export business can be conducted in multiple languages; and providing convenient online payment mechanisms.

LINCOS: Little Intelligent Communities (http://www.lincos.net/)

The LINCOS initiative was developed jointly by the Fundación Costa Rica para el Desarrollo Sostenible, the Media Lab at the MIT, and the Instituto Tecnológico de Costa Rica in 1998 (Saxe et al., 2000). LINCOS selected Hewlett Packard's E-inclusion as the model. It has alliances with over ten academic institutions, and at least ten technology companies (United Nations, 2000). Initially, LINCOS used recycled shipping containers to house computers, peripherals and generators. Each unit comprised of five computers and other facilities to provide a broad range of services including Internet access, health, education, banking, government services, electronic trading, technical support for SMEs, telecom and Information center, video conference and entertainment, forest, soil and water analysis, etc. The ultimate goal of the project is to achieve sustainability by allowing each community within the network to make decisions related to the technologies and advance them independently[6].

Each unit is satellite operated and solar power enabled and can operate independently of traditional infrastructures. The satellite dish antennae link them to any telecom network or master station as needed. Eggers and Siefken (2000) comment on LINCOS' effctiveness:

LINCOS units can be taken anywhere—mountain, jungle or village—and make Web-browsing, telephony and e-mail available even in the most remote spot. Equipped with their own generators, these units need neither external energy nor communication cables; they connect directly via satellite.

The units are installed in a container equipped with five computers. Additional LINCOS units are to be provided if more computers need to be added. The investment for each

unit was as high as $85,000 U.S. in the Dominican Republic and $50,000 U.S. in San Marcos de Terazu, Costa Rica (Proenza, 2001), but is expected to decrease with the increase in production (United Nations, 2000). In 2000, LINCOS won ALCATEL's first place prize for Technological Innovation in Latin America. Latin America participated in the competition[7] with over 30 projects.

The prototype LINCOS sites, which have already been deployed in Costa Rica, are providing several benefits. For instance, coffee growers use LINCOS sites to find the best prices in the world as well as next week's weather. Thanks to LINCOS' assistance, Costa Rican coffee farmers have also created Web pages and learned how to request budgets for buying equipment and register their trademarks (Amighetti and Nicholas, 2003).

While a container has had obvious advantages for carrying the equipments to the remote communities, the "container concept" was later abandoned because it created the concept of "temporariness"; the target users did not regard it as "rooted in the community" and tended to develop the feeling that the project was brought to the community in a "top-down" manner as a wrapped-up "development package"[8]. A second drawback of LINCOS is that it has attracted relatively rich people instead of helping the poor (Amighetti and Nicholas, 2003). According to the World Bank's Charles Kenny, LINCOS' have had mixed results because of the lack of sufficient interest of the target audience. He argues: "Poor people don't seem to think that the Internet is the answer to all their problems" (Rich, 2003, p. 93).

FUTURE TRENDS

Since the global digital divide is the result of fundamental economic, political and social gaps between the developed and the developing world, such a divide is likely to remain in place (Guillén & Suárez, 2005). In the absence of appropriate policy measures, it is likely that the global digital divide may become even wider (Dholakia and Kshetri, 2003; Economist.com, 2000). Policy measures directed at making appropriate networks available to the digitally excluded populations at reasonable costs, however, could bridge the gap or at least decrease the rate at which it widens.

The nature of the 'divide', which entails several gaps (UN Chronicle, 2003) appears to be changing rapidly. While some poor-friendly technologies such as cellular phones (Kshetri, Dholakia and Schiopu, 2006) and open source software (Kshetri, 2004) are bridging the basic form of digital divide in terms of access to technology, other forms of digital divide are widening and new forms are rapidly emerging. Evidence indicates that the digital divide has shifted from basic to advanced communications and more generally from quantity to quality (World Telecommunication Development Report, 2002).

CONCLUSION

Rapidly dropping costs of ICTs, developments of user-friendly software and interfaces, and versatility of the Internet offer the potential for leapfrogging many of the development obstacles. Civil society, governments, and entrepreneurs of developing and industrialized countries can take actions to bridge the digital divide by targeting highly excluded communities, by designing appropriate combination of new and old technologies, and by setting projects in the context of a longer term plan to extend the benefits more widely.

Some companies have already taken exemplary measures against the global digital divide. For instance, in May 2006, Intel announced its plan to invest a billion dollars to help provide access to technology and educational resources in developing countries (Clark, 2006).

Although, the networks discussed in this article are helping to bridge the digital divide between the developing and developed countries to some extent, most of them are not yet able to reach really excluded populations in developing countries. For instance, mainly rich people are benefiting from LINCOS. Similarly, there are no trade point programs in small villages of developing countries.

There is a huge untapped market for modern ICTs in developing countries if the services are *affordable* and *appropriate* to the target population and e-business companies need not provide their services in philanthropic ways. Lyle Hurst, director of HP e-inclusion, a partner of LINCOS, says that the mobile digital community centers will be a significant market opportunity for all involved. To exploit the potential, comprehensive research on the needs of the digitally excluded population and on the most appropriate networks to satisfy such needs by using locally available expertise and resources is needed.

The experiences of LINCOS and GTPNet indicate that lack of awareness and interest with the target audience are the major drawbacks of the networks discussed in this chapter. National governments, international agencies and technology marketers are required to work together to educate the target users about the potential benefits of such networks.

KEY TERMS

Digital Divide: Refers to the fact that people in developing countries use modern ICTs less than those in developed countries.

Gross Domestic Product (GDP): Is the sum of the total value of consumption expenditure, total value of investment expenditure, and government purchases of goods and services.

High-Income Countries: Have per capita income $9,266 U.S. or more (in 2001).

Information and Communications Technologies (ICTs): Are technologies that facilitate the capturing, processing, storage, and transfer of information.

Internet: Is the "global information system that (1) is logically linked together by a globally unique address space based on the Internet Protocol (IP) or its subsequent extensions/follow-ons; (2) is able to support communications using the Transmission Control Protocol/Internet Protocol (TCP/IP) suite or its subsequent extensions/follow-ons, and/or other IP-compatible protocols; and (3) provides, uses or makes accessible, either publicly or privately, high level services layered on the communications and related infrastructure described herein" (The Federal Networking Council definition).

Low-Income Countries: Have per capita income less than $875 U.S. (in 2001).

PPP (Purchasing Power Parity): Is a rate of exchange that accounts for price differences across countries, allowing international comparisons of real output and incomes.

Global Software Team and Inexperienced Software Team

Kim Man Lui
The Hong Kong Polytechnic University, Hong Kong

Keith C. C. Chan
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

Given that the number of qualified programmers cannot be increased drastically and rapidly, software managers in most parts of the world will likely have to live with a human resources shortage in this area for some time. One way of dealing with this shortage is to form global software teams in which members are recruited from all over the world and software is developed in a distributed manner. Forming such a global software teams can have many advantages. In addition to alleviating the problems caused by scarcity of human resources, programmers on a global team would be free to work without being confined by physical location.

Although forming global software teams may increase the size of the pool of programmers that can be recruited, both team quality and software quality are issues of great concern. Some software companies would prefer to establish a global software team with software programmers in developing countries, such as China, Poland, and South Africa (Sanford, 2003). Given the tremendous salary gap between skilled and unskilled developers or between developed and developing countries, it is not difficult to see that maintaining a team with a proportion of less experienced members significantly reduces running expenses (Figure 1). On the other hand, however, it would present the problem of managing inexperienced programmers.

This chatper shares our experience of managing inexperienced software teams in China. To simplify our discussion, we deal separately with the two topics of inexperienced software teams and global software teams. However, it should be noted that a global software team can be composed of both inexperienced and experienced software subteams. We categorize the problems in these two types of software teams which will help software managers learn more how to manage the two types of software teams.

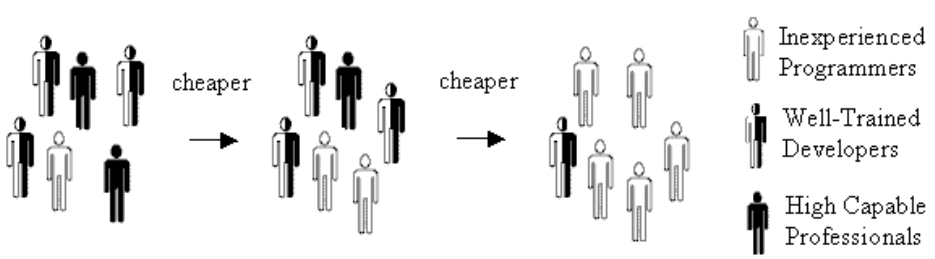
BACKGROUND

This section reviews real cases that have driven the formation of an inexperienced software team and a global software team. The motivation behind managerial decisions to build such teams is both financial and environmental.

Discovering Developing Areas: Inexperienced Software Team

Active rural industrialization involves manufacturing plants moving from more developed regions to less developed ones so as to exploit the lower costs of land, labor, and distribution channels (Otsuka, 2001). In less developed regions it is an

Figure 1. In the software world, the proportion of highly professional to less experienced teams may fall as companies operate under the constraints of tighter cash flows and for reasons of cost replace more experienced programmers with junior programmers and seek to avoid the costs associated with the professional development of senior programmers.



easy matter to recruit labor for manufacturing, but these plants also require management information systems (MIS) and it is not at all easy to find and recruit the IT professionals that are required to develop an integrated, customized MIS.

In developing countries, the demand for IT professionals in larger cities is currently so high that it is almost impossible for any manufacturing plant in a rural area to recruit people. As a result, programmers in poor rural areas are usually inexperienced. Even though the alternative of employing software expatriates might sound reasonable, it is feasible to recruit one or two highly qualified programmers from developed regions but it is not practical to recruit a team of them. Instead of in-house development, we might evaluate a third-party solution. The additional expenses incurred in purchasing vendor products, in consultancy services, annual maintenance, version upgrading, training, traveling, and so forth, outweigh the savings that are sought by setting up in the country in the first place.

In less developed areas, many programmers do not receive proper training in computing. In addition, the turnover rate is typically high. As soon as they have received even a little training, many workers will seek a job with better career prospects in a more developed city. The result is that the project manager always has to work with inexperienced programmers and in a constant mood of crisis management as the high turnover rate is aggravated by resignations without notice as people tender their resignation and leave on the same day. Clearly, the process of handing over work is unsatisfactory, teams are constantly under-staffed and the working environment suffers, making work elsewhere an even more attractive option.

One may suggest that educating inexperienced people or allocating suitable jobs according to an individual's ability should fulfil the same purposes. However, when the knowledge and experience of staff members is not aligned with the tasks assigned, the learning curve can be steep and long (Amrine, Ritchey, Moodie & Kmec, 1993). Nevertheless, when a staff member becomes well trained in some less developed regions in China, or in a small company in Denmark, for example, the determination of the staff member to look for better job prospects elsewhere will become stronger. Training, therefore, does not provide a promising solution in this case. In contrast with what we might find in well-developed regions, in China, staff who are provided with certified professional programs will leave a company or a less developed region even sooner. Senior managers are disturbed by this phenomenon and say that they are always training another company's staff. The idea of allocating developers according to their skill set is not feasible when all team members are inexperienced. Human resource allocation can therefore be implemented only to a limited extent. Better knowledge management, rather than adopting conventional principles, is required.

Around the Clock: Global Team

A small but ambitious company selling weight-loss and nutritional products, which was headquartered in New York, had a number of small offices of 40 employees in different parts of the world. Being close to customers is always a key to business success.

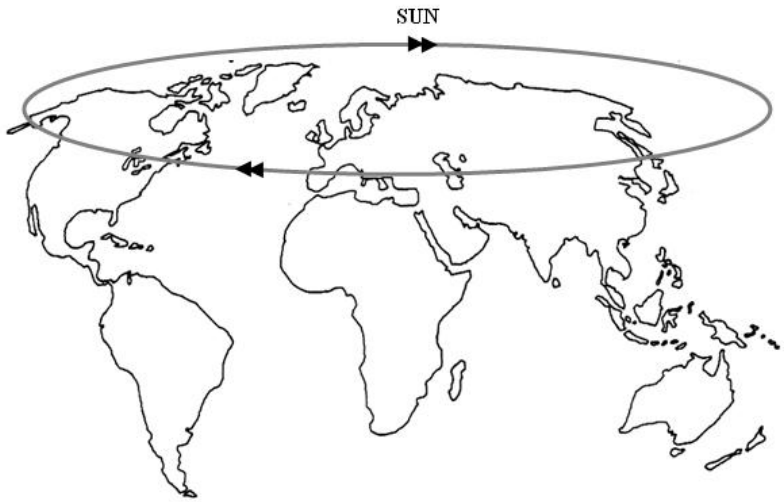
One to two staff members in each office had the task of providing IT support. When the MIS system needed to be modified to meet requirements for local processing, requests for modifications would be sent to the head office. The result was that more resources were required at the head office to provide ongoing support to the branches. Although a larger software team was thus required at the head office, IT staff at the branches might have time to spare.

The load-balancing problem got worse when the number of branches increased. The question, naturally, was to decide if it was possible to link people to establish a global software team. The team in each site then plays a role more or less as distributed agents following a communication scheme from a coordination agent.

A global software team can even be formed locally, if the team is set up in different locations within the same country or in nearby countries or regions. This means that there may not be much difference in time zones and cultures. In such situations, the term "multisite" or "distributed" software team can be used more generally to describe a software system developed by teams that are physically separate from each other in different cities of a country or in different countries. A multisite team in nearby time zones can be managed with less complexity and fewer challenges than a global team and but has more limited service hours. Clients on the other side of the world want a reply inside their own local business hours but if all teams are in the same time zone, it becomes hard to respond promptly outside office hours. In any case, the management framework required for a global or multisite team should be very similar. To further explore around-the-clock development (see Figure 2) and global development, we realize the intrinsic difference is how synchronization of work-in-progress proceeds. We concluded that challenges of managing around-the-clock tasking widely cover managerial and technical problems of non-around-the-clock global software development.

Around-the-clock development exploits time zone differences as a way to improve time-to-market . But, there has not been a model for this kind of global software development (Carmel, 1999; Karolak, 1998). It is easiest to manage a global software team with less strict synchronization among different sites. In this case, a team that is waiting for a result from another site could work on other tasks for the same project. However, in around-the-clock development, work-in-progress and communications are rigidly synchronized and the progress of a team is tied to the progress of

Figure 2. Around-the-clock development (also called around-the-sun development)—A global team with one site in Asia, one in Europe, and one in North America maximizes time use by working around the clock



another team that posts deliverables to another team at the end of the day.

A traditional framework does not provide a sound solution (McMahon, 2001). A less strict model is available if there are recognized steps towards a standard solution because then the work of one team can be continued by another team at the point where they stopped. Work is thus forwarded from team to team and time zone to time zone until it has been finished.

The success of around-the-clock development thus greatly depends on what type of application we build and what methodology we use to manage a global team. It requires standard approaches to standard problems, for example, generic systems for a particular application such as a database or a Web system. The bad news is that this approach is unable to cope with the totality of any new type of project. The good news is that a high portion of information projects nowadays are related to familiar commercial database applications and Web applications.

HOW TWO TEAMS ARE RELATED

At a glance, an inexperienced development team and a global software team conjure up two totally different pictures. However, some problems can be dealt with by the same common solution. We start with the examination of commonalities between them, shown in Table 1.

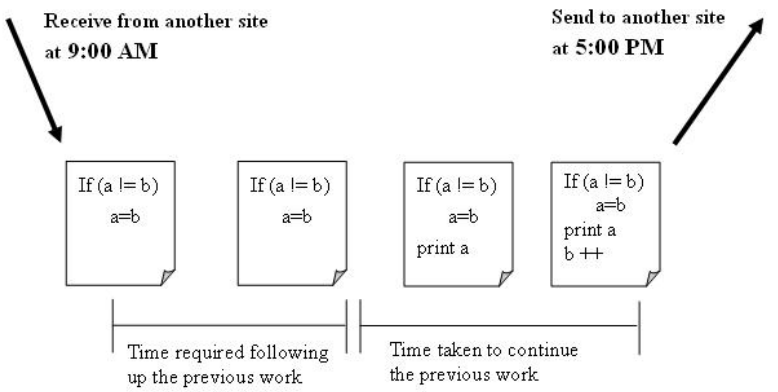
Turnover

In less developed regions in a developing country, programmers are usually inexperienced. As soon as they gain experience and receive some training, many of them will look for a new job in the more developed cities either in the same country or in other countries (Morris, 1995). As a result, the rate of staff turnover is high. This situation is aggravated by the fact that many people who tender their resignations prefer to leave immediately, making work effective work

Table 1. Characteristics of software development teams: An inexperienced team and a global team

	An Inexperienced Software Team in a Less Developed Region	A Global Software Team using Around-the-clock Development
1. Turnover	High Personnel Turnover	High Task Turnover
2. Knowledge Management	Weak IT knowledge	Varied knowledge and skills at each site
3. Communication	Lack of IT project experience for effective team communication	Varied culture at each site

Figure 3. Anatomy of the process of around-the-clock development



handovers either difficult or impossible. It can be seen from this how personnel turnover can severely affect the rate of task turnover.

In some respects, the use of global teams for around-the-clock software development can produce similar problems as a team following up the work done by another team cannnot communicate with the predecessor team in real time as that team is asleep on the other side of the globe.

The basic challenge of around-the-clock work here is the time needed to follow up in order to continue the task delivered electronically from another site, and the remaining time for working and then relaying to another site at sunset, depicted in Figure 3. There are two unconventional problems. The subprocess in a site must not be interrupted, as this will also suspend the whole process. In addition, the sum of the working hours to follow up and to continue is just one day. Suppose each site works for eight hours a day. The efficiency of around-the-clock development at one site will be as follows:

$$\text{Efficiency} = \frac{8\,\textit{hours} - \text{Time used to follow up previous works}}{8\,\text{hours}} \times 100\%$$

Around-the-clock software development has problems similar to those associated with a high personnel turnover rate. Neither guarantees that the expected outcome is achievable. And both strongly require a very quick job handover without face-to-face, lengthy explanations from previous developers.

Personnel turnover and task turnover can unexpectedly interrupt or sometimes even halt our project activities. Many software teams seem to be taking a very ad hoc approach but their project activities are always progressing and these teams normally complete projects on time and on schedule. In these cases, the rhythms of running software projects (referred to as software development rhythms), rather than software methodologies alone, provide a deeper understanding of what and how a software team should plan and execute their projects (Lui & Chan, 2008).

Knowledge Management

In developing a database application, a software team may encounter many kinds of technical problems that require different skill sets, such as inserting records into a database, deleting records from a database, updating those records, controlling data integrity, controlling transactions (Taylor, 2003). In order to do programming, a software team should be equipped with the minimum expertise that allows the team to complete part, if not all, programming jobs. Developers below that level could do nothing by themselves. Figure 4 illustrates this idea.

Our goal is to lower the line of minimum expertise—but how? Let us look at an example: suppose you have a group of people, say those with a learning disability, who are able to count numbers but do not understand addition. If we want them to do the addition without a calculator, the best way would be to teach them the calculation. This would be the minimum expertise for this problem. Still, the learning curve may be long. *(If they are your employees, your boss cannot help wondering why you would hire these people and make the office a learning center. Subsequently, you cannot help worrying about the full support that your boss previously committed to you.)* Another approach to getting the same work done is a mechanical method that asks the workers to

Figure 4. Minimum expertise for programmers

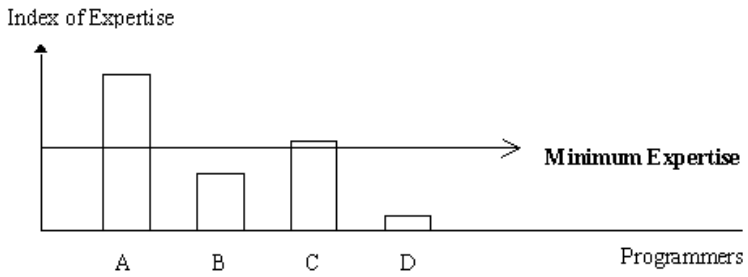


Figure 5. Lowering minimum expertise

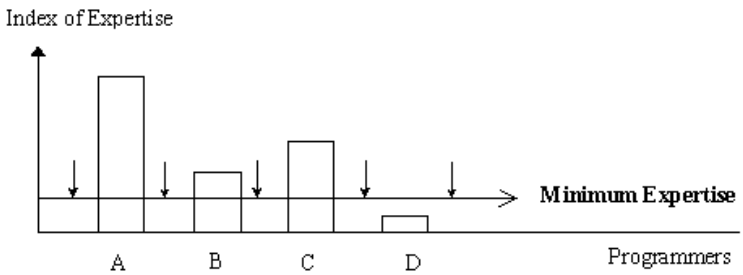

Figure 6. Minimum expertise for development center

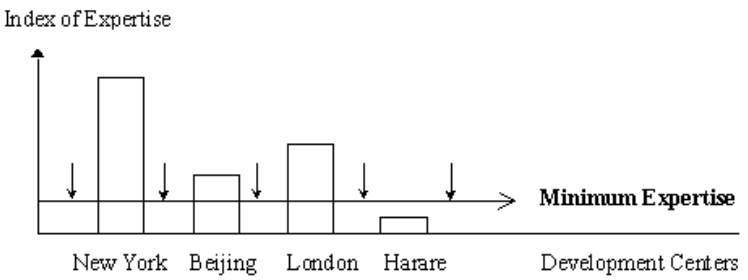

follow a predefined mechanism for counting marbles. As for 4+3, the rule might be as follows:

(*Step 1*) Count four marbles and put them aside.
(*Step 2*) Count three marbles and put them aside as in Step 1.
(*Step 3*) Count all the marbles together.

The minimum expertise is now counting marbles and putting counted marbles aside. Obviously, learning to add numbers first requires understanding how to count numbers. Putting counted marbles together means the workers follow the steps. In short, the minimum expertise is lowered to some degree, as shown in Figure 5, although the approach might not appear to be intelligent, management would be happy with it as employees are able to start working and get the work done in a predictable way and time.

The problem of different technical skills among team members parallels the situation of different knowledge levels among many sites in the global software team, as shown in Figure 6. For example, in Figure 6, programmers in Beijing may use techniques in a program that developers in Harare would spend a whole day figuring out, whereas developers in London may follow up the work quickly and can continue to work.

This may happen that all of the teams spend more time on some of project tasks tremendously owing to technical skills unmatched to a point that requires completing the tasks or technical skills among members being diversified to a point that members do not understand (or even complain) the ways other members have done their jobs.

COMMUNICATION

Communication does not only require the application of knowledge of surface features such as words; it also requires knowledge of the cognitive and cultural practices of different groups and disciplines. This means that on the one hand, global communications between software programmers is aided by the fact that they are all trained in the same field, even if some of the programmers are not as well trained as others. On the other hand, regional cultural differences can also mean there are many very different assumptions about matters of communication, such as who is responsible for clarity in a communication (is it my job to explain or yours to understand?), what can be assumed to be already understood, in what order ideas should be presented, whether authorities can be questioned by subordinates. Clearly, communication can become a central issue in the effectiveness of global teams and so it is important that global teams work within a clear corporate communicative culture. This can be especially critical in software projects, where project progress is intangible and must be constantly assessed and reported in ways that rely very much on communication.

FUTURE TRENDS

Globalism and the expansion of the web will continue to underwrite the global demand for IT professionals (Sangwan et al., 2007). There is no doubt that we will have to either recruit and train less experienced programmers for our software teams or build a global software team so as to acquire human assets not limited to a particular job market. Yet other innovative approaches will also be adopted.

Recently, agile software development (Cockburn, 2007) has provided an alternative way to alleviate some of the software development problems addressed previously. For example, pair programming helps to minimize the impact on personal turnover as every piece of production code is now written by two programmers (Lui & Chan, 2006). Putting the focus on compiling working software daily can also facilitate effective communications not only between customers and programmers but between different programmers as well. Although many agile practices (e.g., daily stand-up meetings and pair programming) appears to be easily adopted for colocated small teams, software practitioners are trying to take the agile philosophy into distributed environments by extending agile practices (Finden, 2006). Unfortunately, some colocated agile software teams still fail to manage their projects (Stephens & Rosenberg, 2003), needless to say distributed agile teams in distributed envrionments; such failures are not due to any difficulty of learning and adopting a single agile practice. The real challenging issue is to combine a number of agile practices (with existing software practices already adopted by a software team) in such a way that the team is able to integration with software practices. This has been referred to as *software development rhythms*. For example, software team members who have been used to writing programs with their private instant massagers on will take more time to get used to pair programming. This however does not mean that it takes time to go agile. It only means that we have to understand the relationships between our team and newly adopted practices. Going back to our example, the team may try to adopt pair-solo programming (Lui & Chan, 2008) to see if it provides an effective rhythm for the team.

CONCLUSION

We have addressed some interesting problems relating to inexperienced software teams and global software teams. Both require new managerial, technical, and social approaches and underline the fact that software projects fail not because of the failure of software methodologies or software teams but because of the failure of software development rhythms.

KEY TERMS

Agile Software Development: Agile software development is a conceptual framework for software engineering that promotes development iterations throughout the life-cycle of the project.

Around-the-Clock Development: A software development style in which software teams that are geographically distributed make use of time zones to develop software.

Around-the-Sun Development: See Around-the-Clock-Development.

Efficiency of Around-the-Clock Development: This is an index used to indicate a ratio between time required to follow up the previous work and time spent advancing the work.

Global Software Team: Software teams located in different countries collaborate as a single team for a clear project objective.

Inexperienced Software Team: Most members of a software team are graduates, or inexperienced in disciplined software development.

Multisite Software Team: Software teams located in different cities and/or in different countries collaborate as a single team for a clear project objective.

Time-to-Market: A work product to the market as quickly as possible, before competitors, in order to get a larger market share or to begin earlier cost recovery.

Software Development Rhythms: Software development rhythms (SDR) respects and builds upon the inherent flexibility of agile practices (e.g., pair programming, refactoring, test-driven development, stand-up meeting, plagiarism programming, etc.), focusing on understanding the "why and when" of the effective application of practice-move-practice or activity-move-activity

Globalization of Consumer E-Commerce

Daniel Brandon, Jr.
Christian Brothers University, USA

INTRODUCTION

This article reviews globalization aspects of "business to consumer" (B2C) electronic commerce. According to *Computerworld*, "Globalization is the marketing and selling of a product outside a company's home country. To successfully do that on the Internet, a company needs to *localize* – make its Web site linguistically, culturally, and in all other ways accessible to customers outside its home territory" (Brandon, 2001). This overview describes the key issues in the globalization of electronic commerce; for more detail, see the full book chapter (Brandon, 2002).

BACKGROUND

"Ever since the end of the Cold War, the world has been rushing toward ever-higher levels of national convergence, with capital markets, business regulation, trade policies, and the like becoming similar" (Moschella, 2000). The value of cross-border mergers grew six-fold from 1991 to 1998 from U.S. $85 billion to $558 billion. The world has not witnessed such a dramatic change in business since the Industrial Revolution (Korper & Ellis, 2000). More than 95% of the world population lives outside of the U.S., and for most countries, the majority of their potential market for goods and services is outside of their borders. Over 60% of the world's *online* population resides outside of the United States (IW, 2000).

Today, the majority of Fortune's 100's Web sites are available only in English (Betts, 2000). In our rush to get on the WWW, we sometimes forget that WW is for "World Wide" (Giebel, 1999). Today's average Web site gets 30% of its traffic from foreign visitors, yet only 1% of small and mid-size American businesses export overseas (Grossman, 2000b).

KEY ISSUES

"Localization" (shortened to L12N in Internet terms) considers five global dimensions: geographic, functional, regulatory, cultural, and economic (Bean, 2000). We shall overview each of these somewhat overlapping and interrelated issues in these groupings: language, cultural, legal, payment/currency, dates/units, and logistics.

Language

According to IDC, by 2005, more than 70% of the one billion Web users around the world will be non-English speakers (Wonnacott, 2001). For the immediate future, most of the Internet community will still understand English, but overall English is the native language to only 8% of the world. Most users in foreign countries prefer content in their own language; for example, 75% of users in China and Korea have such a preference (Ferranti, 1999). It was found that visitors spend twice as long, and are three times more likely to buy from a site presented in their native language (Schwartz, 2000). We also have to take into account differing dialects that are used across various countries speaking a specific language. The combination of language and dialect is called a "locale".

One can convert Web pages by hiring a translator or using a computer-based translation product or service. Hiring a translator will provide the best localization but is more costly than the automatic methods. Translators can easily be found in the Aquarius directory (http://aquarius.net) or Glen's Guide (www.gleensguide.com). It is best to use a translator that "lives" in the local region; if a translator has not lived in a region for a decade, he has missed 10 years of the local culture. There are also many companies that provide translation services such as: Aradco, VSI, eTranslate, Idiom, iLanguage, WorldPoint, and others. The cost of these services is about 25 cents per word per language (Brandon, 2002). Automatic translation software is another option, but it is still in its infancy (Reed, 2000). Some popular software products for translation are: www.e-ling.com, www.lhs.com, and www.systransoft.com. The automatically-translated text typically does not convey the meaning of the original text.

There are several Web sites which provide free translation services such as: http://babelfish.altavista.com, *http://translator.go.com*, and www.freetranslation.com. For example, Figure 1 shows the "BabelFish" Web site where we are requesting a translation of an English sentence into Spanish. Figure 2 shows the translation results.

Another alternative, although certainly not optimal, is to provide a link on your English Web page for these free services so that visitors can translate your content themselves. Figure 3 shows a portion of the CBU School of Business English version Web site.

The automatic Spanish translated version (using BabelFish) is shown in Figure 4. Note that automatic version, while syntactically and grammatically correct, does not

Figure 1.

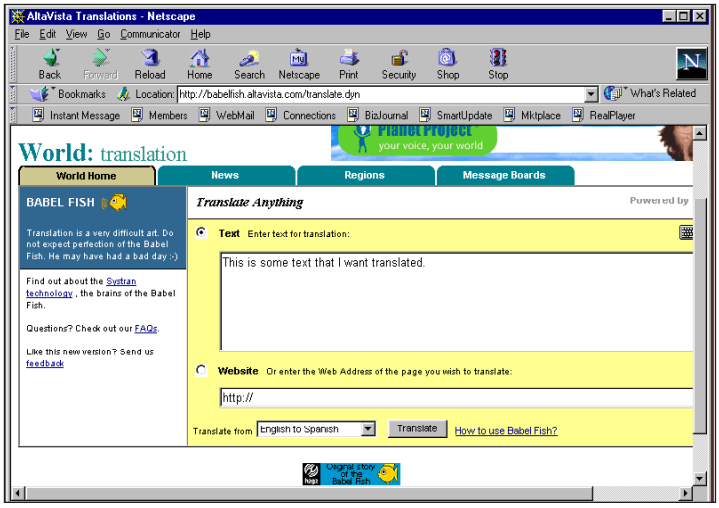

Figure 2.

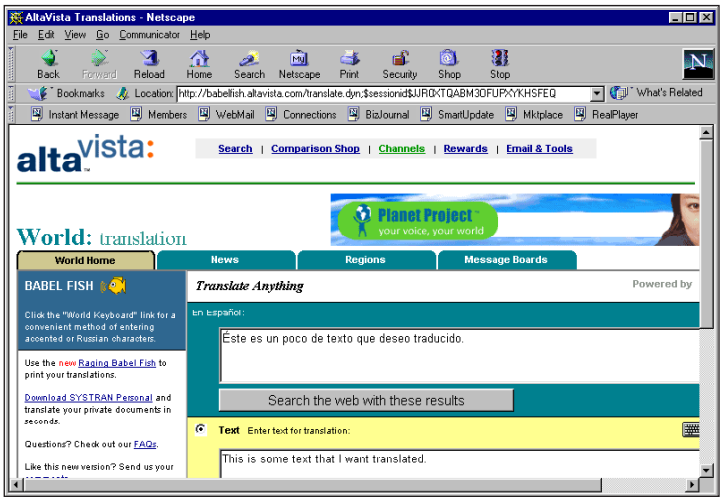

convey the exact intended meaning to most of the titles and phrases.

Figure 5 is the version converted by a translator manually, and even though you may not speak Spanish, you can see the extent of the differences (Brandon, 2000). Shown in Figure 6 is the home page for FedEx (www.fedex.com). One can select from over 200 countries for specific language and content.

Cultural

Creating an effective foreign Web site involves much more than just a good language translation. Not only do languages differ in other countries but semantics (the meaning of words and phrases) and cultural persuasions in a number of key areas are different. "Sensitivity to culture and national distinction will separate success from failure" (Sawhney & Mandai, 2000). To be effective, a Web site has not only to be understandable and efficient, but has to be culturally pleasing and inoffensive. To accomplish that, it may be necessary

Figure 3.

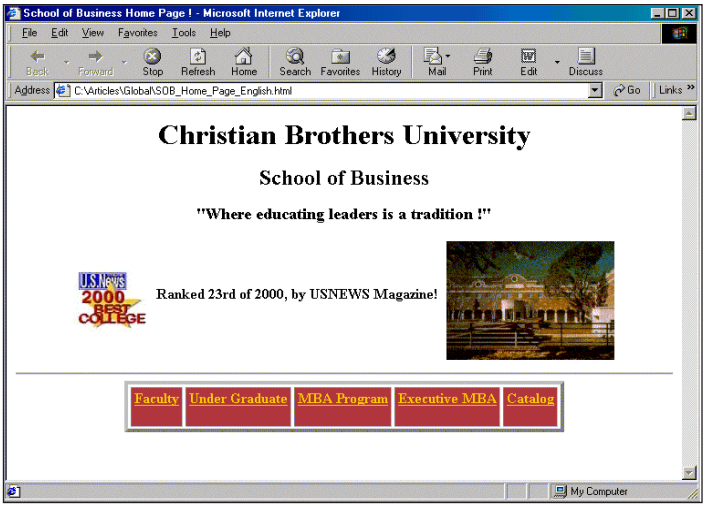

Figure 4.

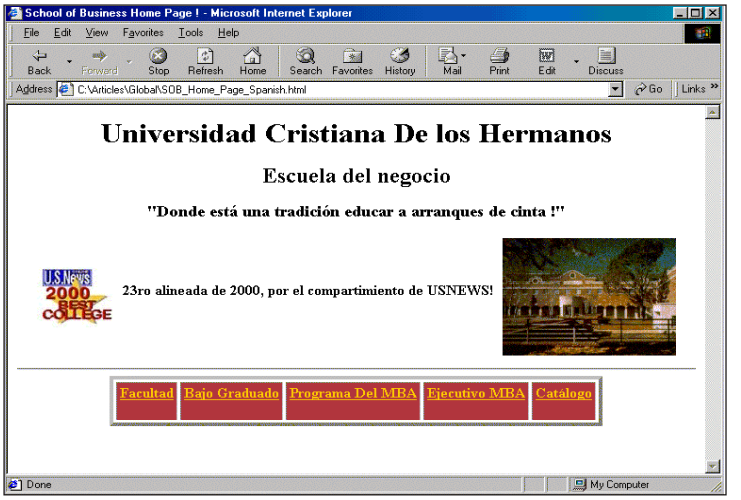

that not only language be localized, but that content, layout, navigation, color, graphics, text/symbol size, and style may be different. Many companies have put forth global Web sites simply by translating the English into the targeted language, but then had to pull back and redesign the localized site due to cultural offenses.

A country's humor, symbols, idioms, and marketing concepts may not send the same messages to other countries in the world. Some areas of global disagreement to avoid are: equality of the sexes or races, body parts and sexuality, abortion, child labor and majority age, animal rights, nudity, guns, work hours and ethic, capital punishment, scientific theories, and religious particulars (Brandon, 2002).

Colors have symbolic and special meaning in most locals. Purple is a problem in many places; it symbolizes death in catholic Europe and prostitution in the Middle East. Euro Disney had to rework its European sites after the first version used too much purple. Overall blue is the most culturally accepted color (Brandon, 2001). It is also very important to respect other cultures "symbols" (heroes, icons, etc.) both positive and negative (swastika). One guide site is *Merriam Webster's Guide to International Business* (*www.bspage.com/address.html*).

Figure 5.

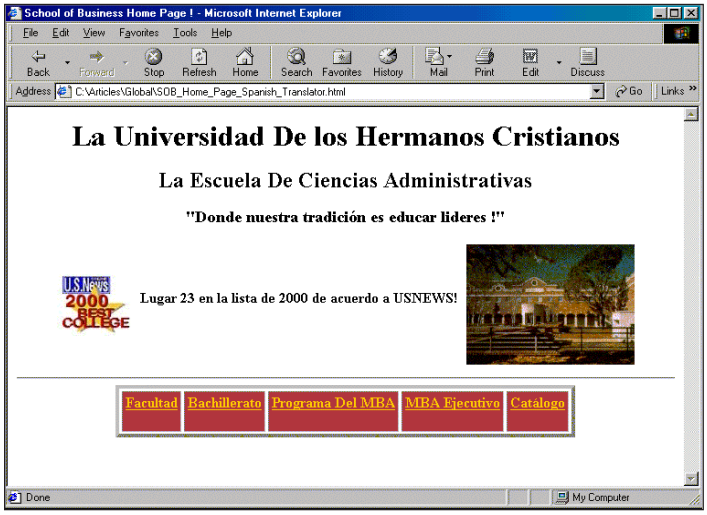

Figure 6.

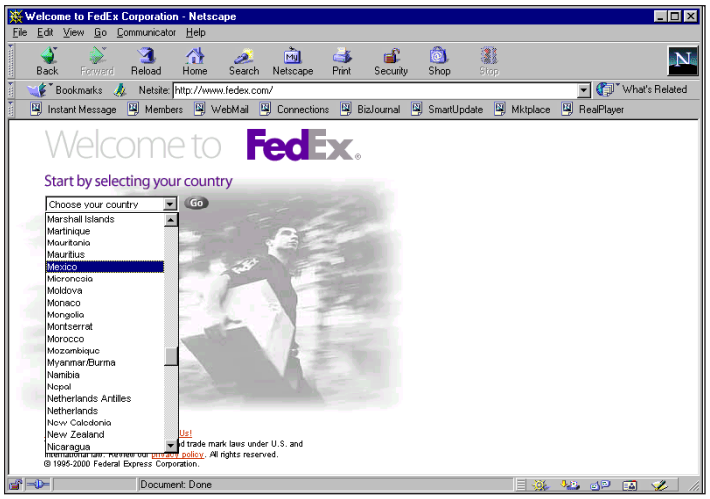
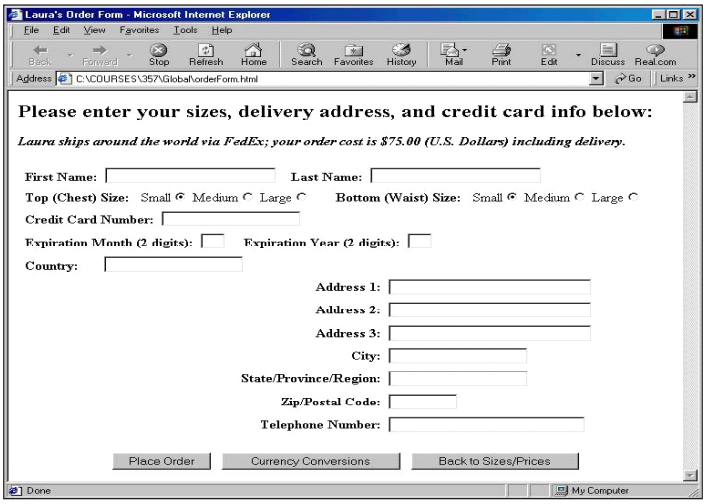


Legal

Recently French court's ruling that Yahoo must make auctions of Nazi memorabilia unavailable in France indicates how uncertain and risky international e-business can be. "The troubling aspect of this case is that different countries can say that content not even targeted at their population breaks the law" (Perrotta, 2000). With the Internet, it is not possible to know for sure where a user is logged in due to "IP tunneling" possibilities.

"Freedom" laws (such as the U.S. First Amendment) are not universal, and saying/printing some things can be illegal in some parts of the world. In the U.S., you can say what you like about "public figures" but not so in most of the rest of the world. Another legal issue concerns the privacy of personal data collected online. Many parts of the world have stricter laws than does the U.S., and U.S. companies have had judgments rendered against them in foreign courts. There are other areas that could cause legal problems, too. One is foreign advertising restrictions; for example, in Germany, one cannot directly compare your product with that of a competitor. In some other countries this comparison may not be illegal but may leave a bad taste.

Figure 7.



Payment and Currency

Nearly half of the U.S. Web sites refuse international orders because they are unable to process them (Grossman, 2000a). Foreign exchange rates vary daily so indicating that your prices are in your country's funds (exclusive of local taxes and custom duties) and using credit cards (so the credit card company does the conversion) is one way to deal with that issue. One can also link to a converter site (www.xe.net/ucc, www.oanda.com) or place a calculator on your page (www.xe.net/currency) as a utility for your customers or do your own conversions (see Figure 8, later).

However, credit cards are rare in Japan as is the use of checks. There, postal workers collect cash on delivery (CODs), and some companies send goods to brick and mortar places for consumers to pick up. In Germany, only 5% of Web users (second to U.S. in overall net usage) use credit cards. Eighty-eight percent of European merchants use invoice billing (with a long net payment due time). So while credit cards are a convenient and popular mechanism in the U.S., it is not so in the rest of the world. To complicate matters even further, there are many (and always changing) international sales taxes, value added taxes (VAT) in Europe, with different exempt items in each country. One approach to avoid all these problems is to use an escrow service such as Paymentech (www.paymentech.com) which now handles about three billion transactions a year.

Time-Date and Units of Measure

Dates are very important in e-commerce when being used for events such as: delivery dates, credit card expiration dates, product expire dates, etc. There is an international standard on dates (ISO 8601 Date Format), and even though you may not use it internally in your programs (for database operations and calculations), your Web display should be in the localized format. For example, the common U.S. format of 10/6/2000 is not uniformly understood; instead use Oct-6-2000. Major databases (i.e., Oracle) allow you to switch date formats per session or connection so the way a date is input (inserted into a table) or output (selected from a table) is automatically converted to the internal table representation of the date.

In the U.S., a 12-hour clock is common, except in U.S. military establishments. The rest of the world uses mostly a 24-hour clock, so it is best to display time in the 24-hour format. Of course, time zones will be different, so include your time zone along with the phone numbers for personal customer support. It is best to spell out the time zone in the native language. You could instead give your support time in GMT (Greenwich 2000 Standard) and use or link to www.timeanddate.com for a customizable world clock and calendar. In addition to dates and times, other units of measure will be different also. Only the U.S. and Canada still use the "English System"; the rest of the world is on the metric system now, even Britain.

"Addressing" a customer may be more involved; some foreign addresses may have longer and more address fields. There is a universal standard of sorts here called the "UPU" (universal address formats). Generally, it is of good advice including a country code (for validation of remaining fields), at least three address lines (40 characters each), city field (30 characters), a "state/province/region" field (20 characters), a postal code/zip field (10 characters), and a contact phone

number (20 characters). Figure 7 shows an order form using these specifications.

Logistics

Logistics involve both getting your products to the customer, as well as allowing the customer to return unwanted goods. Some parts of the world have relatively primitive transportation networks. In China, villages do not have postal service. Also, each locale typically has a set of customs and tariffs that you may need to add to the price of your goods. This "landed cost" of an order is the sum of the price of goods, shipping charges, insurance, duties/customs, VAT, and any import or export fees. You may need a "Shippers Export Declaration" depending on value and mode of transportation (www.census.gov/foreign-trade/www/correct.way.html) or other documents depending on countries and goods. As well as normal shipping insurances, you may need to consider export insurance (www.exim.gov). Of course, the language as well as logistic terminology varies; however, there is a standard set of international logistic acronyms ("incoterms" - *www.schenkerusa.com/incoterms.html*).

Many countries have *foreign import restrictions* and/or quotas. In addition, many countries have certain *export restrictions*. Japan has more than 200 trade laws and 17,000 regulations on imports (Pfenning, 2001). Today, 85% of U.S. companies do not ship to customers seeking delivery abroad, and the 15% that do ship ignore these compliance issues and push the responsibility of customs, restrictions, and payment onto their customers (Shen, 2000).

There are several ways to handle all these logistics issues. One is to use shipping companies that handle all these problems for you (at a nominal charge) such as FedEx (www.fedex.com) or UPS (www.ups.com). Another alternative is to use software or services that handle all these payment, custom, and restrictions issues by preparing the paperwork and calculating "landed costs"; one example can be found at www.mycustoms.com.

Still another alternative is to use a centralized distribution center in foreign regions to reduce shipping costs and eliminate some import taxes and tariffs (Tapper, 2000), either directly or with a partner. There are also total fulfillment providers such as: National Fulfillment Services, DupliSoft, Fill It, SubmitOrder, Equire, FedexLogistics, and so forth. These organizations not only handle delivery but also inventory, returns, customer service, and in some cases, Web ordering and payment.

FUTURE TRENDS

In the not too distant future, the Web will be everywhere, and by "everywhere", we mean not only in all of our electronic devices but everywhere in the world. Future trends in B2C e-commerce will involve this convergence of Web connectivity both in geographics, demographics, and electronics. For example in the future, automobiles are likely to have satellite and wi-fi Internet connections not just for navigation and information, but for marketing and sales also (in several languages). As one drives down a street, they will be able to receive live commercial messages from businesses as they physically approach the retail outlets, and these retail outlets could be outlets for international products as well.

CONCLUSION

Is globalization right for an organization? It can be very costly to build and maintain a foreign presence. We have identified and briefly discussed the key issues in this article. But there are many other issues that may affect your global e-commerce. "Building a global e-business calls for hosts of strategies that include partnering with or acquiring foreign companies, assembling sales and support operations, understanding new laws, languages, cultures, and implementing technology that can sustain a global endeavor" (Bacheldor, 2000). Many organizations are successful by using foreign partners such as: E-Steel, GlobalFoodExchange, and Office Depot. It has been said that the "Net brutally punishes latecomers" (Sawhney & Mandai, 2000), so it is essential to start planning the internationalization and localization of e-commerce now. Also remember the Web is a two-way street; foreign corporations will be coming after your customers soon!

KEY TERMS

Character Set: The set of symbols used to represent a language (alphabet, numerals, special symbols).

Encoding: The bit pattern to use for each symbol in a character set.

Export Restrictions: Restrictions on the type, quantity, or destination of goods that can be exported out of a country.

Globalization: The marketing and selling of a product outside a company's home country.

Import Restrictions: Restrictions on the type, quantity, or origin of goods that can be imported into a country.

Incoterms: A standard set of international logistic acronyms.

Landed Cost: The cost of an order including the price of goods, shipping charges, insurance, duties/customs, value added tax (VAT), and any import or export fees.

Locale: The combination of language and dialect.

Localize: Make a Web site linguistically, culturally, and in all other ways accessible to customers outside ones home territory.

Shippers Export Declaration: Documentation necessary to export goods outside one's home country.

UPU: Universal address formats.

VAT: Value added tax.

Governance Structures for IT in the Health Care Industry

Reima Suomi
Turku School of Economics and Business Administration, Finland

INTRODUCTION

The pressures for the health care industry are well known and very similar in all developed countries (i.e., altering population, shortage of resources for staff and from taxpayers, higher sensitivity of the population for health issues, new and emerging diseases, etc.). Underdeveloped countries experience different problems, but they have the advantage of learning from the lessons and actions that developed countries underwent perhaps decades ago. On the other hand, many solutions also exist, but they all make the environment even more difficult to manage (i.e., possibilities of networking, booming medical and health-related research and knowledge produced by it, alternative caretaking solutions, new and expensive treatments and medicines, promises of biotechnology, etc.).

From the public authorities' points of view, the solution might be easy—outsource as much as you can out of this mess. Usually, the first services to go are marginal operational activities, such as laundry, cleaning, and catering services. It is easy to add information systems to this list, but we believe this is often done without a careful enough consideration. Outsourcing is often seen as a trendy, obvious, and easy solution, which has been supported by financial facts on the short run. Many examples show that even in the case of operational information systems, outsourcing can become a costly option, not to mention lost possibilities for organizational learning and competitive positioning through mastering of information technology.

BACKGROUND

We have found the following reasons for the late adoption of modern information technology in the health care sector (Suomi, 2000):

- Fragmented industry structure
- Considerable national differences in processes
- Strong professional culture of medical care personnel
- One-sided education
- Handcrafting traditions
- Weak customers
- Hierarchical organization structures

ICT and governance structures meet in two ways. On one side, ICT enables new governance structures for the health care industry. On the other, it is an object in need of governing. As both sectors offer a multitude of new possibilities, innovations are called for in the industry (Christensen, Bohmer, & Kenagy, 2000).

IT governance thinking matures in organizations as any other discipline. Van Grembergen, De Haes, and Guldentops (2003) have defined the following stages in their IT Governance Maturity Model:

- Non-existent
- Initial/ad-hoc
- Repeatable but intuitive
- Defined process
- Managed and measurable
- Optimized

Needless to say, in the health care industry, IT Governance thinking is non-existent or initial/ad hoc in the best situation.

THE MEANING OF ICT GOVERNANCE STRUCTURE IN HEALTH CARE

IT is an old acronym for information technology. Nowadays, it is replaced often with the term ICT, referring to information and communication technology. This emphasizes the communication services that are developing very quickly, such as the Internet and mobile services. The letter *C* is often upgraded to the second dimension: alongside communication it can refer to contents. IT or ICT governance is defined (IT Governance Institute, 2001) as follows:

IT governance is the responsibility of the board of directors and executive management. It is an integral part of enterprise governance and consists of the leadership and organizational structures and processes that ensure that the organization's IT sustains and extends the organization's strategies and objectives.

For many, there is a temptation to understand governance as just a synonym for management. This is an oversimplification. Management is a goal-oriented activity, whereas governance is often given from the outside, and organizations just have to live with it. This is not to say that all governance structures would be beyond management control; management can influence most governance structures, at least in the long run. The long run is a key term in many aspects. We talk about structures that are semi-permanent and not changed very frequently. Structure is a term closer to architecture than to infrastructure; governance structures are architectural terms and are then implemented into infrastructures through different organizational forms. The terms *organization form* and *governance structure* are not synonyms. Organizational forms are more formal and touch upon one organization, whereas governance structures are found in a richer selection of forms and organize themselves over a number of organizations. Table 1 summarizes our discussion.

Governance structures are present in almost any human decision-making situation. In Table 2, we have a collection of key aspects of governance structure issues in health care.

FUTURE TRENDS

One of the biggest changes in the industry is that information related to health, sickness and medicines is not scarce. Internet is a rich source of such information, at different levels of expertise and at different languages. The gap between what information is available and what a health-care professional should know is growing very fast (Weaver 2002). This will shift the power balance between health professionals and patients: increasingly often the patients are the best experts on their disease. Different electronic forums or Virtual Communities (Rheingold 1993) related to health are born on the Internet. They have different services and values to offer to the healthy ones and to the chronic and acute sick (Utbult, 2000). Similarly, the interaction between the patients and health care professionals is going to change: electronic means are going to take share from face-to-face meetings (Cain, Sarasohn-Kahn & Wayne 2000; Gibson 2003).

For organizing patient flows through the health care system modern ICT offers many possibilities. Should patient data be all the time available anywhere though electronic means, would the Healthcare Supply Chains be much more effective (More & McGrath 2001). Effectiveness means that patients are taken care of in the best and most effective places, be they public or private, and of right level of expertise. As patient data can be electronically cumulated into huge databases, these databases can be used for different statistical, research and other purposes. This calls for care and proper legislation giving the principles.

Managing and building governance structures for ICT in health care organizations is not that much different from other organizations. Even in health care organizations, the scope and status of information resource management has to be decided. Issues such as sourcing decisions, charging arrangements, data privacy, and security issues all deserve their attention. There are certain problems that need to be solved in this area:

- Data privacy and security needs are extremely important and might sometimes conflict with optimal care.
- As the area is new, legislation is often lagging behind.
- The field is a meeting place for two strong professional cultures—medical doctors and ICT-professionals—that might bring along difficulties.

Table 1. *Comparison of terms management, organizational form, and governance structure*

	Management	Organizational Form	Governance Structure
Time perspective	Short	Medium	Long
Focus	Action	Internal organization	Inter-organizational structures
Management Control	In action	Easy	Difficult
Metaphor	Communication channels	Infrastructure	Architecture
Character	Concrete	Formal	Abstract

Table 2. *ICT governance structure issues in health care*

ICT as an enabler
- Health-related information on the web
- Private-public sector co-operation
- Allocation of patients to different levels of care
- Customer contacts distribution between electronic and classical means
- Ownership, structure and allocation of patient, population-level and other critical data
- Electronic forums for patients to interact
- Electronic prescription systems

ICT as an object to be governed
- New legislation needs because of the new data processing possibilities
- Data privacy and security
- Structure and status of the information resource management in health care units
- ICT-general management partnership
- Sourcing decisions of ICT
- Charging arrangements on ICT-services

CONCLUSION

Health is undoubtedly among the most important issues for all of us. In a modern society, the threats towards health are changing all the time, but at the same time, the possibilities to maintain health and cure illnesses grow exponentially. The task is to make needs and solutions meet in an effective way. This is about information and communication technologies and governance structures.

Modern ICT allows health care organizations to structure themselves in new, innovative ways, and simultaneously to empower the customers to interact with the organizations, with fellow patients, and with information sources in revolutionary new ways. In this environment, health care professionals also have to adjust their roles.

KEY TERMS

Electronic Patient Record: All health-related information related to a patient in electronic form, assembled as a single entity.

Electronic Prescription: Prescriptions created and handled in electronic form in an integrated information system.

Healthcare Supply Chain: A managed set of activities related to the health care activity of a patient, organized so that all necessary information is available all the time and the participants in the chain have a complete picture of the total process.

Sourcing Decision: Decision whether to buy goods/services from the market or to make them self. Sourcing decision can be made as an independent decision unit or as a part of a bigger group.

Virtual Community: A social aggregation on the Internet when people interact long enough to form personal relationships.

Government Intervention in SMEs E-Commerce Adoption

Ada Scupola
Roskilde University, Denmark

INTRODUCTION

Innovation and technological change has been considered an important factor for economic development. Information technology has been among the fastest growing innovations in both production and use in the second half of the last century. In the last decade, a particular type of information technology, the Internet, has been changing business processes, organizational and industrial structures and given form to new communication and business forms as for example e-commerce.

The institutional environment created by governments in the form of policies and interventions is very important for the economic development of developed as well as developing nations (e.g., North, 1990). The external environment, and especially the role of government, has been very important in the adoption and diffusion of technological innovations such as telecommunications and more recently e-commerce (e.g., Tornatzky & Fleischer, 1990). Government intervention is and has been especially important at sustaining technological development in SMEs (Rothwell, 1994). Recently, many governments and international organizations are taking initiatives to foster the adoption of electronic commerce in small and medium size enterprises (OECD, 1999). For example the American government has set up a set of guidelines to foster the diffusion of electronic commerce in SMEs and the European Union has approved a series of "Directives" aiming at guaranteeing free availability of products and services for electronic signatures, copyright protection, taxation policy, and so forth (http://europa.eu.int/).

This study provides insights into small and medium size enterprises' perception of government intervention in e-commerce adoption in Southern Italy. The research question addressed is: "How do SMEs perceive government intervention in adoption and diffusion of e-commerce and what do they believe government intervention should focus on?" This study does not however differentiate between different types of governments, such as local, regional and national governments. The research was designed as a case study (Yin, 1994) and was conducted in Southern Italy.

The chapter is structured as follows. The next section provides a background of the institutional roles in adoption and diffusion of IT. The following section presents the research methodology. This is followed by the main thrust of the chapter that presents the major findings. Finally the last two sections discuss future trends and give some concluding remarks and suggestions for further research respectively.

BACKGROUND

The literature on adoption and diffusion of innovations, especially that focusing on information technology, has mostly focused on the factors affecting adoption and diffusion. These factors have been classified into three main groups or other categories that can be reconnected to these three groups: technological context, organizational context, and environmental context (e.g., Scupola, 2003a; Tornatzky & Fleischer, 1990).

Within the environmental context, the institutional research has focused on the influence of institutions on adoption and diffusion of technological innovations. Institutions have been historically important in the shaping of organizational and economic life and their importance is always increasing. King, Gurbaxani, Kraemer, McFarlan, Raman, and Yap (1994) identifies a series of institutions that influence IT adoption among which government authorities, international agencies and trade and industry associations.

Many studies have used institutional perspectives to study implications of information technology for organization and economic development (e.g., Corbitt & Al-Quirim, 2004; Gengatharen & Standing, 2005; Gibbs, Kraemer & Dedrick, 2002; Kraemer, Gibbs & Dedrick, 2002; Wong, 2003). Recent literature is addressing the disparity in local government readiness and community demand for e-commerce by investigating the tripartite relationship between State, local government and community in e-commerce adoption and diffusion. For example, Howell and Terziovski (2005) investigated adoption and diffusion of e-commerce in 12 local government councils in Australia funded by the Victorian e-Commerce Early Movers Assistance Scheme (VEEM). They found that the VEEM scheme was successful in raising awareness of e-commerce within the community; however there is a wide disparity in local government readiness for e-commerce and community demand for e-com-

merce emphasizing the importance of tripartite relationship between State, local government, and the community in e-commerce diffusion.

The research on the role of institutions in the adoption and diffusion of information technology is summarized here in three main frameworks: Andersen, Bjørn-Andersen, and Dedrick (2003) model of environmental drivers, Lal (2001) analytical framework encompassing the interactions among different factors and King et al. (1994) model of institutional actions.

Andersen et al. (2003) model for analyzing environmental factors mainly focuses on the demand drivers. Such drivers include industry structure (e.g., concentration, sectoral distribution, vertical integration, size of firms, etc.), information infrastructure (telecommunication, wireless and Internet infrastructure, technology acceptance, etc.), financial and human resources (e.g., venture capital, population, IT skills, education) and social and cultural factors (consumption patterns, consumer preferences, language, business culture, etc.). The second group of factors of the model includes initiatives taken by the government and private sector institutions to promote e-commerce. The model identifies four main initiatives: knowledge diffusion, economic incentives, regulation and legislation and electronic government.

Lal (2001) proposes an analytical framework that encompasses the interactions among government policies, information infrastructure, the IT industry and the markets. The framework shows that governments can influence the growth of an industry (in Lal's study the IT industry in India) by embarking on economic policies that affect supply-side and demand-side factors. Supply-side factors include telecommunications networks, power, transport and human resources development, while demand-side factors include encouragement of the use of IT in domestic markets.

King et al. (1994) classify the nature of institutional intervention in IT innovation on whether the desired changes are in production or use. Production concerns the actors that make innovative products, while use concerns the actors and ways in which innovations are used in the society. Institutions can affect IT adoption in several ways, for example

Table 1. Dimensions of institutional intervention (King et al., 1994)

	SUPPLY-PUSH	**DEMAND-PULL**
INFLUENCE	(I) KNOWLEDGE BUILDING Funding of research projects KNOWLEDGE DEPLOYMENT Provision of Educational Services SUBSIDY Funding Development of Prototypes Encouragement of capital markets to support R&D activity Provision of tax benefits for investment in R&D (e.g., investment tax credits, rapid depreciation) INNOVATION DIRECTIVE Direct institutional operation of production facilities for innovation	(II) KNOWLEDGE DEPLOYMENT Training programs for individuals and organizations to provide base of skilled talent for use SUBSIDY Procurement of innovative products and services Direct or indirect provision of complementarities required for use Direct or indirect suppression of substitute products or services MOBILIZATION Programs for Awareness and promotion
REGULATION	(III) KNOWLEDGE DEPLOYMENT Require education and training to the citizens SUBSIDY Reduction in general liabilities for organizations engaging in innovative activity Modification of legal, administrative or competitive barriers to innovation and trade STANDARDS Establishment of standards under which innovative activity might be encouraged INNOVATION DIRECTIVE Establishment of requirements for investment in R&D by organizations	(IV) SUBSIDY Procurement Support for products and processes that facilitate adoption and use STANDARDS Require particular products or processes to be used in any work for the institution Require conformance with other standards that essentially mandate use of particular products or processes INNOVATION DIRECTIVE Require that specific innovative products or Processes be used at all times

by using legal forces or by stimulating demand through the creation of a need for innovative products and processes (Montealegre, 1999).

King et al. (1994) classify the forms of institutional actions into influence and regulation. Influential initiatives have the purpose of changing behavior of those under the institution's way, without direct use of force or exercise of command. Regulatory actions have the purpose of affecting the behavior of entities under formal institutional jurisdiction such as directives. Furthermore, influence and regulation can play different roles depending on whether the innovation is driven by demand-pull or by supply-push. Supply-push forces for innovation come from the production of the innovative product or process. Demand-pull forces arise from the willingness of potential users to use the innovation (King et al., 1994). Based on the categories of influence, regulation, demand-pull and supply-push, King et al. (1994) identify six types of institutional actions that can stimulate or retard IT adoption, summarized in Table 1. These six categories are knowledge building, knowledge deployment, subsidy, mobilization, and standard setting and innovation directives.

Knowledge Building. Knowledge building consists of the institutional actions undertaken with the purpose of providing the base of scientific and technical knowledge necessary to produce and exploit innovations. The most obvious form of knowledge building is sponsored research that can be either basic or applied for which the government is the most common supporter.

Knowledge deployment. Knowledge deployment involves institutional actions aimed at disseminating new knowledge, either in form of knowledgeable individuals and organizations, or in the form of repositories of knowledge as archives and libraries of scientific and technical facts. The most important form of knowledge deployment is the general provision of education to the population. Finally, knowledge deployment can also be achieved by stimulating the use of innovations through the training of a group of potential users.

Subsidy. Subsidies have the purpose of defraying the otherwise unavoidable costs or risks to innovators and users in the process of innovation adoption and diffusion. They take different forms: funding of prototyping, institutional procurement of innovations, and support for provision of necessary complements to be used with innovative products or processes.

Mobilization. Mobilization refers to institutional actions aimed at encouraging decentralized actors to think in a positive or negative way about an innovation as for example through promotional and awareness campaigns.

Standard setting. Standard setting comprises actions that regulate the operation of decentralized actors and institutions to bring them into line with larger social or institutional objectives.

Innovation Directives. Innovation directives are institutional actions aiming at producing innovations, using them, or engaging in some activities facilitating their production or use.

King et al. (1994) model has been the basis for the following analysis (Scupola, 2003).

METHODOLOGY

The data used in this article are part of a larger research project on adoption and diffusion of electronic commerce in Southern Italian SMEs (e.g., Scupola 2002; 2003a; 2003b). The research was designed as a case study (Yin, 1994) to understand issues in adoption and diffusion of e-commerce in small and medium size enterprises, including actual, and desirable government intervention.

The Sample and the Sample Selection Process

Six interviews in six different companies were conducted. The companies have been chosen on the basis of representativeness and accessibility according to the following criteria:

- They should be a registered company and could be classified as SME according to the number of employees that should not exceed 500 according to the OECD (1999) definition.
- They should have been early adopters of Internet. Having had an Internet connection for at least 3 years was chosen as criterion of early adoption. This is based on the consideration that these companies with their experience are in a better position to identify and evaluate issues related to e-commerce adoption, including possible government intervention.
- The companies should be located in the same geographical region. This criteria should ensure that external factors such as government influence, average level of education of the population, availability of qualified labor force, and so forth are the same for all the sample companies.

The sample includes two IT consulting companies, two distributors, one producer of textiles, and an intermediary in the textile business. They are all located in the Southern Italian region called Puglia according to the last selection criterion (Table 2).

The local yellow page directory and a directory of companies distributed by the Chamber of Commerce of the city of Lecce were the primary sources in the selection of the cases. One consulting company and the local chamber of commerce were very helpful to narrow down the sample to

Table 2. Companies description

Company	Type of Business	No. Of Employees	Year of E-commerce Adoption
F1	IT Consultants	80	1996
F2	IT Consultants	1 (family driven)	1996
F3	Distributor of Watches	15	1996
F4	Intermediary in the Textile Business	2 (Family Driven)	1998
F5	Production and Commercialization of Textiles	300	1996
F6	Distributor of Car Parts	19 (family driven)	1998

those companies that satisfied the criteria mentioned previously. Many more companies were contacted by telephone, but only those in Table 2 were willing to participate to the study.

RESEARCH PROCESS AND DATA ANALYSIS

One person was interviewed in each company. The company has suggested the person to be interviewed on the basis of the author's requirement to talk with the employee responsible for and most knowledgeable about e-commerce. In all the cases this person has been the owner, often functioning as CEO. Semistructured interviews were the main data collection method. The interview questions were formulated with the intention of understanding issues of adoption and diffusion of e-commerce in SMEs in this region, including government intervention. Specifically, the questions around government intervention were aiming at understanding what kind of intervention (if any) the companies had been getting from the government and what they believed future intervention should address. The questions did not address whether the intervention was coming or should be come from local, regional or national government. It actually turned out that even though government intervention initiatives had been present in the region, small companies were not aware of their existence. Interviews also covered demographic data on each firm and informant.

The interviews have been conducted by the author at the company's site and have lasted between 1.5 and 3 hours each. Each interview was tape-recorded and the contents of the tape fully transcribed. Notes were also taken during the interview. By following Iacovou, Benbasat, and Dexter (1995) to enhance validity summaries of the major findings of each interview were verified by the participants after the end of each interview session. To increase reliability an interview protocol was used and a case study database was developed (Yin, 2003). The interview protocol was first tested with one of the companies and successively adjusted

to make it more clear and comprehensive. By following Yin (2003) the data were analyzed by following the "general strategy of relying on theoretical orientation" of the case study. By following Miles and Huberman (1994, p. 58) a provisional "start list" of codes was created prior to the field work to guide the analysis. The coding was manual. This "start list" came from the conceptual framework and the research question.

MAIN FOCUS OF THE CHAPTER

Being the focus of this chapter, government intervention in SMEs adoption and diffusion of e-commerce, it is natural to position the analysis in a demand-pull rather then a supply-push perspective (see King et al., 1994). The demand-pull perspective deals, in fact, with influence and intervention regarding the use of technological innovations. The government actions that either are perceived to be taking place or are desired by small enterprises to foster e-commerce adoption are described in the rest of this paragraph.

Knowledge Deployment. Southern Italian SMEs believe that State intervention to deploy knowledge is very essential for their uptake of e-commerce. This could take especially the form of e-commerce training programs and more widespread knowledge of English. These training programs could be used for example to spread knowledge about potential benefits of e-commerce and increase first hand-on experience of the uses of e-commerce as similar studies also have found out (e.g., Poon & Swatman, 1999). Some support for this purpose was available at the time of the study, but small companies were not taking much advantage of it. The companies dealing with suppliers and buyers located in foreign countries also expressed the wish to increase the English language skills among the local population and SMEs employees in particular, similarly to what found by Madon (2000) in Latin America. It seems therefore that intervention aimed at increasing the knowledge of English among the nonEnglish speaking population would contribute to adoption and diffusion of e-commerce.

Subsidies. Direct or indirect subsidies were important both as influence and regulation mechanisms. Small businesses wished generally an increase in indirect subsidies such as procurement of e-commerce technologies and services by governmental institutions and an increase in direct subsidies such as procurement support to small companies for products and processes that facilitate adoption and use. Some companies expressed especially the wish for government institutions and the public administration to procure and use Internet technologies and services both to the public and to the average citizen. By doing so, they believed that government institutions would contribute to decrease uncertainty about e-commerce, serve as role model for corporations and create the need for its use (Rogers, 1995). Another type of subsidy mentioned by SMEs in this study is direct or indirect procurement support for e-commerce systems to small businesses such financial aid for the acquisition of the system and relative training, tax deduction or financial aid that totally or partially covers acquisition and installation costs. This kind of support existed at the time of the study; however some small and medium size enterprises were not aware of it.

Mobilization. Some companies also expressed the wish for more programs aiming at increasing awareness of Internet technologies and e-commerce. This can be achieved through educational and informational campaigns aimed both to the larger population and to small businesses (Poon & Swatman, 1999). However, these campaigns should also have the objective of informing small and medium size enterprises of the existence of government subsidies and other forms of intervention, as they often are not aware of them.

FUTURE TRENDS

As the analysis has showed, small businesses wish government intervention, both in terms of influence and regulation to foster adoption and diffusion of electronic commerce. Such intervention should concentrate on three different areas: knowledge deployment, subsidies, and mobilization. Mobilization should aim at increasing awareness of the technology, related benefits, and ways of use (Poon & Swatman, 1999). In addition, mobilization initiatives should also aim at informing the companies of state and other institutions' e-commerce support programs and initiatives.

Knowledge deployment should aim at increasing knowledge of e-commerce (e.g., through targeted training programs), but also and especially at increasing knowledge of English among the population in general and small businesses employees in particular. Subsidies have emerged important both as influence and regulation mechanisms. The most important desired form of subsidy is indirect subsidies aiming at improving e-government. Direct subsidies such as financial support, tax deductions, and e-commerce pilot programs are also considered important and desirable. The study has not found evidence for standard setting, innovation directives and knowledge creation. Furthermore the study has found significant evidence for Conjuncture 2 and 4 in King et al. (1994) framework stating:

Conjecture 2: "Significant (production or) use of IT innovation requires serious and sustained institutional interventions for knowledge deployment,"

Conjecture 4. "Mobilization efforts are important but not essential in stimulating (production and) use of IT innovation, and are useful mainly in conjunction with other institutional interventions."

The study has, in fact, found that knowledge deployment is considered by SMEs a very important type of intervention

to increase adoption of e-commerce and that mobilization is also important, but not really essential and it would lead to some results mainly in conjunction with knowledge deployment and subsidy.

However the study has found only partial support for Conjecture 3 stating:

Conjecture 3: "Subsidies are often crucial but not always essential instruments of institutional intervention in both the production and use of IT innovation."

In fact, if it is true that financial subsidies such as tax breaks, and so forth are crucial, but not essential, SMEs believe that indirect subsidies in the form of government procurement of e-commerce and e-services are very essential to the adoption and diffusion of e-commerce among SMEs.

CONCLUSION

The main contribution of this study consists in illustrating what are the types of government intervention presently offered to SMEs in Southern Italy, how much these companies know about them and what they desire government intervention should address. This study has showed that SMEs desire institutional intervention, both in term of influence and regulation. Such intervention should concentrate on three main different areas: knowledge deployment, subsidies, and mobilization.

The study has also found that there is starting to be a convergence between what companies want and what the government does. This is especially happening regarding indirect subsidies such as deployment of e-services by the government and public administration.

The study has also not taken into consideration whether the intervention was undertaken by the local, the regional or the national governments. It could be interesting to take this into consideration in future studies as different initiatives have been taken place at different levels within the same nation-state and at a pan European level (e.g., Scupola, 2003c).

To conclude, more attention should be given to understand e-commerce related intervention initiatives at national, regional and local government levels in different geographical regions and what SMEs believe that their needs for intervention are. An analysis of the convergence and divergence of such results could also be done to highlight the successes and failures of current government intervention initiatives.

KEY TERMS

Adoption: E-commerce adoption is here defined as the decision to use Internet technologies and the Web to share business information, maintain business relationships, and conduct business transactions.

Diffusion: It is the spread of the capacity to produce and/or use an innovation, and its use in practice.

E-Commerce: Is here defined as "the sharing of business information, maintaining business relationships, and conducting business transactions by means of telecommunications networks. Here e-commerce is equivalent to Internet commerce.

Government Intervention: Here it includes the set of policy measures and other actions and initiatives that governments and international organizations are taking to foster the adoption of electronic commerce in SMEs.

Innovation: It is characterized by three stages: invention, innovation and diffusion. An invention is a new idea or product, which becomes an innovation when it starts diffusing in the society or move into a usable form.

Institutions: It is any standing, social entity that exerts influence and regulation over other social entities by outlasting the social entities it influences and regulates.

Small and Medium Size Enterprises (SMEs): There are many definitions of SMEs. Here they are defined as companies with up to 500 employees according to the OECD (1999) definition.

Graph Encoding and Transitive Closure Representation

Yangjun Chen
University of Winnipeg, Canada

INTRODUCTION

Composite objects represented as directed graphs are an important data structure that require efficient support Web and document databases (Abiteboul, Cluet, Christophides, Milo, Moerkotte, & Simon, 1997; Chen & Aberer, 1998, 1999; Mendelzon, Mihaila, & Milo, 1997; Zhang, Naughton, Dewitt, Luo, & Lohman, 2001), CAD/ CAM, CASE, office systems, and software management. It is cumbersome to handle such objects in relational database systems when they involve ancestor-descendant relations (or say, reachability relations). In this article, we present a new graph encoding based on a tree labeling method and the concept of branchings that are used in the graph theory for finding the shortest connection networks. A branching is a subgraph of a given digraph that is in fact a forest, but covers all the nodes of the graph. Concretely, for a DAG G (directed acyclic graph) of n nodes, the space needed for storing its transitive closure can be reduced to $O(b \cdot n)$, where b is the number of the leaf nodes of G's branching. Such a compression is, however, at the expense of querying time. Theoretically, it takes $O(\log b)$ time to check whether a node is reachable from another. The method can also be extended to digraphs containing cycles.

BACKGROUND

A composite object can be generally represented as a directed graph (digraph for short). For example, in a CAD database, a composite object corresponds to a complex design, which is composed of several subdesigns. Often, subdesigns are shared by more than one higher-level design, and a set of design hierarchies thus forms a directed acyclic graph (DAG). As another example, the citation index of scientific literature, recording reference relationships between authors, constructs a directed cyclic graph. As a third example, we consider the traditional organization of a company, with a variable number of manager-subordinate levels, which can be represented as a tree hierarchy.

In a relational system, composite objects must be fragmented across many relations, requiring joins to gather all the parts. A typical approach to improving join efficiency is to equip relations with hidden pointer fields for coupling the tuples to be joined. The so-called *join index* is another auxiliary access path to mitigate this difficulty. Also, several advanced join algorithms have been suggested, based on hashing and a large main memory. In addition, a different kind of attempts to attain a compromise solution is to extend relational databases with new features, such as *clustering* of composite objects, by which the concatenated foreign keys of ancestor paths are stored in a primary key. Another extension to relational system is *nested relations* (or NF^2 relations). Although it can be used to represent composite objects without sacrificing the relational theory, it suffers from the problem that subrelations cannot be shared. Moreover, recursive relationships cannot be represented by simple nesting because the depth is not fixed. Finally, *deductive database*s and *object-relational databases* can be considered as two quite different extensions to handle this problem (Chen, 2003; Ramakrishnan & Ullman, 1995).

In the past decade, another kind of research has been done to avoid *join* operation based on *graph encoding*. In this article, we provide an overview on most important techniques in this area and discuss a new encoding approach to pack "ancestor paths" in a relational environment (Chen, 2004; Chen & Cooke, 2006). It needs only $O(e \cdot b)$ time and $O(n \cdot b)$ space, where b is the number of the leaf nodes of the graph's branching. This computational complexity is better than any existing method for this problem, including the graph-based algorithms (Bender, Farach-Colton, Pemmasani, Skiena, & Sumazin, 2004; Schmitz, 1983), the graph encoding (Abdeddaim, 1997; Bommel & Beck, 2000; Zibin & Gil, 2001), and the matrix-based algorithms (La Poutre & Leeuwen, 1988).

TREE LABELING

In this section, we mainly discuss the concept of tree labeling, based on which our algorithm is designed. For any directed tree T, we can label it as follows. By traversing T in *preorder*, each node v will obtain a number $pre(v)$ to record the order in which the nodes of the tree are visited. In a similar way, by traversing T in *postorder*, each node v will get another number $post(v)$. These two numbers can be used to characterize the reachabilities of nodes as follows.

- **Proposition 1:** Let v and v' be two nodes of a tree T. Then, v' is a descendant of v iff $pre(v') > pre(v)$ and $post(v') < post(v)$.

- **Proof:** See Exercise 2.3.2-20 in Knuth (1969).

The following example helps for illustration.

- **Example 1:** See the pairs associated with the nodes of the directed tree shown in Figure 1. The first element of each pair is the preorder number of the corresponding node and the second is its postorder number. Using such labels, the reachabilities of nodes can be easily checked. For instance, by checking the label associated with b against the label for f, we know that b is an ancestor of f in terms of Proposition 1. We can also see that since the pairs associated with g and c do not satisfy the condition given in Proposition 1, g must not be an ancestor of c and *vice versa*.

Let (p, q) and (p', q') be two pairs associated with nodes u and v. We say that (p, q) is subsumed by (p', q'), denoted $(p, q) \prec (p', q')$, if $p > p'$ and $q < q'$. Then, u is a descendant of v if (p, q) is subsumed by (p', q').

GRAPH DECOMPOSITION AND COMPUTATION OF TRANSITIVE CLOSURES

Now we discuss how to recognize the ancestor-descendant relationships w.r.t. a general structure: a DAG or a graph containing no cycles. First, we discuss the concept of branching in 4.1. Then, we address the problem of DAGs in 4.2. Next, cyclic graphs are discussed in 4.3.

Branchings of DAGs

What we want is to apply the technique discussed above to a DAG. For this purpose, the concept of *branchings* needs to be first specified.

- **Definition 1:** (*branching* (Tarjan, 1977)) A subgraph $B = (V, E')$ of a digraph $G = (V, E)$ is called a branching if it is cycle-free and $d_{\text{indegree}}(v) \leq 1$ for every $v \in V$.

Clearly, if for only one node r, $d_{\text{indegree}}(r) = 0$, and for all the rest of the nodes, v, $d_{\text{indegree}}(v) = 1$, then the branching is a directed tree with root r. Normally, a branching is a set of directed trees. Now, we assign each edge e a same cost (e.g.,

Figure 1. Tree labeling

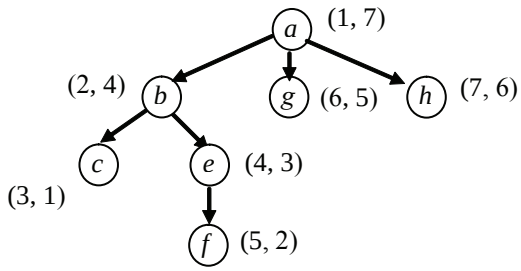

Figure 2. A DAG and its branching

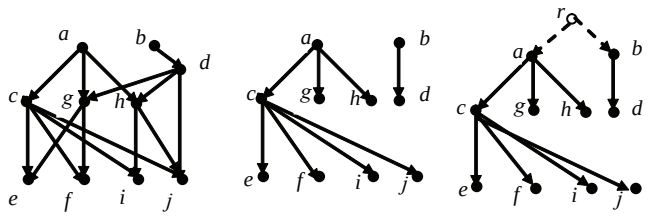


(a) (b (c)

let cost $c(e) = 1$ for every edge). We will find a branching for which the sum of the edge costs:

$$\sum_{e \in E'} c(e),$$

is maximum.

For example, the trees shown in Figure 2(b) are a maximal branching of the graph shown in Figure 2(a) if each edge has a same cost.

Assume that the maximal branching for $G = (V, E)$ is a set of trees T_i with root r_i ($i = 1, ..., m$). We introduce a *virtual root* r for the branching and an edge $r \rightarrow r_i$ for each T_i, obtaining a tree G_r, called the core of G. For instance, the tree shown in Figure 2(c) is the core of the graph shown in Figure 2(a). Using Tarjan's algorithm for finding optimum branchings (Tarjan, 1977), we can always find a maximal branching for a directed graph in $O(|E|)$ time if the cost for every edge is equal to each other. Therefore, the core tree for a DAG can be constructed in linear time.

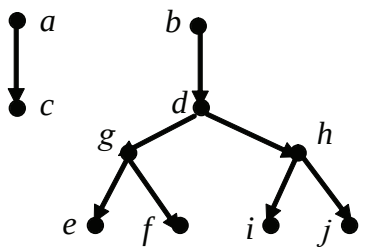
However, we may have more than one branchings for a given DAG. For instance, for the graph shown in Figure 2(a), we can find another branching as shown in Figure 3.

The number of the leaf nodes of this branching is 5 while the number of the leaf nodes of the branching shown in Figure 2(b) is 7.

An interesting question is: can we always find a branching with the least number of leaf nodes in an efficient way? To answer this question, we give the following algorithm, which works in a recursive way and searches G bottom-up as follows. Let S be the set of all nodes in G that have no descendants. We will first determine, in some way, the parents of the nodes (in S) in the branching to be generated. After that, we remove all the nodes in S from G, obtaining another DAG G'. Applying the above procedure to G' recursively, we will eventually get a branching. Whether it has the least number of leaf nodes depends on how we choose the parents of the nodes in S in each recursive step.

In the following algorithm, we use T to represent the set of the nodes, which have only the children in S. Associated with each $v \in T$ is an integer, denoted by $\alpha(v)$, equal to the

Figure 3. A branching



Box 1. Algorithm branching-generation (G,S)

Algorithm *branching-generation*(G, S)
begin
1. find a set T such that each $v \in T$ has all its children in S;
2. $T' \leftarrow \Phi$; $S' \leftarrow S$
3. **while** T is not empty **do**
4. {**find** v in T with the least α-value
5. let $v_1, v_2, ..., v_k$ be the children of v
6. add edges (v, v_i) $(1 \le i \le k)$ into *branching*
7. remove v from T; $T' \leftarrow T' \cup \{v\}$
8. remove $\{v_1, v_2, ..., v_k\}$ from S
9. **for** any singular v' **do**
10. {remove v' from T; $T' \leftarrow T' \cup \{v'\}$
11. Calculate new α-values for any of the remaining nodes in T if some of its children are removed
12. }
13. $G' \leftarrow G/S'$; (* remove all nodes in S from G *)
14. call *branching-generation*(G', T')
end

number of the nodes (in T), whose children all appear in the set of v's children. For instance, for the DAG shown in Figure 2(a), $S = \{e, f, i, j\}$ and $T = \{c, g, h\}$. In addition, $\alpha(c) = 2$, $\alpha(g) = 0$ and $\alpha(h) = 0$. When we generate part of the branching including only S and T, such α-values are used as follows:

1. Choose $v \in T$ such that $\alpha(v)$ is the smallest. (Here, the tie is resolved arbitrarily.) Put all the edges from v to its children into the branching. Remove v from T and its children from S. Remove any node in T, which becomes singular due to the removing of the nodes from S (by a singular, we mean a node not connecting any other node in the graph.) Change the α-values for some of the remaining nodes in T, whose children are partly removed.
2. Repeat step (1) until T is exhausted.

Box 1 shows the formal description of the algorithm.

The algorithm searches G bottom-up. First, we determine the parents of all the nodes in S for the branching to be created. This is done by executing lines 3-12. During this process, we choose a node v with the least α-value from T one by one, and add the edges connecting it to its children into the branching (see line 4-6). After this, both v and its children will be removed from T and S, respectively (see lines 7-8). Also, all those node in T, which become singular, will also be eliminated from T (see lines 9-10). In addition, for some of the remaining nodes in T, their α-values will be accordingly changed (see line 11). This arrangement enables us to find a branching with the least number of leaf nodes. Otherwise, choosing a node in T with a larger α-value earlier as a parent will make more nodes in T become leaf nodes. In a next step, we remove S' (which contains all the nodes in the initial S) from G, getting another DAG G', on which a recursive call *branching-generation*(G', T') will be carried out (see line 14). Here, T' is a copy of T, containing all the nodes that do not have descendants in G'.

The following example helps for illustration.

- **Example 2:** Consider the graph shown in Figure 2(a) once again. When we apply the previous algorithm to it, we will have altogether three recursive calls, which are shown below in great detail.
  - First recursive call - *branching-generation*(G, S_1):
    $S_1 = \{e, f, i, j\}$, $T_1 = \{c, g, h\}$.
    $\alpha(c) = 2$, $\alpha(g) = 0$, $\alpha(h) = 0$.
    Part of the branching generated is shown in Figure 4(a).
    $G_1 = G/S_1$ is shown in Figure 4(b).
  - Second recursive call - *branching-generation* (G_1,S_2):
    $S_2 = \{c, g, h\}$, $T_2 = \{a, d\}$.
    $\alpha(a) = 1$, $\alpha(d) = 0$.
    Part of the branching generated is shown in Figure 5(a).
    $G_2 = G_1/S_2$ is shown in Figure 5(b).
  - Third recursive call - *branching-generation*(G_2, S_3):
    $S_3 = \{a, d\}$, $T_3 = \{b\}$.
    $\alpha(b) = 0$.
    The branching generated is shown in Figure 3.
    $G_3 = G_2/S_3$ contains only node b.
    The process terminates.

The dominant cost of the previous algorithm is the execution of line 4, by which we will search the whole T to find a node with the least α-value. But it is bounded by O(b). Since such an operation can be done at most n times, the total cost of the previous algorithm is on the order of O($b \cdot n$).

Figure 4. Results of the first recursive call

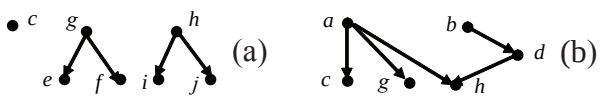


Figure 5. Results of the second recursive call

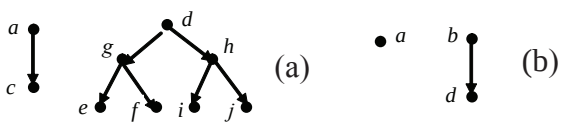

Figure 6. Tree labeling and illustration for transitive closure representation

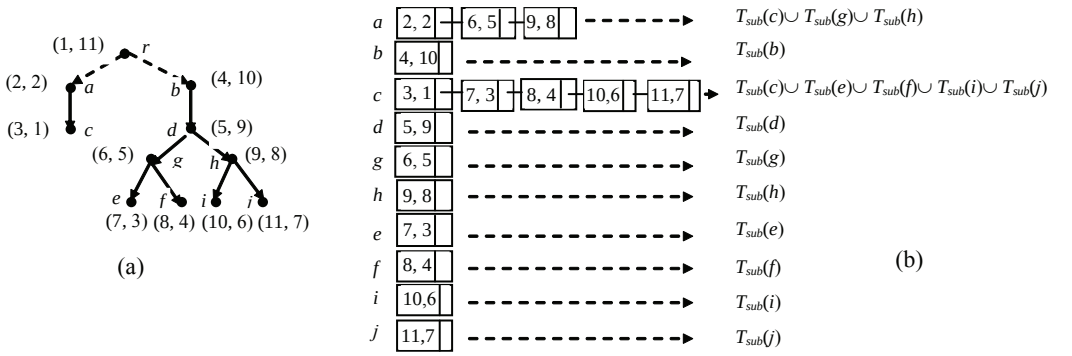

According to the previous discussion, we have the following proposition.

- **Proposition 2:** Algorithm *branching-generation*( ) can always find a branching for any DAG with the least number of leaf nodes.

Transitive Closures of DAGs

Obviously, we can always label G_r (for some G) as discussed in Section 2.

In a G_r, a node v can be considered as a representation of the subtree rooted at v, denoted $T_{sub}(v)$; and the pair (*pre*, *post*) associated with v can be considered as a pointer to v, and thus to $T_{sub}(v)$. (In practice, we can associate a pointer with such a pair to point to the corresponding node in G_r.) In the following, what we want is to construct a pair sequence: $(pre_1, post_1), ..., (pre_k, post_k)$ for each node v in G, representing the union of the subtrees (in G_r) rooted respectively at $(pre_j, post_j)$ ($j = 1, ..., k$), which contains all the descendants of v. In this way, the space overhead for storing the descendants of a node is dramatically reduced. Later we will shown that a pair sequence contains at most O(b) pairs, where b is the number of the leaf nodes of G's branching.

- **Example 3:** The core tree G_r of the DAG G shown in Figure 2(a) can be labeled as shown in Figure 6(a). Then, each of the generated pairs can be considered as a representation of some subtree in G_r. For instance, pair (5, 9) represents the subtree rooted at *d* in Figure 6(a).

If we can construct, for each node v, a pair sequence as shown in Figure 6(b), where it is stored as a linked list, the descendants of the nodes can be represented in an economical way. Let $L = (pre_1, post_1), ..., (pre_k, post_k)$ be a pair sequence and each $(pre_i, post_i)$ be a pair labeling v_i ($i = 1, ..., k$). Then, L corresponds to the union of the subtrees $T_{sub}(v_1)$,..., and $T_{sub}(v_k)$. For example, the pair sequence (2, 2)(6, 5)(9, 8) associated with *a* in Figure 7(b) represents a union of 3 subtrees: $T_{sub}(a)$, $T_{sub}(g)$, and $T_{sub}(h)$, which contains all the descendants of *a* in G.

The question is how to construct such a pair sequence for each node v so that it corresponds to a union of subtrees in G_r, which contains all the descendants of v in G.

First, we notice that by labeling G_r, each node in $G = (V, E)$ will be initially associated with a pair as illustrated in Figure 7. That is, if a node v is labeled with (*pre*, *post*) in G_r, it will be initially labeled with the same pair (*pre*, *post*) in G.

To compute the pair sequence for each node, we sort the nodes of G topologically, that is, $(v_i, v_j) \in E$ implies that v_j appears before v_i in the sequence of the nodes. The pairs to be generated for a node v are simply stored in a linked list A_v. Initially, each A_v contains only one pair produced by labeling G_r.

We scan the topological sequence of the nodes from the beginning to the end and at each step we do the following:

Let v be the node being considered. Let $v_1, ..., v_k$ be the children of v. Merge A_v with A_{vi} each for the child node v_i ($i = 1, ..., k$) as follows. Assume $A_v = p_1 \rightarrow p_2 \rightarrow ... \rightarrow p_g$ and $Av_i = q_1 \rightarrow q_2 \rightarrow ... \rightarrow q_h$, as illustrated in Figure 8. Assume that both A_v and Av_i are increasingly ordered. (We say a pair p is larger than another pair p', denoted $p > p'$ if $p.pre > p'.pre$ and $p.post > p'.post$.)

We step through both A_v and from left to right. Let p_i and q_j be the pairs encountered. We will perform the following checkings to merge into A_v.

1. If $p_i.pre > q_j.pre$ and $p_i.post > q_j.post$, insert q_j into A_v after p_{i-1} and before p_i and move to q_{j+1}.
2. If $p_i.pre > q_j.pre$ and $p_i.post < q_j.post$, remove p_i from A_v and move to p_{i+1}. (*p_i is subsumed by q_j.*)

Figure 7. Graph labeling

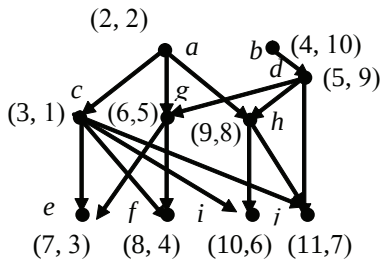

Figure 8. Linked lists associated with nodes in G

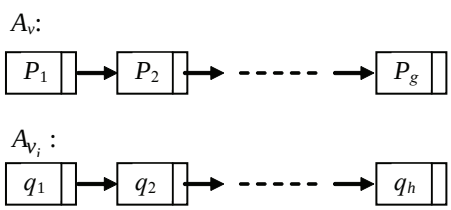

Box 2. Algorithm pair-sequence-merge (A1, A2)

Input: A_1 and A_2 - two linked lists associated with v_1 and v_2.
Output: A - modified A_1, containing all the pairs in A_1 and A_2 with all the subsumed pairs removed.

```
begin
1    p ←first-element(A1)
2    q ←first-element(A2)
3    while p ≠ nil do{
4            while q ≠ nil do{
5            if (p.pre > q.pre ∧ p.post > q.post) then
6            {insert q into A1 before p
7            q ←nextq);} (*nextq) represents the pair next to q in A2.*)
8            else if (p.pre > q.pre ∧ p.post < q.post) then
9                    {p' ←p; (*p is subsumed by q; remove p from A1.*)
10                   remove p from A1
11                   p ←next(p');} (*next(p') represents the pair next to p' in A1.*)
12                   else if (p.pre < q.pre ∧ p.post > q.post) then
13                           {q ←nextq);} (*q is subsumed by p; move to the next element of q.*)
14                   else if (p.pre < q.pre ∧ p.post < q.post) then
15                                   {p ←nextp);}
16                           else if (p.pre = q.pre ∧ p.post = q.post)
17                                   then {p ←nextp); q ←nextq);}
18   if p = nil ∧q ≠nil then
     {attach the rest of A2 to the end of A1;}
end
```

Figure 9. An entire merging process

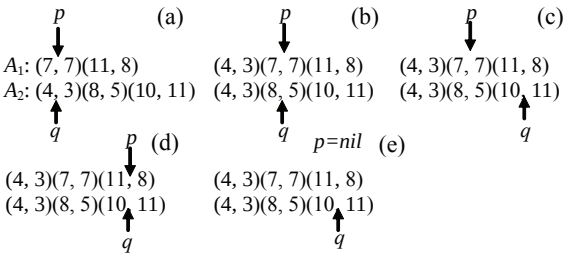

Figure 10. Illustration of merging two pair sequences

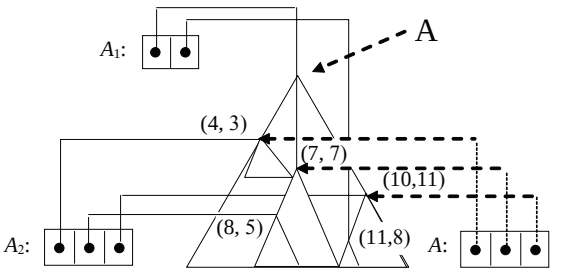


3. If $p_i.pre < q_j.pre$ and $p_i.post > q_j.post$, ignore q_j and move to q_{j+1}. (*q_j is subsumed by p_i; but it should not be removed from .*)
4. If $p_i.pre < q_j.pre$ and $p_i.post < q_j.post$, ignore p_i and move to p_{i+1}.
5. If $p_i = p_j$' and $q_i = q_j$', ignore both (p_i, q_i) and (p_j', q_j'), and move to (p_{i+1}, q_{i+1}) and (p_{j+1}', q_{j+1}'), respectively.

We notice that initially each A_v contains only one pair and is trivially sorted. Then, when we merge a sorted pair sequence into another sorted pair sequence as above, the result pair sequence must also be sorted.

In terms of the previous discussion, we have the algorithm (see Box 2) to merge two pair sequences together.

The following example helps for illustration.

- **Example 4:** Assume that $A_1 = (7, 7)(11, 8)$ and $A_2 = (4, 3)(8, 5)(10, 11)$. Then, A = *pair-sequence-merge*(A_1, A_2) = (4, 3)(7, 7)(10, 11). Figure 9 shows the entire merging process.

In each step, the A_1-pair pointed to by p and the A_2-pair pointed to by q are compared. In the first step, (7, 7) in A_1 will be checked against (4, 3) in A_2 (see Figure 9(a)). Since (4, 3) is smaller than (7, 7), it will be inserted into A_1 before (7, 7) (see Figure 9(b)). In the second step, (7, 7) in A_1 will be checked against (8, 5) in A_2. Since (8, 5) is subsumed by (7, 7), we move to (10, 11) in A_2 (see Figure 9(c)). In the third step, (7, 7) is smaller than (10, 11) and we move to (11, 8) in A_1 (see Figure 9(d)). In the fourth step, (11, 8) in A_1 is checked against (10, 11) in A_2. Since (11, 8) is subsumed by (10, 11), it will be removed from A_1 and p becomes *nil* (see Figure 9(e)). In this case, (10, 11) will be appended to A_1 (see line 18 of Algorithm *pair-sequence-merge*( )), forming the result A = (4, 3)(7, 7)(10, 11) (see Figure 6(e)). Figure 10 is a pictorial illustration of the result of merging A_2 into A_1 (note that A_2 itself is not changed).

In the following, we establish several propositions to clarify the properties of the previous algorithm.

- **Proposition 3:** Let A_1 and A_2 be two pair sequences sorted in ascending order. Let A be the result obtained by merging A_2 into A_1 using Algorithm *pair-sequence-merge*( ). Then, A is also sorted increasingly.
- **Proof:** During the execution of the algorithm, some pairs may be removed from A_1 and some pair of A_2 may be inserted into A_1. Obviously, removing a pair from A_1 will not change the ordering of A_1. Let q be a pair of A_2 inserted into A_1. It may be done at line 6 or at line 18. If it is done at line 6, there must be a pair p in A_1 such that $p > q$. Consider the pair p' before p. We have $p' < q$; otherwise, q will be inserted before p' or will not be inserted into A_1 at all. In this case, the proposition holds. If q is inserted into A_1 by executing line 18, all the pairs in A_1 must be used up before the line 18 is carried out. We notice that at this moment,

Box 3. Algorithm all-sequence-generation

```
begin
1     Let v_n, v_{n-1}, ..., v_1 be the topological sequence of the nodes of G;
2     for i from n downto 1 do
3           {let v_1,...,v_k be the child nodes of v_i;
4                 for j from 1 to k do
5                       call pair-sequence-merge(A_i, Av_i );
6           }
end
```

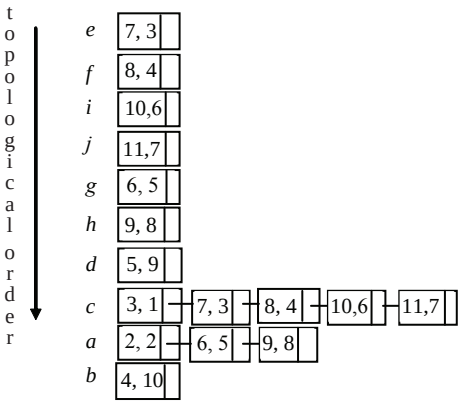
all the pairs in A_1 are increasingly ordered and smaller than all the remaining pairs in A_2, which are originally in ascending order. Therefore, in this case, the proposition holds, too.

- **Proposition 4:** Let A_1 and A_2 be two pair sequences sorted in ascending order. Let A be the result obtained by merging A_2 into A_1 using Algorithm *pair-sequence-merge*( ). If v is a node in a subtree of G_r, which is rooted at some node labeled with a pair in A_2, then there must be a pair in A such that the subtree rooted at it contains v.
- **Proof:** Assume that v is in a subtree rooted at u labeled with (*pre*, *post*) that appears in A_2. If (*pre*, *post*) appears in A, the proposition holds. Suppose that (*pre*, *post*) does not appear in A. In this case, there must be a pair (*pre*', *post*') in A_1, which subsumes (*pre*, *post*). Notice that (*pre*', *post*') cannot be subsumed by any pair in A_2 since it subsumes (*pre*, *post*). Otherwise, we will have a pair (*pre*'', *post*'') in A_2 such that *pre*'' < *pre*' and *post*'' > *post*'. But we have (*pre*, *post*) < (*pre*'', *post*'') or (*pre*, *post*) > (*pre*'', *post*''). In the former case, we have *pre* < *pre*'' < *pre*'. It contradicts the fact that (*pre*', *post*') subsumes (*pre*, *post*). In the latter case, we have *post* > *post*'' > *post*'. It also contradicts the fact that (*pre*', *post*') subsumes (*pre*, *post*). Therefore, (*pre*', *post*') will appear in A. Since v is in the subtree rooted at (*pre*, *post*), it must be in the subtree rooted at (*pre*', *post*'). Thus, the proposition holds.
- **Proposition 5:** Let A_1 and A_2 be two pair sequences sorted in increasing order. Let A be the result obtained by merging A_2 into A_1 using Algorithm *pair-sequence-merge*( ). If v is a node in a subtree of G_r, which is rooted at some node labeled with a pair in A_1, then there must be a pair in A such that the subtree rooted at it contains v.
- **Proof:** Similar to Proposition 4
- **Proposition 6:** The time complexity of Algorithm *pair-sequence-merge* is bounded by $O(\max\{|A_1|, |A_2|\})$.
- **Proof:** During the execution of the algorithm, each pair in A_1 and A_2 is visited at most once.

Based on the merging operation previously discussed, the pair sequences for all the nodes in a DAG can be computed as shown in Box 3.

- **Proposition 7:** The space complexity of Algorithm *all-sequence-generation* is bounded by $O(n \cdot b)$, where b is the number of the leaf nodes of G's branching.
- **Proof:** In the algorithm, each node v is associated with a linked list A_v. We claim that the size of A_v is bounded by b. Assume that A_v contains $b + 1$ pairs that are different from each other. Then, there must exists two pairs p and q so that p subsumes q or *vice versa*. Therefore, the space needed for Algorithm *all-sequence-generation* is bounded by $O(n \cdot b)$.
- **Proposition 8:** The time complexity of Algorithm *all-sequence-generation* is bounded by $O(e \cdot b)$, where b is the number of the leaf nodes of G's branching.
- **Proof:** In the out for-loop of the algorithm, n steps are performed. In each step, d_i merge operations are made for each v_i, where d_i represents the outdegree of v_i. Therefore, the time spent for each step is $O(d_i \cdot b)$. The whole time complexity is thus $O() = O(e \cdot b)$.
- **Proposition 9:** Let v be a node in G. Any descendant u of v must be in a subtree of G_r rooted at a node labeled with a pair in A_v constructed by Algorithm *all-sequence-generation*.
- **Proof:** Assume that $v_n \rightarrow v_{n-1} \rightarrow ... \rightarrow v_1$ *is a topological sequence of* G. We prove the proposition by induction on the ordinal number m in the topological sequence.
  - **Basis:** When $m = 1$, v_n is a leaf node in G and its linked list contains only one label associated with v_n. The proposition holds.
  - **Hypothesis:** Suppose that when $m \leq k$ the proposition holds. That is, each linked list A_i associated with v_i $(i = n, ..., n - k)$ contains all the pairs covering all the descendants of v_i.
  - **Consider m = k + 1:** According to the property of the topological sequence, all the child nodes of v_{n-k-1} must appear in $\{v_n, v_{n-1}, ..., v_{n-k}\}$. Then, from lines 3 - 6 of Algorithm *all-sequence-gen-*

Figure 11. Linked lists representing pair sequences



eration, as well as Proposition 2, 3 and 4, we can see that the linked list A_{n-k-1} associated with v_{n-k-1} must contain all the pairs covering all the descendants of v_{n-k-1}. It completes the proof.

- **Example 5:** A possible topological sequence for the graph shown in Figure 2(a) is: $e \rightarrow f \rightarrow i \rightarrow j \rightarrow g \rightarrow h \rightarrow d \rightarrow c \rightarrow a \rightarrow b$. The initial pairs associated with them are: (4, 1), (5, 2), (6, 3), (7, 4), (8, 6), (9, 7), (11, 9), (3, 5), (2, 8) and (10, 10), respectively. They are obtained by labeling the tree shown in Figure 3(a). Applying Algorithm *all-sequence-generation* to this sequence, we will produce a linked list for each of them as shown in Figure 11.

We notice that each pair sequence associated with a node is increasingly ordered. Therefore, we can store a pair sequence in two integer sequences: one for preorder numbers and the other for postorder numbers. For example, the pair sequence associated with *c* in Figure 11 is (3, 1)(7, 3)(8, 4)(10, 6)(11, 7). It can be stored in two sequences of integers: 3, 7, 8, 10, 11, and 1, 3, 3, 4, 6, 7. To check whether *v* is a descendant of *u*, we do the following. Let *p* be the pair of *v* and *s* the pair sequence of *u*. Assume that *s* is stored in two integer sequences: s_1 (for all the preorder numbers in *s*) and s_2 (for all the postorder numbers in *s*). We first make a binary search of s_1 to find the largest *k* such that $s_1[k] < p{\cdot}pre$. Then, we search s_2 from the 1st to the *k*th element to find whether there exists *l* such that $s_2[l] > p{\cdot}post$. If it is the case, *p* is subsumed by some pair in *s*; otherwise not. Obviously, the time complexity of this process is $O(\log_2|s|)$. Since $|s|$ is bounded by the breadth *b* of the graph, this method requires $O(\log_2 b)$ time for reachability checking.

Transitive Closures of Cyclic Graphs

Based on the method discussed in the previous subsection, we can easily develop an algorithm to compute transitive closures for cyclic graphs. First, we use Tarjan's algorithm for identifying *strongly connected components* (*SCCs*) to find all the cycles in a cyclic graph (Tarjan, 1972) (which needs only $O(n + e)$ time). Then, we take each SCC as a single node (i.e., collapse each SCC to a node) and transform a cyclic graph into a DAG while maintaining all the reachability information. This is because all nodes on a cycle are mutually reachable, and hence have identical reachability properties. Next, we handle the DAG as discussed in 3.2. In this way, however, all nodes in an SCC will be assigned

Figure 12. A cyclic graph and its reduction with SCC collapsed

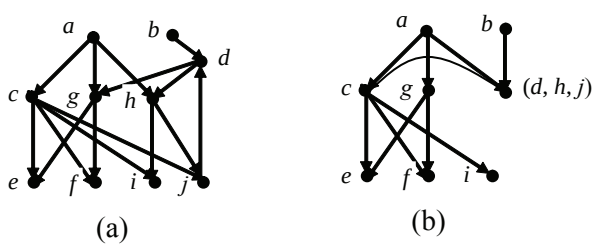


Figure 13. Linked lists representing pair sequences

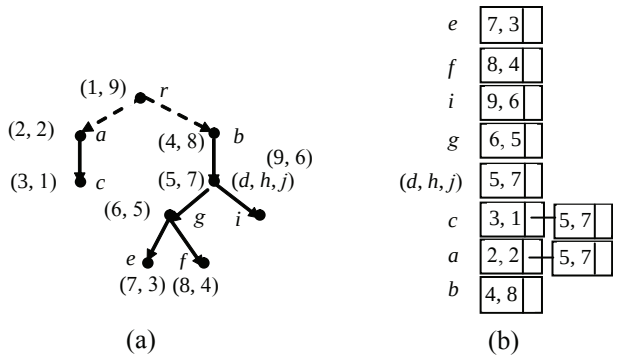

the same pair (and the same pair sequence). For a better understanding, see the following example.

- **Example 6:** Consider the graph shown in Figure 12(a), which is the graph shown 2(a) with one of the edges reversed (i.e., edge (*d*, *j*) is changed to (*j*, *d*)). Then, the nodes *d*, *h* and *j* form an SCC, which can collapse to a single node, denoted by (*d*, *h*, *j*) in the graph shown in Figure 12(b).

The branching of this graph is shown in Figure 13(a) and can be labeled as discussed in Section 2. Along the reverse topological order of the graph shown in Figure 12(a), we will generate the pair sequences for all the nodes as shown in Figure 13(b), which is the representation of the graph's transitive closure.

Finally, we point out that the time complexity of computing transitive closure of a cyclic graph is still O(*e*·*b*) since Tarjan's algorithm runs in O(*n* + *e*) time (Tarjan, 1972). The idea of collapsing an SCC into a single node was first proposed in Munro (1971).

FUTURE TREND

The computation of transitive closures and recursive relationships is a classic problem in the graph theory and has a variety of applications in data engineering, such as CAD/CAM, office systems, databases, programming languages and so on. For all these applications, the problems can be represented as a directed graph with the edges being not labelled, and can be solved using the techniques described in this article. In practice, however, there exits another kind of problems, which can be represented only by using the so-called weighted directed graphs. For them, the edges are associated with labels or distances and the shortest (or longest) paths between two given nodes are often asked. Obviously, the above techniques are not able to solve such problems. They have to be extended to encode path information in the data structure to speed up query evaluation. For this, an interesting issue is how to maintain minimum information but get high efficiency, which is more challenging than transitive closures and provides an important research topic in the near future.

CONCLUSION

In this article, we provide an overview on the recursion computation in a relational environment and present a new encoding method to label a digraph, which is compared with a variety of traditional strategies as well as the methods proposed in the database community. Our method is based on a tree labeling method and the concept of branchings that are used in graph theory for finding the shortest connection networks. A branching is a subgraph of a given digraph that is in fact a forest, but covers all the nodes of the graph. On the one hand, the proposed encoding scheme achieves the smallest space requirements among all previously published strategies for recognizing recursive relationships. On the other hand, it leads to a new algorithm for computing transitive closures for DAGs in O(*e*·*b*) time and O(*n*·*b*) space, where *n* represents the number of the nodes of a DAG, *e* the numbers of the edges, and *b* is the number of the leaf nodes of the DAG's branching. In addition, this method can be extended to cyclic digraphs and is especially suitable for a relational environment.

KEY TERMS

Branching: A branching is a subgraph of a directed graph, in which there is no cycles and the indegree of each node is 1 or 0.

Cyclic Graph: A cyclic graph is a directed graph that contains at least one cycle.

DAG: A DAG is a directed graph that does not contain a cycle.

Graph Encoding: Graph encoding is a method to assign the nodes of a directed graph a number or a bit string, which reflects some properties of that graph and can be used to facilitate computation.

Strongly Connected Component (SCC): A SCC is a subgraph of a directed graph, in which between each pair of nodes there exists a path.

Topological Order: A sequence S of nodes of a DAG $G = (V, E)$: $v_1,\ldots, v_n$ such that $(v_i, v_j) \in E$ implies that v_j appears before v_i in S.

Transitive Closure: The transitive closure of a directed graph G is a graph G^*, in which there is an edge from node a to node b if there exists a path from a to b in G.

Tree: A tree is a graph with a root, in which the indegree of each node is equal to 1.

INTRODUCTION

Mobile commerce is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile, handheld devices such as smart cellular phones and PDAs (personal digital assistants). It is widely acknowledged that mobile commerce is a field of enormous potential. However, it is also commonly admitted that the development in this field is constrained. There are considerable barriers waiting to be overcome. One of the barriers is most software engineers are not familiar with the design and development of mobile applications (Kiely, 2001). This chapter gives a study of handheld computing and programming to help software engineers better understanding this subject. Handheld computing is to use handheld devices to perform wireless, mobile, handheld operations such as personal data management and making phone calls. They can be achieved by using server or client- side handheld computing and programming:

- **Server-side handheld computing and programming:** Server-side handheld computing is to use handheld devices to perform wireless, mobile, handheld operations, which require the supports of server-side computing. The most common applications of server-side handheld programming are the mobile Web contents.
- **Client-side handheld computing and programming:** Client-side handheld computing is to use handheld devices to perform handheld operations, which do not need the supports of server-side computing. Most client-side handheld programming languages are a version of either C/C++ or Java. Examples of the application development of Java ME, a version of Java, and Palm OS, using a version of C, will be given.

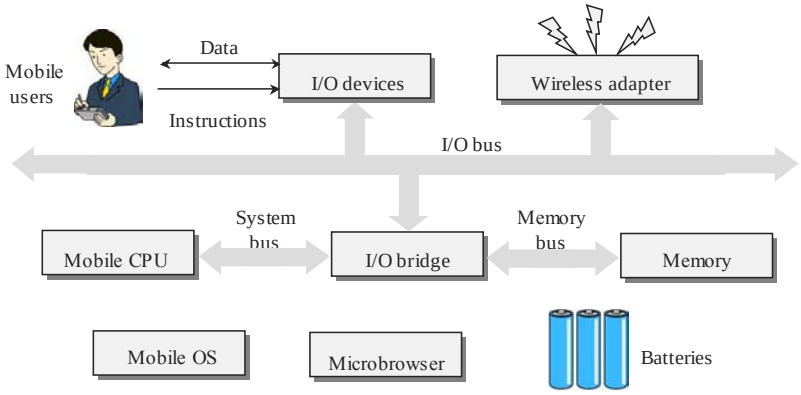
BACKGROUND

Mobile users interact with mobile commerce applications by using small wireless Internet-enabled devices, which come with several aliases such as handhelds, palms, PDAs (personal digital assistants), pocket PCs, and smart phones. To avoid any ambiguity, a general term, mobile handheld devices, is used in this article. Mobile handheld devices are small general-purpose, programmable, battery-powered computers, but they are different from desktop PCs or notebooks due to the following special features:

- Limited network bandwidth,
- Small screen/body size, and
- High mobility.

Short battery life and limited memory, processing power, and functionality are additional features, but these problems are gradually being solved as the technologies improve and new methods are constantly being introduced. The limited network bandwidth prevents the display of most multimedia on a microbrowser. Though the Wi-Fi and 3G networks go

Figure 1. A system structure of mobile handheld devices



some way toward addressing this problem, the wireless bandwidth is always far below the bandwidth of wired networks. The small screen/body size restricts most handheld devices to using a stylus for input.

Figure 1 shows a typical system structure for handheld devices, which includes the following six major components, (i) a mobile operating system, (ii) a mobile central processor unit, (iii) a microbrowser, (iv) input/output devices, (v) a memory, and (vi) batteries (Hu, Yeh, Chu et al, 2005). Synchronization connects handheld devices to desktop computers, notebooks, or peripherals to transfer or synchronize data. Without needing serial cables, many handheld devices now use either an infrared (IR) port or Bluetooth technology to send information to other devices.

MAIN FOCUS OF THE CHAPTER

Handheld computing is a fairly new computing area and a formal definition of it is not found yet. Nevertheless, the author defines it as follows:

Handheld computing is to use handheld devices such as smart cellular phones and PDAs to perform wireless, mobile, handheld operations such as personal data management and making phone calls.

Again, handheld computing includes two kinds of computing: server and client- side handheld computing, which are defined as follows:

- **Server-side handheld computing:** It is to use handheld devices to perform wireless, mobile, handheld operations, which require the supports of server-side computing.
- **Client-side handheld computing:** It is to use handheld devices to perform handheld operations, which do not need the supports of server-side computing.

The terms of computing and programming are sometimes confusing and misused. The handheld programming, defined as programming for handheld devices, is different from handheld computing and includes two kinds of programming too:

- **Server-side handheld programming:** It is design and development of handheld software such as CGI programs that reside on the servers.
- **Client-side handheld programming:** It is design and development of handheld software such as Java ME programs that reside on the handheld devices.

Server-Side Handheld Computing and Programming

Server-side handheld computing and programming usually involve complicated procedures and advanced programming such as TCP/IP network programming. This chapter will focus on the most popular server-side handheld computing and programming, mobile Web contents design and development. For other kinds of server-side handheld computing and programming such as instant messaging and telephony, readers may refer to other technical reports or articles. A database-driven mobile Web site is often implemented by using a three-tiered client/server architecture consisting of three layers as shown in Figure 2: (i) user interface, (ii)

Figure 2. A generalized system structure of a database-driven mobile Web site

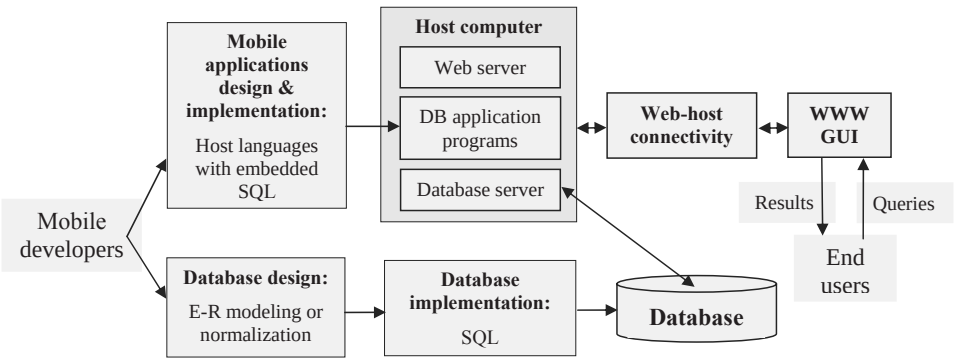


Figure 3. A generalized client-side handheld computing development cycle

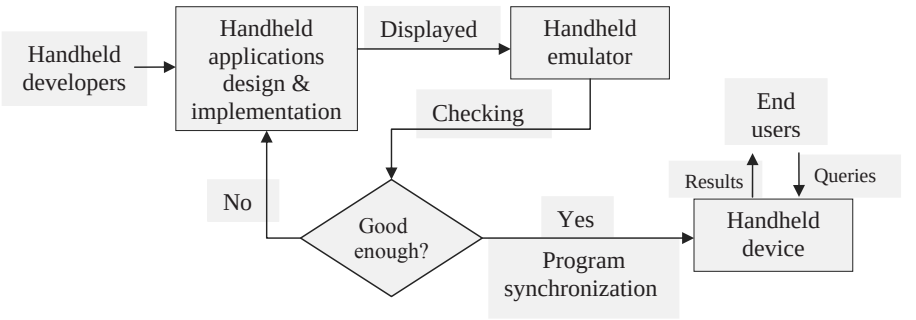


functional modules, and (iii) database management systems. The three-tier design has many advantages over traditional two-tier or single-tier designs, the chief one being: The added modularity makes it easier to modify or replace one tier without affecting the other tiers.

Client-Side Handheld Computing and Programming

Various environments/languages are available for client-side handheld computing and programming. Five of the most popular are (i) BREW, (ii) Java ME, (iii) Palm OS, (iv) Symbian OS, and (v) Windows Mobile. They apply different approaches to accomplishing the development of mobile applications. Figure 3 shows a generalized development cycle applied by them and Table 1 gives a comparison among the five languages/environments.

BREW: Binary Runtime Environment for Wireless

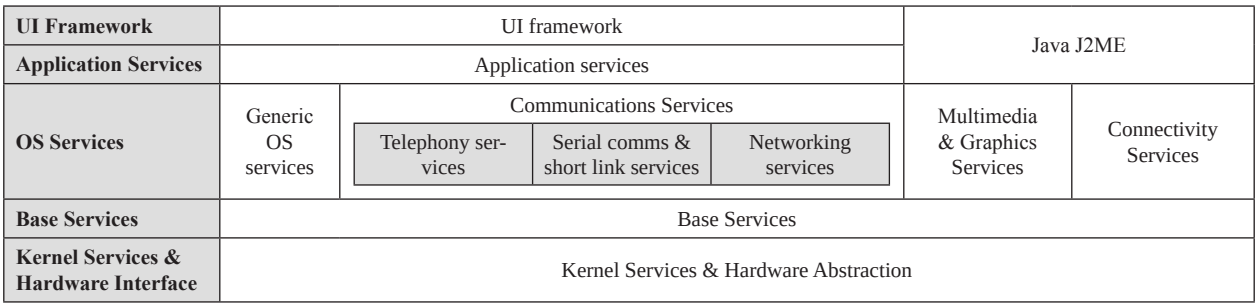
BREW is an application development platform created by Qualcomm for CDMA (code division multiple access)-based mobile phones (Qualcomm Inc., 2003). The CDMA is a digital wireless telephony transmission technique and it has two major features:

- The CDMA allows multiple frequencies to be used simultaneously (Spread Spectrum).

Table 1. A comparison among five handheld-computing languages/environments

	BREW	Java ME	Palm OS	Symbian OS	Windows Mobile
Creator	Qualcomm	Sun Microsystems	PalmSource	Symbian	Microsoft
Language/Environment	Environment	Language	Environment	Environment	Environment
Market Share (PDA) as of 2005	N/A	N/A	3rd	4th	1st
Market Share (Smartphone) as of 2006	?	N/A	4th	1st	5th
Primary Host Language	C/C++	Java	C/C++	C++	C/C++
Target Devices	Phones	PDAs & phones	PDAs	Phones	PDAs & phones

Figure 4. Symbian OS architecture



- The CDMA standards used for second-generation mobile telephony are the IS-95 standards.

BREW is a complete, end-to-end solution for wireless applications development, device configuration, application distribution, and billing and payment. It includes three major components:

- BREW SDK (software development kit) for application developers,
- BREW client software and porting tools for device manufacturers, and
- BREW distribution system (BDS) that is controlled and managed by operators—enabling them to easily get applications from developers to market and coordinate the billing and payment process.

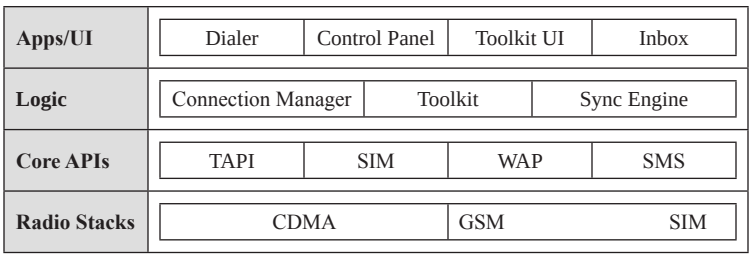
Symbian OS

Symbian is a software licensing company that develops and supplies the open operating system—Symbian OS—for data-enabled mobile phones (Symbian Ltd, 2005). Symbian was established as a private independent company in June 1998. It is an independent, for-profit company whose mission is to establish Symbian OS, whose architecture is given in Figure 4, as the world standard for mobile digital data systems, primarily for use in cellular telecoms. It is owned by Ericsson (15.6 percent), Nokia (47.9 percent), Panasonic (10.5 percent), Samsung (4.5 percent), Siemens (8.4 percent) and Sony Ericsson (13.1 percent). Headquartered in the UK, it has more than 1,300 staff with offices in Japan, Sweden, UK and the USA and a development centre in Bangalore in 2006. It is the most popular mobile operating system for smartphones. Cumulative shipments of Symbian OS phones since Symbian's formation reached 70.5 million phones in 2006.

Windows Mobile

Windows Mobile is a compact operating system for mobile devices based on the Microsoft Win32 API (Microsoft Corp., 2005). It is designed to be similar to desktop versions of Windows. In 1996, Microsoft launched Windows CE, a version of the Microsoft Windows operating system designed specially for a variety of embedded products, including handheld devices. However, it was not well received

Figure 5. Windows Mobile-based Smartphone architecture

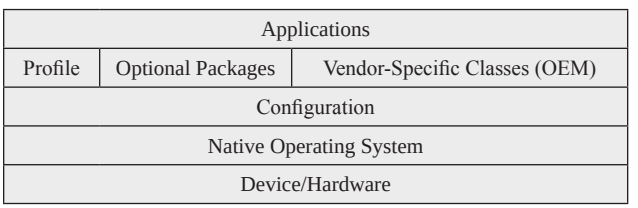


primarily because of battery-hungry hardware and limited functionality, possibly due to the way that Windows CE was adapted for handheld devices from other Microsoft 32-bit desktop operating systems. Windows Mobile includes three major kinds of software: (i) Pocket PC, (ii) Smartphones, and (iii) Portable Media Centers. Figure 5 shows the Smartphone architecture, which provides a core set of services that will abstract a variety of underlying links for both voice and data services (Finan, 2002). The primary Smartphone architecture consists of four layers: (i) applications/UI, (ii) logic, (iii) core APIs, and (iv) radio stack.

Java ME (Java Platform, Micro Edition)

Java ME provides an environment for applications running on consumer devices, such as mobile phones, PDAs, and TV set-top boxes, as well as a broad range of embedded devices (Sun Microsystem Inc., 2002a). Like its counterparts for the enterprise (Java EE), desktop (Java SE) and smart card (Java Card) environments, Java ME includes Java virtual machines and a set of standard Java APIs defined through the Java community process. The Java ME architecture, as shown in Figure 6, comprises a variety of configurations, profiles, and optional packages that implementers and developers can choose from, and combine to construct a complete Java runtime environment that closely fits the requirements of a particular range of devices and a target market. There are two sets of Java ME packages, which target different devices:

Figure 6. Java ME architecture



- **High-end devices:** They include connected device configuration (CDC), foundation, and personal profile.
- **Entry-level devices and smart phones:** They include connected limited device configuration (CLDC) and mobile information device profile (MIDP).

The following description gives an example of Java ME programming (Sun Microsystem Inc., 2004). Sun Java Wireless Toolkit is a toolbox for developing wireless applications that are based on Java ME's CLDC and MIDP. The toolkit includes the emulation environments, performance optimization and tuning features, documentation, and examples that developers need to bring efficient and successful wireless applications to market quickly. Program 1 gives a Java ME example, which displays the text "Hello, World!" and a ticker with a message "Greeting, world." Figure 7 shows an emulator displaying the execution results. For further references, the packages provided by the MIDP are given in Mobile Information Device Profile Specification 2.0 (Sun Microsystem Inc., 2002b). The packages `javax.*` are the extensions to standard Java packages. They are not included in the JDK or JRE. They must be downloaded separately.

PalmOS

Palm OS is a fully ARM-native, 32-bit operating system designed for used on Palm handhelds and other third-party devices. Its popularity can be attributed to its many advantages, such as its long battery life, support for a wide variety of wireless standards, and the abundant software available. The plain design of the Palm OS has resulted in a long battery life, approximately twice that of its rivals (PalmSource Inc., 2002). Two major versions of Palm OS are currently under development:

- **Palm OS Garnet:** It is an enhanced version of Palm OS 5 and provides features such as dynamic input area,

Program 1. An MIDlet program displaying the text "Hello, World!"

```
// This package defines MIDP applications and the interactions between
// the application and the environment in which the application runs.
import  javax.microedition.midlet.*;

// This package provides a set of features for user interfaces.
import  javax.microedition.lcdui.*;

public class HelloMIDlet  extends MIDlet  implements CommandListener {

  public void  startApp( ) {
    Display  display     = Display.getDisplay( this );
    Form     mainForm    = new  Form   ( "HelloMIDlet" );
    Ticker   ticker      = new  Ticker ( "Greeting, World" );
    Command  exitCommand = new  Command( "Exit", Command.EXIT, 0 );

    mainForm.append           ( "\n\n         Hello, World!" );
    mainForm.setTicker        ( ticker );
    mainForm.addCommand       ( exitCommand );
    mainForm.setCommandListener( this );
    display.setCurrent        ( mainForm );
  }

  public void  pauseApp ( ) { }

  public void  destroyApp( boolean unconditional ) {
    notifyDestroyed( );
  }

  public void  commandAction( Command c, Displayable s ) {
    if ( c.getCommandType( ) == Command.EXIT )
      notifyDestroyed( );
  }
}
```

Figure 7. A screenshot of an emulator displaying the execution results of Java ME program in Program 1

Figure 8. Palm OS 5 block diagram

Palm Applications	
PACE: Palm Application Compatibility Environment	
Core Palm OS	Licensee libraries
DAL: Device Abstraction Layer	
HAL: Hardware Abstraction Layer	

improved network communication, and support for a broad range of screen resolutions including QVGA.

- **Palm OS Cobalt:** It is Palm OS 6, which focuses on enabling faster and more efficient development of smartphones and integrated wireless (WiFi/Bluetooth) handhelds.

Figure 8 shows the structure of Palm OS 5, which consists of five layers: (i) applications, (ii) PACE, (iii) core Palm OS and licensee libraries, (iv) DAL, and (v) HAL.

The *Palm OS Developer Suite*, which is the official development environment and tool chain from PalmSource, is intended for software developers at all levels. It is a complete IDE (Integrated Development Environment) for:

- Protein applications (all ARM-native code) for Palm OS Cobalt and
- 68K applications for all shipping versions of the Palm OS.

Program 2 gives a Palm example, which displays the text "Hello, Mobile world!," an image, and a button "OK" on a Palm device. For how to create Palm OS applications, check Palm OS Developer Documentation at http://www.palmos.com/dev/support/docs/ . Figure 9 shows an emulator

Program 2. A Palm OS program displaying the text "Hello, Mobile world!"

```
// This header is from the Palm SDK and contains the needed refer-
ence
// materials for the use of Palm API and its defined constants.
#include  <PalmOS.h>

// The following IDs are from using Palm Resource Editor.
#define   Form1  1000
#define   OK     1003

// ----------------------------------------------------------------------
// PilotMain is called by the startup code and implements a simple
// event handling loop.
// ----------------------------------------------------------------------
UInt32  PilotMain( UInt16 cmd, void *cmdPBP, UInt16 launchFlags ) {
  short      err;
  EventType  e;
  FormType   *pfrm;

  if ( cmd == sysAppLaunchCmdNormalLaunch ) {
    // Displays the Form with an ID 1000.
    FrmGotoForm( Form1 );

    //  Main event loop
    while( 1 ) {
      //  Doze until an event arrives or 100 ticks are reached.
      EvtGetEvent( &e, 100 );
      //  System gets first chance to handle the event.
      if ( SysHandleEvent( &e ) )  continue;
      if ( MenuHandleEvent( (void *) 0, &e, &err ) )   continue;

      switch ( e.eType ) {
        case ctlSelectEvent:
          if ( e.data.ctlSelect.controlID == OK )
            goto  _quit;
          break;
        case frmLoadEvent:
          FrmSetActiveForm( FrmInitForm( e.data.frmLoad.formID ) );
          break;
        case frmOpenEvent:
          pfrm = FrmGetActiveForm( );
          FrmDrawForm( pfrm );
          break;
        case menuEvent:
          break;
        case appStopEvent:
          goto  _quit;
          break;
        default:
          if ( FrmGetActiveForm( ) )
            FrmHandleEvent( FrmGetActiveForm( ), &e );
          break;
      }
    }
_quit:
    FrmCloseAllForms( );
  }
  return 0;
}
```

Figure 9. A screenshot of the execution results of the Palm program in Program 2

displaying the execution results. Since this article is never intended to be a comprehensive Palm programming guide, further references for Palm OS SDK (Software Development Kit) can be found from the Internet (PalmSource Inc., 2004a, 2004b, 2004c).

FUTURE TRENDS

A number of mobile operating systems, as the previous list, with small footprints and reduced storage capacity have emerged to support the computing-related functions of mobile devices. For example, Research In Motion Ltd's BlackBerry 8700 smartphone uses RIM OS and provides Web access, as well as wireless voice, address book, and appointment applications (Research In Motion Ltd., 2005). Because the handheld device is small and has limited power and memory, the mobile OSes' requirements are significantly less than those of desk or laptop OSes. Although a wide range of mobile handheld devices are available in the market, the operating systems, the hub of the devices, are dominated by just few major organizations. The following two lists show the operating systems used in the top brands of smart cellular phones and PDAs in descending order of market share:

- **Smart cellular phones:** Symbian OS, Linux, RIM OS, Palm OS, Windows Mobile-based Smartphone, and others (Symbian Ltd., 2006).
- **PDAs:** Microsoft Pocket PC, RIM OS, Palm OS, Symbian OS, Linux, and others (Gartner Inc., 2005).

The market share is changing frequently and claims concerning the share vary enormously. It is almost impossible to predict which will be the ultimate winner in the battle of mobile operating systems. Because each mobile OS has its own unique development tools and programming languages, handheld computing and programming, especially the client-side ones, become difficult. A dominant mobile OS in the future may not be all that bad as the Microsoft's Windows do to the PCs.

CONCLUSION

Mobile commerce is a coming milestone after electronic commerce blossoming in the late 1990s. However, it is also commonly admitted that the development in this field is constrained. There are some considerable barriers waiting to be overcome. One of the barriers is most software engineers are not familiar with handheld programming, which is the programming for handheld devices such as smart cellular phones and PDAs (personal digital assistants). This chapter attempts to give a study of handheld computing to help software engineers better understand this subject. Client-side handheld computing is to use handheld devices to perform handheld operations, which do not need the supports of server-side computing. Various environments/languages are available for client-side handheld computing and programming. Five of the most popular are:

- **BREW:** It is created by Qualcomm Inc. for CDMA-based smartphones.
- **Java ME:** Java ME is an edition of the Java platform that is targeted at small, standalone or connectable consumer and embedded devices.
- **Palm OS:** It is a fully ARM-native, 32-bit operating system running on handheld devices.
- **Symbian OS:** Symbian OS is an industry standard operating system for smartphones, a joint venture originally set up by Ericsson, Nokia, and Psion.
- **Windows Mobile:** Windows Mobile is a compact operating system for handheld devices based on the Microsoft Win32 API. It is a small version of Windows, and features many "pocket" versions of popular Microsoft applications, such as Pocket Word, Excel, Access, PowerPoint, and Internet Explorer.

They apply different approaches to accomplishing the development of handheld applications and it is almost impossible to predict which approaches will dominate the client-side handheld computing in the future, as the Windows to desktop PCs. Most client-side handheld programming languages are a version of either C/C++ or Java. This chapter also shows application examples of Java ME, a version of Java, and Palm OS, using a version of C.

KEY TERMS

BREW (binary runtime environment for wireless): BREW is an application development platform created by Qualcomm for CDMA (code division multiple access)-based mobile phones.

Client-Side Handheld Programming: It is design and development of handheld software such as Java ME programs that reside on the handheld devices.

Handheld Computing: It is to use handheld devices such as smart cellular phones and PDAs (personal digital assistants) to perform wireless, mobile, handheld operations such as personal data management and making phone calls.

Java ME (Java Platform, Micro Edition): Java ME provides an environment for applications running on consumer devices, such as mobile phones, PDAs, and TV set-top boxes, as well as a broad range of embedded devices.

Mobile Handheld Devices: They are small general-purpose, programmable, battery-powered computers, but they are different from desk or laptop computers mainly due to the following special features: (i) limited network bandwidth, (ii) small screen/body size, and (iii) mobility.

Palm OS: Palm OS, developed by PalmSource Inc., is a fully ARM-native, 32-bit operating system running on handheld devices. Two major versions of Palm OS are currently under development: Palm OS Garnet and Palm OS Cobalt.

Server-Side Handheld Programming: It is design and development of handheld software such as CGI programs that reside on the servers.

Symbian OS: Symbian is a software licensing company that develops and supplies the open operating system—Symbian OS—for data-enabled mobile phones

Windows Mobile: It is a compact operating system for mobile devices based on the Microsoft Win32 API and is designed to be similar to desktop versions of Windows.

INTRODUCTION

The key of the success or failure of a software project depends on solving the right problem (Rumbaugh, 1994; Sawyer, 2005). Thus, software requirements should be correct, unambiguous, consistent, and as complete as possible (Institute of Electrical and Electronics Engineers [IEEE], 1998). Errors in requirements raise software development and maintenance costs notoriously (Katasonov & Sakkinen, 2006). The later the requirement error is detected, the higher the correction cost turns out to be. Error correction costs have been widely studied by many researchers (Bell & Thayer, 1976; Davis, 1993). Errors in requirements may be due to several reasons such as poor communication among requirements engineers, clients, and users; poor or nonexistent requirements validation; and the level of sternness of the models being used, especially to model relevant information captured from the universe of discourse (UofD).

Requirements engineering is the area of software engineering responsible for proposing and developing solutions to elicit, model, and analyze requirements by means of heuristics, guidelines, models, and processes which tend to requirements' completeness, quality, correctness, and consistency. Many proposals have been put forward by many researchers (Bubenko & Wrangler, 1993; Jacobson, Christerson, Jonsson, & Overgaard, 1992; Leite & Oliveira, 1995; Macaulay, 1993; Reubenstein & Waters, 1991).

BACKGROUND

Eliciting and modeling software requirements or related information are two different but highly related activities (Hull, Jackson, & Dick, 2005; Zowghi & Coulin, 2005). They may be coupled in several ways, being canonicals, such as in model-driven elicitation and elicitation-driven modeling. In the former, the requirements engineer tries to capture only the information that he or she needs for the model under construction. In the latter, the requirements engineer creates all models at the same time recording every piece of information gathered in the model it belongs to. Each of these approaches has advantages and drawbacks.

If the information is elicited for a given model, the requirements engineer pays attention only to some part of the things he or she is seeing, reading, or hearing. Then, he or she will discard any information that is not focus oriented. When the requirements engineer starts the creation of another model, he or she will change the focus and perhaps will now pay attention to information previously disregarded, provided that he or she comes across the same information. Unfortunately, this does not always happen, especially when the source of information is people. In other words, model-driven elicitation tends to make completeness difficult.

If all information obtained is registered at the same time, every model of the process is opened at the same time, and also, none are finished during an important period. A lack of coherence among models, poor understanding of the information gathered, and misplaced information are the main drawbacks of this approach. However, the loss of information is minimized.

Most researchers explicitly or implicitly prefer model-driven elicitation over elicitation-driven modeling (Leite, Hadad, Doorn, & Kaplan, 2005; Loucopoulos & Karakostas, 1995; Potts, Takahashi, & Antón, 1994). This means that model-driven elicitation has to deal with the risk of information loss. Looking closely into such risk, it can be seen that regardless of the elicitation technique, whether involving document reading, interviews, observation, or any other method (Goguen & Linde, 1993), the requirements engineer does not get exactly whatever he or she is looking for at any time in the information gathering activity (Faulk, 1996). He or she will need some of the information captured in the later stages of the process; however, he or she also needs some of that information in advance. In other words,

some of the information gathered is out of time (earlier or delayed). Dealing with the risk of loss of information means dealing with extemporaneous information (EI).

The research on which this chapter is founded was collected using a given process (Doorn, Hadad, & Kaplan, 2002; Leite et al., 1997; Young, 2004). However, the conclusions obtained can be applied to any requirements engineering process provided that it builds more than one model, having some degree of precedence among them.

In this article, the existence of extemporaneous information is studied and a proposal for its appropriated handling is given.

ADVANCED INFORMATION

Every phase of the requirements engineering process has its own specific objective. Although the requirements engineer tries to adhere to this objective, usually he or she comes across pieces of unexpected information that will be later necessary in the process. This advanced information (AI) may come from any source of information. However, most likely, AI comes from people.

Two main factors influence the quality and the quantity of Advanced Information in interviews.

Expectations on the new software: When the interviewed person is waiting for the new software to fix some organizational problem, he or she will be biased to describe his or her expectations even when the requirements engineer is trying to elicit knowledge about current business practices or even trying to build a glossary of the macrosystem. On the other hand, when the interviewed person does not have any expectation on the software system, he or she will not be an important source of AI.

Relative position in the organization: When interviewing a person in a relatively high position in the organization (directors, managers), the requirements engineer should be prepared to deal with abundant AI usually expressed as objectives and goals with an important degree of abstraction. On the other hand, operative people in the organization tend to provide less AI.

It should also be taken into account that AI may increase accordingly with the amount of changes planned for the business process after software installation. To estimate such amount of changes, the following factors should be carefully watched, among others.

Internal factors:

- Quality improvement projects
- Outsourcing projects
- Opening of new business lines
- Production technology changes
- Production volume increases
- Products or services changes
- Global organization objective changes

External factors:

- Sociocultural changes affecting the organization
- Economic changes affecting business
- Customer preferences changes

When accessing written sources of information, the risk to lose AI reaches a peak when the document has a moderate amount of AI. This becomes obvious considering that every document with much AI will be tagged to be read later in the process.

The requirements engineer cannot be in any way considered as a passive actor in the process of knowledge elicitation. He or she may usually have useful ideas about the context in which the software system will be involved in the future. On the other hand, it is very well known that short memory might be unfair to creative people in all activities. Sometimes, after having a good idea, the creator recalls just that: He or she has had a good idea. This falls into the paradigm of AI, although it was not originated in clients or users.

It is hard to determine at that early stage whether the elicited information or the requirements engineer's ideas are valuable or not. Perhaps they are the stub of what will be later an important requirement or perhaps they will become unplayable in the future context of the software system.

While model-driven elicitation is applied, the requirements engineer is trying to focus on his or her main current objective, and AI is actually felt as a disturbance; the risk is either to fail to collect the desired information or to lose the main track. The problem, visualized in this way, is very similar to visiting every node in a graph with bifurcations. Thus, the solution should also be very alike. The requirements engineer must keep attached to the main activity as much as possible, but at the same time he or she should find a way to register the minimum information needed to be able to follow the secondary track later.

When registering the minimum information needed to follow the secondary track, an ad hoc notepad could be used or a more structured document might be also chosen.

EXTEMPORANEOUS INFORMATION

In order to choose between a preplanned and an ad hoc registering strategy, it is valuable to quote Faulk (1996) who stated that the use of regular and predictable structures with limited information eases the comprehension and visualization of large quantities of information. This article summarizes the advantages of the use of a minimum card that allows registering the basic information required to

recover the EI when it can be appropriately understood and processed. This card introduces a very small disturbance in the requirements engineering activity when filled in, and it is very valuable when recovered.

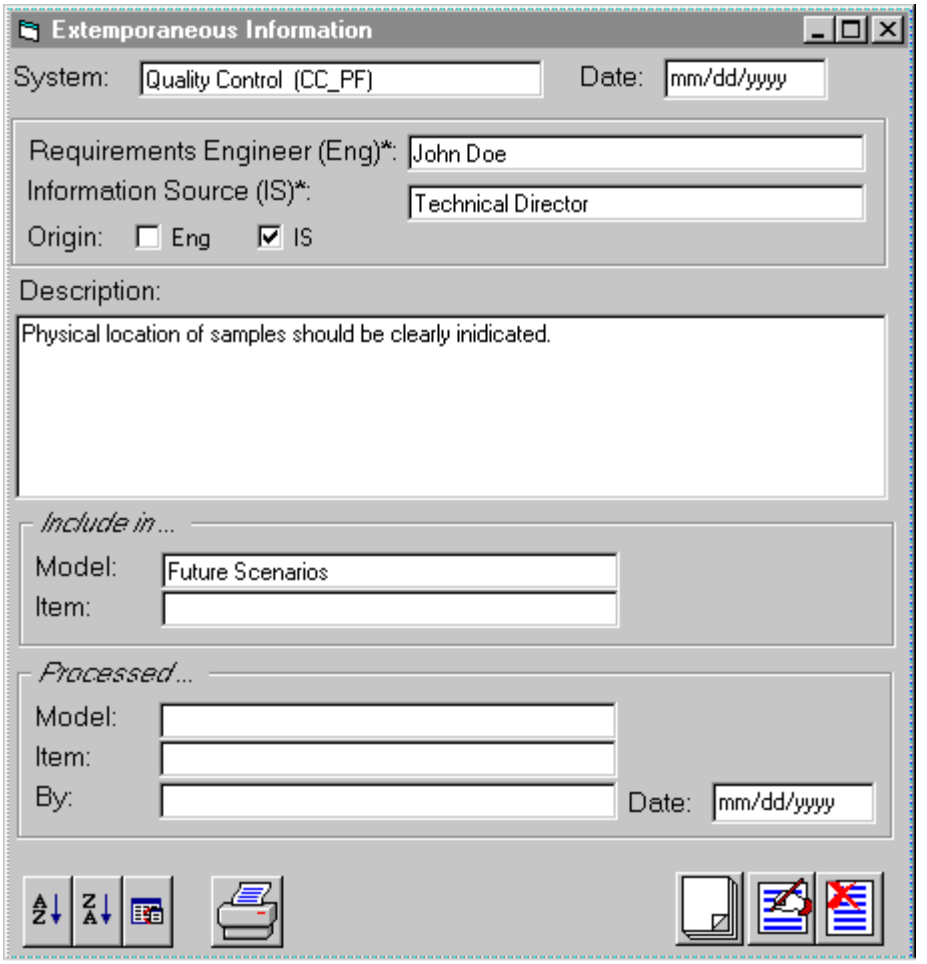
Every card should contain a brief description of the EI, specifying the source of information. If the requirements engineer can figure out how to use EI, the *include in* field could also be filled out (see Figure 1). The *system*, *date*, and *requirements engineer* fields may be automatically completed from previous cards, and other fields should be left blank until the card is used.

Although this study was motivated by the existence of advanced information during the requirements engineering process, the application of this approach in actual cases has shown that retarded information appears almost as much as advanced information. Then, it becomes more appropriate to use extemporaneous information when referring to both.

SOME PRACTICAL EXPERIENCES

During the testing of the registering of extemporaneous information in actual cases, the initial hypothesis was validated in the sense that for the chosen cases, EI could be adequately managed. However, a new and very important unplanned advantage showed up. The existence of an ordered registering of EI introduces an important increment in the points of view from which EI originates, such as security, availability, cost, and customer satisfaction, among many others. In the mainstream of the requirements engineering process, some of these points of view are disregarded. This is not a minor issue; on the contrary, when the requirements engineer begins to evaluate the collected EI cards, he or she puts himself or herself very close to the point of view that originated the EI card. This opens many new lines of thought about unconsidered aspects, becoming an important

Figure 1. EI card



contribution to the completeness of the comprehension and modeling of the problem.

Quantitative studies in two different cases reported 6.7% and 5.2% of requirements elicited by EI cards. These requirements would not have been picked by other means during the requirement phase. There is no way to know how soon such information will show up to the development team.

FUTURE TRENDS

Current experience should be extended to more cases by different requirements engineers. It is expected that some process or personal-flavor changes on the EI card will be introduced. However, it seems that the basic idea of the use of an EI card during any requirements engineering process is useful. A few project keywords may be added to later allow queries on them.

CONCLUSION

The problem of the appearance of EI has been studied in this article, which paid more attention to AI since it is hard to manage. The cases studied showed that EI is an important aspect in the process of UofD modeling, especially future UofD. Most EI deals with the context in which the software system will run. Retarded information will introduce a perturbation factor as it forces the requirements engineer to update already finished models, but it does not carry the risk of losses.

Another important conclusion is that some of the AI surpassed the requirements engineer's expectations in relation to the model in which it was finally included. Consequently, the inclusion point had to be, from a new point of view, deeply analyzed to understand the relationship with previously registered knowledge about the UofD. This means that the insertion of EI in any model is a far more complex task than merely inserting a line of text in a model. In other words, qualitative evaluation shows that EI has more importance than quantitative figures may indicate.

KEY TERMS

Advanced Information: It is information acquired when it is not yet needed.

Elicitation: Elicitation is the activity of acquiring knowledge of a given kind during the requirements engineering process. There exist several techniques for elicitation such as interviews, observation, and document reading, among others.

Extemporaneous Information: It is information acquired before or after the moment it is needed.

Requirements Engineering: It is an area of software engineering that is responsible for acquiring and defining the software system's needs. The aim of requirements engineering is to improve the way in which the services should behave in the future. It covers all activities involved in discovering, understanding, modeling, analyzing, and maintaining the set of requirements for a software system.

Requirements Modeling: It is the activity that represents, organizes, and registers the information gathered during elicitation. The model itself may be composed by more than one representation.

Retarded Information: It is information acquired after the moment it is needed.

Sources of Information: These include documents, key people, books, and so forth that can provide useful information about the subject matter under study.

Universe of Discourse: It is the environment in which the software artifact will be used. It includes the macrosystem and any other source of knowledge.

Heuristics in Medical Data Mining

Susan E. George
University of South Australia, Australia

HISTORICAL PERSPECTIVE

Deriving—or discovering—information from data has come to be known as data mining. Within health care, the knowledge from medical mining has been used in tasks as diverse as patient diagnosis (Brameier et al., 2000; Mani et al., 1999; Cao et al., 1998; Henson et al., 1996), inventory stock control (Bansal et al., 2000), and intelligent interfaces for patient record systems (George at al., 2000). It has also been a tool of medical discovery itself (Steven et al., 1996). Yet, it remains true that medicine is one of the last areas of society to be "automated," with a relatively recent increase in the volume of electronic data, many paper-based clinical record systems in use, a lack of standardisation (for example, among coding schemes), and still some reluctance among health-care providers to use computer technology. Nevertheless, the rapidly increasing volume of electronic medical data is perhaps one of the domain's current distinguishing characteristics, as one of the last components of society to be "automated."

Data mining presents many challenges, as "knowledge" is automatically extracted from data sets, especially when data are complex in nature, with many hundreds of variables and relationships among those variables that vary in time, space, or both, often with a measure of uncertainty, as is common within medicine. Cios and Moore (2001) identified a number of unique features of medical data mining, including the use of imaging and need for visualisation techniques, the large amounts of unstructured nature of free text within records, data ownership and the distributed nature of data, the legal implications for medical providers, the privacy and security concerns of patients requiring anonymous data used, where possible, together with the difficulty in making a mathematical characterisation of the domain.

Strictly speaking, many ventures within medical data mining are better described as exercises in "machine learning," where the main issues are, for example, discovering the complexity of relationships among data items, or making predictions in light of uncertainty, rather than "data mining," in large, possibly distributed, volumes of data that are also highly complex. Large data sets mean not only increased algorithmic complexity but also often the need to employ special-purpose methods to isolate trends and extract "knowledge" from data. However, medical data frequently provide just such a combination of vast (often distributed) complex data sets.

Heuristic methods are one way in which the vastness, complexity, and uncertainty of data may be addressed in the mining process. A heuristic is something that aids discovery of a solution. Artificial intelligence (AI) popularised the heuristic as something that captures, in a computational way, the knowledge that people use to solve everyday problems. AI has a classic graph search algorithm known as A* (Hart et al., 1968), which is a heuristic search (under the right conditions). Increasingly, heuristics refer to techniques that are inspired by nature, biology, and physics. The genetic search algorithm (Holland, 1975) may be regarded as a heuristic technique. More recent population-based approaches have been demonstrated in the Memetic Algorithm (Moscato, 1989), and specific modifications of such heuristic methods in a medical mining context can be noted (Brameier et al., 2000).

Aside from the complexity of data with which the medical domain is faced, there are some additional challenges. Data security, accuracy, and privacy are issues within many domains, not just the medical (Walhstrom et al., 2000). Also, while ethical responsibility is an issue in other contexts, it is faced by the medical world in a unique way, especially when heuristic methods are employed. One of the biggest ethical issues concerns what is done with the knowledge derived combined with a "forward-looking responsibility" (Johnson et al., 1995). Forward-looking responsibility is accountable for high-quality products and methods and requires appropriate evaluation of results and justification of conclusions.

George (2002) first identified and proposed a set of guidelines for heuristic data mining within medical domains. The proposed guidelines relate to the evaluation and justification of data-mining results (so important when heuristic "aids to discovery" are utilised that "may" benefit a solution) and extend to both where and how the conclusions may be utilised and where heuristic techniques are relevant in this field. The remainder of this article summarises some heuristic data-mining applications in medicine and clarifies those proposed guidelines.

BACKGROUND

First, we will explain some of the heuristic methods that have been employed in medical data mining, examining a range of application areas. We broadly categorise applications as clinical, administrative, and research, according to whether they are used (or potentially used) in a clinical context, are infrastructure related, or are exploratory, in essence. We also note that with the exception of some medical imaging applications and mining of electronic medical records, the databases are small.

There is a wide variety of automated systems that have been designed for diagnosis—systems that detect a problem, classify it, and monitor change. Brameier and Banzhauf (2000) described the application of linear genetic programming to several diagnosis problems in medicine, including tests for cancer, diabetes, heart conditions, and thyroid conditions. Their focus was upon an efficient algorithm that operates with a range of complex data sets, providing a population-based heuristic method that is based upon biological principles. Their heuristic method is based on an inspiration from nature about how "introns" (denoting DNA segments with information removed before proteins are synthesised) are used in generating new strings. They suggest that introns may help to reduce the number of destructive recombinations between chromosomes by protecting the advantageous building blocks from being destroyed by crossover. Massive efficiency improvements in the algorithm are reported.

An interesting administrative application of data mining in a medical context comes in the area of interfaces for electronic medical records systems that are appropriate for speedy, accurate, complete entry of clinical data. At the University of South Australia, George et al. (2000) reported on the use of a data-mining model underlying an adaptive interface for clinical data entry. As records are entered, a database is established from which predictive Bayesian models are derived from the diagnosis and treatment patterns. This heuristic is used to predict the treatment from new diagnoses that are entered, producing intelligent anticipation. The predictive model is also potentially incremental and may be re-derived according to physician practice. This application addresses issues in incremental mining, temporal data, and highly complex data with duplication, error, and nonstandard nomenclatures.

One interesting ongoing database mining project at Rutgers is the development of efficient algorithms for query-based rule induction, where users have tools to query, store, and manage rules generated from data. An important component of the research is a facility to remember past mining sessions, producing an incremental approach. They are using heuristics for efficiently "re-mining" the same or similar data in the face of updates and modifications. In their trials, a major insurance company was trying to explore anomalies in their medical claims database. The new data-mining techniques aided the isolation of high-cost claims and scenarios in each disease group that would lead to high-cost claims. They also identified characteristics of people who were likely to drop out of their health plans and locations where there were higher dropout rates. This is a general approach to mining, where information from prior mining is utilised in new mining to prevent the need to compute relationships from scratch every time data is added to the database. This is, naturally, a general approach to mining large-scale changing databases that may be considered in a variety of fields.

Medical data mining is a natural method of performing medical research, where new relationships and insights are discovered in human health. The University of Aberdeen address the problem of mammographic image analysis using neural nets together with conventional image analysis techniques to assist in the automated recognition of pathology in mammograms (Undrill, 1996). The group also addresses the use of genetic algorithms for image analysis, applying this powerful general optimisation technique to a variety of problems in texture segmentation and shape analysis in two-dimensional and three-dimensional images (Delibassis, 1996). Mining information from the data in these tasks must address many of the problems of finding patterns within large volumes of highly complex data.

Banerjee et al. (1998) described the use of data mining in medical discovery. They reported on a data-mining tool that uncovered some important connections between diseases from mining medical literature. The data-mining tool compared the article titles in various medical journals. Medical discoveries were made, such as the connection between estrogen and Alzheimer's disease, and the relationship between migraine headaches and magnesium deficiency. Ngan et al. (1999) reported on medical discovery using data mining based upon an evolutionary computation search for learning Bayesian networks and rules. They were able to discover new information regarding the classification and treatment of scoliosis as well as knowledge about the effect of age on fracture, diagnoses, and operations and length of hospital stays.

Kargupta and colleagues (1999) were interested in an epidemiological study that involved combining data from distributed sources. Their study investigated what affects the incidence of disease in a population, focusing upon hepatitis and weather. They illustrated the collective data-mining approach, emphasising the importance within medicine of merging data from heterogeneous sites. Their solution minimises data communication using decision-tree learning and polynomial regression. As more hospitals and general practitioners, pharmacists, and other health-care-related professions utilise electronic media, mining ventures are going to have to cope with mining across data sources. They will have to address issues such as those addressed by this study, such as minimising data exchange and adopting suitable heuristic approaches.

GUIDELINES FOR HEURISTIC MEDICAL DATA MINING

Responsibility is clearly an issue in medical data mining given the unique human arena in which the conclusions are outworked. If medical data-mining products are ever produced by "professionals" or are ever exploited "commercially," there may be serious legal consequences for their creators in the wake of harmful consequences from information produced. In the context of software engineering, the computer field seeks to promote high-quality software products, so too,

should data miners seek to guarantee high-quality data-mining techniques.

Johnson and Nissenbaum (1995) distinguished "backward-looking" responsibility from "forward-looking" responsibility. A "backward-looking" responsibility asks questions in the wake of a harmful event and seeks to discover who is to blame for the harm and who should be punished. It is often conducted in the context of discovering legal liability. The Therac-25 computer-controlled radiation treatment is a shocking example of a malfunction disaster that resulted in loss of life for people who were receiving computer-controlled radiation treatments for cancer. In contrast a "forward-looking" responsibility addresses the particular responsibilities in advance. It defines guidelines for creating quality products; measures the quality of the product; defines the method of evaluation, and the limitations and scope of the operation in advance of harmful incidents.

One of the biggest ethical issues in medical mining concerns what is done with the knowledge derived. There is tremendous potential for good in improving quality of human life, managing disease effectively, efficiently administering programs, and preserving life, but the same knowledge can also be put to less-constructive ends, or benefit only a few, or conform to the contemporary political agendas influenced by the philosophy of the age. Forward-looking responsibility requires not only making ethical uses of data but also ensuring the quality of automated techniques and knowing the limitations and scope of methods in advance of harmful consequences.

Crucial to forward-looking responsibility is a way to evaluate products. This is not as pertinent as when heuristic methods are utilised to derive that knowledge. Whatever is ultimately done with the conclusions, we know that heuristics do not guarantee "optimality" or even the "accuracy" or "validity" of the conclusion. Forward-looking responsibility within medical data mining will address, among other things, how knowledge is evaluated, how conclusions are justified, what is the scope of validity, and the limitations of "products." One of the best forms of evaluation for clinical data-mining solutions is a clinical trial. Another approach to evaluation makes use of benchmark data sets, where various techniques (heuristic and other) could be compared to assess quality and efficiency of solutions. Additionally, some types of specialist data may be invaluable resources for data-mining researchers. It is also important to define the scope, including justification of explanations, and limitations of systems, from technical to clinical applicability of algorithms (in terms of patient populations and other), especially under heuristic conditions.

CONCLUSION

This article has reviewed heuristic medical data mining and some of the applications of medical mining, identifying administrative, clinical, and medical areas of applicability, focusing on the guidelines for use of heuristics in such a field. Forward-looking responsibility is vital, focusing upon appropriate use of knowledge, a means to evaluate the heuristic solutions and assess the scope and limitations of the system, including explanations of the behaviour.

KEY TERMS

Backward-Looking Responsibility: When backward-looking, we seek to discover who is to blame in wake of a harmful event. There are frequently connotations of punishment, legal intervention, and determination of guilt.

Data Mining: Analysis of data using methods that look for patterns in the data, frequently operating without knowledge of the meaning of the data. Typically, the term is applied to exploration of large-scale databases in contrast to machine-learning methods that are applied to smaller data sets.

Data-Mining Guidelines: A set of standards by which medical data mining, in particular, might be conducted. This is a framework that adopts a forward-looking responsibility in the evaluation of methods and explanation of conclusions, especially in the context of heuristic methods (with outcomes that may be ill-defined). This extends not only to the methods of the data-mining procedure, the security and privacy aspects of data, but also to where and how the results of data mining are utilised, requiring that an ethical reference be made to the final purpose of the mining.

Forward-Looking Responsibility: Addresses the particular responsibilities of individuals, groups, and partners in advance of a product's use or a system's implementation; it defines guidelines for creating quality products, measures the quality of the products, and defines the method of evaluation, the limitations, and the scope of the operation in advance of harmful incidents.

Heuristic: From the Greek "heuriskein," meaning "to discover." A heuristic aids discovery, particularly the search for solutions in domains that are difficult and poorly understood. It is commonly known as a "rule of thumb." Unlike algorithms, heuristics do not guarantee optimal or even feasible solutions and frequently do not have a theoretical guarantee.

Medical data: Frequently demonstrate increased complexity (e.g., uncertainty) and occurrence in large volumes, possibly distributed over many sources. There may be images involved and a high frequency of nonstandardisation (especially in the context of electronic medical records) in coding schemes and other medical concepts utilised. Data security, accuracy, and privacy are particular issues with medical data, as are the ethical issues involved in what is done with the data.

Medical Data Mining: This is the application of data-mining methods to medical data, typically for clinical or administrative and medical research investigation use, particularly in epidemiological studies.

High-Performance Virtual Teams

Ian K. Wong
Queen's University, Canada

D. Sandy Staples
Queen's University, Canada

INTRODUCTION

In the past several decades, we have seen tremendous advancements in the development of communication technology. Since the invention of the Internet in 1969, there has been rapid development of Internet-based communication tools and technologies. This technology has revolutionized business practices by offering another important and effective channel for communication (Foo & Lim, 1997) and has allowed people to work on projects irrespective of their physical location. One resulting business practice that has been adopted in recent years is virtual teamwork. Virtual teams are groups of individuals who work together in different locations (i.e., are geographically dispersed), work at interdependent tasks, share responsibilities for outcomes, and rely on technology for much of their communication (Cohen & Gibson, 2003). The use of virtual teams has become widespread in organizations, and its use is expected to grow (Martins, Gilson, & Maynard, 2004; Powell, Piccoli, & Ives, 2004).

BACKGROUND

In addition to the basic definition of a virtual team, all virtual teams have important characteristics that contribute to their overall success. To analyze the characteristics of the team's situation, Cohen's (1994) model of team effectiveness can be used as an organizing framework. The model identifies strengths and weaknesses that readers can use to inform their own design and operations of effective virtual teams. According to Cohen, there are several broad characteristics that all potentially effect how successful the team will be at meeting its task, and are therefore worthy of examination. These characteristics are listed in Table 1 and will be examined in detail in the following paragraphs. Although Cohen's team effectiveness model is based on traditional teams (i.e., collocated), these characteristics have been found to be very important in empirical research on virtual teams (Pinsonneault & Caya, 2005; Staples & Cameron, 2004; Wong & Staples, 2004).

Table 1. Characteristics of virtual teams affecting team effectiveness

• Design of the team's task
• The characteristics of the members of the team
• The processes used by the team
• The organizational context of the team

TASK DESIGN

Appropriate task design can be a powerful motivator (Cohen, 1994). Both job characteristics theory (e.g., Hackman & Oldman, 1976, 1980) and sociotechnical theory (e.g., Cummings, 1978) suggest that group task design is critical for employee motivation, satisfaction, and performance. Both theories suggest that to positively impact performance and attitudes, the task should be designed according to the criteria specified in Table 2. The design of the virtual team and the structuring of its interactions in the early stages of team development have been found to help team members develop a shared language and shared understanding (Powell et al., 2004).

Job characteristics theory, which has fairly strong empirical support, suggests that task attributes influence effectiveness through their impact on critical psychological states such

Table 2. Task design criteria necessary to positively impact performance and attitudes

The task should be designed such that:
• A variety of skills are required (leadership, communication, different technical skills, etc.) such that a team of people are needed to work together to complete the overall task
• A whole and identifiable piece of work exists so that members can see the outcome of their efforts
• It is perceived to have significant impact on the lives of other people so that team members feel their work is important and are motivated to complete the task
• The team has considerable autonomy and independence in determining how the work will be done so that team members feel empowered and responsible for their actions
• The team is provided with regular and accurate feedback such that the team can understand how it is performing and make adjustments as needed

Table 3. Characteristics of the team members that affect team effectiveness

• The size of the team
• The stability of the team, in terms of turnover
• The skills of the members of the team
• The relative locations of the team members (i.e., their virtualness)
• The team members' beliefs about their team's capabilities
• The diversity of the team

as motivation and satisfaction with the work. For example, in a case study of one particular business development virtual team, team members commented that high satisfaction and motivation levels reflected the high perceived significance of the project (Wong & Staples, 2004). Positive motivation and satisfaction levels have a positive effect on the quality of the work and overall productivity of the team (i.e., an indirect effect exists between task design and productivity and quality) (Cohen, 1994). Also, the team must have autonomy in determining how their work will be done, because autonomy enhances worker attitudes, behaviors, and performance (Cohen & Bailey, 1997). Finally, when a remote worker receives managerial feedback in the form of advice and help, the worker's effectiveness increases (Staples, 2001). This would result in an increase in virtual team performance.

CHARACTERISTICS OF THE TEAM AND ITS MEMBERS

Team member characteristics that influence the success of a virtual team are listed in Table 3 and are described in more detail next (Cohen, 1994).

The size of the team can affect the ability of the team to do its task (Cohen, 1994). If the team is too big, higher coordination costs result (Goodbody, 2005). If the team size is too small, it will not have the resources needed to complete its work, and team members will be less likely to be committed to the team. The size of the team should also correspond to the stage of the project. For example, a virtual team developing a new product may need more human resources as the product moves from the design stage into the manufacturing stage.

Stability of team membership is necessary for team effectiveness. If turnover is high, time and effort will be spent orientating new members, performance norms will not develop, and performance will suffer. However, some turnover can be beneficial, in that it could revitalize a stagnant team and enhance creativity (Cohen, 1994).

The collective knowledge and skills of a team will greatly impact the team's ability to carry out its task. Such skills include technical skills, information systems (IS) skills, and interpersonal skills. Information systems skills are needed to use the information technology tools and systems that are available to communicate virtually and share information virtually, which is the norm given the lack of face-to-face interaction in virtual teams. Effective communication skills among team members are vital to the effectiveness of a virtual team (Jones, Oyund, & Pace, 2005).

The degree of virtuality (degree of team geographic distribution) could contribute to team effectiveness. Most research on virtual teams suggests that geographic distance among team members is detrimental to team performance (Lu, Watson-Mannheim, Chudoba, & Wynn, 2006). This is presumably due to reduced face-to-face contact, reduced opportunities to build social relationships, and the difficulties of communicating and coordinating work using communication technology rather than communicating face-to-face. A recent meta-analysis (Ortiz de Guinea, Webster, & Staples, 2005) did find evidence that virtualness negatively impacts team processes (such as communication), although the total effect of virtualness on team effectiveness (quality, productivity, and satisfaction) was positive. Therefore, it is especially important to design team processes well in highly virtual teams. Other research has also pointed to the benefits of virtual teaming, such as increased rigor in processes and formal documents (Delone, Espinosa, Lee, & Carmel, 2005).

Team performance beliefs have been found to be a strong predictor of group effectiveness in previous research (Cohen, 1994). For example, team beliefs, assessed via a concept called group potency, were found to be positively related to the commitment to the team, satisfaction with being part of the team, and motivation with the team's tasks (Staples & Cameron, 2004). Therefore, it is important that potency beliefs are high within a team. Team members should know each other's strengths and abilities and celebrate achievements together.

Diversity is a characteristic of virtual teams that may positively influence team effectiveness if managed properly. Virtual teams are often composed of team members from various locations with diverse cultural backgrounds. Diversity may benefit a team because it increases the collective knowledge and expertise of the team. However, team diversity can also pose challenges, and thus it would benefit team members to openly discuss individual differences and expectations in order for new team-level expectations to be established (Gibson & Cohen, 2003).

TEAM PROCESSES

There are several behavioral characteristics pertaining to team process that positively affect team effectiveness. These are coordination, caring (i.e., team spirit), sharing of expertise, and effectiveness of communications. According to Cohen

Table 4. Organizational context factors that affect team effectiveness

• Human resource policies that emphasize and reward teamwork
• Human resource policies that do not penalize (i.e., overlook) virtual workers
• The availability of training to work virtually, work effectively in teams, and carry out task responsibilities
• The amount of support management provides to the team
• The degree of autonomy the team is given to make decisions and take responsibility for their own actions
• The ability of the organization to share information that is needed to carry out tasks and make effective decisions

and Bailey (1997), how team members coordinate is an important characteristic of a team. Since team members are interdependent on each other to get their work done, coordinating interdependent tasks is critical. Good coordination among team members leads to working together without duplication and wasted efforts, and has been shown to predict higher performance in virtual teams (Powell et al., 2004). Caring about each other implies working together cohesively with energy and team spirit. This can motivate team members and foster commitment to the team goals, resulting in higher performance. The development of team cohesion/team spirit has been associated with higher levels of performance and satisfaction in virtual teams (Pinsonneault & Caya, 2005; Powell et al., 2004). Sharing and benefiting from others' knowledge and expertise is also important because it supports effective cross training and decision-making to fulfill interdependencies. Empirical results from both virtual and traditional teams support a positive link between sharing of knowledge and team outcomes (e.g., Cohen, 1994; Cummings, 2004; Hong, Doll, Nah, & Li, 2004; Majchrzak, Rice, King, Malhotra, & Ba, 1995). Good communication processes are required in order to make this possible. Effective communication processes were important in building a successful virtual team according to 84% of team members interviewed in six case studies of virtual teams (Staples, Wong & Cameron, 2004). Furthermore, research has found that the effectiveness and frequency of team communication may also help build a more cohesive team (Pinsonneault & Caya, 2005). These team process variables are part of most models of team effectiveness and have been found to be associated with group effectiveness in previous traditional team research (Cohen, 1994) and virtual team research (Ortiz de Guinea et al., 2005).

ORGANIZATIONAL CONTEXT

Lastly, the organizational context that a team works in can create the conditions for a team to be successful or for it to fail (Cohen, 1994). The team with the best internal processes may still perform poorly if it lacks the resources or information needed to do its task. A team will not be able to make good decisions without proper information, without sufficient training, and without adequate resources. The key variables that potentially interact to create an environment where the employee wants to be involved and can participate to complete their tasks effectively are listed in Table 4 and explained next.

According to Duarte and Snyder (2001), human resource policies must be designed and integrated in such a way that virtual team members are recognized, supported, and rewarded for their work. Cohen, Ledford, and Spreitzer (1996) found that management recognition was positively associated with team ratings of performance, trust in management, organizational commitment, and satisfaction for both self-directed and traditionally managed groups in organizations. As such, it is important that an effective reward system with performance measures is in place to reward results. Lurey and Raisinghani (2001) and Hertel, Konradt, and Orlikowski (2004) also suggest that it is important for the organization to reward high levels of *team* performance. If rewards are solely at the individual level, this does not stimulate the completion of interdependent tasks and the sharing of information and expertise.

Next, it is important that team members have access to continual online training and technical support (Duarte & Snyder, 2001; O'Hara-Devereaux, & Johansen, 1994). Training and team building is important because it ensures that employees develop the knowledge required to contribute to organizational performance (Cohen, 1994). It should be available to enable employees to develop the necessary skills and knowledge required to complete their tasks at hand. In addition, providing training to team members shows management's commitment to continual growth and development for members. Research has also shown that training in early stages of team development in particular helps members not only focus on performance, but also to provide structure for their interactions (Jarvenpaa, Shaw, & Staples, 2004).

Management support and the power structure are also key variables in attaining virtual team effectiveness. Teams

not only need to be well budgeted and resourced, but team members also want encouragement and symbolic gestures of appreciation. Symbolic gestures such as a pat on the back or having management verbally communicate that the team is doing a good job demonstrates respect for the team members; this can positively motivate the members. With respect to power structure, it has been shown that team members must have independence and decision-making capability to be successful in virtual groups (Lipnack & Stamps, 1997). In addition, according to Cohen and Bailey (1997), an organization needs to provide team members autonomy in their work. Worker autonomy has been shown to have clear benefits because it enhances worker attitudes, behaviors, and performance (whether measured objectively or rated subjectively by team members).

Finally, access to information is necessary for team members to effectively complete their tasks. A practical study of a project-based virtual team suggested that most of the information team members needed was held either by themselves or by other team members (Wong & Staples, 2004). Therefore, good communication between team members is essential for information to be easily accessed. In addition, resources need to be available for virtual communication to be possible and effective. These resources include information technology infrastructure and information technology tools that are needed to communicate and share information electronically in the virtual setting.

FUTURE TRENDS

The need to compete in a rapidly changing, hypercompetitive, and global marketplace is prompting many organizations to transform their organizational structures from large, hierarchical structures to agile, flexible, new structures (Morris, Marshall, & Rainer, 2001). Consequently, we will see a continuing trend of virtual teams emerging that have team members from multiple countries with different national cultures. Cross-cultural issues are especially important for virtual work (Pinsonneault & Boisvert, 2001); however, recent research has suggested that it remains to be seen what aspects of national culture specifically affect virtual teams (Webster & Staples, 2006). Therefore, future research could focus on the impact of cultural differences of team members in virtual teams, because this information would be useful for designing training program for members and for selecting members.

Furthermore, management will be continually trying to adopt new communication tools and technologies that have improvements in quality and capabilities. As such, training to use new technology will become especially important; how well team members can communicate and interact with each other depends very much on their ability to properly use the communication tools. Future research may deal with the effectiveness of new, emerging technologies and how they may positively or negatively affect virtual team performance. In addition, we need a better understanding of how the effect of different media combinations affects virtual team processes (Pinsonneault & Caya, 2005).

CONCLUSIONS

The success of a virtual team depends heavily on its characteristics. Specifically, the main characteristics are the team's task design, the characteristics of the team members, the processes used by the team, and the organizational context. Analyzing these characteristics can reveal a great deal about how well a team is functioning, and what potential it has to improve. An organization's management also can use these characteristics to effectively design its virtual teams and thereby give it the best chance for success possible. Therefore, it is in management's best interests when putting together a virtual team to carefully consider the characteristics of the team. This will increase the team's chance of success if the variables that yield positive outcomes are maximized.

KEY TERMS

Group Potency: A collective belief in the capability of the group to meet a task objective (Gibson, Randel, & Earley, 2000).

Job Characteristics Theory: Task attributes influence effectiveness through their impact on critical psychological states such as motivation and satisfaction with the work.

Organizational Context: The conditions within the organization that a team works in that influences the successfulness of the team's activities and the involvement of the team members. Reward systems, level of management support, resources provided, and organizational culture all are important organizational factors that potentially affect a team's ability to succeed.

Task Design: The way key attributes of the task are arranged, in terms of the influence of these attributes on the effectiveness of a team in performing the task. Research has found key design attributes include the need for a variety of skills, the perceived importance of the task, the independence and autonomy given to people to determine how the task will be done, and the way task feedback is provided.

Team Characteristics: The composition of the team and the shared beliefs held within the team about the team. Team composition includes such things as the number of team members, the skills the team members collectively possess, and the stability of team membership.

Team Effectiveness: The ability of a team to perform its tasks on time, on budget, and with acceptable quality, as well as the satisfaction, motivation, and commitment of the team members.

Team Processes: "Members' interdependent acts that convert inputs to outcomes through cognitive, verbal, and behavioral activities directed toward organizing taskwork to achieve collective goals" (Marks, Mathieu, & Zaccaro, 2001, p. 357).

Virtual Team: A group of individuals who work at interdependent tasks, who share responsibility for outcomes, and who work together from different locations.

Virtuality/Virtualness: The degree to which team members are geographically distributed such that opportunities for meeting informally and/or face-to-face are reduced.

Highly Available Database Management Systems

Wenbing Zhao
Cleveland State University, USA

INTRODUCTION

In the Internet age, real-time Web-based services are becoming more pervasive every day. They span virtually all business and government sectors, and typically have a large number of users. Many such services require continuous operation, 24 hours a day, seven days a week. Any extended disruption in services, including both planned and unplanned downtime, can result in significant financial loss and negative social effects. Consequently, the systems providing these services must be made highly available.

A Web-based service is typically powered by a multi-tier system, consisting of Web servers, application servers, and database management systems, running in a server farm environment. The Web servers handle direct Web traffic and pass requests that need further processing to the application servers. The application servers process the requests according to the predefined business logic. The database management systems store and manage all mission-critical data and application states so that the Web servers and application servers can be programmed as stateless servers. (Some application servers may cache information, or keep session state. However, the loss of such state may reduce performance temporarily or may be slightly annoying to the affected user, but not critical.) This design is driven by the demand for high scalability (to support a large number of users) and high availability (to provide services all the time). If the number of users has increased, more Web servers and application servers can be added dynamically. If a Web server or an application server fails, the next request can be routed to another server for processing.

Inevitably, this design increases the burden and importance of the database management systems. However, this is not done without good reason. Web applications often need to access and generate a huge amount of data on requests from a large number of users. A database management system can store and manage the data in a well-organized and structured way (often using the relational model). It also provides highly efficient concurrency control on accesses to shared data.

While it is relatively straightforward to ensure high availability for Web servers and application servers by simply running multiple copies in the stateless design, it is not so for a database management system, which in general has abundant state. The subject of highly available database systems has been studied for more than two decades, and there exist many alternative solutions (Agrawal, El Abbadi, & Steinke, 1997; Kemme, & Alonso, 2000; Patino-Martinez, Jimenez-Peris, Kemme, & Alonso, 2005). In this article, we provide an overview of two of the most popular database high availability strategies, namely database replication and database clustering. The emphasis is given to those that have been adopted and implemented by major database management systems (Davies & Fisk, 2006; Ault & Tumma, 2003).

BACKGROUND

A database management system consists of a set of data and a number of processes that manage the data. These processes are often collectively referred to as database servers. The core programming model used in database management systems is called transaction processing. In this programming model, a group of read and write operations on a data set are demarcated within a transaction. A transaction has the following ACID properties (Gray & Reuter, 1993):

- **Atomicity:** All operations on the data set agree on the same outcome. Either all the operations succeed (the transaction commits) or none of them do (the transaction aborts).
- **Consistency:** If the database is consistent at the beginning of a transaction, then the database remains consistent after the transaction commits.
- **Isolation:** A transaction does not read or overwrite a data item that has been accessed by another concurrent transaction.
- **Durability:** The update to the data set becomes permanent once the transaction is committed.

To support multiple concurrent users, a database management system uses sophisticated concurrency control algorithms to ensure the isolation of different transactions even if they access some shared data concurrently (Bernstein, Hadzilacos, & Goodman, 1987). The strongest isolation can be achieved by imposing a serializable order on all conflicting read and write operations of a set of transactions so that the transactions appear to be executed sequentially. Two operations are said to be *conflicting* if both operations access the same data item, at least one of them is a write operation, and they belong to different transactions. Another popular isolation model is snapshot isolation. Under the snapshot

isolation model, a transaction performs its operations against a snapshot of the database taken at the start of the transaction. The transaction will be committed if the write operations do not conflict with any other transaction that has committed since the snapshot was taken. The snapshot isolation model can provide better concurrent execution than the serializable isolation model.

A major challenge in database replication, the basic method to achieve high availability, is that it is not acceptable to reduce the concurrency levels. This is in sharp contrast to the replication requirement in some other field, which often assumes that the replicas are single-threaded and deterministic (Castro & Liskov, 2002).

DATABASE HIGH AVAILABILITY TECHNIQUES

To achieve high availability, a database system must try to maximize the time to operate correctly without a fault and minimize the time to recover from a fault. The transaction processing model used in database management systems has some degree of fault tolerance in that a fault normally cannot corrupt the integrity of the database. If a fault occurs, all ongoing transactions will be aborted on recovery. However, the recovery time would be too long to satisfy the high availability requirement. To effectively minimize the recovery time, redundant hardware and software must be used. Many types of hardware fault can in fact be masked. For example, power failures can be masked by using redundant power supplies, and local communication system failures can be masked by using redundant network interface cards, cables, and switches. Storage medium failures can be masked by using RAID (redundant array of inexpensive disks) or similar techniques.

To tolerate the failures of database servers, several server instances (instead of one) must be used so that if one fails, another instance can take over. The most common techniques are database replication and database clustering. These two techniques are not completely distinct from each other, however. Database replication is typically used to protect against total site failures. In database replication, two or more redundant database systems operate in different sites — ideally in different geographical regions — and communicate with each other using messages over a (possibly redundant) communication channel. Database clustering is used to provide high availability for a local site. There are two competing approaches in database clustering. One uses a shared-everything (also referred to as shared-disk) design, such as the Oracle Real Application Cluster (RAC) (Ault & Tumma, 2003). The other follows a shared-nothing strategy, such as the MySQL Cluster (Davies & Fisk, 2006) and most DB2 shared database systems. To achieve maximum fault tolerance and hence high availability, one can combine database replication with database clustering.

Database Replication

Database replication means that there are two or more instances of database management systems, including server processes, data files, and logs, running on different sites. Usually one of the replicas is designated as the primary, and the rest of the replicas are backups. The primary accepts users' requests and propagates the changes to the database to the backups. In some systems, the backups are allowed to accept read-only queries. It is also possible to configure all replicas to handle users' requests directly. But doing so increases the complexity of concurrency control and the risk of more frequent transaction aborts.

Depending on how and when changes to the database are propagated across the replicas, there are two different database replication styles, often referred to as *eager* replication and *lazy* replication (Gray & Reuter, 1993). In eager replication, the changes (i.e., the redo log) are transferred to the backups synchronously before the commit of a transaction. In lazy replication, the changes are transferred asynchronously from the primary to the backups after the transactions have been committed. Because of the high communication cost, eager replication is rarely used to protect site failures where the primary and the backups are usually far apart. (Eager replication has been used in some shared-nothing database clusters.)

Eager Replication

To ensure strong replica consistency, the primary must propagate the changes to the backups within the boundary of a transaction. For this, a distributed commit protocol is needed to coordinate the commitment of each transaction across all replicas. The benefit for doing eager replication is that if the primary fails, a backup can take over instantly as soon as it detects the primary failure.

The most popular distributed commit protocol is the two-phase commit (2PC) protocol (Gray & Reuter, 1993). The 2PC protocol guarantees the atomicity of a transaction across all replicas in two phases. In the first phase, the primary (which serves as the coordinator for the protocol) sends a *prepare* request to all backups. If a backup can successfully log the changes, so that it can perform the update even in the presence of a fault, it responds with a "Yes" vote. If the primary collects "Yes" votes from all backups, it decides to *commit* the transaction. If it receives even a single "No" vote or it times out a backup, the primary decides to *abort* the transaction. In the second phase, the primary *notifies* the backups of its decision. Each backup then either commits or aborts the transaction locally according to the primary's decision and sends an acknowledgment to the primary.

As can be seen, the 2PC protocol incurs significant communication overhead. There are also other problems such as the potential blocking if the primary fails after all backups

have voted to commit a transaction (Skeen, 1981). Consequently, there has been extensive research on alternative eager replication techniques, for example, the epidemic protocols (Agrawal et al., 1997; Stanoi, Agrawal, & El Abbadi, 1998), and multicast-based approaches (Kemme & Alonso, 2000; Patino-Martinez et al., 2005). However, they have not been adopted by any major commercial product due to their high overhead or complexities.

Lazy Replication

Most commercial database systems support lazy replication. In lazy replication, the primary commits a transaction immediately. The redo log, which reflects the changes made for the recently committed transactions, is transferred to backups asynchronously. Usually, the backup replicas lag behind the primary by a few transactions. This means that if the primary fails, the last several committed transactions might get lost.

Besides the primary/backup replication approach, some database management systems allow a multi-primary configuration where all replicas are allowed to accept update transactions. If this configuration is used with lazy replication, different replicas might make incompatible decisions, in which case manual reconciliation is required.

Database Clustering

In recent years, database clustering has evolved to be the most promising technique to achieve high availability as well as high scalability (Ault & Tumma, 2003; Davies & Fisk, 2006). Database clustering, as the name suggests, uses a group of computers interconnected by a high-speed network. In the cluster, multiple database server instances are deployed. If one instance fails, another instance takes over very quickly so high availability is ensured.

Database clustering not only brings high availability, but the *scaling-out* capability as well. Scaling-out means that the capacity of a database management system can be dynamically increased by adding more inexpensive nodes while keeping the old equipment.

There are two alternative approaches in database clustering. One approach pioneered in Oracle RAC adopts a shared-everything architecture. A number of other products choose to use the shared-nothing architecture. Both approaches have their challenges and advantages.

Shared-Everything Cluster

In a shared-everything database cluster, all server instances share the same storage device, such as a storage area network. The cluster nodes typically connect to the shared storage device via a fiber channel switch or shared SCSI for fast disk I/O. The shared storage device must also have built-in redundancy such as mirrored disks to mask disk failures. To minimize disk I/O, all server instances share a common virtual cache space. The virtual cache space consists of local cache buffers owned by individual server instances. A number of background processes are used to maintain the consistency of the data blocks in the cache space. These processes are also responsible to synchronize the access to the cached data blocks because only one server instance is allowed to modify a data block at a time.

Each server instance has its own transaction logs stored in the shared disk. If a server instance fails, another server instance takes over by performing a roll-forward recovery using the redo log of the failed server instance. This is to ensure that the changes made by committed transactions are recorded in the database and do not get lost. The recovery instance also rolls back the transactions that were active at the time of the failure and releases the locks on the resources used by those transactions.

The shared-everything design makes it unnecessary to repartition the data, and therefore eases the tasks of cluster maintenance and management. However, this benefit does not come for free. The most prominent concern is the cost of inter-node synchronization. Unless high-speed interconnect is used and the workload is properly distributed among the server instances, the inter-node synchronization might limit the scalability of the cluster. Also, the requirement for a high-speed shared disk system also imposes a higher financial cost than using conventional disks.

Shared-Nothing Cluster

In a shared-nothing database cluster, each node runs one or more server instances and has its own memory space and stable storage. Essential to the shared-nothing approach, the data must be partitioned either manually or automatically by the database system across different nodes. Each partition must be replicated in two or more nodes to keep the desired redundancy level. Concurrency control and caching are carried out in each local node, and therefore they are more efficient than those in shared-everything clusters. However, to ensure the consistency of replicated data and fast recovery, the two-phase commit protocol is often used to ensure atomic commitment of the transactions in the cluster. Comparing with the shared-everything approach, the cost of inter-node synchronization is essentially replaced by that of distributed commit.

The shared-nothing approach faces the additional challenge of *split-brain syndrome* prevention (Birman, 2005). The split-brain syndrome may happen if the network partitions, and if each partition makes incompatible decisions on the outcome of transactions or their relative orders. To prevent this problem, typically only the main partition is allowed to survive. The minor partition must stop accepting

new transaction and abort active transactions. Usually, the main partition is the one that consists of the majority of the replicas or the one that contains a special node designated as the arbitration node (Davies & Fisk, 2006).

FUTURE TRENDS

Existing database systems are designed to tolerate process crash fault and hardware fault. However, considering the increased pace of security breaches, future database management systems must be designed to be intrusion tolerant — that is, they should provide high availability against a variety of security threats, such as the unauthorized deletion and alteration of database records, the disruption of distributed commit (may cause replica inconsistency), and the exposure of confidential information.

To make a database system intrusion tolerant, many fundamental protocols such as the 2PC protocol must be enhanced. There may also be a need to design special tamper-proof storage devices to protect data integrity (Strunk, Goodson, Scheinholtz, Soules, & Ganger, 2000). Even though there has been intensive research in this area (Castro & Liskov, 2002; Malkhi & Reiter, 1997; Mohan, Strong, & Finkelstein, 1983; Deswarte, Blain, & Fabre, 1991), the results have rarely been incorporated into commercial products yet. The primary barrier is the high commutation and communication cost, the complexity, and the high degree of replication required to tolerate malicious faults.

CONCLUSION

Database systems are the cornerstones of today's information systems. The availability of database systems largely determines the quality of service provided by the information systems. In this article, we provided a brief overview of the state-of-the-art database replication and clustering techniques. For many, a low-cost shared-nothing database cluster that uses conventional hardware might be a good starting point towards high availability. We envisage that future generation of database management systems will be intrusion tolerant — that is, they are capable of continuous operation against not only hardware and process crash fault, but a variety of security threats as well.

KEY TERMS

Database Cluster (Shared-Everything, Shared-Nothing): A database management system runs on a group of computers interconnected by a high-speed network. In the cluster, multiple database server instances are deployed. If one instance fails, another instance takes over very quickly to ensure high availability. In the shared-everything design, all nodes can access a shared stable storage device. In the shared-nothing design, each node has its own cache buffer and stable storage.

Database Recovery (Roll-Backward, Roll-Forward): Recovery is needed when a database instance that has failed is restarted or a surviving database instance takes over a failed one. In roll-backward recovery, the active transactions at the time of failure are aborted and the resourced allocated for those transactions are released. In roll-forward recovery, the updates recorded in the redo log are transferred to the database so that they are not lost.

Database Replication (Eager, Lazy): Multiple instances of a database management system are deployed in different computers (often located in different sites). Their state is synchronized closely to ensure replica consistency. In eager replication, the updates are propagated and applied to all replicas within the transaction boundary. In lazy replication, the changes are propagated from one replica to others asynchronously.

High Availability (HA): The capability of a system to operate with long uptime and to recover quickly if a failure occurs. Typically, a highly available system implies that its measured uptime is five nines (99.999%) or better, which corresponds to 5.25 minutes of planned and unplanned downtime per year.

Split-Brain Syndrome: This problem may happen if the network partitions in a database cluster, and if each partition makes incompatible decisions on the outcome of transactions or their orders. To prevent this problem, typically only the main partition is allowed to survive.

Transaction: A group of read/write operations on the same data set that succeeds or fails atomically. More accurately, a transaction that has atomicity, consistency, isolation, and durability properties.

Two-Phase Commit Protocol (2PC): This protocol ensures atomic commitment of a transaction that spans multiple nodes in two phases. During the first phase, the coordinator (often the primary replica) queries the prepare status of a transaction. If all participants agree to commit, the coordinator decides to commit. Otherwise, the transaction is aborted. The second phase is needed to propagate the decision to all participants.

Histogram Generation from the HSV Color Space

INTRODUCTION

Digital image databases have seen an enormous growth over the last few years. However, since many image collections are poorly indexed or annotated, there is a great need for developing automated, content-based methods that would help users to retrieve images from these databases. In recent times, a lot of attention has been paid to the management of an overwhelming accumulation of rich digital images to support various search strategies. In order to improve the traditional text-based or SQL (Structured Query Language)-based database searches, research has been focused on efficient access to large image databases by the contents of images, such as color, shape, and texture. Content-based image retrieval (CBIR) has become an important research topic that covers a large number of domains like image processing, computer vision, very large databases, and human computer interaction (Smeulders, Worring, Santini, Gupta & Jain, 2000). Several content-based image retrieval systems and methods have recently been developed.

QBIC (Query By Image Content) is one of the first image retrieval systems developed at IBM (Niblack et al., 1993). Color, texture, and shape features are combined to represent each image in this system. The VisualSeek system, developed at the Columbia University, is an image retrieval system based on visual features (Chang, Smith, Mandis & Benitez, 1997). The NeTra system is a prototype image retrieval system, which uses color, texture, shape, and spatial location information as features to retrieve similar images (Ma & Manjunath, 1997). Some of the other popular CBIR systems are MARS (Ortega et al., 1998), Blobworld (Carson, Thomas, Belongie, Hellerstein & Malik, 1999), PicToSeek (Gevers & Smeulders, 2000), and SIMPLIcity (Wang, Li & Wiederhold, 2001).

An analysis of these systems reveals that all of them give a lot of importance on the image color for retrieval. In fact, color is always considered to be an important attribute, not only in content-based image retrieval systems, but also in a number of other applications like segmentation and video shot analysis. In color-based image retrieval, there are primarily two methods: one based on color layout (Smith & Chang, 1996) and the other based on color histogram (Swain & Ballard, 1991; Wang, 2001). In the color layout approach, two images are matched by their exact color distribution. This means that two images are considered close if they not only have similar color content, but also if they have similar color in approximately the same positions. In the second approach, each image is represented by its color histogram. A histogram is a vector whose components represent a count of the number of pixels having similar colors in the image. Thus, a color histogram may be considered to be a signature extracted from a complete image. Color histograms extracted from different images are indexed and stored in a database. During retrieval, the histogram of a query image is compared with the histogram of each database image using a standard distance metric like the Euclidean distance or the Manhattan distance. Since color histogram is a global feature of an image, the approaches based on color histogram are invariant to translation and rotation, and scale invariant with normalization.

Color histograms may be generated using properties of the different color spaces like RGB (Red, Green, and Blue), HSV (Hue, Saturation, and Intensity Value), and others. In this article, we give an overview of the different histogram generation methods using the HSV color space. We first present a brief background of the HSV color space and its characteristics, followed by the histogram generation techniques for various applications.

BACKGROUND

A color space or a color model is a specification of a coordinate system and a subspace within that system where a single point represents a distinct color value. There are several well-known color spaces that are used to represent the pixels of

an image. This representation is used for image analysis like extraction of color histograms. Each color space has its own merits and demerits depending on the application and hardware specification where it is going to be used. RGB, CMY, CMYK, and HSV are some of the popular color spaces. The RGB color space contains three color components, namely red, green and blue, each of which appears in its primary spectral components. Devices that deposit colored pigments on paper use CMY color space, and the representation of this color space is with the secondary colors of light, which are Cyan, Magenta, and Yellow. CMYK (Cyan, Magenta, Yellow, Black) color space is similar to CMY but is used to produce true black color, which is muddy-black in the CMY color space.

The HSV (Hue, Saturation, Value) color space, on the other hand, closely corresponds to the human visual perception of color. The HSV color space can be represented as a three-dimensional hexacone, where the central vertical axis represents intensity which takes a value between 0 and 255 (Shapiro & Stockman, 2001). Hue is defined as an angle in the range $\pi[0,2]$ relative to the red axis with red at angle 0, green π at 2/3, blue π at 4/3, and red again π at 2. Saturation is the depth or purity of color and is measured as a radial distance from the central axis to the outer surface. For zero saturation, as we move higher along the intensity axis, we go from black to white through various shades of gray. On the other hand, for a given intensity and hue, if the saturation is changed from zero to one, the perceived color changes from a shade of gray to the most pure form of the color represented by its hue. When saturation is near zero, all pixels, even with different hues, look alike and as we increase the saturation towards one, they tend to get separated out and are visually perceived as the true colors represented by their hues. Thus, the effect of saturation may be considered as that of introducing visual shadows on the image for any given value of hue and intensity.

The HSV model is an ideal tool for developing image and video processing algorithms based on color descriptions. A number of histogram generation methods from the HSV color space have recently been proposed for different applications. We next describe some of these approaches.

HISTOGRAM GENERATION FROM THE HSV COLOR SPACE

The HSV color space in general, and the HSV color histogram in particular, plays an important role in image analysis. A color histogram can be used in image retrieval, segmentation, video shot detection, color and intensity-based clustering, place recognition for topological localization, person identification and authentication using biometric techniques, as well as in many other applications.

For image retrieval applications, an HSV color histogram can be generated using an approach similar to the RGB color space. The hue scale is divided into eight groups, saturation scale is divided into two groups, and the intensity scale is divided into four groups. By combining each of these groups, we get a total of 64 cells to represent a 64-component HSV color histogram. The reason for having a different number of groups for the three scales is that, of the three axes, hue is considered to be the most important, followed by intensity, and finally, saturation. For the H, S, and V combination of values, the corresponding histogram component is determined. The respective histogram component is updated by one for each pixel having the corresponding color combination. An efficient indexing of the histograms can enhance the performance of a CBIR application to a great extent. Smith and Chang (1996) exploit this idea in their color set approach. This method extracts spatially localized color information and provides efficient indexing of the color regions. The large single color regions are extracted first, followed by multiple color regions. They utilize binary color sets to represent the color content as a color histogram. The H and S dimensions are divided into N and M bins, respectively, for a total of N×M bins (Ortega et al., 1998). Each bin contains the percentage of pixels in the image that have corresponding H and S colors for that bin. Intersection similarity is used as a measure to capture the amount of overlap between two histograms.

From the properties of the HSV color space, it is observed that for low values of saturation, a color is approximated by a gray value specified by the intensity level while for higher saturation, the color is approximated by its hue. This captures the human visual properties effectively and can be used to generate a histogram for image retrieval applications (Sural, 2003; Sural, Qian & Pramanik, 2002). The saturation threshold that determines this transition is once again dependent on the intensity. Thus, the value of saturation projected onto the hue and intensity plane is useful for the extraction of color information. A threshold function can be used to determine if a pixel should be represented by its hue or by its intensity in the color histogram. For an intensity value of zero, all the colors are considered as black, whatever their hue or saturation may be. On the other hand, with increasing values of intensity, the saturation threshold that separates hue dominance from intensity dominance goes down. This approach treats the pixels as a distribution of "colors" in an image where a pixel may be of a "gray color" or of a "true color." The histogram is a logical combination of two independent histograms—one for the true colors and one for the gray colors. One drawback of this approach is that for saturation values near the threshold, a pixel is neither a true color pixel nor a gray color pixel. In order to capture the fuzzy nature of human visual perception of color, there is a need for using a soft threshold to determine the dominant property of a pixel. In the soft threshold approach, two

components of the histogram are updated for each pixel in an image, namely, a gray color component and a true color component. The quantum of update is determined both by the saturation and the intensity of the pixel, and the sum of the weights of the two contributions equals unity. Also, for the same saturation, the weight varies with intensity. For a lower intensity value, the same saturation gives a lower weight on the true color component and vice versa. This histogram has a high recall and precision of retrieval, and is effectively used in content-based image retrieval systems (Vadivel, Majumdar & Sural, 2003). The soft threshold approach can also be used for video shot detection (Sural, Mohan & Majumdar, 2004).

An input image in a content-based retrieval system may be textured or non-textured. Similarly, the images stored in a database can also be classified as textured or non-textured. When the query image is compared with the database images, the search should be restricted to the relevant portion of the database. An HSV histogram can be effectively used to classify an image into a textured or a non-textured class (Li, Wang & Wiederhold, 2000). In this approach, an image is first segmented into 4X4 pixel regions. HSV color histogram is extracted for each such region. When an image is a color-rich image, hue plays an important role in its representation. Although, hue can represent millions of colors, the human visual system cannot distinctly recognize all of them. The visually similar colors can be combined together in the same color band, as suggested by Gong, Proietti, and Faloutsos (1998). After combining the similar colors, the image is segmented and indexed for content-based retrieval. It is observed that human visual system can perceive distinct colors depending on the NBS (National Bureau of Standards) color distance. Colors with NBS distance below 3.0 are indistinguishable to the human eye. Besides hue, if the intensity axis is also divided into a number of bands, then segmentation, clustering, indexing, and retrieval of images can be done even more effectively (Zhang & Wang, 2000). In this approach, the histograms are generated separately—one from the hue component and the other from the intensity component. K-means clustering algorithm is then applied on these two histograms to obtain the center for each class for indexing.

It should be noted that the histogram of an image does not keep track of the spatial information of the pixels in an image. Two images with the same number of color pixels but at different locations would have the same histogram. This results in higher false-positives. If the spatial relationship is also captured during histogram generation, then the retrieval performance can be enhanced. Color correlogram is a type of histogram generated from the HSV color space that retains spatial information (Ojala, Rautiainen, Matinmikko & Aittola, 2001).

In addition to content-based image retrieval, the HSV histogram is used for a large number of other applications. One important class of applications is the domain of topological localization in robotics. Ulrich and Nourbakhsh (2000) use the HSV histogram for appearance-based place recognition. They first determine the candidate locations based on the current belief of a robot's location and transform the input image into six one-dimensional histograms. Then for each candidate location and for each of the two color bands, RGB and HSV, the reference histogram is determined that matches the input histogram most closely. In order to reduce the resource requirements for storage and transmission of image and video, various data compression techniques are used in practice. A fundamental goal of data compression is to obtain the best possible fidelity for a given data rate or, equivalently, to minimize the rate required for a given fidelity. Matching Pursuit (MP) image representation has proven to give good compression results. It is found that the MP coefficients are interestingly distributed along the diagonal of the color cube. Coding of the MP coefficients is done in the HSV color space, where V becomes the projection of RGB coefficients on the diagonal of the cube, S is the distance of the coefficient to the diagonal, and H is the direction perpendicular to the diagonal where the RGB coefficient is placed. MP coefficients are quantized and a histogram of the quantized coefficients is generated in the HSV space for efficient data compression (Rosa, Ventura & Vandergheynst, 2003).

FUTURE TRENDS

The HSV color space provides a close representation of human visual perception of color. New and effective algorithms are being developed to extract more useful information from the HSV color space. Recent research shows that the HSV color space can even be used to represent both color and texture information in a single histogram. An extension of this work could be in the domain of fuzzy feature extraction for segmentation and retrieval. Further theoretical and experimental comparisons should be made between the HSV and other color spaces.

CONCLUSION

We have discussed a number of histogram generation techniques using the HSV color space and made a critical assessment of their merits and demerits. Color histograms generated from the HSV color space have been used in a variety of image and video processing applications. Content-based image retrieval is one of the most popular domains in which the HSV histogram has been used effectively for high recall and precision of retrieval. The histogram may also be combined with other features for representing semantic contents in image and video.

KEY TERMS

Content-Based Image Retrieval: Retrieval of images similar to a given image based only on features present in the image and not any external information.

Histogram: A vector whose components represent similar colors in an image. The value of a component is the number of image pixels having that color.

HSV Color Space: A color space consisting of hue, saturation, and intensity value. It is a popular way of representing color content of an image.

Precision: The number of relevant images retrieved as a percentage of the total number of images retrieved.

Recall: The number of relevant images retrieved as a percentage of the total number of relevant images in the database.

Soft Threshold: A fuzzy approach to decide the importance of a feature. This is in contrast to a hard threshold where a yes/no decision is made.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 1333-1337,

Histogram-Based Compression of Databases and Data Cubes

Alfredo Cuzzocrea
University of Calabria, Italy

INTRODUCTION

Histograms have been extensively studied and applied in the context of *Selectivity Estimation* (Kooi, 1980; Muralikrishna & DeWitt, 1998; Piatetsky-Shapiro et al., 1984; Poosala et al., 1996; Poosala, 1997), and are effectively implemented in commercial systems (e.g., Oracle Database, IBM DB2 Universal Database, Microsoft SQL Server) to **query optimization** purposes. In statistical databases (Malvestuto, 1993; Shoshani, 1997), histograms represent a method for approximating **probability distributions**. They have also been used in data mining activities, intrusion detection systems, scientific databases, that is, in all those applications which (*i*) operate on huge numbers of detailed records, (*ii*) extract useful knowledge only from condensed information consisting of summary data, (*iii*) but are not usually concerned with detailed information. Indeed, histograms can reach a surprising efficiency and effectiveness in approximating the actual distributions of data starting from **summarized information**. This has led the research community to investigate the use of histograms in the fields of database management systems (Acharya et al., 1999; Bruno et al., 2001; Gunopulos et al., 2000; Ioannidis & Poosala, 1999; Kooi, 1980; Muralikrishna & DeWitt, 1998; Piatetsky-Shapiro et al., 1984; Poosala, 1997; Poosala & Ioannidis, 1997), *online analytical processing* (OLAP) systems (Buccafurri et al., 2003; Cuzzocrea, 2005a; Cuzzocrea & Wang, 2007; Furfaro et al., 2005; Poosala & Ganti, 1999), and data stream management systems (Guha et al., 2001; Guha et al., 2002; Thaper et al., 2002), where, specifically, compressing data is mandatory in order to obtain fast answers and manage the endless arrival of new information, as no bound can be given to the amount of information which can be received.

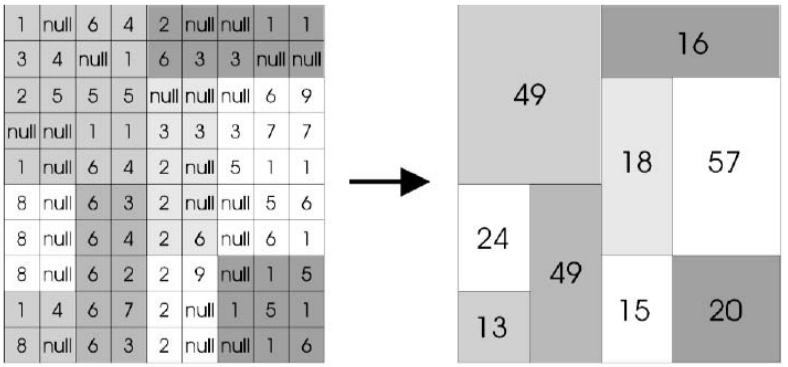
Histograms are data structures obtained by partitioning a **data distribution** (or, equally, a data domain) into a number of mutually disjoint blocks, called ***buckets***, and then storing, for each bucket, some **aggregate information** of the corresponding range of values, like the sum of values in that range (i.e., applying the SQL aggregate operator SUM), or the number of occurrences (i.e., applying the SQL aggregate operator COUNT), such that this information retains a certain "summarizing content."

Figure 1 shows an instance of a histogram built on a two-dimensional **data cube** (left-side of the figure), represented as a matrix. The corresponding (two-dimensional) histogram (right-side of the figure) is obtained by (*i*) partitioning the matrix into some rectangular buckets which do not overlap, and (*ii*) storing for each so-obtained bucket the sum of the measure attributes it contains.

Histograms are widely used to support two kinds of applications: (*i*) selectivity estimation inside *Query Optimizers* of DBMS, as highlighted before, and (*ii*) *approximate query answering* against databases and data cubes. In the former case, the data distribution to be compressed consists of the frequencies of values of attributes in a relation (it should be noted that, in this vest, histograms are mainly used within the core layer of DBMS, thus dealing with databases properly). In the latter case, the data distribution to be compressed consists of the data items of the target domain (i.e., a database or a data cube) directly, and the goal is to provide fast and approximate answers to resource-intensive queries instead of waiting-for time-consuming exact evaluations of queries. To this end, a widely-accepted idea is that of evaluating (with some approximation) queries against ***synopsis data structures*** (i.e., succinct, compressed representations of original data) computed over input data structures (i.e., a database or a data cube) instead of the same input data structures. Histograms are a very-popular class of synopsis data structures, so that they have been extensively used in the context of approximate query answering techniques. Some relevant experiences concerning this utilization of histograms are represented by the work of Ioannidis and Poosala (Ioannidis & Poosala, 1999), that propose using histograms to provide approximate answers to set-valued queries, and the work of Poosala and Ganti (Poosala & Ganti, 1999), that propose using histograms to provide approximate answers to *range-queries* (Ho et al., 1997) in OLAP.

In both utilizations, a relevant problem is how to reconstruct the original data distribution form the compressed one. In turn, this derives from the fact that the original data distribution summarized within a bucket cannot be reconstructed exactly, but can be approximated using some estimation strategies, like *continuous value assumption* (CVA) (Colliat, 1996) or *uniform spread assumption* (USA) (Poosala et al., 1996). For a given storage space reduction, the problem of determining the "best" histogram (i.e., the histogram which minimizes the approximation of reconstructing the original content of ranges corresponding to buckets) is crucial. Indeed,

Figure 1. A two-dimensional data cube and its corresponding two-dimensional histogram



different partitions lead to dramatically different errors in reconstructing the original data distribution, especially for *skewed* (i.e., asymmetric) data. This issue has been investigated for some decades, and a large number of techniques for arranging histograms have been proposed (Buccafurri et al., 2003; Christodoulakis, 1984; Donjerkovic et al., 1999; Ioannidis & Poosala, 1995; Jagadish et al., 2001). The aim of every partition technique is to build a histogram whose buckets contain values with "small" differences, so that one can estimate a range query inside a bucket assuming that data distribution is uniform, thus successfully exploiting linear interpolation. Indeed, finding the optimal solution to this problem in multiple dimensions is NP-hard (Muthukrishnan et al., 1999). Several techniques and heuristics have been proposed to find sub-optimal solutions with provable quality guarantees (Jagadish et al., 1998; Gilbert et al., 2001). These guarantees regard the "distance" of the provided solution from the optimal one, but do not provide any measure of the approximation of each estimated answer to a range-query.

Another important, more recent utilization of histograms concerns with the *data visualization problem*, where the data compression paradigm is intended as a solution to aid the visualization of complex and multidimensional domains. This is a quite-unexplored line of research: pioneeristic works can be found in the DIVE-ON (Ammoura et al., 2001) and *Polaris* (Stolte et al., 2002) projects, whereas recent works can be found in (Cuzzocrea et al., 2007).

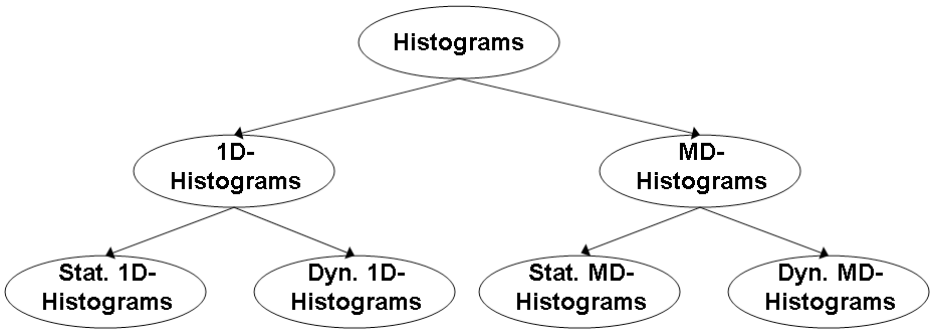
In this chapter, we survey several state-of-the-art histogram-based techniques for compressing databases and data cubes, ranging from one-dimensional to multidimensional data domains. Specifically, we highlight similarity and differences existing among the investigated techniques, and put-in-evidence how proposals have evolved over time towards more and more sophisticated and very-efficient solutions, beyond early experiences focused on selectivity estimation issues within the core layer of DBMS.

BACKGROUND

A *database* D is a tuple $D = \langle W,I,F \rangle$ such that (*i*) W is the *schema* of D; (*ii*) I is the *instance* of D, that is, its realization in terms of collections of tuples adhering to W; (*iii*) F is the collection of *functional dependencies* defined over W. In turn, W is a collection of *relation schemas* $W = \{T_0, T_1,\ldots, T_P\}$, with $P = |W| - 1$, such that T_i, with $0 \leq i \leq P$, is defined as a tuple $T_i = \langle K, A_{i,0}, A_{i,1},\ldots, A_{i,G} \rangle$, with $G = |T_i| - 1$, such that K is the *key* of T_i, and $A_{i,j}$ is the j^{th} *attribute* of T_i. A functional dependence is expressed as a *logical rule* over attributes of T_i. The instance of a relation scheme T_i is named as *relation*, and denoted by R_i.

A *data cube* L is a tuple $L = \langle C,J,H,M \rangle$, such that: (*i*) C is the data domain of L containing (OLAP) *data cells*, which are the basic SQL aggregations of L computed against the relational data source S alimenting L; (*ii*) J is the set of *dimensions* of L, that is, the *functional attributes* (of S) with respect to which the underlying OLAP analysis is defined (in other words, J is the set of attributes with respect to which relational tuples in S are aggregated); (*iii*) H is the set of *hierarchies* related to the dimensions of L, that is, hierarchical representations of the functional attributes shaped-in-the-form-of generic trees; (*iv*) M is the set of *measures* of L, that is, the *attributes of interest* (of S) for the underlying OLAP analysis (in other words, M is the set of attributes with respect to which SQL aggregations stored in data cells of L are computed).

Figure 2. A taxonomy of histograms



HISTOGRAM-BASED COMPRESSION TECHNIQUES FOR DATABASES AND DATA CUBES

Classes of Histograms

We distinguish between *one-dimensional histograms*, those devoted to compress one-dimensional data domains, and *multidimensional histograms*, those working on multidimensional data domains, which are more interesting than the former, and can be found in a wide range of modern, large-scale, *data-intensive* applications. Moreover, we can also further distinguish between *static histograms* and *dynamic histograms*. The first ones are statically computed against the target domain, and are not particularly suitable to efficiently accomplish data updates occurring on original data sources. The second ones are dynamically computed by taking into consideration, beyond the target domain, or, in some cases, a synopsis of it, other entities related to the dynamics of the target DBMS/OLAP server such as *query-workloads*, *query feedbacks*, *load balancing issues,* and so forth. Contrary to the previous histogram class, dynamic histograms efficiently support update management, being their partition dependent on a "parametric" configuration that can be easily (re-)computed at will. From this classification, a simple-yet-effective *taxonomy* of histograms can be derived (see Figure 2).

Static One-Dimensional Histograms

One-dimensional histograms deal with the problem of approximating a one-dimensional data domain or, equally, a one-dimensional data distribution. As an example, one-dimensional histograms can be used to approximate the domain/distribution of an attribute R.A of a given relation R of a RDBMS server to selectivity estimation purposes. Such histograms represent first research experiences in this field, and have been proposed in the context of query optimizers mainly (Kooi, 1980).

Let B be the whole number of buckets of the final histogram, obtaining an equal number of rows per bucket is the goal of (one-dimensional) *Equi-depth histogram*, introduced by Piatetsky-Shapiro and Connell (Piatetsky-Shapiro et al., 1984), that propose a simple construction procedure based on first sorting, and then taking B—1 equally-spaced splits of the target domain. This approach can be improved by first *sampling*, and then taking equally-spaced splits of the sampled domain instead of the original domain (Piatetsky-Shapiro et al., 1984), or applying *one-pass quantile algorithms* (Greenwald & Khanna, 2001). Maintaining such histogram is also very efficient as it can be maintained using one-pass algorithms, or a *backing sample* (Gibbons et al., 1997), which, essentially, consists in keeping bucket counts up-to-date.

Poosala et al. (1996) propose *compressing Equi-Depth* histograms by creating singleton buckets for largest values, and maintaining the equi-depth strategy over the rest of data. This allows the "original" version of the *Equi-Depth* histogram to be improved significantly, as exact information is kept for largest values, whereas less-detailed information is maintained for the rest of data. The construction of such compressed histogram can be implemented by (*i*) sorting buckets, (*ii*) scanning the buckets looking for the largest values (this is done in time $O(B \cdot logB)$), and, finally, (*iii*) performing a one-pass scan in order to process the remaining data. Alternatively, sampling can be used to improve performance, similarly to the "original" version of the histogram. Gibbons et al. (1997) propose *maintaining* compressed *Equi-Depth* histograms by using the *split-&-merge* approach as in the

uncompressed ones, but also taking in account the issue of deciding when to create and remove singleton buckets.

In a *V-Optimal histogram*, introduced by Ioannidis and Poosala (1995), buckets are selected in such a way as to minimize frequency variance within them. In Ioannidis and Poosala (1995), authors show that *V-Optimal* histogram minimizes the average selectivity estimation error for equality-joins and selections. Following the original idea, *V-Optimal* construction method has been further improved by Jagadish et al. (1998), that give-to-this-end an $O(B \cdot n^2)$ time dynamic programming algorithm, such that (*i*) B is (still) the overall number of buckets of the histogram, and (*ii*) n is the number of items of the input data domain D (i.e., the size of D).

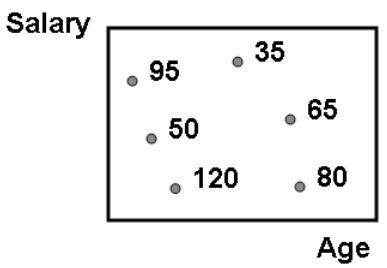
Dynamic One-Dimensional Histograms

In the case of dynamic one-dimensional histograms, the final histogram is computed by considering additional information apart from the target data domain (or a synopsis of it). A relevant instance of such class of histograms is represented by the so-called *Self-Tuning histogram* (*ST-histogram*), introduced by Aboulanaga and Chaudhuri (1999), that propose improving the original version of *Equi-Depth* histogram via tuning bucket frequencies by (*i*) comparing actual selectivity to histogram estimate, (*ii*) using this information to adjust bucket frequencies by dividing the values of each bucket by a quantity equal to $D_F \cdot S_E$, where D_F is the *dampening factor*, and S_E is the *actual* error, and, finally, (*iii*) restructuring the histogram by merging buckets of near-equal-frequencies and splitting large-frequency buckets.

Static Multidimensional Histograms

The basic problem addressed by techniques for compressing multidimensional domains is to approximate the *joint data distribution* of multiple attributes, obtained by jointly combining the distributions of singleton attributes. For instance, in Figure 3 a two-dimensional data domain on salary and age of employers is depicted; in each dimension, a distinctive data distribution related to the singleton attribute can be identified.

Figure 3. A two-dimensional joint data distribution



The goal of these techniques is to provide selectivity estimation for queries with multiple predicates, like in Muralikrishna and DeWitt (1998), and to approximate general relations, like in Poosala and Ioannidis (1997), or OLAP data cubes, like in Vitter et al. (1998). A popular and conventional approach is based on the well-known *attribute-value independence* (AVI) assumption (Selinger et al., 1979), according to which any query involving a set of attributes can be answered by applying it on each attribute singularly. This approach is theoretically reasonable, but it has been recognized as source of gross errors in practice (e.g., (Christodoulakis, 1984; Faloutsos & Kamel, 1997; Poosala, 1997; Poosala & Ioannidis, 1997). To cope with this problem, multidimensional histograms use a small number of multidimensional buckets to *directly* approximate the joint data distribution. The approximate d-dimensional distribution $\tilde{f}$ is obtained from the actual d-dimensional distribution f via (*i*) setting the total bucket frequency F, and (*ii*) approximating data points of f on a $w(0) \times w(1) \times \ldots \times w(|d|-2) \times w(|d|-1)$ uniform grid G, such that $w(k)$ is the number of distinctive values along the dimension d_k, and each cell of G has a bucket frequency equal to $F / (w(0) \cdot w(1) \cdot \ldots \cdot w(|d|-2) \cdot w(|d|-1))$.

However, even if reasonable, this approach introduces serious limitations when applied to real-life databases and data cubes. Indeed, constructing histograms is much harder for two dimensions than for the one-dimensional case, as recognized by Muthukrishnan et al. (1999). This problem gets worse in the case that the dimension number increases, and becomes a problematic bottleneck in real-life data-intensive systems where corporate databases and data cubes with more than 100 dimensions can be found. From this evidence, various and heterogeneous alternatives to the problem of computing multidimensional histograms have been proposed in literature, each of them based on one or more properties of data distributions characterizing the input data domain. Conventional approaches take into consideration statistical and error-metrics-based properties of data distributions. Other approaches expose *greedy solutions*, as traditional approaches introduce excessive computational overheads on highly-dimensional data domains.

Among all the alternatives, we focus our attention on the following (static) multidimensional histograms, mainly because they can be considered as representative and significant experiences in this context: *Equi-Depth* (Muralikrishna & DeWitt, 1998), *MHist* (Poosala & Ioannidis, 1997), *Min-Skew* (Acharya et al., 1999), *GenHist* (Gunopulos et al., 2000), and *GHBH* (Furfaro et al., 2005) histograms.

Given a d-dimensional data domain D (e.g., a data cube), (multidimensional) *Equi-Depth histogram* $H_{E\text{-}D}(D)$, proposed by Muralikrishna and DeWitt (1998), is built as follows: (*i*) fix an ordering of the d dimensions; (*ii*) set α

$\approx |d|^{th}$ root of desired number of buckets; (*iii*) initialize $H_{E\text{-}D}(D)$ to the input data distribution of D; (*iv*) for each k in $\{0, 1, \ldots, |d|\text{-}1\}$ split each bucket in $H_{E\text{-}D}(D)$ in α equi-depth partitions along d_k; finally, (*v*) return resulting buckets to $H_{E\text{-}D}(D)$. This technique presents some limitations: fixing α and the dimension ordering can result in poor partitions, and, consequently, there could be a limited level of *bucketization* that, in turn, involves low quality of $H_{E\text{-}D}(D)$ in its general goal of approximating D.

MHist histogram, proposed by Poosala and Ioannidis (1997), overcomes *Equi-Depth* performance. *MHist* build procedure depends on the parameter p (specifically, such histogram is denoted by *MHist-p*): contrarily to the previous technique, at each step, the bucket b_i in a *MHist* histogram $H_{MH}(D)$ containing the dimension d_k whose *marginal* is the most in need of partitioning is chosen, and it is split along d_k into p (e.g., $p = 2$) buckets. Experimental results shown in Poosala and Ioannidis (1997) state that *MHist* overcomes AVI and *Equi-Depth*.

Min-Skew histogram was originally designed by Acharya et al. (1999) to tackle the problem of selectivity estimation of *spatial data* in *geographical information systems* (GIS). Spatial data are referred to *spatial* (or *geographical*) *entities* such as points, lines, poly-lines, polygons and surfaces, and are very often treated by means of minimal rectangles containing them, namely *Minimum bounding rectangles* (MBR). *Min-Skew* is more sophisticated than *MHist*. The main idea behind a *Min-Skew* histogram $H_{M\text{-}S}(D)$ is to follow the criterion of minimizing the *spatial skew* of the histogram by performing a *binary space partitioning* (BSP) via recursively dividing the space along one of the dimensions each time. More formally, each point in the space of a given GIS instance is associated to a *spatial density*, defined as the number of MBR that contain such a point. When performing the partition, each bucket b_i is assigned the spatial skew s_i, defined as follows: $s_i = \sum_{j=0}^{n_i-1} (f_j - \bar{f})^2 / n_i$, where (*i*) n_i is the number of points contained within b_i, (*ii*) f_j is the *spatial frequency* of the j^{th} point within b_i, and (*iii*) $\bar{f}$ represents the *average frequency* of all the points within b_i. The total skew S of $H_{M\text{-}S}(D)$ is defined as follows: $S = \sum_{i=0}^{B-1} n_i \cdot s_i$, where (*i*) B is the total number of buckets, (*ii*) s_i is the spatial skew associated with bucket b_i, and (*iii*) n_i is the number of points of b_i. The construction technique of $H_{M\text{-}S}(D)$ tries, at each step, to minimize the overall spatial skew of the histogram by selecting (*i*) a bucket to be split, (*ii*) a dimension of the multidimensional space along which split, and (*iii*) a splitting point along that dimension such that the overall spatial skew computed after the split is smaller than the one computed at the previous step (i.e., before the current split). Finally, noticing that the spatial skew captures the variance of the spatial density of MBR within each bucket, we can say that *Min-Skew* follows, in some sense, the spirit of *V-Optimal*.

Gunopulos et al. propose *GenHist histogram* (2000), a new kind of multidimensional histogram that is different from the previous ones with respect to the build procedure. The key idea is the following: given an histogram H whit h_b buckets on an input data domain D, a *GenHist* histogram $H_{GH}(D)$ is built by finding n_b overlapping buckets on H, such that n_b is an input parameter. To this end, the technique individuates the number of distinct regions that is much larger than the original number of buckets h_b, thanks to a greedy algorithm that considers *increasingly-coarser grids*. At each step, such algorithm selects the set of cells J of highest density, and moves enough randomly-selected points from J into a bucket to make J and its neighbors "close-to-uniform." Therefore, the novelty of the proposal consists in defining a truly multidimensional splitting policy, based on the concept of *tuple density*. A drawback of the *GenHist* proposal is the difficulty of choosing the right values for setting the input parameters, which are: (*i*) the degree of the grid ξ used to obtain regular partitions of the data domain at each iteration; (*ii*) the number of buckets b created at each iteration; (*iii*) the value α, which controls the rate by which ξ decreases. Indeed, authors state that: (*i*) the optimal setting for the initial value of ξ, denoted by ξ_0, must be such that, at the first iteration, the percentage of points that are removed from the input data cube to provide b buckets is at least

$$\frac{1}{\log_{1/\alpha} \xi};$$

(*ii*) the optimal setting for α is $\alpha = (1/2)^{1/d}$, such that d is the number of dimensions of the input data cube.

More recently, Furfaro et al. (2005) propose a new kind of multidimensional histogram which can be considered as very innovative if compared with previous ones. They first propose the definition of a new *class* of histograms, called *flat binary histogram* (FBH), which are characterized by the property that buckets are represented independently from one another, without exploiting the hierarchical structure of the underlying partition. Then, they classify *MHist* and *Min-Skew* inside the class FBH histograms, and give theoretical motivations to this claim. Finally, they introduce the *grid hierarchical binary histogram* (GHBH), a new histogram belonging to the FBH class. The partition scheme used by a *GHBH* histogram $H_{GHBH}(D)$ is the same of that of *MHist* and *Min-Skew* histograms, thus based on (*i*) statistical properties of data, like the standard deviation, and (*ii*) greedy (generating) algorithms. The novelty of $H_{GHBH}(D)$ is that the hierarchy adopted to determine the structure of the histogram is also used to represent it, thus introducing surprising efficiency in terms of both space consumption and accuracy of query estimations. Furthermore, $H_{GHBH}(D)$ is based on a constrained partition scheme, where buckets of data cannot be split anywhere along one of their dimensions, but the

split must be laid onto a grid partitioning the bucket into a number of equally-sized sub-buckets. The adoption of this constrained partitioning enables a more efficient physical representation of the histogram with respect to other histograms using more traditional partition schemes. Thus, the saved space can be invested to obtain finer grain buckets, which approximate data in more detail. Indeed, the ability of creating a larger amount of buckets (in a given storage space) does not guarantee a better accuracy in estimating range-queries, as it could be the case that buckets created by adopting a constrained scheme contain very skewed (i.e., non-uniform) distributions. In Furfaro et al. (2005), authors show that given a *d*-dimensional data domain *D* and the space bound *M* (i.e., the storage space available for housing the output compressed data structure), the maximum number of buckets $\beta_{FBH}^{\max}$ within *M* of a FBH over *D*, denoted by $H_{FBH}(D)$, is

$$\beta_{FBH}^{\max} = \left\lfloor \frac{M}{32 \cdot (2 \cdot |d| + 1)} \right\rfloor$$

assuming that an integer value is represented using 32 bits. On the contrary, using $H_{GHBH}(D)$, the maximum number of buckets $\beta_{GHBH}^{\max}$ within *M* is

$$\beta_{FBH}^{\max} = \left\lfloor \frac{M + \log \delta + \lceil \log |d| \rceil - 30}{3 + \log \delta + \lceil \log |d| \rceil} \right\rfloor,$$

such that δ is the "degree" of the grid-based constrained partition scheme.

Dynamic Multidimensional Histograms

Dynamic multidimensional histograms extend capabilities of static multidimensional histograms by incorporating inside their generating algorithms the amenity of building/refining the underlying partition in dependence on non-conventional entities related to the dynamic behavior of the target DBMS/OLAP server, such as query-workloads. Among this class of histograms, relevant proposal are: *wavelet-based* (Matias et al., 1998) and *STHoles* (Bruno et al., 2001) histograms, and our innovative data structure **TP**-*Tree* (Cuzzocrea & Wang, 2007).

Wavelet-based histograms, proposed by Matias et al. (1998), aim at combining the benefits coming from the usage of *wavelet transformations* in the context of data-compression/approximate-query-answering (Vitter et al., 1998) (basically, these benefits can be synthesized in a greater flexibility in supporting different classes of queries rather than histograms) with histograms. The key idea of this approach is to use a compact subset of *Haar* (or linear) *wavelet coefficients* to approximate the data distribution. This approach has provided good results in range-query selectivity estimation issues, and has outperformed performance of original histograms. Subsequently, authors have then addressed the problem of the *dynamic maintenance of wavelet-based histograms* (Matias et al., 2000). Here, they observe that updates in singleton distribution value can affect the values of many coefficients through propagations like paths-to-the-root of the *decomposition tree* given by the wavelet transformation; therefore, they develop a dynamic technique in which as distribution changes, "most significant" (e.g., largest) wavelet coefficients are updated consequentially.

Bruno et al. (2001) propose a different kind of multidimensional histogram, based on the analysis of the query-workload on it: the *workload-aware histogram*, which they call *STHoles*. Rather than an arbitrary overlap, a *STHoles* histogram $H_{ST}(D)$ allows bucket nesting, thus achieving the definition of the so-called *bucket tree*. Query-workloads are handled as follows: the query result stream Q^R to be analyzed is intercepted and, for each query Q_j belonging to Q^R and for each bucket b_i belonging to the current bucket tree, the number $|Q_j \cap b_i|$ is counted. Then, "holes" in b_i for regions of different *tuple density* are "drilled" and "pulled out" as children of b_i. Finally, buckets of similar densities are merged in such a way as to keep the number of buckets constant. $H_{ST}(D)$ makes use of a tree-like in-memory-data-structure, since the parent-child relationship in a tree is comparable to the nest relationship, and the sibling-sibling relationship is represented by buckets nested within the same external bucket, (nested buckets look-like holes within external buckets—the name *STHoles* comes from this). The construction algorithm of $H_{ST}(D)$ does not take into account the original data set; indeed, the needed information is instead gathered by inspecting the target query-workload and query feedbacks. This amenity makes $H_{ST}(D)$ *self tunable*, that is, adaptable to updates and modifications in the original data cube. On the basis of this approach, a relevant amount of the total storage space available for housing the histogram is invested in representing "heavy-queried regions," thus providing a better approximation for such regions, whereas a fewer storage space is reserved to "lowly-queried regions," admitting some inaccuracy (however, tolerable in OLAP context (Cuzzocrea, 2005a)) for such regions. More specifically, $H_{ST}(D)$ construction algorithm is outlined in the following. Given an input data cube L and a query-workload $QWL = \{Q_0, Q_1, ..., Q_{|QWL|-1}\}$, for each query $Q_j \in QWL$ at iteration *j*, new buckets are generated by intersecting each bucket b_i of the current partition $P_j(L)$ with Q_j, thus determining the set of candidate buckets $U = \{b_c \mid b_c = Q_i \cap b_i, b_i \in P_j(L), Q_i \in QWL, Q_i \cap b_i \neq \emptyset\}$; if such buckets have densities notably different from their parents' ones, then these new buckets are definitively added to the current partition. This process is iterated until the histogram reaches the maximum number of allowed buckets (i.e., the whole available storage space

is consumed). At this point, in order not to exceed the given amount of storage space, after candidate buckets are added to the current partition, the algorithm finds couples of buckets linked together by either a parent-child relationship or a sibling-sibling relationship, and having the closest densities. The size reduction is accomplished by performing either a parent-child or a sibling-sibling merge between the components of these couples, until the histogram fits within the given amount of storage space. A thorough set of experimental results on both real-life and synthetic data sets demonstrates that *STHoles* overcomes performance of *Equi-Depth*, *MHist*, and *GenHist*; in addition to this, (Bruno et al., 2001) authors also show that, on the DBMS Microsoft SQL Server, query-workload analysis overheads introduced by *STHoles* are very low, less than 10 percent of the overall DBMS throughput.

T*unable*-**p***artition-tree* (**TP**-*Tree*), proposed by Cuzzocrea & Wang (2007), is a tree-like, highly-dynamic data structure that codifies a multidimensional histogram for massive (multidimensional) data cubes, denoted by $H_{TP}(D)$, whose partition *varies over time* according to the query-workload against the target OLAP server. For this reason, partitions of $H_{TP}(D)$ are named as *tunable partitions*, and $H_{TP}(D)$ is said to be a "workload-aware" synopsis data structure. This approach resembles that proposed by Bruno et al. (2001). The main contribution of the **TP**-*Tree* proposal with respect to previous techniques consists in introducing models and algorithms having low computational costs, whereas previous techniques are, usually, time-consuming and resource-intensive. Data stored inside buckets of **TP**-*Tree* partitions are obtained by (*i*) *sampling* the input data cube (from this solution, low computational costs required by the **TP**-*Tree* approach follow), and (*ii*) separately representing, storing, and indexing *outliers* via high performance *quad-tree* based (data) structures. Outlier management is another innovative and relevant contribution of the **TP**-*Tree* proposal, as it allows us to provide *probabilistic guarantees* over the degree of approximation of the answers, which is a leading research topic very often neglected by the research community (for instance, see (Cuzzocrea, 2005b)). Finally, the **TP**-*Tree* data organization is characterized by a hierarchical and multi-resolution nature, which allows us to efficiently answer relevant-in-practice classes of OLAP queries, like range-queries.

FUTURE TRENDS

For what regards the basic problem of computing histograms, in order to achieve more and more sophisticated representations beyond actual capabilities of state-of-the-art techniques, next years' challenges for histogram research are the following. (*i*) *Error guarantees*. No one of the surveyed state-of-the-art techniques consider the relevant issue of building histograms capable of ensuring a fixed threshold over the (query) error due to the approximate evaluation of queries against such data structures. Indeed, the next frontier of histogram research is represented by the challenge of ensuring error guarantees over the final data structures; some initiatives devoted to fill the actual gap in this context are (Cuzzocrea & Wang, 2007; Koudas et al., 2000), whereas similar efforts in wavelet-based database and data cube approximation, which is a research issue close to ours, are Garofalakis and Gibbons (2002); Garofalakis and Kumar (2004). (*ii*) *Flexibility for wide families of queries*. One of the most important limitations of histograms is the fact that they are "build-one-use-many-times" data structures, meaning that state-of-the-art techniques construct histograms for a *specific* family of queries, for example, those given by typical query-workloads of the target DBMS/OLAP server, so that it could happen to obtain high accuracy on certain queries, and, contrarily, low accuracy on different queries. This is a problematic issue to be handled, and can be reasonable considered as a leading open problem for histogram research.

Also in-consequence-of influencing insights given by Ioannidis (2003), for what regards the integration of histogram-based techniques with other popular data-intensive techniques, main future directions can be summarized by the following points. (*i*) *Integration of histogram-based and clustering techniques*. Computing *clusters* of a given item set defines the same problem of computing a histogram as a collection of buckets over that item set, given that (*i*) clustering is, similarly to histogram-based ones, a partition-based technique, and (*ii*) buckets are conceptually the same of clusters, since in clustering we want to generate clusters such that intra-cluster distance is small and extra-bucket distance is big, and, symmetrically, in buckets we aggregate data having, for instance, low variance (which, in turn, is a *distance*-based metrics), whereas among buckets we want to obtain big variance. In literature, there exists a wide number of clustering techniques, so that it is very interesting to study how these proposals can be applied to the problem of computing histograms, and, specifically, multidimensional histograms, given that research communities have devoted a great deal of attention to the problem of clustering high-dimensional domains. (*ii*) *Integration of histogram-based and pattern recognition techniques*. Choosing the parameters according to which computing buckets (e.g., variance, skewness, etc.) is similar to the problem of establishing which parameters are similar for items of a given item set in order to group items according to these parameters. The simplest case of such kind of problems is to choose a dimension among all the dimensions of a given domain to grouping/clustering purposes. Specifically, this general problem is recognized in literature as the *pattern recognition problem*. Just like the histograms/clustering symmetry, it is also very interesting to study how pattern recognition techniques can influence

histogram research. (*iii*) *Integration of histogram-based and tree-like indexing techniques*. A hierarchical indexing data structure is very similar to a *hierarchical histogram*, where each level is partitioned according to a criterion that is inspired to classical histogram-based techniques. This similarity leads to, from a side, (*i*) the definition of high-performance indexing data structures for massive data sets that exploit consolidate results of histogram research, and, from the other side, (*ii*) the idea of adopting successful methodologies of RDBMS indexes (e.g., B^+-trees, *R*-trees, etc.) to the problem of computing histograms for one-dimensional and multidimensional domains.

CONCLUSION

Due to an impressive proliferating of data-intensive systems in real-life applications, the problem of compressing massive databases and data cubes play a critical role in database and data warehouse research. On the other hand, this problem has significantly stimulated research communities during the last two decades, and, presently, it continues attracting attention and efforts of research communities, also thanks to innovative, previously-unrecognized knowledge production, processing, and fruition paradigms drawn by emerging technologies like those of data stream management systems and sensor network data management systems. In consequence of this, a plethora of database and data cube compression techniques have been proposed in literature, with different aims and goals (and fortune). Among these, histogram-based techniques are a very popular solution of tackling research challenges posed by compressing massive databases and data cubes, and have been extensively studied and investigated since early 1980 and before. The result we observe at now is a wide literature on histogram-based techniques, which, in our opinion, will continue to stimulate research communities towards investigating new and exciting problems that, basically, concern the core layer of DBMS and OLAP servers, with also important influences on commercial platforms. Given these considerations, in this article we surveyed state-of-the-art histogram-based techniques for compressing databases and data cubes, ranging from one-dimensional to multidimensional data domains. As an additional contribution, a simple-yet-effective taxonomy of histograms has been provided.

KEY TERMS

Multidimensional OLAP (MOLAP): An in-memory-storage model that represents a multi-dimensional data cube in form of a multi-dimensional array.

OLAP Query: A query defined against a data cube that introduces a multidimensional range (via specifying an interval for each dimension of the data cube) and a SQL aggregate operator, and returns as output the aggregate value computed over cells of the data cube contained in that range.

Online Transaction Processing (OLTP): A methodology for representing, managing and querying DB data generated by user/application transactions according to flat (e.g., relational) schemes.

Online Analytical Processing (OLAP): A methodology for representing, managing and querying massive DW data according to multidimensional and multi-resolution abstractions of them.

Relational Query: A query defined against a database that introduces some predicates (e.g., Boolean) over tuples stored in the database, and returns as output the collection of tuples satisfying those predicates.

Selectivity of an OLAP Query: A property of an OLAP query that estimates the cost required to evaluate that query. It is usually model in terms of the geometrical volume of the query range.

Selectivity of a Relational Query: A property of a relational query that estimates the cost required to evaluate that query. It is usually model in terms of the number of tuples involved by the query.

Historical Overview of Decision Support Systems (DSS)

Udo Richard Averweg
eThekwini Municipality and University of KwaZulu-Natal, South Africa

INTRODUCTION

During the late 1970s the term "decision support systems" was first coined by P. G. W. Keen, a British Academic then working in the United States of America. In 1978, Keen and Scott Morton published a book entitled, *Decision Support Systems: An Organizational Perspective* (Keen & Scott Morton, 1978), wherein they defined the subject title as computer systems having an impact on decisions where computer and analytical aids can be of value but where the manager's judgment is essential. Information systems (IS) researchers and technologists have developed and investigated decision support systems (DSS) for more than 35 years (Power, 2003b).

The structure of this article is as follows: The background to DSS will be given. Some DSS definitions, a discussion of DSS evolution, development of the DSS field and frameworks are then presented. Some future trends for DSS are then suggested.

BACKGROUND

Van Schaik (1988) refers to the early 1970s as the era of the DSS concept because during this period the concept of DSS was introduced. DSS was a new philosophy of how computers could be used to support managerial decision-making. This philosophy embodied unique and exciting ideas for the design and implementation of such systems. There has been confusion and controversy in respect of the interpretation of the decision support system notion and the origin of this notion originated in the following terms:

- **Decision** emphasises the primary focus on decision-making in a problem situation rather than the subordinate activities of simple information retrieval, processing or reporting.
- **Support** clarifies the computer's role in aiding rather than replacing the decision maker.
- **System** highlights the integrated nature of the overall approach, suggesting the wider context of machine, user and decision environment.

DSS deal with semi-structured and some unstructured problems.

DECISION SUPPORT SYSTEMS

With the ever-increasing advances in computer technology, new ways and means of computer-assisted decision-making was born. As a result hereof, over the passage of time, different DSS definitions arose:

- Little (1970) defines DSS as a "model-based set of procedures for processing data and judgments to assist a manager in his decision making (*sic*)."
- The classical definition of DSS, by Keen and Scott Morton (1978), states that "Decision Support Systems couple the intellectual resources of individuals with the capabilities of the computer to improve the quality of decisions. It is a computer-based support system for management decision makers who deal with semi-structured problems."
- Mann and Watson (1984) state that "a decision support system is an interactive system that provides the user with easy access to decision models and data in order to support semi-structured and unstructured decision-making tasks."
- Bidgoli (1989) defines DSS as "a computer-based information system consisting of hardware/software and the human element designed to assist any decision-maker at any level. However, the emphasis is on semi-structured and unstructured tasks."
- Sprague and Watson (1996) define a DSS as computer-based systems that help decision makers confront ill-structured problems through direct interaction with data and analysis models.
- Sauter (1997) notes that DSS are computer-based systems that bring together information from a variety of sources, assist in the organisation and analysis of information and facilitate the evaluation of assumptions underlying the use of specific models.
- Turban, Rainer, and Potter (2005) broadly define a DSS as "a computer-based information system that combines models and data in an attempt to solve semi-structured and some unstructured problems with extensive user involvement."

From these definitions it seems that the basis for defining DSS has been developed from the perceptions of what a DSS

does (e.g., support decision-making in semi-structured or unstructured problems) and from ideas about how a DSS's objectives can be accomplished (e.g., the components required and the necessary development processes).

Bidgoli (1989) contends that as the DSS field is in a state of flux, an exact definition of DSS is elusive. Turban (1995) indicates that previous researchers have collectively ignored the central issue in DSS; that is, "support and improvement of decision-making". Bidgoli (1989) suggests that there are several requirements for a DSS which must embrace a definition of a DSS. These are that a DSS:

- requires hardware;
- requires software;
- requires human elements (designers and end-users);
- is designed to support decision-making;
- should help decision makers at all levels; and
- emphasises semi-structured and unstructured tasks.

Turban (1995) states that there is no consensus on what a DSS is and there is therefore no agreement on the characteristics and capabilities of DSS. As the definition by Turban et al. (2005) underscores Bidgoli's (1989) DSS requirements, for the purposes of this article, the DSS definition by Turban et al. (2005) will be used.

Evolution of DSS

During the 1970s and 1980s, the concept of DSS grew and evolved into a field of research, development and practice (Sprague & Watson, 1996). Clearly DSS was both an evolution and a departure from previous types of computer support for decision-making.

Currently DSS can be viewed as a third generation of computer-based applications. Sprague and Watson (1996) note that initially there were different conceptualisations about DSS. Some organisations and scholars began to develop and research DSS which became characterised as *interactive* computer based systems which *help* decision makers utilise *data* and *models* to solve *unstructured* problems. According to Sprague & Watson (1974), the unique contribution of DSS resulted from these key words. However, a serious definitional problem arose in that the words had certain "intuitive validity"—any system that supports a decision (in any way) is a "decision support system". This term had such an instant intuitive appeal that it quickly became a "buzz word" (Sprague & Watson, 1996). However, neither the restrictive nor the broad DSS definition provided guidance for understanding the value, the technical requirements or the approach for developing and implementing a DSS. For a discussion of DSS implementation, see, for example, Averweg (1998).

Development of the DSS Field

According to Sprague and Watson (1996), DSS evolved as a "field" of study and practice during the 1980s. During the early development of DSS, several principles evolved. Eventually, these principles became a widely accepted "structural theory" or framework—see Sprague and Carlson (1982). The four most important of these principles are summarised:

- **The DDM Paradigm:** The technology for DSS must consist of three sets of capabilities in the areas of **d**ialog, **d**ata and **m**odelling and what Sprague and Carlson call the DDM paradigm. The researchers make the point that a good DSS should have *balance* among the three capabilities. It should be *easy to use* to allow non-technical decision makers to interact fully with the system. It should have access to a *wide variety of data* and it should provide *analysis and modelling* in a variety of ways. Sprague and Watson (1996) suggest that many early systems adopted the name DSS when they were strong in only one area and weak in the other. Figure 1 shows the relationship between these components in more detail and it should be noted that the models in the model base are linked with the data in the database. Models can draw coefficients, parameters and variables from the database and enter results of the model's computation in the database. These results can then be used by other models later in the decision-making process.
  Figure 1 also shows the three components of the dialog function wherein the database management system (DBMS) and the model base management system (MBMS) contain the necessary functions to manage the data base and model base respectively. The dialog generation and management system (DGMS) manages the interface between the user and the rest of the system.
- **Levels of Technology:** Three levels of technology are useful in developing DSS and this concept illustrates the usefulness of configuring *DSS tools* into a *DSS generator* which can be used to develop a variety of *specific DSS* quickly and easily to aid decision makers—see Figure 2. The system which actually accomplishes the work is known as the *specific DSS*, shown as the circles at the top of the diagram. It is the software/hardware that allow a specific decision maker to deal with a set of related problems. The second level of technology is known as the *DSS generator*. This is a package of related hardware and software which provides a set of capabilities to quickly and easily build a specific DSS. The third level of technology is *DSS tools* which facilitate the development of either a DSS generator or a specific DSS.

Figure 1. The components of DSS (Source: Adapted from Sprague & Watson, 1996)

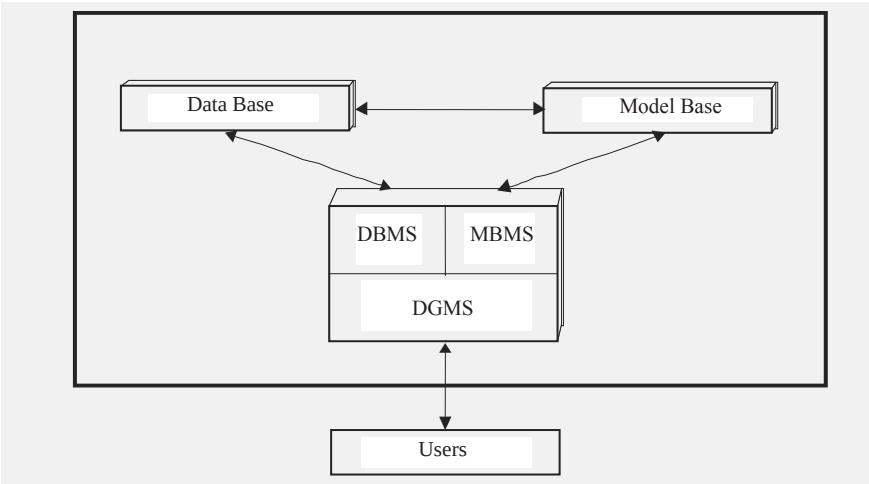

Figure 2. Three levels of DSS technology (Source: Adapted from Sprague & Watson, 1996)

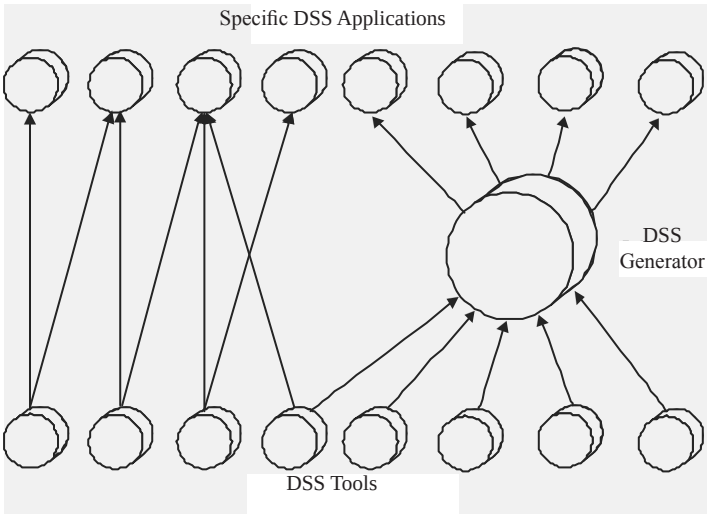

While new technologies such as World Wide Web ("Web") browsers and data warehouses have emerged since Sprague and Watson's (1996) conceptual framework, nowadays the framework is still relevant.

- **Iterative Design:** Instead of the traditional development process, DSS require a form of iterative development which allows them to evolve and change as the problem or decision situation changes. They need to be built with short, rapid feedback from users thereby ensuring that development is proceeding correctly. In essence they must be developed to permit change quickly and easily.
- **Organisational Environment:** The effective development of DSS requires an organisational strategy to build an environment within which such systems can originate and evolve. The environment includes a group of people with interacting roles, a set of software and hardware technology, a set of data sources and a set of analysis models.

The IS called DSS are not all the same. DSS differ in terms of capabilities and targeted users of a specific system and how the DSS is implemented and what it is called (Power, 2003a). Some DSS focus on data, some on models and some on facilitating collaboration and communication. DSS can also differ in terms of targeted users, for example, a "primary" user or "generic" users.

Holsapple and Whinston (1996) identified five specialised types of DSS:

- Text-oriented;
- Database-oriented;
- Spreadsheet-oriented;
- Solver-oriented; and
- Rule-oriented.

Donovan and Madnick (1977) classified DSS as *ad hoc* DSS or institutional DSS. An *ad hoc* DSS supports problems that are not anticipated and which are not expected to reoccur. An institutional DSS supports decisions that reoccur. Hackathorn and Keen (cited in Power, 2003a) identified DSS into three interrelated categories:

- Personal DSS;
- Group DSS; and
- Organisational DSS.

DSS Frameworks

Power (2003a) suggests that the following DSS frameworks help categorise the most common DSS currently in use:

- **Communications-Driven DSS:** These systems are built using communication, collaboration and decision support technologies.
- **Data-Driven DSS:** These systems analyse large "pools of data" found in major organisational systems and they support decision-making by allowing users to extract useful information that was previously buried in large quantities of data. Often data from various transactional processing systems (TPS) are collected in data warehouses for this purpose. Online analytical processing (commonly known as OLAP) and data mining can then be used to analyse the data.
- **Document-Driven DSS:** These systems integrate a variety of storage and processing technologies to provide complete document retrieval and analysis.
- **Knowledge-Driven DSS:** These systems contain specialised problem-solving expertise wherein the "expertise" consists of knowledge about a particular domain (and understanding of problems within that domain) and "skill" at solving some of those problems.
- **Model-Driven DSS:** Early DSS developed in the late 1970s and 1980s were model driven as they were primarily standalone systems isolated from major organisational IS that used some type of model to perform "what if" and other kinds of analysis. Such systems were often developed by end-user groups or divisions not under central IS control (Laudon & Laudon, 1998). A DSS is not a black box—it should provide the end-user with control over the models and interface representations used (Barbosa & Hirko, 1980). Model-driven DSS emphasise access to and manipulation of a model.

Watson (2005) suggests that "I don't think that we need to find a single theory or framework. Furthermore, I don't think that we will see a single overarching theory emerge. Rather, there will be multiple theories, each one being appropriate for specific situations". Despite all the rapid developments of the late 1980s, 1990s, and early 2000s, DSS as a field is now at a crossroads. Some functions that were once considered part of DSS now appear to be migrating to other areas. For example, Watson (2005) suggests that there is an increasing trend to integrate and embed decision support applications into operational systems (e.g., fraud detection system embedded in credit card processing).

FUTURE TRENDS

In future, it is envisaged that traditional DSS applications will be extended to a larger number of potential applications where the data required is only an interim stage or a subset of the information required for the decision. This will require the construction of DSS where the end-user can concentrate on the variables of interest in their decision while "other" processing is performed without the need of extensive end-user interaction. Some future trends for DSS are suggested:

- Organisations that consolidate there is into a single environment reduce administration and license costs. By consolidating organisational data into a Web visualisation application, will facilitate better decision support.
- All organisations use metrics and key performance indictors to undertaken business and remain competitive. With the advent of Web-based technologies (e.g., portal technologies), a decision support portal will be able to present key information to the right audience.
- In the future all data collection and analysis will be automated. This will "free up" domain experts from verifying the validity of data from TPS and data warehouses allowing them to *act* on the information from DSS instead.
- There will be an increase in visualised information in context with user-centric displays. By having the most recent data correlated and aggregated, will allow for better decisions and which are more relevant to a user's current conditions.
- There will be a surge to use advanced display techniques to highlight key issues. Consequently the design of future DSS interfaces will receive greater prominence since the interface should bring attention to the most important areas almost immediately.
- Decision support technology will continue to broaden to include monitoring, tracking and communication tools to support the overall process of unstructured

problem solving. The broadening of this technology will be as a result of an increased availability of mobile computing and communication.

CONCLUSION

DSS continue to impact decision-making in organisations and this is largely dependent on the nature of the application. In order that optimal solutions may be identified, more alternatives may need to be explored and some decisions may need to be automated. The Internet and the Web have accelerated developments in decision support and decision-making and nowadays provide a new research focus area for DSS development and implementation.

KEY TERMS

Analytical Processing: Involves analysis of accumulated data, frequently by end-users in an organisation. Analytical processing activities include data mining, decision support and querying.

Communications-Driven DSS: Systems built using communication, collaboration and decision support technologies.

Data-Driven DSS: These systems analyse large "pools of data" found in major organisational systems and they support decision-making by allowing users to extract useful information that was previously buried in large quantities of data.

Data Warehouse: A repository of subject-oriented historical data that is organised to be accessible in a form readily acceptable for analytical processing activities.

Document-Driven DSS: These systems integrate a variety of storage and processing technologies to provide complete document retrieval and analysis.

Information Systems (IS): A combination of technology, people and process to capture, transmit, store, retrieve, manipulate and display information.

Knowledge-Driven DSS: These systems contain specialised problem-solving expertise wherein the "expertise" consists of knowledge about a particular domain.

Model-Driven DSS: Model-driven DSS emphasise access to and manipulation of a model.

History of Artificial Intelligence

Attila Benkő
University of Pannonia, Hungary

Cecília Sik Lányi
University of Pannonia, Hungary

INTRODUCTION

George Boole was the first to describe a formal language for logic reasoning in 1847. The next milestone in artificial intelligence history was in 1936, when Alan M. Turing described the Turing-machine. Warren McCulloch and Walter Pitts created the model of artificial neurons in 1943, and it was in 1944 when J. Neumann and O. Morgenstern determined the theory of decision, which provided a complete and formal frame for specifying the preferences of agents. In 1949 Donald Hebb presented a value changing rule for the connections of the artificial neurons that provide the chance of learning, and Marvin Minsky and Dean Edmonds created the first neural computer in 1951.

Artificial intelligence (AI) was born in the summer of 1956, when John McCarthy first defined the term. It was the first time the subject caught the attention of researchers, and it was discussed at a conference at Dartmouth. The next year, the first general problem solver was tested, and one year later, McCarty—regarded as the father of AI—announced the LISP language for creating AI software. Lisp, which stands for list processing, is still used regularly today.

Herbert Simon in 1965 stated: "Machines will be capable, within twenty years, of doing any work a man can do." However, years later scientists realized that creating an algorithm that can do anything a human can do is nearly impossible. Nowadays, AI has a new meaning: creating intelligent agents to help us do our work faster and easier (Russel & Norvig, 2005; McDaniel, 1994; Shirai & Tsujii, 1982; Mitchell, 1996; Schreiber, 1999).

Perceptrons was a demonstration of the limits of simple neural networks published by Marvin Minsky and Seymour Papert in 1968. In 1970, the first International Joint Conference on Artificial Intelligence was held in Washington, DC.

PROLOG, a new language for generating AI systems, was created by Alain Colmerauer in 1972. In 1983, Johnson Laird, Paul Rosenbloom, and Allen Newell completed CMU dissertations on SOAR.

BACKGROUND

In 1950 Alan Turing suggested a definition for deciding whether software is intelligent or not. In his theory the software's intelligent behavior can be measured like a human intellectual efficiency. The software is intelligent when a human being does not know if he or she is chatting with the software or with another human. That test was called the Turing test, and here is how it works: if the software passes the test, it is called intelligent software—also called intelligent agent—which percepts the environment with sensors and acting with effectors.

The term *embodied conversational agent* (ECA) (Cassel, 2007; Huget, 2003; Cassel, Sullivan, Prevost, & Churchill, 2000) is used for special software or hardware as an extension of an intelligent agent, not just because these are able to communicate with the user via natural language, but also for their emotion system (Benkő & Sik Lányi, 2007). There are many emotional models (Ruebenstrunk, 1998) for creating an embodied conversational agent, including:

- Theory of Ortony, Clore and Collins;
- Theory of Roseman;
- Theory of Scherer;
- Theory of Frijda; and
- Theory of Oatley and Johnson-Laird.

Virtual reality (VR) can be used for designing and testing an ECA because the developing process can be easier and cheaper with VR technology (Ortiz, Oyarzun, Carretero, & Nestor, 2006; Takacs & Kiss, 2003). An avatar is a spatial creature that usually symbolizes or simulates a human being in exterior and in behavior also. The next article describes the VTR, the modeled emotions, and the avatars that were created for a virtual therapy room.

INTELLIGENT AGENTS WITH EMOTIONS

The term *embodied conversational agent* (Cassel et al., 2000) stands for intelligent software with an emotion system

that simulates human emotions. Churchill, Cook, Hodgson, Prevost, and Sullivan (2000) described the method of designing ECA using scenarios and storyboards. The levels of description and the embodied agent issues were determined as personality, appearance, communication, and domain expertise. The dimensions of agent embodiment were also described by them.

The method of the communication via conversational dialogs and the aspects of human-computer interaction were discussed by Ball and Breese (2000). Computational models of emotions and the problem of recognizing human emotions were also discussed.

In an ambient intelligent environment, it is important for the user to have a good human-centric computer interface. It is possible to design a more natural interface using the techniques of natural language processing during the development. With such an interface the user is able to communicate with the intelligent environment via natural language. A virtual therapy room (Benkő & Sik Lányi, 2007) was created for aphasic patients. With the VTR the therapist can furnish the room, and the patient can practice at home also. During the therapy, patients can learn to express their emotions in a good way. Therapy is represented by special exercises created for practicing communication. Avatars in a virtual therapy room with the methods of artificial intelligence can answer the user's questions. Emotions can also be expressed by the avatars. The emotion system of an avatar was described as a deterministic finite automaton, and it uses the emotion model of Oatley.

An avatar is the virtual therapist or the virtual patient in the exercise. Usually, there are several virtual patients and only one therapist. They are sitting behind the table. The arrangement can be altered, but it is essential for the patient to think that the user interface is convenient and appropriate to solve exercises. Exercises are appearing on the virtual blackboard. Patients are capable of doing exercises like in a real therapy room.

Oatley assumed a hierarchy of parallel working processing instances, which work on asynchronously different tasks. A central control system—also called an operating system—manages the instances. The control system has a model from the entire system. Two kinds of communication—symbolical and emotional—exist between the modules. The name "Communicative Theory of Emotions" was chosen because it is the task of emotions to convey certain information to all modules of the overall system.

Introverted or extroverted personalities can be created with a push-down automaton-controlled emotion system. The methods of artificial intelligence can be used for creating more intelligent ECAs. The therapist decides the avatars' exterior and interior characteristics based on the type of the therapy and the abilities of the aphasic patients. Generating the ECA's knowledge base is also important in order to make progression in therapy and develop the communication abilities of the patients. VTR can also be used for language teaching because the exercises can be modified by the therapist. Integrating a text-to-speech engine and sound recognition engine provides user friendliness. The emotion model can be improved also.

El-Nasr, Ioerger, and Yen (2000) presented a fuzzy logic adaptive model of emotions. A new computational model of emotions was proposed that can be incorporated into intelligent agents and other complex, interactive software. It uses a fuzzy logic representation to map events and observations to emotional states. The model includes several inductive learning algorithms for learning patterns of events, associations among objects, and expectations. The adaptive components of the model are crucial to users' assessments of the believability of the agent's interactions.

FUTURE TRENDS

Dr. Rodney Brooks, the director of MIT's artificial intelligence laboratory, says that right now, AI is about at the same place as the PC industry was in 1978. Within 30 years, we will have an understanding of how the human brain works that will give us "templates of intelligence" for developing strong AI, and by 2050, our lives will be populated with all kinds of intelligent robots.

"Referring to Spielberg's movie AI in which a company creates a robot that bonds emotionally like a child, Dr. Brooks says: 'A scientist doesn't wake up one day and decide to make a robot with emotions.' Despite the rapid advance of technology, the advent of strong AI will be a gradual process, they say. 'The road from here to there is through thousands of these benign steps,' Mr. Ray Kurzweil says." (BBC News, 2001)

CONCLUSION

Because of the combinatorial explosion, there is no algorithm that can solve all types of problems. Every agent has its own knowledge base, each fit for only a specific field of science. In the early 1980s these types of software were called expert systems because they have special knowledge based on human experiences. Nowadays, expert systems are used in hospitals to help the doctor diagnose a disease or in geology to identify materials. There are many types of expert systems, and they can give very good advice to humans. In the future, expert systems are going to be necessary in our everyday life as well.

However, in addition to expert systems, another form of artificial intelligence aims to understand the operation of how a human brain functions and simulate its emotions. There are several emotion models already in place that can nearly

describe the emotion changes of a human, but there is no full representation of brain functions. It is still a philosophical question if there is any.

KEY TERMS

Artificial Intelligence: The capability of a device to perform functions that are normally associated with human intelligence, such as reasoning, learning, and self-improvement.

Backward Reasoning: Searching from the initial state to the final state in, for example, action planning.

Bayesian Network: A mathematic model in graphic form that represents a set of variables and their probabilistic independencies. It can be used, for example, to calculate the probability of a patient having a specific disease.

Expert System: A computer program that contains subject-specific knowledge of human experts. Such systems are used for giving advice. Also known as a knowledge-based system.

Forward Reasoning: Searching from the initial state to the final state in, for example, action planning.

Fuzzy Logic: Techniques for reasoning under uncertainty. It is capable of working with concepts such as 'thin', 'fat', 'long', and 'short', if there is no exact data for supporting the decision.

General Problem Solver: Uses means-ends-analysis heuristic for solving formalized symbolic problems. A GPS computer program solves simple problems that can be formalized such as the Towers of Hanoi.

Genetic Algorithm: A method of evolutionary computation for problem solving. There are states also called sequences and a set of possibility final states. Methods of mutation are used on genetic sequences to achieve better sequences.

Heuristic: General advice that is usually efficient but sometimes cannot be used; also it is a validate function that adds a number to the state of the problem.

Intelligent Agent: An agent is an entity with the capability to observe and act in an environment. It is intelligent if it interacts like a human being. It can be a robot or a software system, depending on the environment.

Knowledge Engineering: Related to mathematical logic, and building, maintaining, and developing knowledge-based systems.

Knowledge Representation: Describes how information can be stored efficiently. It uses state space and the information is represented with a graph. States are represented with nodes and actions with arcs.

Neural Network: A computation system containing a set of connected elements to solve arithmetic problems. The basis of the neural network computation is to analyze how the brain works and simulate it.

Robot: A device that performs programmed operations or that operates by remote control. A robot senses external feedback derived from ongoing operations and reacts to sensed data by modifying its actions accordingly.

Searching: A searching problem contains the initial state, the operators, the final state, and the cost of searching. The searching is efficient if it finds an optimal solution if a solution exists and it can be reached in a short time. Searching methods include: blind search (breadth-first, depth-first, depth-limited, iterative deepening, iterative broadening, uniform-cost) and heuristic search (hill-climbing, best-first, A, A*, IDA*, SMA*, simulated annealing).

Strong AI: The main goal of strong AI is to create an AI agent that can *think* and have a *mind.*

Turing Test: Test created by Alan M. Turing, who said that a machine can think. The test analyzes if a person in an isolated room can decide exactly who he or she is chatting with—a human being or an AI agent. The agent is in the other room and the chatting is in written form.

Weak AI: Refers to software to study or solve problems and reasoning tasks that do not need the full range of human cognitive abilities.

History of Artificial Intelligence Before Computers

Bruce MacLennan
University of Tennessee, USA

INTRODUCTION

The history of artificial intelligence (AI) is commonly supposed to begin with Turing's (1950) discussions of machine intelligence, and to have been defined as a field at the 1956 Dartmouth Summer Research Project on Artificial Intelligence. However, the ideas on which AI is based, and in particular those on which symbolic AI (see below) is based, have a very long history in the Western intellectual tradition, dating back to ancient Greece (see also McCorduck, 2004). It is important for modern researchers to understand this history for it reflects problematic assumptions about the nature of knowledge and cognition: assumptions that can impede the progress of AI if accepted uncritically.

BACKGROUND

Symbolic AI is the approach to artificial intelligence that has dominated the field throughout most of its history and remains important. It is based on the physical symbol system hypothesis, enunciated by Newell and Simon (1976), which asserts, "A physical symbol system has the necessary and sufficient means for general intelligent action." In effect, it implies that knowledge is represented in the brain by language-like structures, and that thinking is a computational process that rearranges these structures according to formal rules. This view has also dominated cognitive science, which applies computational concepts to understanding human cognition (Gardner, 1985).

Many symbolic AI systems are based on formal logic, which represents propositions by symbolic structures, in which all meaning is conveyed in the structure's form, and which implements inference by the mechanical manipulation of those structures. Therefore, we will discuss the origins of formal logic and of the idea that knowledge and inference can be represented in this way. We will also consider the combinatorial methods used before the invention of computers as well as in modern AI for generating possible solutions to a problem, which leads to combinatorial explosion, a fundamental limitation of symbolic AI. Then we describe early modern attempts to design comprehensive knowledge representation languages (predecessors of those used in symbolic AI) and mechanical inference machines. We conclude with a mention of alternative views of knowledge and cognition.

THE HISTORICAL ROOTS OF SYMBOLIC AI

Formal Logic

It is surprising, perhaps, that the original inspiration for symbolic knowledge representation can be found in ancient Greece, in particular in Pythagorean number theory (Burkert, 1972, Riedweg, 2005). In ancient Greece, as in many cultures, ancient and modern, pebbles were used for calculation by being moved in grooves in a similar way to the beads on an abacus. Indeed, the Latin word for *pebble* is *calculus*, and our word *calculate* comes from this manipulation of *calculi* (pebbles). In logic and mathematics, we use the word *calculus* for any system of notation in which we can accomplish some purpose by the manipulation of tokens according to formal, game-like, mechanical rules. (For example we have differential and integral calculi in mathematics and propositional and predicate calculi in logic.) To the extent that the rules are purely mechanical, they can, in principle, be carried out by a machine, which is why calculi are important in AI; if a process can be reduced to a calculus, it can be calculated by a machine.

The ancient Pythagoreans (Pythagoras, 572–497 B.C.E.) investigated number theory by means of arrangements of pebbles (Burkert, 1972; Riedweg, 2005). For example, they observed that certain numbers could be arranged into a square shape, and we still call these numbers *squares*. However, they also investigated triangular numbers as well as rectangles, pentagons, cubes, pyramids, and so forth. Although they did not prove theorems in the modern sense, they were able to demonstrate the truth of theorems in number theory by means of these arrangements. Thus, they discovered calculi could be used for reasoning as well as computation.

According to tradition, Pythagoras was the first to explain consonant musical intervals in terms of numerical ratios (Burkert, 1972). For example, a string one-half the length of another string sounds an octave higher; the shorter of two strings of lengths with the ratio 2:3 sounds a fifth higher, and so forth. Thus, a subtle perceptual distinction (the rela-

tive consonance of pitches) could be rendered logical and rational by reducing it to numerical ratios (Greek *logoi* and Latin *rationes*, terms that also refer to the articulation of thought in words or symbols; Maziarz & Greenwood, 1968). It is an example of the representation of expertise in terms of formal structures; judgments of consonance can be replaced by calculation.

The Pythagoreans believed that everything could be reduced to numbers and thus made intelligible, rational, and logical (Burkert, 1972; Burnet, 1930). Therefore, they were committed to the idea that all knowledge could be represented in terms of arrangements of otherwise meaningless tokens, that is, in formal structures (and hence, we may conclude, in computer data structures).

Aristotle (384-322 B.C.E.) is known as the originator of the science of logic, but two of his contributions in this area are especially relevant to AI. First, he began the development of formal logic by showing that valid inference could be distinguished from invalid inference on the basis of its form rather than on the meaning of its particular terms (words). In other words, Aristotle showed that valid inference is a matter of syntax (the grammatical form of an argument) rather than semantics (its meaning). This is important because it shows how inference can be carried out by the manipulation of symbols independently of their meaning, which means that, in principle, inference is a kind of computation. Stated differently, there is a calculus of valid inference.

Aristotle also began the study of modal logic, that is, logic in which propositions are not simply true or false, but in which the propositions may be possible, impossible, necessary, or contingent (Bocheński, 1970; Kneale & Kneale, 1962). Modal logic and its derivatives (such as tense logic, which deals with propositions whose truth values may change in time) are important in AI (Sowa, 1984).

Another contribution of Aristotle was the organization of knowledge into formal deductive structures, in which all the facts of a science were either stated as axioms or formally derivable from the axioms. The best-known example is Euclidean geometry, which was the exemplar of a systematic body of knowledge for over two millennia (Maziarz & Greenwood, 1968). Similar formal axiomatic structures are used in AI for representing a knowledge domain.

The investigation of logic continued over the following centuries. For example, the medieval scholastics (roughly 6th to15th centuries) refined logic into a very precise instrument, although it was still based on a natural language (Latin) in contrast to modern symbolic logic. As a consequence, they became conscious of the limitations of natural language for exact knowledge representation and strove to compensate for its deficiencies. For example, they knew that the word *dogs* is used differently in the propositions "dogs are mammals" and "*dogs* is a plural noun." AI knowledge representation languages have to deal with similar issues (Sowa, 1984). In the end, dissatisfaction with natural languages led to an interest in developing artificial languages that were intended to be more rational (logical and precise). Behind this was the assumption that there is a universal grammar underlying all natural languages, and that it corresponds to the "language of thought"; therefore an artificial language, as an ideal vehicle for thought, ought to reflect this deep structure. Similar motivations underlie the development of AI knowledge representation languages (see below).

Combinatorial Methods

The Middle Ages also saw the development of combinatorial approaches to solving problems (Bocheński, 1970). For example, the medieval scholastics used a combinatorial procedure to generate the 192 possible Aristotelian syllogisms, and then they crossed out the invalid ones. This is an example of a generate-and-test procedure, an approach still widely used in AI. The problem with generate-and-test procedures is combinatorial explosion: The number of combinations to be tested increases exponentially with their size.

These combinatorial procedures acquired an increased significance, which contributed to the eventual development of AI, from the kabbalah, a Jewish mystical tradition with Pythagorean affinities, which became popular in the Middle Ages (Eco, 1997; Scholem, 1960). According to this tradition, the text of the Torah reflects the logos (rational structure) of the universe. Therefore, since the Torah is written in the letters of the Hebrew alphabet, these letters correspond to the elementary categories and archetypal forms underlying the universe. As a consequence, the letters of the Hebrew words for things reveal their logical structure to one who knows how to interpret them. Combinatory processes figure prominently in kabbalah, and significant words, especially the names of God, were permuted in order to reveal hidden wisdom and discover new truths. For this purpose the kabbalists used rotating wheels and other devices to ensure that they did not omit any combinations of letters, an example of a mechanized generate-and-test procedure.

Similar in spirit to the kabbalah, and perhaps in part inspired by it, was the Great Art (Ars Magna) of Raymond Lull (also spelled Llull, 1232-1315; Bonner, 1985; Johnston, 1987; Yates, 1966). He intended it to be a "universal science of all sciences," a systematic method by which knowledge could be discovered and proved. There were several versions of his system, but the most common one made use of nine "divine dignities," or attributes of God, which took different forms in each domain of knowledge but provided the fundamental categories in each domain. These abstract qualities (Goodness, Magnitude, Duration, etc.) correspond closely to certain kabbalistic names of God. In Lull's Art, as in kabbalah, we see an attempt to isolate the most basic categories that constitute all knowledge and to discover, therefore, an alphabet of thought. This remains an important goal in contemporary symbolic AI.

A distinctive characteristic of Lull's Art was the extensive use of rotating wheels to generate combinations of these elementary categories in order to discover and to demonstrate philosophical truths. Thus, the Great Art combines an alphabet of elementary concepts with mechanical procedures for generating their combinations in order to produce an automated method of knowledge discovery and proof. Such, at least, was its goal. In fact, it did not work, and for the most part it could be used only for proving the theological propositions that the operator already believed. Nevertheless, it inspired many later thinkers to attempt to correct its deficiencies and to construct machines for knowledge discovery and inference, but first it had to be recast into a more logical form.

Knowledge Representation and Mechanized Inference

As knowledge and inference became more systematized, the idea developed that reasoning, when carefully and methodically executed, was a kind of calculation. One clear exponent of this view was Thomas Hobbes (1588-1679), who said, "By *ratiocination* I mean *computation*" (*Elem. Phil.*, 1.1.1.2). He explained, however, that the addition and subtraction of concepts was not the same as the addition and subtraction of numbers.

Hobbes also distinguished reasoning from causes to their effects (forward chaining in modern AI terminology) and reasoning from effects to their causes (backward chaining). In both cases, thought is a kind of mental discourse, which corresponds to a defining assumption of symbolic AI: that there is a language of thought (sometimes called "Mentalese"). Words, whether external or in the mind, are tokens, manipulated according to mechanical rules, and correct reasoning is analogized to balancing account books. That is, thought is calculation. Furthermore, since Hobbes was a complete materialist, he understood thought as a kind of matter in motion, a strictly mechanical process.

Over the centuries there have been many attempts to design ideal languages, that is, artificial languages without the perceived deficiencies of natural languages (Eco, 1997; Large, 1985). As modern science emerged in the 17th century, the goal was often to develop a philosophical language, that is, a language suitable for philosophical analysis and scientific discourse. One of the most famous of these projects was the Real Character of John Wilkins (1614-1672), the first president of the Royal Society (Large; Lewis, 2007; Rossi, 2000; Vickers, 1987). He began by isolating a universal grammar that he believed to underlie the particular grammars of all natural languages, and so it is in effect the grammar of Mentalese and hence reflects the laws of thought. Inspired by Chinese writing, Wilkins also concluded that the forms of words should reflect their logical analysis (based on a class hierarchy), and he designed a vocabulary and symbolic writing system based on a comprehensive conceptual taxonomy. His language had little direct impact beyond inspiring the conceptual taxonomy used by *Roget's Thesaurus*, but symbolic logic and AI knowledge representation languages have similar goals and approaches (and, arguably, similar failings).

Gottfried Wilhelm von Leibniz (1646-1716) investigated knowledge representation and mechanized reasoning, in which he was influenced by kabbalah, Lull, Wilkins' language, Hobbes, and Chinese writing and philosophy (Buchanan, 2005; Coudert, 1995; Kneale & Kneale, 1962; Perkins, 2004; Styazhkin, 1969). For example, although he had already invented the binary number system, he later found it in the Chinese *I Ching* (*Book of Changes*) and saw how it reduced all change in the universe to two opposites (yin and yang). This accorded with the kabbalistic and Lullian idea that the world was organized in terms of an alphabet of fundamental ideas and with his own rationalistic philosophy, which sought the true essences of concepts in a small number of atomic (indivisible) categories.

Leibniz was very impressed by Lull's Great Art and by Wilkins' Real Character, but concluded that they would not work, and so he constructed a number of knowledge representation schemes on a more logical plan. For example, any positive integer can be decomposed into a unique product of prime numbers, which is analogous to the rationalist idea that any concept can be reduced to a unique conjunction of atomic concepts. Therefore, if a prime number were assigned to each atomic concept, then every possible concept would have a unique numerical value. Conversely, if we looked up in a philosophical dictionary the number corresponding to any concept, we could discover its essence, or true definition, by reducing the number into its prime factors.

There are two ways that classes are treated in mathematics and logic: extensionally and intensionally. The extensional approach is to define a class in terms of its members, its extension, whereas the intensional approach defines it in terms of its intension, or essential attributes. Although modern logic and mathematics tend to treat classes extensionally, AI treats them intensionally (i.e., a concept is represented by a property list) for the simple reason that most concepts have small intensions but infinite extensions, so it is easier to compute with intensions. For the same reasons, Leibniz settled on an intensional representation.

Leibniz agreed with Hobbes' assertion that thought is computation, and worked on a calculus for logical inference. For example, he discovered that propositions of the form "all *S* are *P*" can be decided computationally if we know the numbers corresponding to *S* and *P*. For if all *S* are *P*, then the essential attributes of *P* are among the essential attributes of *S*; numerically, the prime factors of *P* are among the prime factors of *S*. Therefore, to decide if a proposition "all *S* are *P*" is true, all we need to do is to look up the numbers for *P* and *S* and see if the number for *P* evenly divides the number for *S*.

In summary, we can see that Leibniz had all the components of a system of knowledge representation and mechanical inference. In principle, all concepts could be analyzed into a relatively small number of elementary atomic concepts, and each concept could be assigned a unique number on the basis of this analysis. All philosophical questions, then, could be answered rationally and logically by calculation, literally by ratios (*rationes*, *logoi*). Indeed, Leibniz constructed one of the earliest digital calculating machines (1671), the first capable of multiplication and division, and so he had in principle (but not capacity) the means for actual mechanized reasoning.

George Boole (1815-1864) is well known to computer scientists and information technologists as the inventor of Boolean algebra, which is applied to digital circuit design and in many other ways to computer technology. However, his goals were much more ambitious, for in his *Investigation of the Laws of Thought*, he says he intends "to investigate the fundamental laws of those operations of the mind by which reasoning is performed" and to express them in a calculus (Boole, 1854, p. 1). In common with contemporary logicians, he expressed logical operations in an algebraic notation as opposed to a natural language, thus contributing to the development of symbolic logic. He developed an extensional class logic, in which operations on classes correspond to operations on their extensions, that is, on the sets of their members, and so he invented the algebra of sets. However, he also showed how the same algebraic operations could be interpreted as a propositional logic, which laid the foundation for Boolean circuit design, later developed by Claude Shannon (1938), the inventor of information theory. Boole stressed the formality of his logic, that is, that its rules of inference depended only on the algebraic properties of the operators (commutativity, associativity, etc.) and not on any interpretation of the terms. Therefore, these operation were not restricted to human thought, but could be implemented by machines, which was accomplished about a decade later by W. S. Jevons.

William Stanley Jevons (1835-1882) was a prolific mathematician, scientist, and philosopher who contributed to statistics, economics, meteorology, and the philosophy of science (Mays & Henry, 1953). However, he was also the first to construct fully functional logic machines capable of automated reasoning (Jevons, 1870, 1894, 1958), and thus predecessors of AI technology. His system is based, first, on the idea of a logical alphabet that lists all the possible conjunctions of a given set of terms and their complements. Second, he uses an indirect method of deduction, which is simply to eliminate from the logical alphabet those combinations that are inconsistent with the premises. Obviously, this is a generate-and-test procedure: List all the possible combinations and remove the impossible conclusions; the result is the broadest conclusion compatible with the premises.

Jevons' indirect method, like most generate-and-test procedures, is too tedious and error prone to perform manually, so he invented a succession of devices that increasingly automated the process. His most sophisticated was a completely mechanical device, called the logical piano. It had a keyboard marked with the terms (*A*, *B*, *C*, *D*, and their complements) and with various logical symbols, which was used for entering a series of logical equations representing the premises of a deduction. Above the keyboard was a (mechanical) display, a kind of spreadsheet, which represented all of the logical combinations consistent with the premises that had been entered so far. Thus, the operator could watch the developing mathematical analysis, and even try out hypothetical premises to see how they might affect the conclusion. In 1869, Jevons constructed and demonstrated a four-term machine and planned the development of a 10-term reasoning engine, which would have required an entire wall to display the 1,024 combinations of its logical alphabet. Although the machine performs relatively simple operations on bit strings, Jevons (1958, pp. 110-111) enthused that "after the Finis key has been used the machine represents a mind endowed with powers of thought," and that as each proposition is entered, "the machine analyses and digests the meaning of it and becomes charged with the knowledge embodied in that proposition." Thus, Jevons invented AI hype!

FUTURE TRENDS

In the light of this history, symbolic AI, which has dominated AI research, can be seen as the continuation of a centuries-old tradition concerning the nature of knowledge and inference. This, of course, does not imply that it is the best approach to AI, or conversely that it is not. Although some prominent researchers have declared that the symbolic approach to cognition is "the only game in town," there are alternatives, most notably connectionism (or parallel distributed processing), which is based on simplified models of neural networks in the brain (Garson, 2007; Rumelhart, McClelland, & PDP Research Group, 1986). This new approach promises to compensate for many of the limitations of the symbolic approach, and also to shed light on cognitive processes in the brains of humans and other animals. Connectionism, however, is beyond the scope of this article.

This article has focused on a few of the principal thinkers who contributed to AI before the era of the computer, but there were many others. Therefore, much work remains to be done in exploring and explaining the intellectual background of artificial intelligence. Through a deeper understanding of the assumptions we bring to knowledge and cognition, we may see new approaches to AI technology.

CONCLUSION

We may draw several conclusions from this historical survey. First, symbolic AI is built upon a foundation of philosophical and psychological premises that have been part of Western intellectual history since ancient Greece. Since these assumptions are so deeply embedded in our intellectual background, they easily may be taken for granted and escape adequate scrutiny. Nevertheless, alternatives, such as connectionism, are being explored. Second, although earlier philosophers discussed the idea that thought is a kind of computation, it was only with the advent of modern computers that there was sufficient computing power to test these theories empirically. As a consequence, experimental AI research in the late 20th century revealed both the capabilities and limitations of symbolic AI and motivated the search for alternatives. Finally, perhaps the most important conclusion is that AI is not an isolated technological discipline, nor simply the applied side of cognitive science, but it is intimately related to intellectual issues about the mind and thought that have occupied civilization for millennia.

KEY TERMS

Calculus: A calculus is a system of physical symbols and mechanical rules for their manipulation intended to accomplish some purpose, such as calculation, differentiation, integration, or formal inference. In principle, any process that can be accomplished by a calculus can be programmed on a digital computer.

Generate-and-Test Procedure: Is a common method of search, used in AI and other applications, in which possible solutions are generated systematically and evaluated until a suitable solution is found. For example, a game-playing program might generate possible moves, which are evaluated in terms of their likelihood of leading to a win. The greatest weakness of generate-and-test procedures is combinatorial explosion, which refers to the exponential increase of the number of possible solutions of increasing complexity (e.g., the number of moves that a game-playing program looks forward).

Knowledge Representation Language: Is a formal language, implementable in the data structures of a digital computer, intended to be capable of representing all knowledge or at least all knowledge in some AI application domain. It is intended as a medium for storing knowledge and for mechanized inference in its domain. A knowledge representation language is the analogue in AI of the language of thought in cognitive science.

Language of Thought ("Mentalese"): Is a hypothesized language-like system in whose terms all human cognition is supposed to take place. Advocates of this hypothesis acknowledge that not all of our thinking is discursive (by means of an inner dialogue), but they argue that the systematic structure of ideas and thinking implies that there must be a language of thought, albeit below the level of conscious access. The language-of-thought hypothesis partly justifies symbolic AI as a sufficient basis for AI.

Semantics: Refers to the meanings of expressions in a natural or artificial language and to the study of these meanings and their relation to the expressions. It is often contrasted with syntax. Since formal systems, calculi, and symbolic AI systems deal only with the forms of expressions, they can be sensitive to semantics only to the extent that the semantics is encoded in the system's syntax.

Symbolic AI: Is an approach to AI based on the manipulation of knowledge represented in language-like (symbolic) structures in which all relevant semantics (meaning) is explicit in the syntax (formal structure). The language-of-thought hypothesis provides part of the justification of the sufficiency of the symbolic approach to AI.

Syntax: Refers primarily to the grammar rules of a language (natural or artificial), that is, to the allowable forms of expressions without reference to their meaning (semantics). In the context of AI, syntax refers to the rules of knowledge representation in terms of data structures and to the computational processes that operate on these structures.

History of Simulation

INTRODUCTION

The great philosopher Aristotle said, "If you would understand anything, observe its beginning and its development." Therefore, understanding simulation requires observing its history.

Accordingly, simulation can be understood in many ways: "Simulation is the use of a model to represent over time essential characteristics of a system under study" (El Sheikh, 1987). Another definition is "Simulation is the imitation of the operation of a real-world process or system over time" (Banks, 1999).

Simulation was known long before computers. According to Araten et al. (1992), "The first econometrics model of the United States economy was constructed by J. Tinbergen in 1939." Later, as computers developed in the late 1950s and early 1960s, a spawn of computer simulation methodologies and approaches came to life. Computer simulation, like any industry, both affected and was affected by the development of different programming languages and computer capabilities and advances.

This article will first give a background about simulation in general, then it will discuss the classical simulation methodologies. We will address the current trends in simulation by presenting currently used Java-based simulation languages. In this regard, the classical simulation methodologies discussed in this article include the three-phase approach, activity scan, process interaction, event scheduling, transaction flow approach, Petri nets, and Monte Carlo. The languages discussed are simjava, DEVSJAVA, JSIM, JavaSim (J-Sim), JavaGPSS, Silk, WSE (Web-enabled simulation environment), SLX, and SRML (simulation reference markup language). As such, this article will tackle the history of the approaches and methodologies while shedding light on the genealogy of the simulation languages.

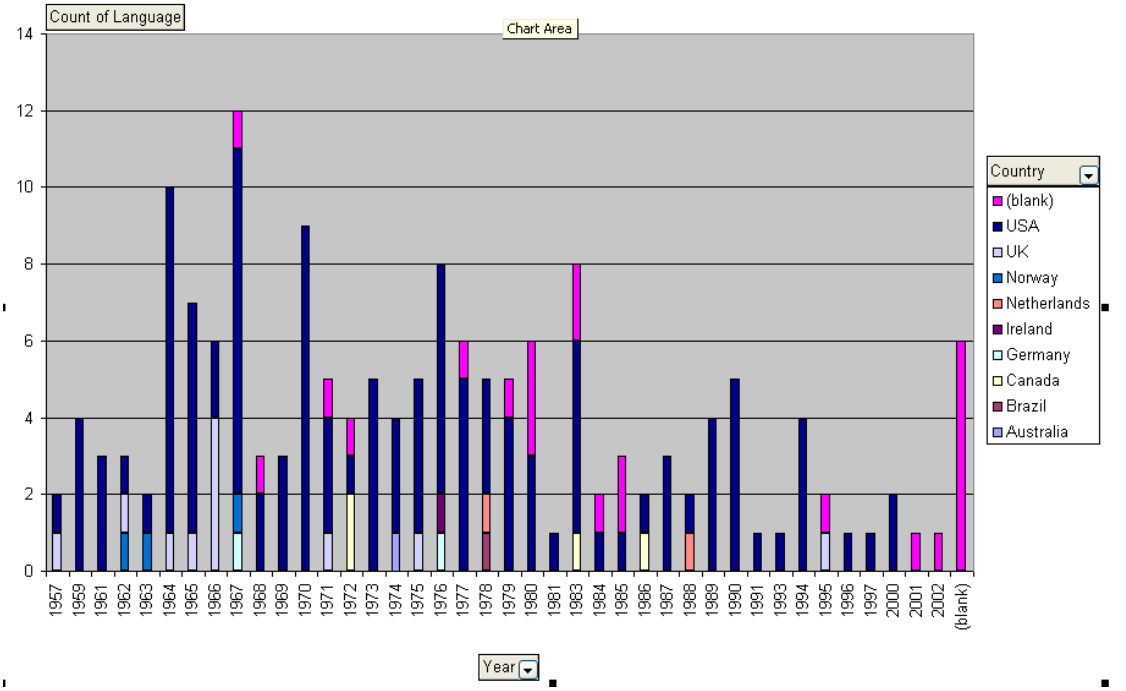
BACKGROUND

Defining simulation in its broadest aspect, we can say that it embodies a certain model to represent the behavior of a system, whether that may be an economic or an engineering one, with which conducting experiments is attainable. When studying models currently used, such a technique enables management and allows us to take appropriate measures and make fitting decisions that would further complement today's growth sustainability efforts, apart from cost decreases as well as service delivery assurance. As such, the computer simulation technique contributed to cost decline, depicted cause and effect, pinpointed task-oriented needs and service delivery assurance, explored possible alternatives, identified problems, proposed streamlined measurable and deliverable solutions, provided the platform for change-strategy introduction, introduced potential prudent investment opportunities, and finally provided a safety net for conducting training courses. Yet, simulation development is hindered due to many reasons. Like a rose, the computer simulation technique does not exist without thorns. Simulation reflects real-life problems; hence, it addresses numerous scenarios with a handful of variables. Not only is it costly and liable to human judgment, but also, the results are complicated and can be misinterpreted.

Within this context, there are four characteristics that distinguish simulation from any other software-intensive work according to Page and Nance (1997). First, simulation uses time as an index variable. Second, one of the objectives in simulation is to achieve correctness. Third, simulation software is involves computational intensiveness. Last but not least, the use of simulation is not typical; in fact, "no typical use for simulation can be described" (Page & Nance, 1997, p. 91).

Hence, there are many methodologies and approaches that simulation practitioners use when working on a simula-

Figure 1. Simulation languages in chronological order



tion project: the three-phase approach, activity scan, process interaction, event scheduling, transaction-flow approach, Petri nets, and Monte Carlo (Abu-Taieh & El Sheikh, 2007). Based on the previously mentioned methodologies and approaches, as well as other programming languages, more than 170 simulation programming languages and more than 60 simulation packages (Abu-Taieh & El Sheikh) were developed, for example, GPSS, GSP, GASP, SIMULA, and so forth. The simulation programming languages are reflected in *Figure **1*** in terms of the date and country of origin for each programming language.

CLASSICAL SIMULATION APPROACHES AND METHODOLOGIES

There are many simulation approaches and methodologies. For this purpose, the most familiar will be thoroughly discussed, namely, the three-phase approach, activity scan, process interaction, event scheduling, transaction flow approach, Petri nets, and Monte Carlo.

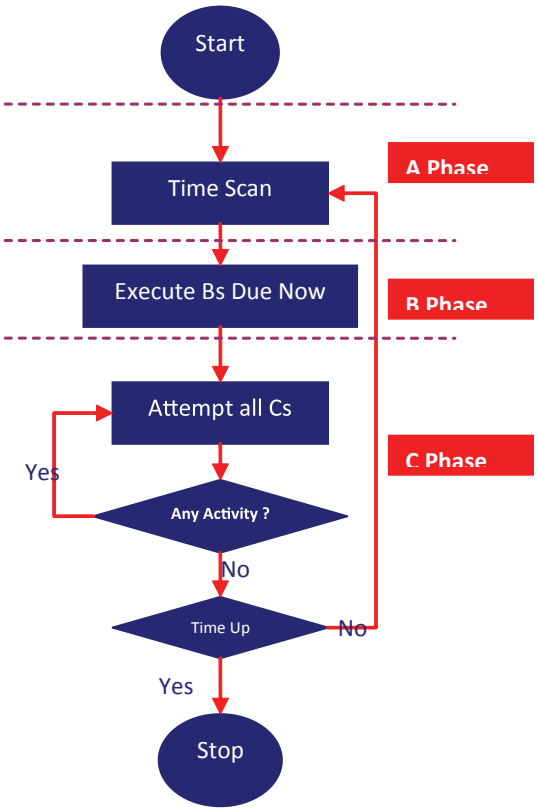
Three-Phase Approach

The first simulation modeling structure is known as the three-phase method. It was described by Keith Douglas Tocker in 1963 in his book *The Art of Simulation* (Odhabi, Paul, & Macredie, 1998), and then discussed in detail by Pidd and Cassel (1998).

Tocker introduced the three-phase approach through the General Simulation Program (GSP), which is considered as the first language effort (Nance, 1995; Pidd, 1998). In 1966, Tocker introduced wheel charts, which were later replaced by the activity cycle diagram and the language CSL (control and simulation language), which represented a simpler approach called activity scan (Nance). Tocker claimed that the structure would enable automatic programming simulation as Nance (1995) states was obvious in the development of OPS-1, OPS-2, OPS-3, and OPS-4, which are simulation languages intended for non-computer-programmers developed by students in MIT.

The three-phase approach has, as the name suggests, three phases—the A phase, B phase, and C phase—as seen in Figure 2. Each phase will be further discussed next.

Figure 2. A three-phase executive (Pidd, 1998)



In the A phase, time is advanced until there is a state change in the system or until something happens next. The system is examined to determine all of the events that will take place at this time (that is, all the activity completions that occur). The A phase is defined formally by Pidd and Cassel (1998): "the executive finds the next event, and advances the clock to the time in which this event is due."

The B phase is the release of those resources scheduled to end their activities at this time. According to Pidd and Cassel (1998), the B phase "executes all B activities (the direct consequence of the scheduled events) which are due at the time."

The C phase starts the activities given a global picture of resource availability. The C phase is defined formally by Pidd and Cassel (1998): "the executive tries to execute all of the C activities (any actions whose start depends on resources and entities whose states may have changed in the B phase)."

In this regard, Michael Pidd (1998) criticized the three-phase model and claimed that this methodology will be less popular as computer power continues to grow, indicating that the reason is "because discrete time slices must be specified. If the time interval is too wide, detail is lost." It is worthwhile to note that Pidd attributed the same criticism to activity scanning, which will be discussed next.

Activity-Scanning Approach

In 1963 the activity-scanning approach was introduced by John Buxton and John Laski (Nance, 1993, 1995). Activity scanning is also known as the two-phase approach. Activity scanning produces a simulation program composed of independent modules waiting to be executed. In the first phase, a fixed amount of time is advanced or scanned. In Phase 2, the system is updated (if an event occurs) as seen in Figure 3. Activity scanning is similar to rule-based programming (if the specified condition is met, then a rule is executed).

Many simulation packages adopted activity scanning, one of which is FirstSTEP.

The activity-scanning approach was represented by CSL, which in turn was influenced by the FORTAN programming language. Later in 1966, Clementson published the research paper *Extended Control and Simulation Language*, which introduced the ECSL simulation programming language. ECSL is based on C.S.L., yet one must note here that CSL is not C.S.L.

In 1978 Parkin and Coats published a research paper titled *EDSIM: Event Based Discrete Simulation using General Purpose Languages such as FORTRAN*. According to Nance (1993, 1995), EDSIM built on ECSL, but reintroduced the FORTRAN-like component.

Figure 3. An activity-scanning executive (Pidd, 1998)

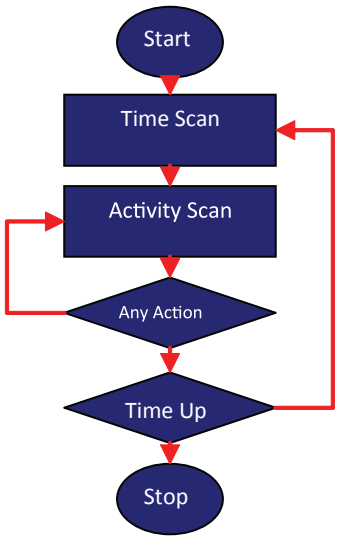


Figure 4. A process-interaction executive (Pidd, 1998)

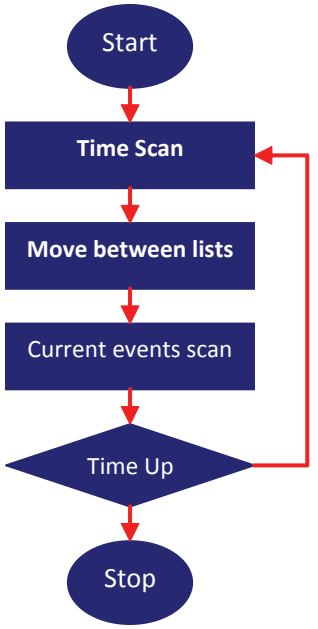


Process-Interaction Approach

During the early 1960s, the process-interaction approach was introduced in the form of the simulation-oriented language (SOL) and SIMULA. SOL, created by Knuth and McNeley, was an extension of ALGOL, according to Nance (1993, 1995). However, SIMULA was created between 1962 and 1965, and later SIMULA was developed in 1967 by Ole-Johan Dahl and Kristen Nygaard. SIMULA produced CØNSIM (conflict simulator) and DEMOS in the late 1970s (Clema & Kirkham, 1971).

The simulation structure that has the greatest intuitive appeal is the process-interaction method. In this method, the computer program emulates the flow of an object (for example, a load) through the system. The load moves as far as possible in the system until it is delayed and either enters an activity or exits from the system. When the load's movement is halted, the clock advances to the time of the next movement of any load.

This flow, or movement, describes in sequence all of the states that the object can attain in the system as seen in Figure 4. The process-interaction approach was used by many commercial packages, among them, Automod.

Transaction-Flow Approach

The transaction-flow approach was first introduced by GPSS in 1962 as stated by Henriksen (1997). Transaction flow is a simpler version of the process-interaction approach as the following clearly states: "Gordon's transaction flow world-view was a cleverly disguised form of process interaction that put the process interaction approach within the grasp of ordinary users" (Schriber, Ståhl, Banks, Law, Seila, & Born, 2003).

The transaction-flow models consist of entities (units of traffic), resources (elements that service entities), and control elements (elements that determine the states of the entities and resources) as described by Henriksen (1997), Schriber and Brunner (1997), and *GoldSim Web* (n.d.). Discrete simulators that are generally designed for simulating detailed processes such as used in call centers, factory operations, and shipping facilities rely on such an approach, such as in "ProModel, Arena, Extend, and Witness" (GoldSim Web, n.d.). Some scholars (Schriber & Brunner, 1997) it as a "transaction-flow world view" and they add that it "often provides the basis for discrete-event simulation."

In view of the aforementioned, the same scholars continue to describe the best fitted applications to such an approach: "manufacturing, material handling, transportation, health care, civil, natural resource, communication, defense, and information processing systems, and queuing systems in general" (Schriber & Brunner, 1997).

Stock and Flow Approach

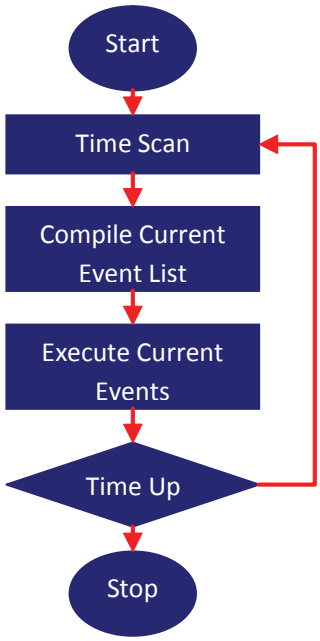
Another approach that is worth mentioning is the stock and flow approach, which is used in dynamic systems. This approach was created at MIT in the '60s by J. W. Forrester (GoldSim Web, n.d.). Stock and flow is based on system dynamics that are built using three principal element types: stocks, flows, and converters.

Event-Scheduling Approach

The event-scheduling approach came into existence through SIMCRIPT in the mid 1960s. SIMSCRIPT spawned from the programming language FORTRAN. The major designer of SIMSCRIPT is Harry Markowitz (Nobel prize winner) and the sole programmer is Bernard Hausner. SIMSCRIPT was fathered by SPS-1 and GEMS, and resembles SEAL (simulation, evaluation, and analysis language). SPS-1 was developed by Jack Little of RAND and Richard W. Conway of Cornell University, and the sole programmer was Bernard Hausner. Many versions came from SIMSCRIPT, like CLP, QUICKSCRIPT, SIMSCRIPTII, SIMSCRIPTII plus, SIMSCRIPTII.5, ESC II, and CSP II, according to Nance (1993, 1995) and Araten et al. (1992).

The basic concept of the event-scheduling method is to advance time to the moment when something happens next (that is, when one event ends, time is advanced to the time of the next scheduled event). An event usually releases a resource. The event then reallocates available objects or

Figure 5. An event-scheduling executive (Pidd, 1998)



entities by scheduling activities, in which they can now participate. Time is advanced to the next scheduled event (usually the end of an activity) and activities are examined to see whether any can now start as a consequence, as seen in Figure 5. The event-scheduling approach has one advantage and one disadvantage as Schriber et al. (2003) states, "The advantage was that it required no specialized language or operating system support. Event-based simulations could be implemented in procedural languages of even modest capabilities." On the other hand, the disadvantage "of the event-based approach was that describing a system as a collection of events obscured any sense of process flow." As such, "in complex systems, the number of events grew to a point that following the behavior of an element flowing through the system became very difficult." Many simulation packages adopted the event-based approach, of which are Supply Chain Builder, Factory Explorer, GoldSim, and ShowFlow.

Petri Nets

Petri nets have been under development since the 1960s, when Carl Adam Petri defined the language in *Kommunikation mit Automaten* (History, 2004): "It was the first time a general theory for discrete parallel systems was formulated."

Furthermore, the idea of Petri nets was developed to answer the question of concurrency, which naturally always arises when discussing simulation. As such, Petri nets handle concurrent discrete events in dynamic systems simulation. As an example, some simulation packages like Optsim (Artifex) use Petri nets.

In order to understand Petri nets, a comprehensive definition must be initially realized. Following are two formal

Table 1. Classical simulation approaches

Approach	Creator	Year	Tool	Language
Three-Phase	Keith Douglas Tocker	1963	wheel charts	General Simulation Program (GSP)
Activity-Scanning Approach	John Buxton and John Laski	1963	activity cycle diagram	CSL
Process-Interaction Approach	Knuth and McNeley Ole-Johan Dahl & Kristen Nygaard	1963		SOL, SIMULA
Event Scheduling	Major Designer: Harry Markowitz (Nobel prize winner) Sole programmer: Bernard Hausner	1963		SIMSCRIPT based on SPS-1 and GEMS
Stock and Flow Approach	Professor Jay W. Forrester at MIT	1960s		GoldSim
Petri Nets	Carl Adam Petri	1960s	tokens	graphical
Monte Carlo Methods (statistical sampling)	Enrico Fermi	1930s	many flavors	

definitions of Petri nets: one that calls it a technique, while the other calls it a language. The first definition follows: "A formal, graphical, executable technique for the specification and analysis of concurrent, discrete-event dynamic systems; a technique undergoing standardization" (PetriNets, 2004).

The second definition states, "Petri Nets is a formal and graphical appealing language, which is appropriate for modeling systems with concurrency….The language is a generalization of automata theory such that the concept of concurrently occurring events can be expressed" (History, 2004).

Petri nets were classified in different ways. The following classifications were listed on *Class Web* (n.d.), among others: Petri net systems of Level 1, Petri net systems of Level 2, and Petri net systems of Level 3. The Level 1 Petri nets systems are characterized by Boolean tokens; on the other hand, Level 2 uses integer tokens. Level 3 is characterized by high-level tokens.

Monte Carlo Methods

At the onset, the Monte Carlo methods were used in the 1930s and denoted generic names (statistical sampling). Enrico Fermi used Monte Carlo to calculate the properties of the neutron. Consequently, during the 1950s, the Monte Carlo methods were used at Los Alamos for the development of the hydrogen bomb. Monte Carlo was popularized and pioneered by Stanislaw Marcin Ulam, Enrico Fermi, John von Neumann, and Nicholas Metropolis (http://en.wikipedia.org/wiki/Monte_Carlo_methods). Another alternative to Monte Carlo is applied information economics (AIE), which is a decision analysis method.

In this context, the Monte Carlo method is formally defined: "Numerical methods that are known as Monte Carlo methods can be loosely described as statistical simulation methods" (*CSEP Web*, 1995). Note that three words stand out in the definition—*loosely, random,* and *statistical*—while statistical simulation is also defined as a "method that utilizes sequences of random numbers to perform the simulation" (*CSEP Web*), as can also be seen within the following definition: "Monte Carlo was coined by Metropolis (inspired by Ulam's interest in poker) during the Manhattan Project of World War II, because of the similarity of statistical simulation to games of chance" (CSEP Web, 1995).

Furthermore, Monte Carlo was referenced in 1987 when Metropolis wrote, "Known to the old guards as statistical sampling: in it new, surroundings and owing to its nature there was no denying its new name of the Monte Carlo Method."

Monte Carlo methods, known for its diversity of applications, are used in nuclear reactor simulation, quantum chromo dynamics, radiation cancer therapy, traffic flow, stellar evolution, econometrics, Dow Jones forecasting, oil well exploration, and VSLI design.

THE JAVA INCLINATION

Since Java came to life in the 1990s, many people from the simulation arena thrived for its utilization. This did not come as a surprise given the history of the object-oriented trail of thought. Additionally, upon examining the process interaction methodology, it was bound to be the basis for today's object-oriented mind-set.

In this context, currently there are several Java-based discrete simulation environments (Kuljis & Paul, 2000): simjava, DEVSJAVA, JSIM, JavaSim (J-Sim), JavaGPSS, Silk, WSE, SLX, and SRML. Following is an elaborated overview.

The first in this list of definitions is simjava, which is based on the process-interaction approach with the purpose of being able to build complex systems. Obviously, simjava is based on the Java programming language, which is inherently objecting oriented (Kuljis & Paul, 2000; Page, Moose, & Gri, 1997).

The second on the list is the DEVSJAVA environment, which was built using Java and is based on the discrete event system specification (Kuljis & Paul, 2000): "A user of DEVSJAVA is able to experiment with any DEVS model from any machine at any time and to interactively and visually control simulation execution."

Likewise, the third on the list is JSIM, which is described by Kuljis and Paul (2000) as a "Java based simulation and animation environment supporting web based simulation as well component-based technology." The component-based technology that JSIM utilizes in this case is Java Beans, as Kuljis and Paul claim in their paper. The idea is to build up the environment from reusable software components that "can be dynamically assembled using visual development tools" (Kuljis & Paul).

In this regard, it is worth noting that JavaSim was later changed to the name J-Sim, which is the fourth definition on the list. J-Sim is considered to be "a set of Java packages for building discrete event process-based simulation" (Kuljis & Paul, 2000). JavaSim was renamed because the word Java is a trade mark owned by SUN Microsystems. J-Sim is an implementation of a simulation tool kit named C^{++}SIM developed in the University of Newcastle (Kuljis & Paul). The official Web site of J-Sim describes it as a "component-based, compositional simulation environment" (*J-Sim Web*, n.d.). Yet, the Web site adds "unlike the other component-based software packages/standards, components in J-Sim are autonomous" (*J-Sim Web*).

The fifth on the list is the JavaGPSS compiler: "The *JavaGPSS* compiler is a simulation tool which was designed for the Internet" (Kuljis & Paul, 2000). JavaGPSS was built so that GPSS can be run on the Internet (Kuljis & Paul).

Within this context, Silk, being the sixth on the list, is defined as the "general-purpose simulation language based around a *process-interaction* approach and implemented

in Java" (Kuljis & Paul, 2000). The purpose of silk is "to encourage better discrete-event simulation through better programming by better programmers" (Kilgore, 2003). According to Healy and Kilgore (1997), "The *Silk* language is an opportunity to make simulation more accessible without sacrificing power and flexibility."

Furthermore, the Web-enabled simulation environment is the seventh item on the list. WSE "combines web technology with the use of Java and CORBA" (Kuljis & Paul, 2000). Also, according to Kuljis and Paul, the WSE environment provides location and distribution transparency, and platform independence.

The eighth on the list, SLX is considered a simulation language that is "C-like," as cited by Henriksen (1997), who first introduced the framework of SLX in 1995 and went on to describe it as a "wolverine software" for the next generation. R. C. Crain discussed SLX in 1997 in the paper entitled "Simulation Using GPSS/H" at the winter simulation conference, and later Henriksen also covered it in his paper entitled "Introduction to SLX" in 1998.

Finally, the simulation reference markup language and the simulation reference simulator were both developed by Boeing and used in many projects (Reichenthal, 2002). Like HTML (hypertext markup language), SRML represents simulation models and as a Web browser represents universal client application. SRML binds the declarative with procedures and like HTML contains both declarative and procedural definitions. According to Reichenthal, "*SRML* is an XML-based language that provides generic simulation markup for adding behavior to arbitrary XML documents."

FUTURE TRENDS

Simulation is not a stand-alone science; it interacts with technology simultaneously as technology advances. There are two major things driving simulation today: the Internet and object-oriented thinking. While the major driving force for simulation is still the need for simulation, the need for virtual reality and augmented reality inter alia demands the prompt advancement of many aspects of simulation. Nevertheless, the elimination of the usual inhibitors like computer hardware speed is yet another prerequisite for advancement in this regard.

CONCLUSION

This article tried to shed light on the numerous facets of simulation history, spanning over the approaches and methodologies of discrete event simulation. The article discussed the most famous discrete event simulation methodologies (three-phase approach, activity scan, process interaction, event scheduling, transaction-flow approach, Petri nets, and Monte Carlo) represented in the programming languages that stemmed from the methodologies. Then the article discussed the future trends through the current history by discussing nine Java-based languages.

KEY TERMS

Continuous Simulation Systems: These are systems that deal with time as a continuous function, for example, when simulating the flow of water from a reservoir.

Discrete Simulation Systems: These are simulation systems that treat the time variable as a discrete variable. Usually any systems that deal with queues (supermarkets, banks) are of discrete nature.

Monte Carlo Methods: These are statistical simulation methods.

Petri Nets: Petri nets are "a formal, graphical, executable technique for the specification and analysis of concurrent, discrete-event dynamic systems; a technique undergoing standardization" (PetriNets, 2004).

Simulation: It "is the imitation of the operation of a real-world process or system over time" (Banks, 1999).

Simulation Methodology: It is a world view of abstracting the real world and mapping it into a computer program.

How Teachers Use Instructional Design in Real Classrooms

Patricia L. Rogers
Bemidji StateUniversity, USA

INTRODUCTION

"I've learned how to use the [insert new instructional technology here], so now how do I use it in class?"

From filmstrips and mimeographs, to computer-based simulations and virtual reality, technology seems to dominate teachers' lives as they master the new instructional media for use in their classrooms. Good teaching and learning practices tend to take a back seat while the focus on mastery of the technology reduces teaching into basic presentations and lectures, a format most easily controlled by the instructor. While most pre-K-12 and post-secondary instructors do develop effective courses in which students learn, many would be hard pressed to describe *how* they arrive at certain goals and teaching strategies.

BACKGROUND

The field of instructional design provides sound practices and models that, once modified for use by working teachers, can be used to design effective instruction in any content area (Rogers, 2002). The more difficult issue is helping teachers move beyond the tendency to focus on technology rather than instructional goals. Such focus occurs at lower levels of what can be described as a technology adoption hierarchy (summarized in Table 1): familiarization, utilization, integration, reorganization, and evolution (Hooper & Rieber, 1999).

Somewhere at the integration stage, a "magic line" is crossed and the focus is no longer on the technology but on the teaching and learning. A supporting practical design model can help teacher-designers cross this magic line more efficiently and with a high degree of success.

FUTURE TRENDS

A Modified Instructional Design Model

Prescriptive behavioral models in learning would seem, at first encounter, to be inappropriate in light of the more constructivist practices of current educators. However, most constructivists would concur that one must have solid building blocks or elements before construction of new knowledge can be achieved. Dick and Carey's (1990) original systems design model and subsequent modifications by Gagné, Briggs and Wager (1992) and others offer examples of all of the elements necessary for designing and evaluating effective instruction. What the models lacked, however, was a connection to real classroom teachers: those of us who are really teacher-designers and who must create and develop our courses without benefit of design teams and lengthy pilot tests with target audiences.

Figure 1 is a modification based on several interpretations of the most typical instructional design model (Dick & Carey, 1990). Notice that the five phases of design: analyze, design, develop, implement, and evaluate, are focused not

Table 1. A summary of the technology adoption hierarchy

EVOLUTION	Highest level: is most able to cope with change and has skills to adapt newer technologies as needed or desired in teaching and learning environment.
REORGANIZATION	Re-designs teaching strategies with focus on learning and goals of instruction. Students become more involved in the learning environment.
INTEGRATION	Beginning to accept the technology. Focus soon shifts from learning the technology (and fearing its breakdown) to effective use of the technology in teaching.
UTILIZATION	Basic trial of the new technology. Focus is on finding a use for the technology that may or may not continue, particularly if the technology breaks down.
FAMILIARIZATION	Lowest level of exposure to a technology.

on designing teacher-proof curricula but rather on teacher-designers staying focused on their own environment and learners.

The model helps teachers begin designing with the constraints, issues, community demands, and state and federal mandates in mind before thinking about instructional media or "activities". Once parameters are identified, teacher-designers move into the design phase as they document the overall goals of their course (or, in the case of primary teachers, their school year) while simultaneously considering their learners. What does it mean to be a 3rd grade person? What skills should learners have as they move into 4th grade? What new knowledge is gained in 4th grade to allow learners to become 5th grade students? And so on.

Within this phase, assessments are also considered. Effective design, as well as effective teaching, requires teacher-designers to carefully match goals and objectives to appropriate assessments. Desired types of learning, from basic verbal information to higher order thinking skills (Gagné, Briggs & Wager, 1992) must have matched assessments that allow learners to demonstrate their new skills and abilities. Mismatched goals and assessments are common errors in designing instruction.

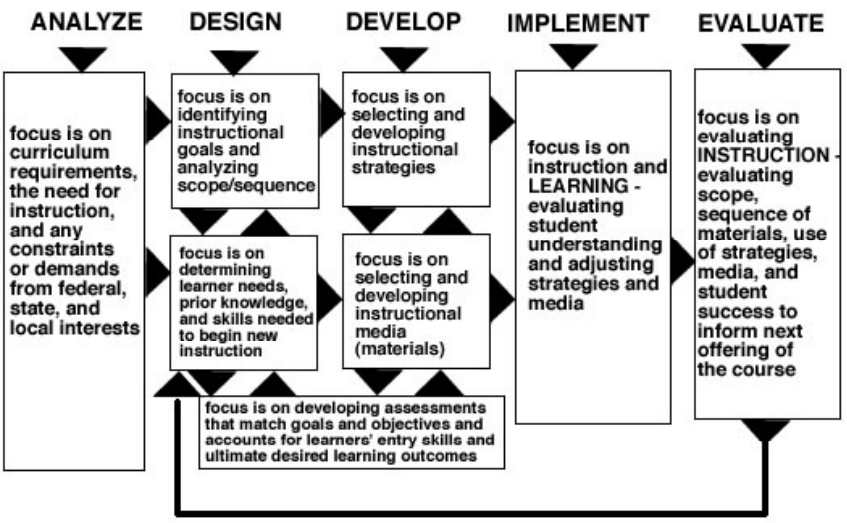
Using this model essentially forces us to wait until the development phase to select teaching strategies and instructional media. For those teachers who are struggling to leave the lower levels of the technology adoption hierarchy, this placement will seem uncomfortable. However, starting with the technology and trying to build an instructional environment is, as should be apparent, in essence turning the design process inside out! Once the focus is away from the goals and objectives and the *learners,* any further course development will likely result in a design that falls far short of the intended learning:

I am elated that I had the opportunity to work on curriculum design for the first time the right way and with a group of faculty members who supported my learning. I have watch[ed] part-time faculty members and even seasoned classroom teachers jump into material they are not familiar with, plan day by day, never really having clear objectives and methods of evaluation [in mind]. (A. Vidovic, personal communication, July 30, 2003)

Notice that the development of assessments also crosses this phase of the design. It is critical to select strategies and media that support the goals and objectives as well as allow students to demonstrate their understanding. Using strategies and media that are similar to the assessment situation strengthens the learning. For example, if students were learning to write poetry, a true-false test would be a very inadequate measure of their skills.

Implementation, *teaching*, is the phase of a teacher-designer's true test. It is here that this model is quite different from traditional instructional design models in that teacher-designers rarely have a chance to "try out" a course on a sample of students. Rather, they often have to simply try things and hope it all works well. However, by follow-

Figure 1. Modified instructional design model for teacher-designers. Modifications first introduced in Designing Instruction for Technology-Enhanced Learning*, Rogers, 2002, Idea Group Publishing. Further modifications by Patricia L. Rogers and Catherine E. McCartney, Bemidji State University, for the Online Graduate Program, 2002-2003).*



ing the model thus far, teacher-designers have an advantage over others who do not have clear goals and objectives in mind. During this phase, student achievement and perhaps student evaluations of the course should be examined as evidence that all elements of the design thus far actually form a cohesive course that meets the goals of the instruction. Teacher-designers should take notes on a daily basis regarding which strategies are working with learners, which activities supported new learning, and which instructional medium was appropriate for certain types of learning.

The evaluation phase in this model relies heavily on the evidence from the previous phase and includes a critical look at any notes from the teaching experience, comparison to a previous experience teaching the course, and so on:

In designing and developing this online class using the first couple assignments (objectives, goals, subgoals, etc.), I really feel like [my] course's material fits together much better than it has when I taught it in the past. Though this [instructional design] process took a fair amount of time, I know I would never tackle another class design without using this process first. It does seem to speed up the material/content piece considerably by doing this first. (N. Gregg, personal communication, July 28, 2003)

Barriers to Designing Effective Instruction in Distance Learning

By following a model that is based in practical, real-world experiences of teachers, teacher-designers are able to develop effective and well-documented instruction. However, we should note that there are many reasons good instructional design practices are not followed, and that most are out of the teacher-designer's control. Table 2 is a summary of some of the issues and barriers faced by teacher-designers.

CONCLUSION

A strong case can be made for working with teacher-designers at all levels of education on sound instructional design practices. "Winging it" when it comes to designing effective instruction is ill-advised in the rarified air of the 21st century knowledge and information age, with many demands from

Table 2. A summary of barriers to designing effective instruction

Fear of change
Changing teaching methods (strategies) to accommodate newer technologies, different modes of delivery, and the reality of managing a larger student market carries a certain amount of risk and challenge. The human tendency to want things to remain the same introduces a fear factor in designing and delivering instruction in the 21st century (Dublin, June 2003).

Unfamiliarity with newer technologies
The introduction of newer technologies in teaching usually results in teachers defaulting to presentations and lectures. Once the "magic line" is crossed, teaching and learning with technology refocuses from the technology to learning (Dublin, June 2003; Hooper & Rieber, 1999; Strauss, June 2003).

Correspondence, Lecture, and Interactive Learning
Real classrooms rely on interactions among students and the instructor. Some online courses are actually stand-alone correspondence courses that are self-paced and lack high interactivity levels. Lecture courses tend to be one-way communications while other strategies emphasize interactivity. There is a critical need to be clear about levels of interactivity in learning environments (Cavalier, June 2003).

Ill-defined goals and objectives
Defining goals and objectives is often a new experience for many faculty. Goals and objectives may not match teaching style or adequately address desired learner outcomes.

Unrealistic administrative, policy, or economic pressures
Some teachers have encountered serious constraints when designing instruction. A partial list includes: forced use of traditional "activities" that become the central focus of the instruction, district-wide adoption of specific texts or programs designed to be "teacher-proof" with little flexibility, limited development time for teachers, and a focus on state-wide test scores directly tied to school funding (Rogers, 2000).

Difficulty in translating from one environment to another, such as onground to online
Moving a course from onground delivery to the online environment sets up barriers for inexperienced teachers: some try to limit all transactions to real time and have a felt need to recreate their onground course exactly. Others err on the other side and resort to a type of glorified correspondence approach.

learners for high-quality educational experiences. Educational institutions, particularly colleges and universities, are faced with harsh competition for the teaching aspect of their institution from for-profit companies. Such companies outspend higher education in development, maintenance, and marketing of educational offerings, particularly in online learning (Rogers, 2001). Non-profit educational institutions can compete most effectively by providing (a) affordable pricing, (b) greater accessibility to education, and (c) high-quality, personalized educational experiences for their learners. A and B are usually easily attained. High quality education (c) begins with great teachers and support staff and is built and sustained with solid instructional design practices.

KEY TERMS

ADDIE: The five phases of most instructional design models: analyze, design, develop, implement, and evaluate. Some models follow the phases in a linear fashion, while others may approach the phases in a holistic or phenomenologic manner.

E-Learning: A term used to describe learning that takes place usually online, but includes all forms of electronically-enhanced and mediated learning. Computer-aided instruction, just-in-time learning, and intelligent systems can be included in the term "e-learning".

Instructional Design: The field of instructional design includes a range of professions from programmers and graphic artists, to the instructional designer. Designers are able to analyze instruction, learners, environments, strategies, and media to develop effective instruction of training. Designers may or may not be subject matter experts.

Instructional Design Models: Traditional design models are prescriptive step-by-step processes, usually associated with behaviorist instructional strategies. Phenomenological models incorporate constructivist philosophies and practices. In either aspect, design models guide the user in designing effective instruction that takes all aspects of design (see ADDIE) and reminds the user of critical elements and decisions in designing effective instruction.

Instructional (Educational) Technology: Instructional technology is the theory and practice of design, development, utilization, management and evaluation of processes and resources for learning (Seels & Richey, 1994).

Teacher-Designer: "…if you have any experience with instructional design you know that the field and the various models of design associated with it seem most appropriate for teams of people working on the course materials together. Once in a while, some of us are fortunate enough to have instructional designers, subject matter experts, graphic artists, programmers and so on available on our campus or in our school district to assist us with our technology-enhanced course. But most often, it the teacher alone who must rethink and redesign his or her course for technology-enhanced learning. And very often it is the teacher who must also prepare the materials for the Internet, interactive television, or some other delivery medium. They often do not have any background in instructional design theory or practices and have only just mastered the skills for using the delivery medium. These are the people I call 'teacher-designers'" (Rogers, 2002, p. 2).

Technology Adoption Hierarchy: "The model…has five steps or phases: familiarization, utilization, integration, reori-

entation, and evolution. The full potential of any educational technology can only be realized when educators progress through all five phases; otherwise, the technology will likely be misused or discarded…The *traditional* role of technology in education is necessarily limited to the first three phases, whereas contemporary views hold the promise to reach the evolution phase" (Hooper & Rieber, 1999, p. 253).

INTRODUCTION

This article studies the transformation processes occurring in industry and business at large. It deals with the social and economic challenges, and explores the new concepts arising from an unprecedented technology revolution underpinned by advances and innovation in ICT. In addition it sets the scene for a new era of industrial capitalism.

Over the last decade of the twentieth century, a large number of companies faced the future with trepidation while others lacked a good strategy (Possl, 1991; Kidd, 1994; Ashkenas, 1997). Many changes had taken place including Just In Time (JIT) manufacturing and logistics, lean manufacturing (Womack, Jones, & Roos, 1990), shorter product lifecycles (Davenport, 1993), more intelligent approaches to IT (Drucker, 1992; MacIntosh, 1994; Nonaka, 1998), and costing (Wilson, 1995; Ansari, Bell, & the CAM-I Target Cost Core Group, 1997), but making money was becoming more and more difficult. It was a time and climate for dramatic new approaches (Warnecke, 1993; Drucker, 1994; Goldman, Nagel, & Preiss, 1995) with greater agility. New technologies were replacing old at a faster rate, and information technology provided better management and control vision, albeit on a limited local scale (Arguello, 1994; Leachman, Benson, Lui, & Raar, 1996; Makatsoris, Leach, & Richards, 1996). Also, push to pull manufacturing (Mertins, 1996) distinctly changed the approach to customers and service, which increased competitive and economic pressures resulted from the global reach of customers, manufacturers, and service providers keen to exploit the wealth of opportunities in both global markets and differences in worldwide regional markets (Bitran, Bassetti, & Romano. 2003). Even players only operating in local markets (Bologni, Gozzi, & Toschi, 1996; Zabel, Weber, & Steinlechner, 2000; Bonfatti & Monari, 2004) could not resist the tide of change. As a result many companies and economies (Hutton, 1995) were in a state of upheaval, and as a consequence some fell by the wayside. This was a climate in which there was an uncertain outcome, and it was into this melting pot that the Internet and the World Wide Web (WWW) were to produce an environment for a much-needed revolutionary change in the industrial approach. Later, broadband for landline and also wireless networking provided a much-needed speedier access.

Businesses looked to the wider horizons and the dynamics of their supply chains as well as their markets to discover new ways of working with both customers and suppliers, to grow and remain viable. The diverse industrial, commercial, and operational practices and processes needed to be remolded. And the collaborative aspects of external relationships to the advantage of company performance and the creation of new opportunities were the ones to be targeted. This resulted in increasing use of new forms of communication and innovation in multimedia technologies. In this unsettled environment, once fear of change had been forced into the background, chaos became the domain of creative experimentation (Weiland-Burston, 1992). It is during this period of confusion and anxiety that the process of metamorphosis started to take place.

A surge of new software tool ideas have helped, including Enterprise Resource Planning (ERP) Supply Chain Management (SCM) (Chang, McFarlane, & Shaw, 2001); Customer Relationship Management (CRM) (Greenberg, 2002); electronic commerce (e-commerce) and procurement (Chang, Makatsoris, & Richards, 2004); extensions in order management, fulfillment, and demand lifecycle control (Makatsoris, Chang, & Richards, 2004a, 2004b; Makatsoris & Chang, 2004); electronic business (e-business) (CEC, 2000); and new forms of conducting business, among many others. Further, mobile devices have enabled access to systems and software from any place in the world, and these technological improvements are transforming the way people work. All of these have stimulated the reformation of business attitudes to the flow of goods, services, information, and knowledge (Hardwick, Spooner, Rando, & Morris, 1996; Richards, Dudenhausen, Makatsoris, & de Ridder, 1997; Bouet & Martha, 2000; Johnston, 2001; Introna, 2001; Zobel & Filos, 2002).

BACKGROUND

Life has become more hectic: the hustle and bustle of global business, developing everyday situations, and worldwide

instant news coverage have intermingled business with leisure more than ever before. Collaboration, especially e-collaboration, is very important for today's business. It can take place at any time between enterprises and organizations, and moreover can be between people who are located in different places around the globe. But people are different and are motivated in many different ways, as well as having to work in multi-tasking environments within a variety of e-collaboration activities. Understanding how to work effectively with others in modern industrial and service-oriented society is key.

To bring about real benefits to society and business, modern communication means will need to be improved, extended, and seamlessly integrated with support services that can speedily call upon suitable tools, models, data, information and knowledge, and visualizations of entities from anywhere and at anytime to match priority and context. These will be the new e-collaboration environments, or electronic collaborative working environments, that are human centered and intuitive for the practical use of people, teams, and heterogeneous groups in an enriched virtual world serving them in their everyday tasks.

THE VISION

An enterprise network in an e-business context must be considered holistically with respect to its scale and scope to enable better e-collaboration across all its nodes and enable efficient and sustainable operations (Ballesteros & Richards, 2006). However, understanding and embracing people's needs is critical to support human interaction in such working environments (CEC, 2005, 2006). This calls upon the development of better and newer forms of approaches that are in stark contrast to existing approaches and practice. The transformation process involves bridging the gap between the way people think and work with others with the emergence of virtual service-oriented collaborative working environments. The challenge though is to have more than just an intuitive interface. To be human centered is more about having the right services with responsive personalized features in a fully immersive virtual environment that must be designed and implemented with full involvement of the real users.

THE CHALLENGES

ICT tools and systems are important enablers (CEC, 2000) in enterprise management and the transformation processes taking place. They have played and will continue to play a major role in the emergence of new ways of conducting business and ensuring their sustainable development. However, open global standards, protocols and interfaces, interoperable applications and platforms, trusted and sustainable infrastructure, and compatibility between business practices must be developed before interconnection for broader-based business is fully realized (Frick & Lill, 2000; Kidd, 2001).

However, innovative ICT alone is not enough. The necessary social and organizational changes to business (McCarthy, 1996) are at least as significant and are enabled by ICT. For instance, a Web-like organizational network has emerged from the more loosely coupled supply chains of the 1990s. The adaptive value network (Makatsoris, 2004) and virtual enterprise permit new forms of communication, participation, leadership, and decision making to develop. In turn these create new economic balances, shared learning, and new procedures embracing human involvement rather than strict structures dictated by inflexible ICT, which would just collapse space and time (Franke, 2001; Duttas, 2001) and increase resistance to change that must be overcome (Hunziker & Sieber, 1999; Deloitte & Touche, 2000).

Three basic aspects to change have emerged, before smarter business is accomplished, to drive the change process. These are developing in parallel to carry business forward to the future.

- **Organization:** How organization and inter-company relations are developed to ensure greater collaboration—that is, working jointly together, cooperating, and coordinating; trusting each other; sharing information and knowledge where appropriate and refining the skills in the organization to cope with the economics, strategic aims; and increasing the rate of innovation, day-to-day operations, and service excellence.
- **Information and Communication Technologies:** How tools and systems are created, developed, and introduced to ensure open, effective, and efficient dynamic engagement between companies, using all the appropriate communication channels open to them as necessary and of preferred choice. This applies in business networks, supply chains, and value networks, as well as at the retail end where new opportunities may be found. Such opportunities include competencies and innovative products and services that can enable the creation, enlargement, or optimization of adaptive value networks. For example such tools include, among others: distributed planning, distributed event-driven decision assistance and tracking, demand lifecycle control, collaborative management of uncertainty and risk, and collaborative design and provision of an environment for context-based e-collaboration services which can rapidly switch the context of working on demand.
- **Environment:** How exclusivity may be stripped away to provide global trade opportunities for all in the world of electronic trade, not only buying but also selling to any region or nation irrespective of differences in

language, culture, or local laws or regulation. Also importantly when designing, making, distributing, and selling products, discovering how to ensure a sustainable development of business that balances economic growth with energy consumption and environmental impact.

Some of these challenges are outlined in Tables 1 to 3.

FUTURE TRENDS

Consolidation of ideas and rethinking of strategy has been enabled not only by a political will (Timmers, 2002; CEC, 2002) and further research and development (CEC, 2003; CEC, 2005), but also by the current global socio-economic, environmental, and energy trends as well as by a greater respect for the social and economic changes among all the industrial players.

ICT providers and consultants to date have provided much of the impetus for industrial change, but industry has now to fully engage with strategic plans to complete the transformation process. One of the challenges highlighted in European statistics is that less than 20% of SMEs[1] had put in place any CRM or SCM software. Change through national incentives, joint projects, and education through regional clusters of companies in the same industry sector is being encouraged. However, it is now realized that technology cannot do it alone in the context of industry, business, and services. Both social and cognitive facets need to be fully understood and solutions found for deficiencies in order to create truly human-centered systems.

Europe, one of the world's largest trading blocks, has reconfirmed its Lisbon objective. The March 2005 European Council declared the aim of increasing the potential for economic growth and of strengthening European competitiveness by investing above all in knowledge, innovation, and human capital. This is reflected in other relevant and complementary work and objectives taking place in the Asian and American trading blocks. Current CEC research has provided many strategies for future manufacturing (Geyer, Scapolo, Boden, Dory, & Ducatel, 2003), e-collaboration (CEC, 2005), as well as delivering results for biometrics (IBG, 2003) of particular relevance to future authentication, and specific industrial supply chain innovations. Research initiatives, such as EC's Framework 7 with a focus on key information

Table 1. Some challenges to organization

- Lack of awareness by very large sections of the business community:
  - How best to educate and train staff
  - Provision of systems and interactive tools to encourage catalytic creative thinking
- Lack of trust for successful e-business
- Insufficient partners in an e-market — liquidity of an e-market
- Lack of perceived benefit
- Inequitable benefits:
  - How benefits and risk are fairly shared
- Lack of sustainable business models
- Limitation of e-collaboration to low-tier suppliers
- Needs to accelerate the business performance targets, for example:
  - Reduction of 'time to market'
  - Better precision for 'just-in-time production and logistics'
  - Provision of faster innovation cycles
  - Working capital efficiency
  - Increased resource utilization across the whole network
  - Improvements to distributed inventory and capacity management
  - Creation of new metrics for value network performance improvement
- Demand for specialty products in small batches through intelligent automated production planning and logistics systems
- Demand for astute fast mobile complex service engineering
- Inter-company e-collaborative design of high-quality complex products
- Lack of standard models and metrics for e-collaboration
- Lack of relevant support for people in multi-tasking jobs
- Lack of ability to manage and control large equipment/product integration produced in value networks to meet the necessary performance targets
- Needs to meet the demand of mass customization and personalization through detailed models and processes and smart, agile order processing
- Ability of companies to conceptualize a value network that is advantageous to them and to identify requirements for new skills, new metrics, and changes to be made
- Needs to have the ability to use shared knowledge and interpret shared information effectively among partners in a value network
- How much transparency should be between partners in a value network
- Belonging to many value networks at the same time
- Lack of standard business processes

Table 2. Some challenges for ICT

• Lack of a cost-effective and affordable, real-time worldwide communication of complex business information to serve the globally distributed nature of business
• Lack of interoperability between systems and applications
• Lack of appropriate multi-lingual facilities
• Lack of an affordable end-to-end high-quality seamless integration
• Lack of integrated workflow
• Free-flowing information flow in an end-to-end, timely, and secure manner
• Right economics for ICT suppliers
• Lack of smart applications and good decision assistance tools for collaborative business
• Need for data capture and filter systems that communicate in real time pertinent information to all partners in the value network
• Knowledge sharing and usage across the value network
• Cognitive decision making
• Tracking individual ordered products from source to consumer and providing a succinct record of such; the human food chain is a critical issue
• Development of intelligent agents as electronic proxies for individuals
• Serve the special needs of SMEs
• How to respond against unplanned/unexpected event with less cost
• Provision of an immersive environment that will automatically handle priorities by user choice, switch contexts of collaboration fast and in real time, and quickly provide all the necessary tools, data, information and knowledge, advanced visualizations to all involved in the collaboration process, and provide the means of management and administration for collaborations, which include new generation security measures and user choice IP protection
• Context orientation
• Intelligent lifecycle for both products and their demand support
• Integration methodologies and technology
• Provision of truly human-centered system
• Easy access to advanced simulators and computing power

Table 3. Some challenges for the business environment

• Too many standards developers and lack of coordination with sources of new work
• Slowness of standards take-up by commercial ICT developers
• Legal challenges:
○ Contract law
○ Cross-border provision of services
○ Protection of intellectual property rights
○ Privacy
○ Consumer protection
○ Electronic payments
• Regulation

and communication technologies, will be a catalyst over the next few years for new working methods through the use of more innovative ICT and application. Other publications suggest that in the near future every single object will be connected to the Internet through a unique wireless address identifier allowing complete lifecycle tracking (Sarma, Brock, & Ashton, 2000; Murray, 2003; Datta, 2004). A roadmap for intelligent agent research is also available (SEEM, 2002).

Productivity is as much to do with people and organization than anything else, and a new way of thinking is highly desirable to deal with business survival and economics. New management styles that allow for greater flexibility and rapid smart responses and lifelong learning are essential to get right. Freeing up time is essential through proper prioritizations of all incoming messages, and events for pressures in the workplace are increasing, such as the overload from e-mail. Help from technology through personal electronic agents looking after both context and priority is one way of accomplishing this. Encouragement of effective and efficient collaboration too between people and mixed discipline teams within and without businesses will result in more creative thinking and help to increase the rate of innovation. Early studies and analysis of organizational webs (Tatnall & Gilding, 1999), value (Zobel & Filos, 2002), and inter-node relationships (Underwood, 2002) and new methodologies for design of networks (Soares, Sousa, & Barbedo, 2003), among many others, have helped to develop the social processes in complex organizations and their symbiosis with new business systems. And the Semantic Web will help to foster the much-needed greater understanding between organizations (Berners-Lee, 2001).

New people—known as the 'gaming generation'—are already arriving at the workplace and are more used to working in virtual spaces that supplement the already diverse backgrounds, characteristics, and behaviors found.

CONCLUSION

Metamorphosis will not be completed over night; the transformation process will take many years before completed. It is expected that a new end state for global business is characterized by an expanding global economy, greater collaboration in smarter value networks, versatile virtual organizations, better deployment of knowledge, greater dynamism, versatility and unhindered opportunities in markets, highly dynamic processes, new standards of customer service excellence, better use of both capital and human resource, and better decision making. This will be brought about through better designed and correct deployments of ICT, for structured, trusted, and secure electronic exchanges between companies. How we procure software and services will change dramatically. Technological advances will continue unabated to feed the desires for improvement. Also applications and tools

will continue to improve with aids for helping organization building, revising or creating new inter-business processes, as well as providing aids for flexible sizing for smart e-collaboration value network configurations. Universal standards will make integration between applications and distributed databases and knowledge bases both easier and cheaper. And new telecommunications technology will improve both the speed and the volume of information flow per unit time from anywhere at anytime. The workforce and end customers will experience a new way of living and fulfillment with the help of human-centered systems. The basic novelty of our age is the spirituality of consumerism and voracious appetite for information. How these may be blended with an increasing capacity for sympathy and mutual understanding will inspire both ways of life and collaborative e-business.

KEY TERMS

Adaptive Value Network (AVN): An arrangement where companies form a web of close relationships and work together as a system that delivers the right customized product and expected service at the right quality in a coordinated manner and are responsive and adaptable to changes in the environment (Makatsoris et al., 2004b).

Collaborative Working Environment: A virtual environment that allows seamless access to all the necessary services for the context of effective and efficient collaboration, and permits all people and teams involved that may be located in any global site and belong to any organization to be fully engaged. The highly distributed and integrated and connected resources are managed to provide fast context switching, IP protection, intuitive user interfaces, multimedia and smart assistance tools, and so forth.

Electronic Business (E-Business): Any form of business or administrative transaction or information exchange that is executed using information and communications technology. This may be transaction performed in a peer–to-peer fashion between companies or organizations or with a customer. Electronic business impacts the way business is perceived.

Electronic Market (E-Market): A market free from inhibiting constraints and affordable for all businesses in any shape, form, or size, and to allow them to easily take part in e-business with beneficial returns. It is a market in which trust, security, and dependability apply and in which regulatory and legal issues are unified. It is a market where buyers and sellers ubiquitously execute business transactions online. These may include searching and identifying competence; ability to identify the right product or service together with quality, price, and quantity; and virtual auctions. It is also based on an open, secure, and reliable collaborative platform for knowledge exchange, joint product design, production planning, and logistics in stable customer-supplier relationships.

Intelligent Software Agent: Acts at speed over the electronic communication channel on behalf of human individuals or companies as their proxy; a program acting on behalf of another person, entity, or process. An intelligent software agent is an autonomous program that is capable of perceiving and interpreting data sensed from its environment, reflecting events in its environment, and taking actions to achieve given goals without permanent guidance from its user. Agents must have the intrinsic ability to communicate, cooperate, coordinate, negotiate, and learn, as well as have the capability to evolve through interactions with other agents. Agents can be standalone or part of a multi-agent system.

Smart Organization: A further evolution of value networks and virtual corporations through the use of more advanced business models taking account of human ICT symbiosis and utilizing more intelligent applications and tools for collaborative work and holistic development of both product and service engineering.

Supply Chain: In its basic form, a buyer-centric chain or network of independent companies that are loosely interlinked by activity along a manufacturing, servicing, and distribution channel of a product service specialty, from sources of raw material to delivery to an end customer. Supplementary to this supply chain management is a set of approaches utilized to integrate suppliers, manufacturers, warehouses, retail stores, and so on. Consequently, merchandise is produced and distributed in right quantities, to right locations at the right time, to minimize system-wide costs while at the same time satisfying service-level requirements.

Value Network: This term is ambiguous, as the analytical perspective colors its meaning. Nevertheless, the value network in general terms evolves from a supply chain through mutual use of ICT and more closely linked collaboration and mutual dependency between the partner organizations or independent companies. Collaboration means electronic communication via extranet, or Internet, co-operation and co-ordination of work flow, information and knowledge exchange, negotiation and dynamic trading, and joint decision making. Value is derived through the exchanges with partner organizations in the network and its shared knowledge. The value network also aims to deliver the highest value to the end consumer and to its stakeholders.

Virtual Enterprise/Virtual Corporation: A virtual corporation or enterprise is formed from a pool of competencies and capabilities resulting from a club of pre-qualified partners that may be expanded or contracted through the mutual desires of the club. The management body for a virtual enterprise selects partners from the pool of competence available to provide products or comprehensive services to any industry in direct competition to single companies or other virtual enterprises. It is necessary to have strong collaborative relationships between partners in the club. The virtual enterprise may exist only on a temporary basis to take market chances, for example tendering. It may also exist for a longer term for optimization of a value network to service a market need.

ICT and E-Democracy

Robert A. Cropf
Saint Louis University, USA

INTRODUCTION

The virtual public sphere does not exist and operate the same everywhere. Every virtual public sphere is different because each country's economic, social, political, and cultural characteristics and relations are varied. As a result, the impact of **information communication technology** (ICT) on political and social conditions will also differ from one country to another. According to the German philosopher, **Jürgen Habermas** (1989,1996), the public sphere is a domain existing outside of the private sphere of family relations, the economic sphere of business and commerce, and the governmental sphere dominated by the state. The public sphere contributes to democracy by serving as a forum for deliberation about politics and civic affairs. According to Habermas, the public sphere is marked by liberal core beliefs such as the freedoms of speech, press, assembly and communication, and "privacy rights, which are needed to ensure society's autonomy from the state" (Cohen & Arato, 1992, p. 211). Thus, the public sphere is defined as a domain of social relations that exist outside of the roles, duties and constraints established by government, the marketplace, and kinship ties.

Habermas' public sphere is both a historical description and an ideal type. Historically, what Habermas refers to as the bourgeois public sphere emerged from the 18th century Enlightenment in Europe and went into decline in the 19th century. As an ideal type, the public sphere represents an arena, absent class and other social distinctions, in which private citizens can engage in critical, reasoned discourse regarding politics and culture.

The remainder of this article is divided into three parts. In the first part, the background of virtual public spheres is discussed by presenting a broad overview of the major literature relating to ICT and democracy as well as distinguishing between virtual and public spheres and e-government. The second section deals with some significant current trends and developments in virtual public spheres. Finally, the third section discusses some future implications for off-line civil society of virtual public spheres.

BACKGROUND

ICT, in the eyes of some forward-thinking observers, (e.g., Abramson, Arterton, & Orrren, 1988; Barber, 1984; Becker & Slaton, 2000; Cleveland, 1985; Clift, 2004; Coleman & Gøtze, 2001; Cropf & Casaregola, 1996, 1998; Davis, Elin, & Reeher, 2002; Grossman, 1995; Negroponte, 1998; Rheingold, 1993; Saco, 2002) makes possible the type of public sphere envisioned by Habermas. According to these e-democracy advocates, ICT provides citizens with numerous opportunities to engage in the political process and take a more active role in the governance process. For example, a guide to effective public engagement notes: "A spectacular array of tools are emerging that give ordinary citizens a greater 'voice' in nearly every aspect of society today" (Lukensmeyer &Torres, 2006). Benkler (2006), for example, asserts ICT, in the form of the ubiquitous World Wide Web, encourages a more open, participatory, and activist approach to politics because it enables users to interact with other users in a way that the mass media does not and is therefore less susceptible to corruption than the mass media (p. 11). Nonetheless, the view that ICT can facilitate deliberative democracy is far from universal; a number of authors assert that technology creates its own set of problems with regard to democratic discourse practices (e.g., Margolis & Resnick, 2002; Sunstein, 2001; Taylor & Saarinen, 1995) Furthermore, these critics of technology argue correctly that advocates do not adequately account for the continued tenacity of mass media's stranglehold over the public discourse in liberal democracies well into the 21st century.

HOW ICT MAKES VIRTUAL PUBLIC SPHERES POSSIBLE

The idea that ICT serves as a catalyst for social and political change has been a motivating force behind netactivism since the dawn of the personal computing era. The ability of individuals to gain access to, store and manipulate vast amounts of information, which ICT makes possible, would lead to a situation where "vast numbers of people empowered by knowledge…assert the right or feel the obligation to make policy" (Cleveland, 1985). The potential of ICT, then and now, is that it enables a many-to-many, decentralized, and nonhierarchical flow of information. By contrast, mass media information flows in a top-down, one-to-many and centralized manner, which requires large amounts of capital investment, concentrating political and economic power in the hands of a small number of multinational or state-run corporations.

ICT consists of numerous tools that create linkages across space and time; allow people to build and participate in communities of their own choice; spread their message to diverse constituencies and collaborate over a networked environment. These tools include but are not limited to: 1) the World Wide Web (WWW), the graphical interface with the Internet; 2) **wikis**, a tool that enables individuals to collaborate on content creation using the WWW; 3) **blogs**, or Web logs, which allows individuals to upload personal content to the WWW; 4) social networking sites, which allow individuals with no pre-existing ties with each other to form online communities and engage in **peer-production**; and 5) handheld and other portable computing devices, which can be used by individuals and groups to communicate "from the field."

HOW VIRTUAL PUBLIC SPHERES DIFFER FROM E-GOVERNMENT

It is necessary here to distinguish between e-governance, which is the "product" of virtual public spheres, and **e-government**. E-government is the use of IT to provide governmental information to citizens and to assist in the delivery of public goods and services. E-government emerged as a phenomenon among Western governments during the mid-1990s. At that time, governments borrowed techniques and processes involving ICT already in use by businesses to facilitate consumer access to goods and services and to optimize management and organizational operations. The principal focus, then and now is on a "services first, democracy later approach" (Clift, 1998); in other words, using technology to provide government services more efficiently, that is, cut costs, rather than as a means to foster greater public engagement and civic deliberation about politics and government (Northrup, Kraemer, Dunkle, & King, 1990).

In this article, I define virtual public sphere as the use of ICT to achieve two chief ends of **e-democracy**: 1) to empower ordinary citizens to engage in effective public discourse regarding the proper ends of politics and the means to attain those ends and 2) to provide the technological means to effect public policy change. While building the necessary public infrastructure to support e-governance typically lags behind a service-based strategy in terms of public sector online efforts, more governments are collaborating with civil society to build online deliberation and policy-making spaces. As the global ICT revolution reshapes social and economic institutions, e-democracy, or "the use of information and communication technologies and strategies by democratic actors (government officials, the media, political organizations, citizens/voters)" (Clift, 2004, p. 38) will continue to make significant strides. Interestingly, the country with perhaps the greatest international reputation for the advanced use of ICT, the U.S., actually lags behind in the global e-government revolution of other countries such as Canada, South Korea and the UK. According to a report issued by the IBM Center for the Business of Government, the above-named countries "have taken giant strides toward modernizing citizen participation by creating policy frameworks and departments with mandates to coordinate citizen engagement online" (p. 34).

CURRENT TRENDS AND DEVELOPMENTS IN VIRTUAL PUBLIC SPHERES

As noted, a growing body of literature builds the case for ICT creating the necessary infrastructure for virtual public spheres, best exemplified currently by the WWW. According to empirical research, small-scale, virtual public spheres have emerged around the world, which closely resemble the ideas put forth by the visionary thinkers discussed earlier. This article, however, can provide only a surface treatment of the numerous experiments in deliberative e-democracy such as those below (year of implementation is in parentheses after project):

1. **The Hansard Society eDemocracy Programme, UK. (Ongoing). (http://www.hansardsociety.org.uk/programmes/e-democracy).** An effort to develop virtual public spheres around policy deliberations involving members of the UK Parliament, public officials and private citizens. The group's official Web site refers to these as "digital dialogues" or the use of ICT to enable and enhance civic engagement. A current initiative, as of October 2007, involves the Ministry of Justice and has three principal aims: 1) to promote knowledge of ICT-based engagement, 2) to cultivate online engagement skills in the central government, and 3) to analyze case studies to develop benchmarks for administrator and user demographics, attitudes and behaviors.
2. **Dialogue with the City, Perth, Australia (2003**). According to the Web site (http://www.wapc.wa.gov.au/Coast/Perth+coastal+planning+strategy/306.aspx), this process was implemented by the Western Australian government to engage the citizens of Perth in planning for their future in the face of some of the highest population and economic growth rates of any city in Australia, which places a significant demand on land, resources and environment. The stated aim of the project is to make Perth the most livable city by 2030.
3. **The International Centre of Excellence for Local eDemocracy (ICELE). UK. (2006).** The goal of

ICELE (http://www.icele.org/site/index.php), according to one of its founders, is "to harness new technologies to make it easy for people across the country to get involved in the democratic process." The Centre carries forward the work of the UK E-Democracy project, which commissioned the study of local best practices in e-democracy in the UK and ended in February 2005. The stated goal of the ICELE is to "provide best practice advice, support and practical solutions to help local authorities increase national eParticipation rates."

4. **North Jutland Democracy Project, Denmark. (2000).** The object of the Democracy Project was to create a virtual public sphere to facilitate deliberative e-democracy among the government and civil society just prior to Election Day, in response to the lowest voter turnout in Danish history just 4 years earlier. Citizens and public officials took part in the project, which resulted in "a very lively and well-visited Web site" (Coleman & Gøtze, 2001, p. 45).
5. **Kalix, Sweden. (2001)** An online "town hall" was created (http://www.stockholmchallenge.se/data/kalix_radslag) in September 2000 as a forum for citizens to engage directly with local politicians and public officials. Some limited electronic voting takes place and residents were given the opportunity to suggest city center redesigns. According to the Web site listed above, the project engaged 86% of its participants through the WWW.
6. **21st Century Town Meeting, USA (Ongoing)**. This is more of a series of ongoing deliberative democracy events rather than any one particular forum. The process was developed by AmericaSpeaks, a nonprofit organization for civic engagement (http://www.americaspeaks.org/). The objective of these town meetings is to bring together a diverse group of individuals to discuss issues and develop policy options. The importance of these deliberative forums from this article's standpoint stems from their innovative use of ICT: Networked laptop computers and wireless technology are used to share small group results with the larger body and decision makers. Examples of 21st Century Town Meetings include a national forum on social security reform, redevelopment of the World Trade Center site after the 9/11 terrorist attack, and as part of a process for biennial strategic planning in Washington, DC (Lukensmeyer & Torres, 2006, p. 25). More recently, 21st Century Town Meetings have been used to help New Orleans residents displaced by Hurricane Katrina develop a housing plan and to plan for pandemic flu outbreak in Maryland.
7. **Canadian International Polcy eDiscussions, Canada (Ongoing).** In 2003, Foreign Affairs Canada launched an effort to involve ordinary Canadians in online discussions on foreign policy issues affecting their country (See http://geo.international.gc.ca/cip-pic/participate/menu-en.aspx). Topics covered in the e-discussions have included "Canada's Role in North America" and "Canada's Approach to Democracy Promotion." E-discussion summaries are distributed to senior Canadian officials whose response is put up on the Web site.

These seven examples barely scratch the surface of the literally hundreds of other virtual public spheres which could have been chosen to illustrate the variety of deliberative e-democracy around the world. Clearly, the virtual public spheres described above indicate the promise inherent in the use of ICT in strengthening democracy. Benkler (2006), however, adds a note of caution: There is not much actual experience with public spheres "built on a platform that is widely distributed and independent of both governmental control and market demands" (p. 176). Thus, while citizens' ability to enter into direct contact with governments is greatly enhanced by ICT, it is still far more common for even democratic Western governments to downplay or ignore virtual public spheres in favor of those elements of the technology which largely improve operational efficiency.

FUTURE TRENDS

In general, while most of democratic governments' online efforts are well meaning, they often stop far short of enhancing civil society. However, as several of the earlier examples show, the truly outstanding efforts have been undertaken by grassroots, nongovernmental organizations that are actively engaged in virtual public sphere creation throughout the world. Indeed, the literature strongly suggests that ICT can help facilitate off-line civil society. Thus, the increase and augmentation of information sharing across individuals and groups in the future will be a major factor in social capital formation, which can be translated into collective action directed toward a common goal (Kavanaugh & Patterson, 2001). For example, in a study of a community technology center, the researchers found that the social relations engendered by the center were critical in promoting community change (Alkalimat & Williams, 2001). The effects on civil society of a virtual public sphere in Melbourne, Australia, found an increase in bonding capital (Meredyth, Hopkins, Ewing, & Thomas, 2002). Another study found that Internet usage bolsters social ties in a suburban community near Toronto, Canada (Hampton & Wellman, 1999). A study of over 20,000 Internet users found that ICT links geographically dispersed groups and individuals sharing common interests (Quan-Haase & Wellman, 2002). What all these studies have in common is the idea that online communities can help strengthen off-line communities. In the future, as

online communities grow and in many cases become intertwined, this will have a beneficial effect in bolstering off-line democracy, whether or not government takes an active role in promoting virtual public spheres.

CONCLUSION

Virtual public spheres, mostly on a small scale, are a reality in many parts of the world today. The networked and widely distributed nature of ICT renders virtual public spheres less vulnerable to the centralizing tendencies of the broadcast mass media, which has resulted in the concentration of economic and political power. ICT de-concentrates and diffuses power as exemplified by peer-production, the wide-scale cooperative behavior of the type that makes open-source software (e.g., **Linux**) and massive projects such as Wikipedia possible. Moreover, ICT makes possible the types of communications and linkages that enhances and expands social capital, thereby serving to strengthen civil society.

KEY TERMS

Blog: Short for Web log. Generally, blogs are personal journals that are kept on the WWW and that can be updated frequently by a user, also known as a "blogger."

Civil Society: Refers to the sector that is different from business and government, which is constituted by voluntary associations including religious groups, labor organizations, citizens' groups and more.

E-Democracy: Using telecommunications technology by democratic actors, including governments, elected representatives, civic organizations, communities, political groups, and activists to improve the political process and political institutions. Examples of e-democracy include online discussion groups, blogs, government Web sites, and other forms of networked participation and civic engagement.

E-Government: Using telecommunications technology as a means to facilitate public administration and improve public access to government information and services.

Linux: An example of open-source software that is peer-produced. A free operating system for servers originally created by Linus Torvalds.

Peer-Production: Large-scale, often worldwide, collaborative efforts to create information, knowledge, and culture (see "Linux" and "Wikis."). Coined by Internet scholar, Yoshai Benkler.

Public Sphere: A concept that originates with the German social thinker, Jürgen Habermas, that refers to communications and relationships that are separate from the state, marketplace, and family structures. It serves to strengthen democratic institutions by serving as a space for deliberation regarding the means and ends of government and politics.

Social Networking: The use of ICT, particularly the WWW, to connect people who share common interests. Examples of successful social networking sites include MySpace, YouTube and Facebook.

Virtual Public Sphere: A group of people whose primary interaction is online but the felt experience of the individuals constituting the group is similar to an actual physical community.

Wiki: A software platform which enables any user to create, edit and otherwise add to Web page. An example of peer-production.

ICT Exacerbates the Human Side of the Digital Divide

Elspeth McKay
RMIT University, Australia

INTRODUCTION

Ethnic and racial tensions are aggravated by social inequities; perhaps it is the media that unwittingly feeds this dilemma. Look at how often we are directed to the Internet for further information. While exploring the Internet may be easy for some computer users, others demonstrate a complete avoidance for this type of knowledge exchange. Moreover, some misunderstandings that occur between cultural communities may be exacerbated by a phenomenon that has become known as the digital divide. There are various definitions of this term. One view takes a purely socio-political focus relating to a socio-economic gap between communities that have access to computer technologies and the Internet and those who do not. Another view covers a broader technological spectrum to include media of any sort, and the information and communications technologies (ICTs). No matter which definition is used, the lack of access to information, for whatever reason, may perpetuate a meaningful gap in cultural differences; the result of which may lead to a more serious communication breakdown throughout the community. This short article argues for more research on measuring the effectiveness of increased opportunities for Web-mediated cross-cultural/intergenerational knowledge sharing that is designed to overcome the ever widening digital divide.

BACKGROUND

It is useful to look at the ways in which a country such as Australia faces its significant socio-economic challenges. The literature reveals that this nation is one of the most multicultural countries in the world (Tsang, 1995), weaving cultural diversity and associated tensions into the social fabric. Furthermore, like many other nations, census statistics show us that Australia is fast becoming an aging nation. These two demographic features may give rise to communication problems associated with cultural and intergeneration discord. Unfortunately, current research appears to be ignoring the importance of the relationship between socio-cultural interaction and Web-mediated knowledge exchange. Moreover, there has been an unrealistic expectation that Web technologies would facilitate the engagement of people to share information through collaborative team work. Consequently, there were calls for researchers to become involved with ICTs to investigate these promises of collaborative Web-mediated information-sharing. Although this work has been taken up by the computer-supported collaborative learning (CSCL) protagonists, projects are still needed to correctly identify the complexity of the Web-mediated interactivity between humans and technology.

Even though the problem of rapidly evolving electronic multimedia was identified over a decade ago, the technologists are still excited today with our ability to create virtual information environments. However, for the more technologically challenged person, it would seem that we have become oblivious to how much we rely on ICTs that continue to change at an ever-increasing rate (Flicker, 2002). Using Australia again as the example, there is a distinct gap between theory and practice that exists within the population for opportunities to utilize ICTs to promote multicultural interaction and knowledge sharing. This disparity can be seen in terms of marked differences in access to the Internet for: enhancing multicultural sharing, promoting knowledge transfer between generations, and facilitating quality outcomes in special education (Stephanidis, 2001).

The aim of this short article is to suggest that ICTs can provide a useful set of easy tools to reduce some of the accessibility problems created by rapidly changing communications media. Issues that are causing concern among the communities who are cognizant of the harmful effects of the digital divide include: the forgotten human-dimension, cultural diversity, and the unequal accessibility to online information.

HUMAN ICT INTERFACE: IMPACTING FACTORS CAUSING CONCERN

To the discerning reader, the dualistic nature of human-computer interaction (HCI) is apparent. Some believe there is an intrinsic capability for HCI to span a socio-dimension in seeking solutions for people's problems; and moreover that ICTs provide effective conduits for producing appropriate outcomes. Yet as we get brighter, smarter machinery, the greater the perils of the digital divide become (McKay, 2005). If, in time, research can show this is the case, then, the predicted Big Brother phenomenon of the 1960s has

won. One only needs to look at the wireless technologies currently available. Consider the mobile phone technologies; the connectivity that is possible today is amazing. However, it is no secret that people do need to be in a position to purchase these smart-technology devices in order to join in this electro-knowledge revolution.

Inappropriate Web-Technologies can Exacerbate the Digital Divide

Deciding which technology to implement adds to the dilemma. While hardware and software standards are still evolving (Sonwalkar, 2005), the standards development's emanating from the Institute of Electrical and Electronics Engineers Inc. (IEEE) and the International Organization for Standardization (ISO) are largely mechanistic and concentrate on interoperability and integration. However, the human-dimension is taken up by the World Wide Web Consortium (W3C) and Web Access Initiative (WAI) accessibility standards (W3C, 2005). The W3C makes recommendations for Web-technologies; while the WAI deals with the issues of increasing accessibility for people with disabilities. The WAI Web-content accessibility guidelines are making progress to clarify the distinctions between technology and content. Unfortunately, Web-technologies can only be viewed as inert mechanisms that initiate nothing more than a means for online communication. Instead, our expectations of the social interface that implements ICT in a global context should involve two levels (Chan, 2003): secure ideological exchange between individuals, and clear representation of cultural perspectives. Therefore, Web-mediated knowledge sharing in this multi-dimensional environment will always be problematic.

Forgotten Human-Dimension

What is to happen with the people who cannot join in? This is where the human-dimension of HCI has an important role to play; to avoid or lessen the inevitable widening digital divide. Sadly, this role is not currently being fulfilled. Inequable access to information through ICT remains the status quo. The digital divide emphasizes the weaknesses of the human-dimensions of current HCI ideology. Moreover, there is a wrongly-focused assumption that all people can access information through a normal range of perceptual senses. To this end, we can see that the literature reveals there is a growing awareness of the belief that one-size-fits-all. This is more poignant through the business/government sectors where access to information affects the bottom line. An example of where ICT is not serving the wider community is to recall our recent graphic witnessing of naturally occurring disasters that affect whole nations; much of this global information sharing was only made possible through ICTs. These types of macro-events test out our ability to provide accessible information to all. Although the initial tsunami struck Indonesia 3½ hours before landing in Sri Lanka and India, our ICTs failed to convey any effective warnings! When it may be reasonable to think that equitable access to information is on the rise, the reverse may be true.

Why has this problem surrounding equal access to global information not been solved? In searching for an explanation of why the issue is now so acute; part of the answer may be that many of us with easy access to computers and the Internet appear to be blinded by technology. We have become accustomed to working quickly, many suffering from information overload. No wonder e-mail has become a common communications tool. However, in the rush to increase their coverage of the electronic information placed before them, tracking the snippets of misplaced knowledge scattered throughout our server mailboxes soon becomes unmanageable. Because of this, the human-dimension of HCI is now quite frail. To understand this, it is useful to reflect on how far we have come in a relatively short period of time.

It has taken less than 2-decades to see the information revolution unfolding. Our obsession on machinery was identified early by Dreyfus and Dreyfus (1986). Another example of where we commenced clinging to the notions that HCI could bring about the seamless ICTs we experience today can be seen in work on the Pask Conversation Theory and the subsequent computer language called *Protologic* (Lp). Pask concentrated on how to emulate the unique ways humans communicate. Although he was convinced that computer learning systems could teach by adapting to a learner's requirements (Pask, 1984), we are still unable to say this has been achieved (Izard & McKay, 2004).

Nonetheless, there is more compelling evidence of this ongoing tension between effective HCI and ICT continuing into the coming decade. Here is where the biggest problem exists. This is perhaps the real nexus of the HCI divide. Questions continue to arise about how best to represent human intelligence on a machine. Nobody really knows! The social sciences and artificial intelligence (AI) proponents cannot agree. On the one hand, the AI view of HCI continues to reflect their commitment towards a more mechanistic view of this phenomenon. While the softer sciences (philosophy, sociology, and anthropology) argue for understanding of the consequences for the human-dimension of technological developments (Preece, 2002). This vexing struggle is about making balanced and sensible choices for the type of HCI employed by our ICTs to advantage the human-dimension. No wonder that effective HCI remains unconquered. Even when there are recognized standards in place, where are the mechanisms in place to maintain compliance?

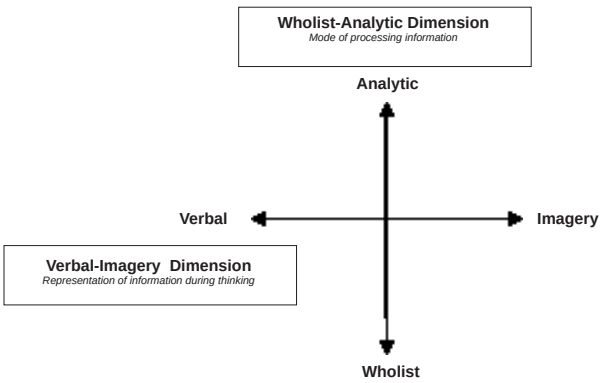
Cultural Sharing

With aging populations in the Western World and global migration in increasing numbers, intergenerational and cultural conflicts are major concerns. Web-mediated cross-cultural/intergenerational knowledge sharing can be designed to overcome facets of the ever-widening digital divide. According to Henry Tsang OAM, the success of cultural diversity depends on the spirit of sharing (Tsang, 1995). One common vehicle for cross-cultural sharing is through the abundant courses available for learning a second language (including ESL). Collecting experimental evidence is underway to provide the opportunity for dealing with the diverse nature of cultural and socio-contexts (McKay & Nishihori, 2004). This work adopts three distinct experiential environments. The first involves senior citizens in recalling traditional stories and games. The second engages youth (teenagers) to interact in multicultural settings, while the third relates to young children's delight in playful sharing of experiential learning. This notion of bringing about such interaction between the generations is not new. Nevertheless, much of this previous work is carried out within, not across, the disparate age groups. At the younger end of the age scale, new works are coming forward to describe early childhood development and ICT. More evidence is available for the youth with a rapidly growing interest in mobile technology for the school-aged group (Friedlander, 2004). While at the upper end of the age scale, there is a more limited number of successful projects that can describe intergenerational knowledge sharing (Kolodinsky, Cranwell, & Rowe, 2002). To bring about a positive change in this rather blinkered approach to reducing the negative effects of the so-called digital divide, this article suggests there is a real possibility of making positive inroads drawing on the strengths of HCI.

The Human Dimension of Accessibility

Perhaps all is not lost. There is a refreshed interest in the ways humans communicate online. The literature reveals research which distinguishes human ability to process information, as a combination of mode of processing information, and the way people represent information during thinking (see Figure 1). Riding and Rayner (1998) identified two fundamental cognitive dimensions (wholist-analytic and verbal-imagery) that affects performance in two ways. The first way is in how we perceive and interpret information we are given. While the second way is how we conceptualise related information already in our memory. Cognitive style is understood to be an individual's preferred and habitual approach to organizing and representing information. Measurement of an individual's relative right/left hemisphere performance and their cognitive style dominance has been a target of researchers from several disciplines over the last decade. Different theorists make their own distinctions on an individual's cognitive

Figure 1. Cognitive style construct (Riding & Rayner, 1998)



differences. However, little is known about the interactive effects of the cognitive style construct and multimedia delivery techniques on performance outcomes.

FUTURE TRENDS

Experimentation of the interactivity between humans and technology within a Web-mediated context has renewed the innovations that are emerging within the CSCL community (McKay & Nishihori, 2004). The expected collaborative interactions within such an online knowledge sharing entity are not just computerised collections of traditional games and stories but an opportunity for the capture and reuse of the interactive play with embedded instructional strategies.

It is proposed that Web-mediated knowledge sharing opportunities will nurture and cultivate individual creativity in both children and adult learners of English (Schank, 1988), by offering them an abundant supply of traditional games and stories. Children can be invited to a tightly-monitored, Web-mediated playing system, which includes specially designed playing environments where they can participate in a virtual exhibition room to enjoy collaborative play with other children. This type of research project pioneers Web-mediated processes for capturing and analysing this cross-cultural and inter-generational interaction (Nishihori, Okabe, & Yamamoto, 2002).

Spin-offs from this type of research project will provide an understanding of new ways to unite members of the community that are enjoyable, playful, and encourage lifelong learning. There is a real chance to discover ways to engage a diverse cross-cultural user network, including elderly citizens and younger family members to benefit from the collaborative story telling activities. Breaking down barriers to the digital divide will assist in strengthening family relationships and reduce cross-cultural tension in the Asia/Pacific region. Equitable access to information technol-

ogy will ensure each person has the choice to partake in the richness of 21st century communications technologies.

CONCLUSION

Seamless navigation tools are a move in the right direction. System's development teams must establish an understanding of their project's linguistics. Developing such a common nomenclature promotes synergies between ordinarily divergent disciplines. For example, product engineers are more familiar with technological issues than their end-user consulting counterparts who concentrate on the human factors relating to accessibility issues. More work is needed to bring about a paradigmatic knitting together of disparate professional communities of practice. For instance, in a system's development team, the knowledge engineer may not have sufficient technological skills to build the devices they perceive; while the software specialist may not be able to articulate the human-dimension.

Unless research can correctly evaluate the ingredients of the digital divide, the gap between theory and practice will continue to widen. Lost will be the understanding of the benefits that semiotic/discovery activities may elucidate for cross-cultural sharing. Lost too will be the knowledge and experiences of a dying generation who fought wars to allow our creativity to flourish.

KEY TERMS

Cognitive Style Construct: This term represents Richard Riding's cognitive style dimensions. First, the wholist-analytic dimension (mode of processing information) defines that wholist learners are able to perceive the whole concept, but may find difficulty in disembedding its separate facts (McKay, 1999). Whereas Analytic learners analyse material into its parts but find difficulty in seeing the whole concept. Second, the verbal-imagery continuum (mode of representing information while thinking) measures whether an individual is inclined to represent information verbally, or in mental pictures, during thinking (Riding & Rayner, 1998).

Computer-Supported Collaborative Learning (CSCL): An emerging and important educational research paradigm that focuses on socially-oriented theories of learning using computer technologies to support collaborative methods of instruction.

Cross-Cultural/Intergeneration Knowledge Sharing: The issue of cross generational communications breakdown. Difficulties that arise through intergenerational perspectives (Thomas, 1998) can be witnessed in many parts of the community: at home with parents and siblings, in workplace reporting networks with age differences of employees, and at school between staff and students. Knowledge sharing across these boundaries will improve the disparity that currently exists.

Digital Divide: Understanding of this term is changing with time. Originally, it signified a socio-political environment and referred to the socio-economic gap between groups of people who had access to computers and the Internet. However, in 2005, this term reaches much further to bring about a more international context to highlight where disadvantaged groups and developing or poorer nations are pitted against the wealthy countries that have unlimited access to the plethora of electronic gadgetry.

Human-ComputerInteraction (HCI): The concept of HCI is not new. However, the proliferation of HCI has only occurred during the last decade. People building computerized systems have struggled for many years to define interactive relationships of HCI. The term should not be used just for the physical interaction between humans and computers; it includes all the cognitive processes required for humans to effectively utilize computerized medium.

Interoperability: Hardware and software devised to help people exchange information ensuring computer systems can to talk to each other, interpret data, and exchange information.

Smart-Technology Devices: Hardware/products that have AI enhanced capabilities and/or the ability to access the Internet. Some of these devices are designed to sense your actions or learn your patterns and alter their behaviour accordingly.

Virtual Information Environments: Internet-based information systems that provide a user with an interface that implements a multi-dimensional and real-world context through AI contrived metaphors that create highly visualized and often interactive experiential space.

Web Content Accessibility Guidelines (WCAG): The four design principles for Web accessibility include:

1. content must be perceivable;
2. interface elements in the content must be operable;
3. content and controls must be understandable; and
4. content must work with current and future Web technologies (WAI, 2002).

Web-Mediated Knowledge Exchange: The interactive use of online instruction as an effective tool in bringing about a knowledge-sharing culture, linking professional practice and education in life-long learning.

IDS and IPS Systems in Wireless Communication Scenarios

Adolfo Alan Sánchez Vázquez
University of Murcia, Spain

Gregorio Martínez Pérez
University of Murcia, Spain

INTRODUCTION

In principle, computers networks were conceived to share resources and certain computing devices among a select group of people working in academic institutions. In this context, the security did not have high importance. Today, through the network circulates a lot of valuable data (budgets, credit card numbers, marketing data, etc.), much of which can be considered confidential. Here is where security takes great importance—so that these data cannot be read or modified by any third party, and the services offered are always available and only to authorized people (confidentiality, integrity, and readiness).

When we refer to security, there are some terms of great importance. *Risk* is defined as any accidental or not prospective exhibition of information as consequence of the bad operation of hardware or the incorrect design of software. *Vulnerabilities* indicate when a failure in the operation of software and/or hardware elements exposes the system to penetrations. Starting from here we can define *attack* as an event against the good operation of a system, and it can be successful or not. If the attack is successful and access is obtained to the files and programs or control is obtained to the computers without being detected, then we are dealing with a *penetration.* This leads to an *intrusion,* which is a group of actions compromising the integrity, confidentiality, and readiness of computer resources (Sobh, 2006).

The main objective of this article is to explain to the reader the main concepts regarding intrusion detection systems (IDSs) and intrusion prevention systems (IPSs), and the particular issues that should be additionally considered when protecting wireless communication scenarios (in comparison with IDSs/IPSs in traditional wired networks). It also includes an extended view of the current state of the art of IDSs and IPSs in wireless networks, covering both research works done so far in this area, as well as an analysis of current open source IDSs and IPSs, and how they are dealing with the specific requirements of wireless communication networks.

This article is organized as follows: First, we start with a summary of the main related works in the *background* section; then we give a description of the important concepts of security, a classification of intrusion detection systems, and a brief comparative of the operation of IDSs in wired and wireless networks. Next, we highlight certain research works exemplifying efforts done so far in wireless scenarios. We present the main ideas behind our current research work to model intrusions in wireless scenarios, before offering future directions of work and a summary of the main ideas expressed in the article.

BACKGROUND

Many have been the efforts carried out to counteract the main weaknesses of IDSs and IPSs in wireless networks. In this sense, we can speak of different investigations directed to specific attacks in wireless scenarios by means of detection mechanisms based on artificial intelligence, design of monitoring IDSs, proactive IDSs, modeling of IDSs, and approaches based on system requirements and political issues.

Aime, Calandriello, and Lioy (2006) propose a mechanism of attack detection based on the shared monitoring of the networks by all the nodes, where one will be able to determine if the event is a bad behavior or an attack. The key idea is to install a monitor (ethereal) in each node of the network, and to produce evidence (information about the state of the network) and to share that among all the nodes. For each captured package, the system spreads a complete view of the packet headers, some general statistics are added such as timestamp, frame number, and longitude in bytes. The focus is 802.11 frames, although they are also considering source, destination, and BSSID addresses, sequence number, frame type, subtype, and retry flag. With this data, a list of events is built in each node.

We also find efforts based on anomaly detection by means of artificial neural networks, where the intrinsic characteristics and observables of the normal behavior are different from the abnormal behavior. A clear example is the proposal of Liu, Tian, and Li (2006), whose method of detection of intrusions is based on DGNN (dynamic grow-

ing neural network) and consists of Hebbian learning rules to which are added new neurons under certain conditions. Three of the more common attacks in wireless networks are: war driving, MAC spoofing, and WEP cracking, and we find investigation focused on preventing this type of attack. Hsieh, Lo, Lee, and Huang (2004) developed a proactive wireless hacker detection system (WIDS) basically based on a framework that proposes an answer plan designed to prevent the user in intranets of additional damages for each attack type. The structure of this proposal consists of five modules: packet capture, session analysis, hacker detection, honeypot, and alarm modulates. Tsakountakis, Kambourakis, and Gritzalis (2007) propose a design of WIDS modules to tackle 802.11i-specific attacks. Also, it evaluates the 802.11i-enabled WIDS modules, namely WIDZ. The tests were performed utilizing the majority of well-known open source attack tools and specific attack generators. Some types of attacks were detected and others were not detected.

WIRELESS INTRUSION DETECTION AND PREVENTION SYSTEMS

Wireless networks are particularly susceptible to attacks as interception and injection, to mention just one example. The problem is inherent to wireless protocols since they use the air as its primary means of transmission. Contrary to the conventional network where the location of a network is physically limited by the infrastructure of the network, the locus for a wireless device is not limited to a connection network backplane. This represents serious problems in the moment of deploying IDS. In wireless networks, IDSs receive packages of any closer networks or next antennas; this means that the IDS may process a great quantity of malicious packages and of unknown origin. The signs in wireless networks vanish in cloud form around the access point, and the signal radiated is attenuated, allowing that, in the periphery of the cloud, a corrupted signal and certain packets originate.

The IDS based on a network (NIDS) commonly listens to the network, captures and examines the packages flowing through the same network in contrast with the firewalls; NIDS can analyze the entire packet, not just the header. It is able to look at the payload within a packet to see which particular host application is being accessed, and raise alerts when attackers try to exploit a bug in such code. NIDSs are host independent, and can run like "black box" monitors to cover entire networks. In practice, active scanning slows down the network considerably and can effectively analyze a limited bandwidth network. NIDSs often required dedicated hosts/special equipment and can be prone to the network attack (Kachirski & Guha, 2003).

The IDS based on a host (HIDS) only cares what is happening in each individual host; monitors specific files, logs, and registries installed in a single computer; and they can alert any access or modification in the object monitored (Chari & Cheng, 2003).

They are able to detect actions such as repeated failed access attempts or changes to critical system files, and normally operate by accessing log files or monitoring real-time system usage. To ensure effective operation, host IDS clients must install every host of the network, tailored to specific host configuration. Host-based IDSs do not depend on network bandwidth and are used for smaller networks, where each host dedicates processing power towards the task of system monitoring (Kachirski & Guha, 2003).

IDSs, according to their functionality, are classified in anomaly detection and misuse detection systems (Tombini, Devar, Mé, & Duccassé, 2004). Anomaly detection consists of the detection of intrusions based on the non-habitual behavior of a system or the resources of the same one. The objective is to evaluate the correct use and acceptable behavior of a certain system, pointing out any activity that is outside of this behavior. Among the more highlighted efforts in this aspect, we find the use of statistical analysis, data mining, and limitation of flow or traffic.

Misuse detection is directed to the identification of intrusions in a system by means of the establishment of static information, providing a necessary base to determine a malicious activity according to how the static information is structured. A classification is obtained that is of vital importance; a classifier trains to discriminate, being based on the data of the network traffic.

The use of wireless networks has generated important changes in the implementation of the IDS, as wireless networks are conceptually and operationally different. For the wired system, the IDSs are distributed applications analyzing events in a network system to identify malicious behavior (Vigna, Valeur, & Kemmerer, 2003). And for wireless systems, intrusion detection systems analyze events in mobile and ad hoc networks. For this reason any discussion in relation to these architectures and their operational atmospheres will allow an in-depth exploration of the important aspect to consider in the moment of displays in an effective way wireless intrusion detection systems.

Stallings (2003) shows us in the Table 1 the clear limitation of IDS systems in wireless networks.

Already mentioned were the natural risks of a wireless network, helping us to identify a series of possible attacks that put in risk the security of the information and the stability of the computational systems. Table 2 summarizes these possible attacks, found in a recent investigation by Zhong, Khoshgoftaar, and Nath (2005).

IPS

An intrusion prevention system (IPS) is a mechanism that tries to provide an automatic, efficient, quick, and exact answer

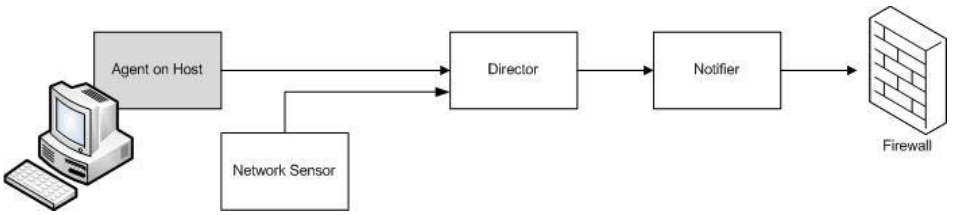
Table 1. A summary of the clear limitation of IDSs in wireless networks

• Network-based IDS sensors that have been placed on the wired network behind the wireless access point will not detect attacks directed from one wireless client to another wireless client (i.e., peer to peer) on the same subnet.
• Network-based IDS sensors on the wired network usually will not detect attempts to "dissociate" a legitimate client from the wireless network and will not detect the association of an unauthorized wireless client with the wireless network.
• A network-based IDS for a wired network will not be able to detect the physical location of the compromised host or rouge access point.
• A network-based IDS for a wired network will not be able to detect an authorized wireless device communicating peer to peer with an unauthorized wireless device.

Table 2. A summary of possible attacks to wireless networks

Attack Type	Attack Name
Passive	War Driving
	Man-in-the-Middle Attack
	High-Power Amplifiers
	Dictionary Attack–WPA
Masquerade	MAC Address Spoofing
	Bypassing Access Control List
	Authenticated User Impersonation
	Invalid State
	De-Authentication
	Disassociation
	ARP Poisoning
	MAC-Based Inference of ACL
	Virtual Carrier Sense Attack
Replay	Packet Re-Routing
Modify	Packet alteration
	Packet insertion
Denial of Service	Denial of Service
	RTS/CTS Flood
	Fragmentation Attacks
	Wormhole Attacks
	Network Injection Attacks
	Multiple Virtual Access point

Figure 1. The architecture of an IPS (Bishop, 2003)



to an intrusion attempt or attack that can cause damages in computational resources. The objective of the IPS is mainly to prevent attacks against the place being protected. Some of the main characteristics of such a system are that it should be easily adjustable and be integrated in the same way to the network of the organization. In this way, it can quickly answer, in real time, an attack (well known) in progress, although it is important to mention that these systems should have an index of false negatives. The main decisions of an IPS take in the expert motor of the system based on training; these periods of training should be minimal, thus allowing that details in a manual way are tuned. Figure 1 shows the architecture of an IPS.

MOTIVATION FOR AN INFORMATION MODEL IN WIRELESS INTRUSION DETECTION SYSTEMS

Network, service, and application management today face numerous challenges, ones that older ways of doing things cannot solve. The concept of policy-based management (PBM) addresses some of these problems and offers possible solutions. It provides a system-wide view of the network and its services and applications, and shifts the emphasis of network management and monitoring away from specific devices and interfaces towards users and applications. One of the main goals of policy-based management (Verma, 2002) is to enable network, service, and application control and management at a high abstraction layer.

The administrator specifies rules that describe domain-wide policies that are independent of the implementation of the particular network node, service, and/or application. It is then the policy management architecture that provides support to transform and distribute the policies to each node and thus enforce a consistent configuration in all the elements involved.

Policy rules are independent of a specific device and implementation, but they define in abstract terms a desired behavior. There are two main perspectives to define a policy (Westerinen, Schnizlein, & Strassner, 2001), and each represents a different level of abstraction: business level and technological level. A human policymaker initially provides the business-level policy using an informal language, then the task of a policy administrator is to transform the business policies into formal policies using a representation. For doing this, the administrator uses a policy language that assures that representation of policies will be unambiguous and verifiable.

As part of our investigation, and following this motivation, we are currently developing a common model based on the CIM (common information model) standard of the Distributed Management Task Force for the representation of intrusions in wireless scenarios. Since there are a lot of attacks that can be developed in these wireless environments, and authors do not come to an agreement on the exact meaning and scope of concepts like virus, worm, and so forth, this has led us to the idea of extracting the semantic content and providing the concept of patterning the power that allows the user to create a classification by him or herself.

FUTURE TRENDS

As statement of direction, we are now designing and testing an extensible information model where different concepts relevant to wireless IDSs can be expressed. We are also implementing this model as part of Snort and linking the information expressed here with the attack rules provided by the international community already working in wireless IDSs. Additionally, this model will be tested in our labs using complex attacks for wireless scenarios, as those explained as part of this article.

CONCLUSION

Intrusions in wireless networks represent a serious problem for economic, political, and educational organizations since many of them are supporting their main activities in wireless environments. Wireless intrusion detection/prevention systems are still needed tools for this monitoring and management of countermeasures against attacks.

In this article, we have provided a revision of the state of the art of IDSs in wireless environments and their possible attacks. This allows having a clear idea of the problem of representing attack information and its possible solutions.

Wireless devices and their corresponding protection have propitiated an increment in the use of intrusion detection systems which generates in many occasions the problem of representing the same information in diverse formats as a result of the generation of heterogeneous environments. It is necessary to highlight that there is a need to generate a model that represents in a uniform way the intrusions that can be generated in these environments.

KEY TERMS

Common Information Model (CIM): An approach from the Distributed Management Task Force for the man-

agement of systems and networks; it applies to the basic techniques of the object-oriented paradigm. The approach uses a uniform modeling formalism that, together with the basic repertoire of object-oriented constructs, supports the development of an object-oriented schema across multiple organizations.

Host-based Intrusion Detection System (HIDS): Protects the machine in which it is installed. The data generated are used as a source of information, especially by the computer that operates at the operating system level: audit files of the system, files logs, or any file that the user wants to protect.

Intrusion Detection System (IDS): Hardware and/or software with certain intelligence monitoring able to analyze automatic events that happen in a computing system or network. The system's main objective is to identify possible threats and to carry out response actions.

Intrusion Prevention System (IPS): The set of mechanisms trying to provide an automatic, efficient, quick, and exact answer to intrusion intent or attack that can cause damages in a host or network. The objective of the IPS is mainly to prevent attacks against the entity (or entities) being protected.

Network Security: Those activities, techniques, or rules dedicated to prevent, protect, and preserve information and resources.

Network-based Intrusion Detection System (NIDS): Uses traffic networks and TCP/IP packages as sources of information. These systems revise the packages that circulate through the network searching for elements that denote an attack against some of the systems located in it. Of these packages they verify the validity of some parameters and the behavior of the protocols.

Policy Rules: Set of management rules independent of a specific device and implementation, and defining in abstract terms a desired behavior. These are stored and interpreted by the policy framework, which provide a heterogeneous set of components and mechanisms that are able to represent, distribute, and manage policies in an unambiguous, interoperable manner, thus providing a consistent behavior in all affected policy enforcement points

Wireless Attack: Malicious activities putting at risk the security of the information and of the computing resources in wireless scenarios.

Image Compression Concepts Overview

INTRODUCTION

Image compression aims to produce a new image representation that can be stored and transmitted efficiently. It is a core technology for multimedia processing and has played a key enabling role in many commercial products, such as digital camera and camcorders. It facilitates visual data transmission through the Internet, contributes to the advent of digital broadcast system, and makes possible the storage on VCD and DVD. Despite a continuing increase in capacity, efficient transmission and storage of images still present the utmost challenge in all these systems. Consequently, fast and efficient compression algorithms are in great demand.

The basic principle for image compression is to remove any redundancy in image representation. For example, simple graphic images such as icons and line drawings can be represented more efficiently by considering differences among neighbor pixels, as the differences always have lower entropy value than the original images (Shannon, 1948). These kinds of techniques are often referred to as lossless compression. It tries to exploit statistical redundancy in an image so as to provide a concise representation in which the original image can be reconstructed perfectly.

However, statistical compression techniques alone cannot provide high compression ratio. To improve image compressibility, lossy compression is often used so that visually important image features are preserved while some fine details are removed or not represented perfectly. This type of compression is often used for natural images where the loss of some details is generally unnoticeable to viewers.

This articles deals with image compression. Specifically, it is concern with compression of natural color images because they constitute the most important class of digital image. First, the basic principle and methodology of natural image compression is described. Then, several major natural image compression standards, namely JPEG, JPEG-LS, and JPEG 2000 are discussed.

BACKGROUND

A common characteristic of most images is that the neighboring pixels are correlated and thus contain redundant information. The main goal of image compression is to reduce or remove this redundancy. In general, two types of redundancy can be identified (Gonzalez & Woods, 2002):

- **Spatial redundancy:** This refers to the correlation between neighboring pixels. This is the only redundancy for grayscale images.
- **Spectral redundancy:** This refers to the correlation between different color planes or spectral bands. This redundancy occurs in color images or multispectral images and exists together with the spatial redundancy.

Image compression techniques aim at reducing the number of bits needed to represent an image by removing the spatial and spectral redundancies as much as possible. The compression is lossless if the redundancy reduction does not result in any loss of information in the original image.

Besides redundancy, an image may also contain visually irrelevant information. The visually irrelevant information refers to information that is not perceived by human observers. Irrelevancy reduction thus aims at removing certain information in the image that is not noticeable by the Human Visual System (HVS). In general, some form of information loss is incurred when irrelevancy reduction is performed (Xiao, Wu, Wei, & Bao, 2005).

A number of standards have been established over the years for natural image compression. JPEG is the most common image file format that is found in existing Internet and multimedia systems (Pennebaker & Mitchell, 1993; Wallace, 1991). JPEG stands for Joint Photographic Experts Group. It is the name of the joint ISO/CCITT committee that created the image compression standard in 1992. There are two compression modes in the JPEG compression standard: lossless and lossy. However, the lossy mode dominates in almost all applications. The JPEG image compression codec has low complexity and is memory efficient. However, its

main criticism is the appearance of the blocking artifacts, especially at high compression ratios.

In 2001, the Joint Photographic Experts Group created another new image compression standard, called the JPEG 2000 (Taubman & Marcellin, 2002). This new standard provides an improved compression performance over JPEG and avoids the blocking artifacts completely. Besides the better compression performance, it also provides progressive capability in which the JPEG 2000 bitstream is organized in such a way that the image quality gets better progressively in terms of quality or resolution (Lee, 2005). Compared to the JPEG standard, JPEG 2000 is not widely supported at present. It is hindered by the fact that some of the algorithms are patented. As a result, it cannot be included in open-source Web browsers, which affects its popularity.

IMAGE COMPRESSION METHODOLOGY

Basic Compression Scheme

In general, most natural image compression schemes have a common structure, as shown in Figure 1. The first stage is usually a color space conversion module. Typically, a color image is stored in the RGB format. Because compression in the RGB domain is very inefficient, the image is converted into a luminance-chrominance color representation, that is, YCbCr, where the Y component represents the luminance information while the Cb and Cr components represent the color information. The image is then subjected to a transformation like the discrete cosine transform (DCT) (Ahmed, Natarajan, & Rao, 1974) or discrete wavelet transform (DWT) (Heil, Walnut, & Daubechies, 2006). The transformation decorrelates the image data, and thus reduces redundancy. The resulting coefficients are next quantized and entropy encoded. To quantize a signal means to describe it with less precision. Hence, some image information is inevitably discarded. Scalar quantization quantizes each coefficient separately using a predefined quantization table. It is the most common quantization scheme due to its simplicity. The rate-distortion (RD) unit controls the quantization step-size as a function of the bit-rate R and distortion D (Sarshar & Wu, 2007). Sometimes a RD unit is not explicitly defined, but is indirectly controlled by the nature of the quantizer.

Instead of quantizing each coefficient separately as in a scalar quantizer, vector quantization (VQ) can be used to represent a signal piecewisely by short vectors from a codebook. The codebook generally contains a limited number of entries that approximate the signal pieces. Compression is achieved in VQ because only the index of the best codebook entry needs to be encoded and transmitted.

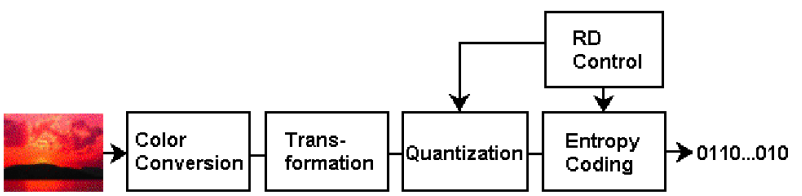
Exploiting the Limitations of the Human Visual System (HVS)

High compression ratio is usually achieved by aggressively exploiting the limitations of the HVS. Psycho-visual experiments have shown that the HVS has reduced sensitivity for patterns with high spatial frequencies. The phenomenon is parameterized by the contrast sensitivity function (CSF). Exploiting this behavior can significantly improve the compression ratio without incurring noticeable distortion. The quantization table in JPEG makes use of this phenomenon to some extent by using a large quantization step for high spatial frequency DCT transform coefficients in the luminance channel.

The sensitivity of the HVS for compression artifacts also varies with respect to the strength of local contrasts. Thus, an artifact might be hidden by the presence of strong contrasts or locally active image regions. This phenomenon, referred to as masking, is exploited in some sophisticated compression schemes (Gonzalez & Woods, 2002).

Subjective quality evaluations showed that the HVS is very sensitive to the loss of texture information. Blurred image with texture loss usually appear unnatural. However, the exact encoding of texture information is bit-rate intensive. To overcome this problem, a generative approach for texture region encoding is sometime employed in advance compression algorithms (Egger, Fleury, Ebrahimi, & Kunt, 1999; Ryan et. al. 1996). In this approach, the texture is characterized by only a few parameters that can be encoded for a modest increase in bit-rate. During decoding, the texture is synthe-

Figure 1. General structure of image compression algorithms



sized from these parameters. Even if the synthesized texture is pixel-wise different from the original texture, the HVS is nevertheless deceived due to their apparent similarity.

The HVS is unable to distinguish small differences in color as easily as it can to changes in brightness value. This phenomenon is exploited in chroma subsampling by dropping half or more of the chrominance information in the image (Poynton, 2003). At normal viewing distances, there is no perceptible loss incurred by sampling the color detail at a lower bit rate.

Compression Quality Evaluation

For lossy image compression, the image is not reproduced exactly. An approximation of the original image is enough for most purposes, as long as the error between the original and the compressed image is tolerable. Two type of quality evaluation are often used to assess the performance of different compression algorithms: (i) objective error metrics and (ii) subjective quality evaluation. Objective error metrics are quantitative and do not take into account the properties of the HVS, whereas subjective quality evaluation measures only the perceptually important distortion as determined by the HVS and is usually qualitative.

The Peak Signal to Noise Ratio (PSNR) is the most commonly used objective error metrics for measuring the quality of the reconstructed image. The PSNR is defined as:

$$PSNR = 10 * \log_{10}(MAX_I^2 / MSE),$$

where MAX_I is the maximum pixel value of the image (255 for 8 bit grayscale image). The MSE is the Mean Square Error between two images I and I', and is given by:

$$MSE = 1/MN \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} [I(i,j) - I'(i,j)]^2.$$

It is well known that PSNR does not correlate well with perceptual judgment of reconstruction quality.

The most common subjective quality evaluation is by visual inspection. Mean opinion score (MOS) can also be used to provide a numerical indication of the perceived quality of reconstruction quality (ITU-R Recommendation, 1992). The MOS averages the subjective evaluation of a group of viewers on different visual criteria based on a numerical score, for example, 1 = lowest perceived quality to 5 = highest perceived quality. Subjective quality evaluation is a difficult problem and currently there is no universally accepted method of performing subjective quality evaluation (Wei, Li, & Chen, 2006).

Post-Processing for Compression Artifacts Removal

Highly visible compression artifacts appear in the reconstructed image at high compression ratio. These artifacts are usually visually annoying to the viewers and a lot of research has been done to suppress them. Post-processing the reconstructed image for compression artifacts suppression has been a popular solution to this problem (Liew & Yan, 2004; Liew, Yan, & Law, 2005; Yarnatani & Saito, 2006).

For coding algorithms based on block-based DCT such as JPEG, the major artifacts are characterized by blockiness in flat areas and ringing along object edges. For wavelet-based coding techniques, ringing is the most visible artifact. Reduction of these artifacts can result in a significant improvement in the overall visual quality of the decoded images. The general approach is to reduce the block discontinuities along the 8×8 block boundaries by certain form of smoothing while preserving genuine edges in the image (Law & Siu, 2001). Alternatively, smoothing can be applied to region segments that exhibit slow intensity variation (Liew, Yan, & Law, 2005). Ringing suppression can be done by locally suppressing ringing ripples near the vicinity of strong edges (Liew & Yan, 2004).

Compression Choices

Some of the important choice/considerations for image compression are as follows:

- **Lossless compression:** For some applications, lossless compression is required. In this case the reconstructed image will be exactly equal to the original image. Lossless compression is usually used for medical applications. The best compression factor that can be achieved is typically around three.
- **Visually lossless compression:** If a human observer cannot see any difference between the original and the compressed image, the compression is visually lossless. Most compression algorithms exploit the properties of the human visual system (HVS) to achieve high compression factor, that is, up to 20 or 30, without noticeable degradation of the perceived image. This is done by discarding part of the image information that is not perceivable by the HVS.
- **Scalable or progressive coding:** A nonprogressively encoded bitstream must be received in its entirety before the inverse transform can be applied. However, for a progressively encoded bitstream, the inverse transform can be applied to a partially decoded bitstream. Progressive encoding arranges the bitstream in such a way that the most important information is near the

front end of the bitstream and decreasingly important information is toward the back of the bitstream. During decoding, the critical information at the front of the bitstream can be used to construct an approximate version of the image and the quality or resolution of the reconstructed image is progressively increased when further bitstream is received and decoded.

CURRENT IMAGE COMPRESSION STANDARDS

JPEG

The lossy mode in the JPEG image compression standard is widely used in WWW and multimedia systems. First, the image is converted from the RGB color space to the YCbCr color space. Because the human eye is relatively insensitive to the chrominance information, the Cb and Cr components are usually downsampled. Next, each of the Y, Cb and Cr components are grouped into 8×8 blocks. Discrete cosine transform (DCT) is then applied independently to each block to get the DCT coefficients. This is followed by the process of quantization in which each DCT coefficient is divided by a number and rounded to the nearest integer. Because humans are not good at seeing differences in high frequency components as compared to the low frequency components, the DCT coefficients are quantized differently: the divisor for the low frequency DCT coefficients is much smaller than that for the high frequency DCT coefficients. Many high frequency components are rounded to zero after quantization. "Zig-Zag" scanning then organized the two dimensional DCT coefficients block into a one dimensional coefficient stream so that similar frequency components are grouped together. Run-length or Huffman coding can then be applied to further compress the resulting bitstream.

The image quality depends greatly on the choice of the divisors in the quantization process. Good image quality is often obtained for a compression ratio of less than 10. For compression ratio larger than 100, images appear to be blocky due to the fact that quantization is applied independently to each of the 8×8 blocks.

The JPEG standard also has a lossless mode. Lossless JPEG was developed as a late addition to JPEG in 1993, using a completely different technique from the lossy JPEG standard. It uses a predictive scheme based on the three nearest neighbors (upper, left, and upper-left), and entropy coding is used on the prediction error. It was never widely adopted and its performance is not state-of-the-art.

JPEG-LS

JPEG-LS is the new lossless/near-lossless compression standard for continuous-tone images, ISO-14495-1/ITU-T.87. JPEG-LS was developed with the aim of providing a low complexity lossless image compression standard that could be able to offer better compression efficiency than lossless JPEG. Part 1 of this standard was finalized in 1999. The standard is based on the LOCO-I algorithm (LOw COmplexity LOssless COmpression for Images) developed at Hewlett-Packard Laboratories, that relies on prediction, residual modeling and context-based coding of the residuals (Weinberger, Seroussi, & Sapiro, 2000). Most of the low complexity of this technique comes from the assumption that prediction residuals follow a two-sided geometric distribution (also called a discrete Laplace distribution) and from the use of Golomb-like codes, which are known to be near-optimal for geometric distributions. Besides lossless compression, JPEG-LS also provides a lossy mode where the maximum absolute error can be controlled by the encoder. Compression for JPEG-LS is generally much faster than JPEG 2000 and much better than the original lossless JPEG standard.

JPEG 2000

JPEG 2000 is another newly developed image compression standard, which provides better image quality and stronger compression power than JPEG. Instead of using the block-based DCT, JPEG 2000 uses the wavelet transform so that the blocking artifacts can be avoided completely. Similar to the JPEG standard, an image is first converted from the RGB color space to YCbCr or the reversible component transform (RCT) color space. The image is then split into rectangular regions called tiles so that wavelet transform can be applied to each tile independently with different decomposition levels. The JPEG 2000 standard uses the floating-point biorthogonal 9/7 wavelet kernel for lossy compression and integer 3/5 kernel for lossless compression.

The wavelet coefficients are organized into a set of subbands that shows spatial details under a certain frequency range. These coefficients are then quantized to produce a set of integer numbers. The quantized subbands are split into rectangular regions in wavelet domain called precincts. Precincts are further split into codeblocks in which the Embedded Block Coding with Optimal Truncation scheme is employed to each code block in a biplane order. There are three coding passes: significant propagation, magnitude refinement and clean up passes. The significant propagation encodes bits of insignificant coefficients with significant neighbors while the magnitude refinement refines the significant coefficients.

A context-driven binary arithmetic coding is then used to code the bits after the three coding passes. The resultant

bit stream is organized into packets where a packet groups selected passes of all code blocks from a precinct into one unit. These packets can be organized in a flexible way depending on the target application. For example, these packets from all subbands can be arranged into layers in such a way that the image quality gets improved progressively from layer to layer.

Because of the inherent multiresolution nature of wavelets and the encoding schemes, the image compressed by the JPEG 2000 standard has bitstreams arranged progressively, from very low image quality (i.e., small number of bits and high compression ratio) to effectively lossless image compression. Often compression ratio of 20 can be achieved for natural images without any visible artifacts. In JPEG 2000, blocking artifacts are totally removed but smoothing and ringing artifacts are introduced at high compression ratio.

JPEG 2000 includes a lossless mode based on a special integer wavelet filter (biorthogonal 3/5). JPEG 2000's lossless mode runs more slowly and usually has worse compression ratios than JPEG-LS. However, it is scalable and progressive, and, because its algorithm is similar to JPEG 2000, it is more widely supported.

NEW FEATURES IN IMAGE COMPRESSION

The aim of the JPEG 2000 is not only to have an improved compression performance as compared to the JPEG standard, but also to introduce some added features which are valuable to various kinds of applications. New features introduced include region of interesting coding, random access and progressive transmission concept (Lee, 2005).

Region of interest coding implies that certain parts of the image can be encoded with higher (or lossless) quality than other regions. This feature is important for applications such as medical imaging where certain critical parts can be coded with very high quality while other less critical parts are coded with low resolution. JPEG 2000 also introduces the idea of random codestream access. This means that the compressed image bitstream support random spatial access at varying resolutions.

JPEG 2000 induces a scalable structure on image representation. This scalable structure enables the generation of a single bit-stream for different purposes without having to rerun the compression algorithm. For example, the quality or the image resolution/size can be progressively improved. Thus, the same bit-stream can be used in a High Definition Television with a 1280×720 display, as well as in a PDA with a 160×160 display.

FUTURE TRENDS

Next generation compression algorithms are characterized by the use of an object-oriented image representation and a single universal bit-stream for different transmission/display media. The object-oriented compression enables the manipulation of objects in the scene as individual items that can be processed separately. The single universal bit-stream allows the compressed data to be transmitted or displayed by different media without having to rerun the compression algorithm. The JPEG 2000 bitstream enables region of interest coding for objects and are scalable due to the use of wavelet transforms. Its popularity, however, is hindered by the software patents. Either the standards need to be modified to avoid those patented software or more researches have to be done to replace these software with other free license software. Otherwise, the open-source Web browsers cannot include the JPEG 2000 decoder.

CONCLUSION

Image compression is a core technology for multimedia systems. Efficient transmission and storage of images is often required despite the continuing increase in network bandwidth. Transform coding is currently the most popular class of compression method for natural images. To achieve high compression ratio, lossy compression that exploits the limitation of the HVS is often employed. There are a number of international standards in image compression. The JPEG standard was established in 1992 and is very popular in WWW and multimedia systems. However, it is well known that blocking artifacts would appear at low bit-rates, which could greatly affect the perceived image quality. For near lossless compression applications, the JPEG-LS standard was introduced in 1999. Recently, the JPEG 2000 standard was introduced. It not only removes the blocking artifacts completely and improves the compression performance over the JPEG standard, but also induces a scalable structure on image representation. This scalable structure fits well with the perception of human eyes. It enables the generation of a single bit-stream for different transmission/display media, and potentially induces an object-oriented image representation. However, because of the software patent issue, the JPEG 2000 has not been included in open-source Web browsers. This affects its popularity.

KEY TERMS

Blocking Artifacts: This is one of the artifacts often exhibited by JPEG standard at high compression ratios. Images appear to have regular block structures.

JPEG: An image compression standard proposed in 1992 by ISO/CCITT committee. It is one of the most common image file format that is found in Internet and consumer products.

JPEG 2000: An image compression standard that aims not only to provide an improved compression performance over JPEG, but also to provide new features such as region of interest coding, random access and progressive coding.

Progressive Transmission: This implies that the bitstream is arranged so that most important information is near the front end of the bitstream and the least important information is at the back of the bitstream. Thus, in decoding, the quality of the decoded image is progressively increased.

Region of Interest Coding: This means that certain parts of the image (i.e., the interested regions) are encoded with more bits and thus have better quality than other parts of the image.

Ringing Artifacts: This type of artifacts often appears near the edges of an image in which edges are blurred and have oscillating effect.

Scalability: It refers to a successive quality change by bitstream manipulation. For example, PSNR scalability means the PSNR improves as more bits in the bitstream are decoded.

Significant Wavelet Coefficients: This refers to wavelet coefficients that have large absolute magnitude. Usually, this implies important structural information such as edges in an image.

Transform Coding: This refers to a type of compression in which the image data is first transformed into another domain so that the data becomes uncorrelated in this new domain for further processing.

Wavelet Subband: This refers to a group of the wavelet coefficients at certain frequency ranges.

Image Segmentation Evaluation in this Century

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

Image segmentation consists of subdividing an image into its constituent parts and extracting those parts of interest (objects). Due to its importance in image analysis, many research works have been conducted for this process. After 40 years of development, a large number of image (and video) segmentation techniques have been proposed and utilized in various applications (Zhang, 2006). With many algorithms developed, some efforts have been spent also on their evaluation, and these efforts have resulted around 100 evaluation papers that can be found in literature for the last century. Several studies have been made in the past in attempt to characterize these existing evaluation methods (Zhang, 1993; Zhang, 1996; Zhang 2001).

Segmentation evaluation methods can be classified into analytical methods and empirical methods (Zhang, 1996). The analysis methods treat the algorithms for segmentation directly by examining the principle of algorithms while the empirical methods judge the segmented image (according to predefined criteria or comparing to reference image) so as to indirectly assess the performance of algorithms.

Empirical evaluation is practically more effective and usable than analysis evaluation (Zhang, 1996). Recent advancements for segmentation evaluation are mainly made by the development of empirical evaluation techniques. After providing a list of evaluation criteria and methods proposed in the last century as background, this article will provide a summary of the recent (in 21st century) research works for empirical evaluation of image segmentation. These new research works are classified into three groups: (1) those based on existing techniques, (2) those made with modifications of existing techniques, and (3) those that used dissimilar ideas than that of existing techniques. A comparison of these evaluation methods is made before going to the future trends and conclusion.

BACKGROUND

Empirical evaluation methods can be classified into *goodness method group* and *discrepancy method group* (Zhang, 1996). They use different empirical criteria for judging the performance of segmentation algorithms. The goodness method can perform the evaluation without the help of reference images while the discrepancy method needs some reference images to arbitrate the quality of segmentation. In Zhang (1996) the eight mostly used criteria (three goodness ones and five discrepancy ones) have been discussed in details. All these criteria have been grouped into a table in Zhang (2001, pp. 148-151), and the table is reproduced in Table 1.

There are other criteria discussed in Zhang (1996), though they were not very well liked in that time. One is the number of regions in a segmented image. In case no ground truth was available, it would be expected to get a modest result, so the *moderate number of regions* could be counted as a criterion. Some others come from the class D-5, such as *region consistency*, *grey level difference*, and *symmetric divergence (cross-entropy)*. Finally, several criteria used in special methods have attracted certain attention recently, such as *amount of editing operations, visual inspection,* and *correlation between original image and segmented bi-level image.* All these criteria are listed now in Table 2 as a complementary of Table 1.

MAIN FOCUS OF THE CHAPTER

Getting into the new century, the research on segmentation evaluation has attracted even more attention in the segmentation community. In the following section, some evaluation works published since 2002, that is, after the last review paper on evaluation (Zhang, 2001), are sketched and discussed. Among these new empirical evaluation works, some are based on existing techniques, some are made with modifications/improvements of existing techniques, and some have dissimilar ideas than that of existing techniques.

Evaluation Works Based on Existing Techniques

In Cavallaro, Gelasca, and Ebrahimi (2002), a single objective metric is formed by using both spatial and temporal consistency information. The metric was defined based on two types of errors. One is the number of (both positive and negative) false pixels. Another is the distance of false pixels to their correct places. The spatial context was introduced to weight the false pixels according to their distance to the

Table 1. A list of empirical criteria and their method groups

Class	Criterion name	Method group
G-1	Intra-region uniformity	Goodness
G-2	Inter-region contrast	Goodness
G-3	Region shape	Goodness
D-1	Number of mis-segmented pixels	Discrepancy
D-2	Position of mis-segmented pixels	Discrepancy
D-3	Number of objects in the image	Discrepancy
D-4	Feature values of segmented objects	Discrepancy
D-5	Miscellaneous quantities	Discrepancy

Table 2. A complementary list of empirical criteria and their method groups

Class	Criterion name	Method group
G-4	Moderate number of regions	Goodness
D-5a	Region consistency	Discrepancy
D-5b	Grey level difference	Discrepancy
D-5c	Symmetric divergence (cross-entropy)	Discrepancy
S1	Amount of editing operations	Special
S2	Visual inspection	Discrepancy like
S3	Correlation between original image and bi-level image	Goodness like

reference boundary. In addition, temporal context has been used to assign weight inversely proportional to the duration of an error for evaluating the quality variation over time. The overall metric was eventually formulated as nonlinear combination of the number of false pixels and the distances, weighted by the temporal context factor.

In Prati, Mikic, and Trivedi (2003), a comparative empirical evaluation of representative segmentation algorithms selected from four classes of techniques (two statistical ones and two deterministic ones) for detecting moving shadows has been made with a benchmark for indoor and outdoor video sequences. Two quantitative metrics: (1) good detection (low probability of misclassifying a shadow point) and (2) good discrimination (the low probability of classifying non-shadow points as shadow) are employed.

In Rosin and Ioannidis (2003), an evaluation of eight different threshold algorithms for shot change detection in a surveillance video has been made. Pixel-based evaluation is applied by using true positive (TP), true negative (TN), false positive (FP), and false negatives (FN).

In Lievers and Pilkey (2004), a comparison of 12 automatic global thresholding methods has been made. Among them, eight are point-dependent algorithms and four are region-dependent algorithms. Some multimodal images have been tested. Authors defined a cost function for selecting the appropriate thresholds. This cost function is based on intra-class variations, so it is not surprising that the best algorithm found by authors is a minimum cross-entropy method.

In Marcello, Marques, and Eugenio (2004), a survey of 36 image thresholding methods, with a view to assess their performance when applied to remote sensing images and especially in oceanographic applications, has been conducted. Those algorithms have been categorized into two groups: local and global thresholding techniques. For performance judgment, only visual inspection is carried out.

In Renno, Orwell, and Jones (2004), four different shadow suppression algorithms have been evaluated by using video from a nightly soccer match with quite some shadow because of the lighting used. All evaluation metrics are based on the number of correctly detected pixels. The metrics used are the detection rate, the false positive rate, the signal-to-noise ratio, and the tracking error (the average distance between ground truth boxes and tracked targets). Finally, using an average over time, the performances of shadow segmentation of the four shadow suppression algorithms are compared.

In Carleer, Debeir, and Wolff (2004), four algorithms were applied to high spatial resolution satellite images and their performances were compared. Two empirical discrepancy evaluation criteria are used: (1) the number of mis-segmented pixels in the segmented images compared with the visually segmented reference images, and (2) the ratio between the number of regions in the segmented image and the number of regions in the reference image.

In Ladak, Ding, and Wang (2004), a comparison of three kinds of segmentation algorithms for 3-D images: (1) segmenting parallel 2-D slice images, (2) segmenting rotated 2-D slice images, and (3) directly segmenting volume-based 3-D image, was carried out. The judging parameter used is the percent difference in volume (volume error) between automatically segmented objects and the manually determined (by a trained person) ground truth. The times needed for editing the segmented objects obtained by using the three kinds of algorithms to fit the ground truth are also compared.

Evaluation Works Made with Modifications/Improvements

In Oberti, Stringa, and Vernazza (2001), Receiver Operating Curve (ROC) is used to extract useful information about the segmentation performance when changing external parameters that describe the conditions of the scene. ROC has also been used in Niemeijer, Staal, and Ginneken (2004) for studying the performance of five vessel segmentation algorithms.

In Udupa, LeBlanc, and Schmidt (2002), three groups of factors: (1) precision, (2) accuracy, and (3) efficiency, are considered for evaluating segmentation methods in assessing

how good a segmentation method is and in comparing it with other methods. Precision factors assess the reliability of the method; accuracy factors describe the validity of the method; and efficiency factors determine the human operator time and computational time required to complete segmentation task. To characterize the range of behavior of a segmentation method from accuracy point of view, a Delineation Operating Characteristic (DOC) analysis is proposed, and the DOC curves have been used for comparing the accuracy of three segmentation methods: (1) thresholding, (2) fuzzy connectedness, and (3) fuzzy c-means (Udupa & Zhuge, 2004).

In Li, Li, and Chen (2003), four metrics have been used for evaluation of video segmentation. They are metrics for contour-based spatial matching, temporal consistency, user workload, and time consumption. The first two metrics can be considered as combined extensions of the number of mis-segmented pixels and the position of mis-segmented pixels. The last two metrics are somewhat closely interrelated.

In Kim, Chalidabhongse, and Harwood (2004), a Perturbation Detection Rate (PDR) analysis has been proposed. It measures the sensitivity of a background subtraction algorithm in detecting low contrast targets against background. Four background subtraction algorithms are evaluated for their segmentation performance.

In Erdem, Sankur, and Tekalp (2004), three goodness measures to evaluate quantitatively the performance of video object segmentation and tracking methods have been proposed. The spatial differences of color and motion along the boundary of the estimated video object plane and the temporal differences between the color histogram of the current object plane and its predecessors are used to localize (spatially and/or temporally) regions where the segmentation results are good or bad. They are further combined to yield a single numerical measure to indicate the goodness of the boundary segmentation and tracking results over a video sequence.

Evaluation Works Supplying New Inspiration

One of the major focuses in the evaluation of segmentation in this century is in combining different metrics. Though the earliest work of this kind was made a quarter of century ago (Zhang, 1996), new research in this direction still attracts attention, only they have used different strategies.

In Everingham, Muller, and Thomas (2002), an approach to formulate the evaluation problem as finding out the Pareto front in a multi-dimensional fitness space is proposed.

In Li et al. (2003), the aforementioned idea has been followed. One 4-D fitness space has been built for four different evaluation metrics. A search in multi-dimensional space is performed to find the best choice of a system with optimal parameters.

In Zhang, Fritts, and Goldman (2005), another cooperation framework is proposed, in which different effectiveness measures are combined by using a machine-learning approach, which combines the results obtained from different measures. Three strategies based on training for combinations are used: (1) weighted majority (WM), (2) Bayesian, and (3) support vector machine (SVM).

In Correia and Pereira (2003), they considered that the evaluation of video segmentation quality could have two targets: (1) individual object segmentation quality evaluation, in which single object identified by the segmentation algorithm is independently evaluated in terms of its segmentation quality, and (2) overall segmentation quality evaluation, in which the complete set of objects (for the whole scene) identified by the segmentation algorithm is globally evaluated in terms of its segmentation quality.

In Desurmont, Wijnhoven, and Jaspers (2005), an outlined framework for performance evaluation of video content analysis (VCA) system is proposed. Four main components of this framework are: (1) creation of ground-truth (GT) data, (2) available evaluation data sets, (3) performance metrics, and (4) presentation of the evaluation results.

Classes of Criteria

In this section, the criteria used in the aforementioned works are analyzed and the results are summarized for each group of methods by using existing techniques, with modified criteria and with novelties.

Table 3 gives the list of evaluation works using existing techniques. Most works are based on discrepancy criteria, in which the criteria belonging to class D-1 appears more frequently than others do. Still few works use goodness criteria, but most of them use discrepancy criteria.

Table 4 gives the list of evaluation works with some modifications to existing techniques. Most of these works are still based on discrepancy criteria, in particular on class D-1. Several works made the use of the combination of criteria from different classes. The newly defined class S-1 has also been used by two works.

Table 5 gives the list of evaluation works with some novelties. In general, these approaches are quite divergent, one can only reveal that all the first three take the procedure of combining different criteria for evaluation.

Comparison of Methods

To compare different methods for segmentation evaluation, the following four factors have been considered, taking into consideration of the techniques and criteria used in evaluation (Zhang, 1993; Zhang, 2001): (1) generality for evaluation; (2) subjective versus objective and qualitative versus quantitative; (3) complexity for evaluation; and (4) evaluation requirements for reference images.

Table 3. Evaluation methods using existing techniques

Method #	Source	Criteria used	Method #	Source	Criteria used
M-1	(Cavallaro et al., 2002)	D-1, D-2	M-5	(Marcello et al., 2004)	S-2
M-2	(Prati et al., 2003)	D-1	M-6	(Renno et al., 2004)	D-1, D-4
M-3	(Rosin & Ioannidis, 2003)	D-1	M-7	(Carleer et al., 2004)	D-1, D-3
M-4	(Lievers & Pilkey, 2004)	G-1	M-8	(Ladak et al., 2004)	D-1, S-1

Table 4. Evaluation methods with modified criteria

Method #	Source	Criteria used (modification)
M-9	(Oberti et al., 2001)	D-1 (ROC, curve of FP vs. FN)
M-10	(Udupa et al., 2002)	D-1, S-1 like (efficiency)
M-11	(Li et al., 2003)	D-1 and D-2, (contour matching, temporal consistency), S-1
M-12	(Erdem et al., 2004)	G-1, G-2 (with extension to color, motion, color histograms)
M-13	(Niemeijer et al., 2004)	D-1 (ROC, curve of TP vs. FP)
M-14	(Udupa & Zhuge, 2004)	D-1 (DOC, curve of TP vs. FP)
M-15	(Kim et al., 2004)	D-1 (PDR, modified detection rate)

Table 5. Some evaluation works with novelties

Work #	Source	Novelty
W-1	(Everingham et al., 2002)	Finding out the Pareto front in a multi-dimensional fitness space
W-2	(Li et al., 2003)	Finding out the Pareto front in a 4-D fitness space
W-3	(Zhang et al., 2005)	Using WM, Bayesian, and SVM
W-4	(Correia & Pereira, 2003)	Using contextual relevance metric to match human visual system (HVS)
W-5	(Desurmont et al., 2005)	Performing evaluation in different semantic levels

Table 6. A comparison of methods listed in Table 3 and Table 4

Method #	Generality	Complexity	Method #	Generality	Complexity
M-1	Video [1]	Medium/High	M-9	General	Medium
M-2	General	High	M-10	General	Medium
M-3	Video [1]	Medium	M-11	General	High (Human) [3]
M-4	Thresholding [2]	Medium	M-12	Video [1]	High
M-5	General	High (Human) [3]	M-13	General	Medium
M-6	General	Medium/High	M-14	General	Medium
M-7	Numerous objects [4]	Low/Medium	M-15	Video [1]	Medium
M-8	General	High (Human) [3]			

[1]*Only usable for video segmentation evaluation (mostly because temporal factor is critical).*
[2]*Only suitable for evaluating thresholding technique.*
[3]*Human visual factors are involved, so the complexity becomes high.*
[4]*More appropriate for treating images composed of numerous object regions.*

Among these four factors, some of them are related to the method groups. For example, most empirical criteria provide quantitative results. On the other side, the subjective versus objective and the consideration of segmentation application are closely related and can be determined according to the criteria which belong either to goodness group or discrepancy group.

As mentioned in the beginning, only empirical methods are compared here, so the focus will be put on the generality for evaluation and the complexity for evaluation. Thus,

obtained comparison results for the methods listed in Table 3 and Table 4 are given in Table 6.

FUTURE TRENDS

Following the recent evolution of segmentation evaluation as described previously and by analyzing and comparing the methods and criteria used in these works, it seems two further research directions should be considered:

1. **To make evaluation in reflecting the final goal of segmentation:**
   Image segmentation is the first step in image analysis; its performance will influence all the subsequent processes. Therefore, the purpose of segmentation, especially the goals of analysis task, should be considered in segmentation evaluation. From one side, the consideration of the final goal of segmentation would make the evaluation procedure more objective and the results more useful. From other side, the success of the following processes would be a suitable indication of the success of image segmentation.
2. **To efficiently combine multiple metrics in evaluation:**
   The results of segmentation and the performance of segmentation algorithms are related to many factors, so it is not surprising that the strategy of using several criteria to form multiple metrics for evaluation was considered a long time ago, and the recent works on evaluation also show this tendency as indicated before. The tactic for combining multiple metrics has evolved from simply making weighted sums to complicated techniques, such as matching learning approaches. Further works to combine multiple metrics to effectively cover different aspects of evaluation in wide range of applications are still needed.

CONCLUSION

According to the aforementioned investigation with more than 20 works for less than 4 years, it is clear that much more efforts have been put on segmentation evaluation in the beginning of 21st century than in the last century. We have seen a number of works based on previous proposed principles; a number of works made modifications and/or improvements on previous proposed techniques; and also several works with new ideas have appeared.

The generality and complexity of these newly proposed evaluation methods and performance criteria have been thoroughly compared. It seems that though much more efforts have been put in this subject, no (or very few) radical progress has been reported. Many evaluation works were just using previously proposed methods and criteria for particular application; some evaluation works made certain improvements on early works but still used similar principles. To probe further, continuing efforts for segmentation evaluation are still called for.

KEY TERMS

Composite Criteria: Criteria formed by combining several performance metrics in order to better cover the various aspects of the algorithms in segmentation. The combination can be made in different ways, such as by linear combination, by machine learning approach, etc. and so forth.

Evaluation Criteria: Criteria used in evaluation process to judge the performance of segmentation algorithms under consideration. They are also called performance metrics, performance measures, or performance indices.

Image Segmentation: A process consists of subdividing an image into its constituent parts and extracting these parts of interest (objects) from the image. It is a fundamental step and a critical task in image analysis.

Objective Criteria: Criteria based on objectively determined quantities or values, which indicate the difference between the segmented images and reference images. They are mostly used in empirical discrepancy methods for segmentation evaluation.

Segmentation Characterization: Segmentation characterization is an intra-algorithm process of segmentation evaluation. The purpose of evaluation for a specific algorithm is to quantitatively recognize its behavior in treating various images and/or to help appropriately setting its parameters regarding different applications to achieve the best performance of this algorithm.

Segmentation Comparison: Segmentation comparison is an inter-algorithm process of segmentation evaluation. The purpose of comparison for different algorithms is to rank their performance and to provide guidelines in choosing suitable algorithms according to applications as well as to promote new developments by effectively taking the strong points of several algorithms.

Segmentation Evaluation: Segmentation evaluation is a process used to judge the performance of segmentation algorithms based on some defined quality criteria and/or ground truth in view to assess or reveal the property of algorithms in use.

Subjective Criteria: Criteria based on human judgment or perception, which reflect some desirable properties of segmented images. They are used in empirical goodness methods for segmentation evaluation.

Image Segmentation in the Last 40 Years

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

Image segmentation is an important image technique well known by its utility and complexity. To extract the useful information from images or groups of images, an inevitable step is to separate the objects from the background. Segmentation is just the right process and technique required for this task. Image segmentation is often described as the process that subdivides an image into its constituent parts and extracts those parts of interest (objects). It is one of the most critical tasks in automatic image analysis, which is at the middle layer of image engineering. Image engineering (which is composed of three layers from bottom to top: (1) image processing, (2) image analysis, and (3) image understanding) is a new discipline and a general framework for all image techniques (Zhang, forthcoming).

The history of segmentation of digital images using computers can be traced back to 40 years ago. In 1965, an operator for detecting the edges between different parts of an image, Roberts operator (also called Roberts edge detector), was introduced and used for partition of image components (Roberts, 1965). Since then, the field of image segmentation has evolved very quickly and has undergone great change (Zhang, 2001a). In this article, after an introduction and explanation of the formal definition of image segmentation as well as three levels of research on image segmentation, the statistics for the number of developed algorithms in these years are provided; the scheme for classifying different segmentation algorithms is discussed; and a summary of existing survey papers for image segmentation is presented. All these discussions provide a general picture of research and development of image segmentation in the last 40 years.

BACKGROUND

Formal Definition of Image Segmentation

A formal definition of image segmentation, supposing the whole image is represented by R and R_i, $i = 1, 2, \ldots, n$ are disjoint nonempty regions of R, consists of the following conditions (Fu & Mui, 1981):

$$\bigcup_{i=1}^{n} R_i = R; \quad (1)$$

For all i and j, $i \neq j$, there exits $R_i \cap R_j = \varnothing$; (2)

For $i = 1, 2, \ldots, n$, it must have $P(R_i) = TRUE$; (3)

For all $i \neq j$, there exits $P(R_i \cup R_j) = FALSE$; (4)

where $P(R_i)$ is a uniformity predicate for all elements in set R_i and $\varnothing$ represents an empty set.

The following condition is also important for segmentation and is often included in the conditions for the formal definition (Zhang 2001a):

For all $i = 1, 2, \ldots, n$, R_i is a connected component. (5)

In the aforementioned conditions, each of them has particular meanings. The condition (1) points out that the union of segmented regions could include all pixels in an image. The condition (2) points out that the different segmented regions could not overlap each other. The condition (3) points out that the pixels in the same regions should have some similar properties. The condition (4) points out that the pixel belonging to different regions should have some different properties. The condition (5) points out that the pixels in the same region resulted from segmentation are connected.

Three Levels of Research on Image Segmentation

Though many efforts have been devoted to the research of segmentation techniques, there is no general theory for image segmentation, yet. Therefore, the development of segmentation algorithms has traditionally been an ad hoc process. As a result, many research directions have been exploited, some very different principles have been adopted, and wide varieties of segmentation algorithms have appeared in the related literatures. It was noted by many people that none of the developed segmentation algorithms are generally applicable to all kinds of images and different algorithms are not equally suitable for a particular application (Zhang, 2006).

With the increase of the number of algorithms for image segmentation, how to evaluate the performance of these algorithms becomes indispensable in the study of segmentation. Considering the various modalities for acquiring different images and the large number of applications requiring image segmentation, how to select appropriate algorithms for segmentation turns into an important task. A number

of evaluation techniques have been proposed. For those published in the last century, see survey papers by Zhang (1996) and Zhang (2001b).

While the evaluation of segmentation techniques has gained more and more attention, with numerous evaluation methods frequently designed, how to characterize the different existing methods for evaluation has also attracted some interest in recent years (Zhang, 2001a). In fact, different evaluation criteria and procedures, their applicability, advantages, and limitations need to be studied carefully and systematically.

According to the previous discussion, the research for image segmentation is carried out in three levels (Zhang, 2006). The first one and the basic one is the level of algorithm development. The second one is the level of algorithm evaluation. The third one is the level of systematic study of evaluation methods. This present article will mainly concentrate on the first level.

MAIN THRUST

The current study focuses on three points:

1. A worldwide statistics about the number of segmentation algorithms already developed.
2. A method for classifying different segmentation techniques into groups.
3. A general overview of survey papers for segmentation, published in the last 40 years.

Amount of Developed Segmentation Algorithms

Over the last 40 years, the research and development of segmentation algorithms are going on and making very rapid progress. A great number of segmentation algorithms have been developed and this number continually increases each year. Table 1 gives a list of the numbers of records (for every 5 years) found in EI Compendex (the most comprehensive bibliographic database of engineering research available today, see http://www.ei.org) by using the term *image segmentation* to search only in the field of "Subject/Title/Abstract."

Figure 1 gives a plot of the number of records found, together with a tendency curve obtained by using the third order polynomial. It is interesting to note the very fast increasing rate (an exponential raise) for the number of papers published. It is also interesting to note there is not any sign for the slowdown of augmenting.

A Classification of Segmentation Algorithms

With so many publications appearing in the literature and so many segmentation algorithms being developed, the classification of various algorithms for image segmentation becomes an essential task in studying image segmentation.

A classification of algorithms into groups, in principle, is a problem of set partition into subsets. With reference to the conditions for the definition of segmentation (Fu & Mui, 1981), it was believed that the resulted groups after

10	20	233	680	1499	3423	7665	12727	26257

Figure 1. Number of records and the tendency of development in the last 40 years

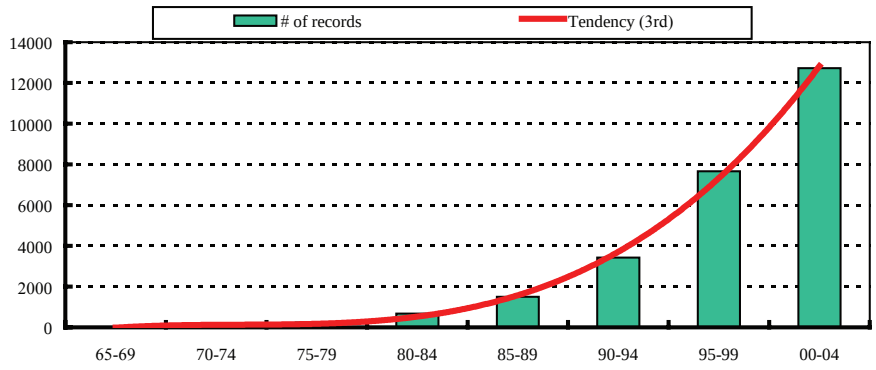

Table 2. General classification of segmentation algorithms

Classification	Edge-based (discontinuity)	Region-based (similarity)
Parallel process	G1: Edge-based parallel process	G3: Region-based parallel process
Sequential process	G2: Edge-based sequential process	G4: Region-based sequential process

an appropriate classification of segmentation algorithms, according to the process and objective, should satisfy the following four conditions (Zhang, 1997):

1. Every algorithm must be in a group,
2. all groups together can include all algorithms.
3. The algorithm in the same group should have some common properties and
4. the algorithm in different groups should have certain distinguishable properties.

Classifications of algorithms are performed always according to certain classification criteria. The first two conditions imply that the classification criteria should be suitable for classifying all different algorithms. The last two conditions imply that the classification criteria should determine the representative properties of each algorithm group.

Taking the aforementioned conditions in mind, the following two criteria turn up to be suitable for the classification of segmentation algorithms. The first is the discontinuity or similarity of pixel property; the second is the sequential or parallel of processing strategy. All segmentation algorithms can be classified into four groups, namely G1, G2, G3, and G4, according to these two criteria. The results are shown in Table 2.

Some simple and typical examples of each group are as follows (they can be easily found in the literature):

- **G1:** Edge detector, gradient operator, SUSAN operator, fuzzy edge detection.
- **G2:** Graph search, dynamical programming, active contour model, active shape model (snake).
- **G3:** Thresholding, K-means, feature space clustering, pixel classification.
- **G4:** Region growing, split, and merge, morphological watersheds.

Overview of Survey Papers on Image Segmentation

Along with the development of image segmentation algorithms, a number of survey papers for general image segmentation algorithms have been presented in the literature over the last 40 years (Borisenko, Zlatotol, & Muchnik, 1987; Buf & Campbell, 1990; Davis, 1975; Fu & Mui, 1981; Haralick & Shapiro, 1985; Nevatia, 1986; Pal & Pal, 1993; Pavlidis, 1986; Peli & Malah, 1982; Riseman & Arbib, 1977; Rosenfeld, 1981; Sahoo, Soltani, Wong, & Chen, 1988; Sarkar & Boyer, 1993; Weszka, 1978; Zucker, 1976; Zucker, 1977).

By partitioning the last 40 years into four decades, it is interesting to note that all these survey papers are dated in the second and third decades. The reason for no survey paper published in the first decade is that the research results were just cumulated in that period (some important works for this period have been indicated in the survey papers published in the second period). The reason for no survey in the last decade could be attributed to the fact that so many techniques have already been presented, thus a comprehensive survey becomes less feasible.

Though no general survey for the whole scope of image segmentation has been made in the last 10 years, some specialized surveys are nevertheless published in recent years. These survey papers can be classified into two subcategories:

1. Survey Papers Focused on Particular Group of Segmentation Algorithms

Many segmentation algorithms have been developed by using certain mathematical/theoretical tools, such as fuzzy logic, genetic algorithm, neural network (NN), pattern recognition, wavelet, and so forth; or based on some unique framework, such as active contour model (ACM), thresholding, watershed, and so forth. Some surveys for algorithms using the same tools or based on the same frameworks have been made. The following paragraphs present some examples.

Considering that the fully automatic methods sometimes would fail and produce incorrect results, the intervention of a human operator in practice is often necessary. To identify the patterns used in the interaction for the segmentation of medical images and to develop qualitative criteria for evaluating interactive segmentation method, a survey of computational techniques for human-computer interaction in image segmentation has been made (Olabarriaga & Smeulders, 2001). This survey has taken into account the type of information provided by the user, how this information affects the computational part, and the purpose of interaction in the segmentation process for the classification and comparison of a number of human-machine dialog methods.

Algorithms combining edge-based and region-based techniques will take the advantage of the complementary nature of edge and region information. A review of differ-

ent segmentation methods, which integrate edge and region information has been made (Freixenet, Muñoz, Raba, Martí, & Cufí, 2002). Seven different strategies to fuse such information have been highlighted.

Active shape model (ASM) is a particular structure for finding the object boundary in images. Under this framework, various image features and energy functions as well as different search strategies can be used, which makes a wide range of ASM algorithms. A number of these variations for segmentation of anatomical bone structures in radiographs have been reviewed in Behiels, Maes,Vandermeulen, and Suetens (2002).

Thresholding technique is a very popular, relatively simple and fast technique. A survey of thresholding methods with a view to assess their performance when applied to remote sensing images has been made recently (Marcello, Marques, & Eugenio, 2004). Some image examples are taken from oceanographic applications in this work.

2. Survey Papers Focused on a Particular Application of Image Segmentation

Image segmentation has many applications. For each application, a number of segmentation algorithms could be developed. Some surveys for certain particular application areas have been made.

In medical imaging applications, image segmentation is used for automating or facilitating the delineation of anatomical structures and other regions of interest. A survey considering both semi-automated and automated methods for the segmentation of anatomical medical images has been made (Pham, Xu, & Prince, 2000). The advantages and disadvantages of these methods for medical imaging applications are also discussed and compared.

While video could be considered as a particular type of general images, its segmentation is just an extension of image segmentation. For video data, the temporal segmentation is used for determining the boundary of shots. A survey has made for techniques that operate on both uncompressed and compressed video stream (Koprinska & Carrato, 2001). Both types of shot transitions: abrupt and gradual transitions are considered. The performance, relative merits, and limitations of each of the approaches are comprehensively discussed.

For temporal video segmentation, except the ability and correctness of shot detection, the computation complexity is also a criterion that should be considered, especially for real-time application. A review of real-time segmentation of uncompressed video sequences for content-based search and retrieval has been made (Lefèvre, Holler, & Vincent, 2003). Depending on the information used to detect shot changes, algorithms based on pixel, histogram, block, feature, and motion have been selected.

Vessel extraction in bioengineering is essentially a segmentation process. A survey for related algorithms has been made (Kirbas & Quek, 2003). Six groups of techniques proposed for this particular application are involved: (1) pattern recognition techniques; (2) model-based approaches; (3) tracking-based approaches; (4) artificial intelligence-based approaches; (5) neural network-based approaches; and (6) miscellaneous tube-like object detection approaches.

In many vision applications, moving shadows must be detected. Moving shadows can be considered as object in video streams, and the detection of moving shadows is a video segmentation problem. A survey has been made for four classes of techniques (two statistical ones and two deterministic ones) designed specially for detecting moving shadows (Prati, Mikic, Trivedi, & Cucchiara, 2003).

FUTURE TRENDS

Though much progress has been made in the last 40 years, the subject of image segmentation still needs additional study efforts, a few further research directions would be:

- **Incorporating Human Factors:** Since image segmentation is a process at the middle layer of image engineering, it is influenced strongly by human factors. It seems that the assistance of humans, who are knowledgeable in the application domain, will remain essential in any practical image segmentation method. Incorporating high-level human knowledge algorithmically into the computer should be a challenge in the future.
- **Introducing More Mathematical Models and Theories:** The introduction of various mathematical models and theories into the research of image segmentation has proved to be quite effective. Since many novel models and theories have been invented and/or created in these years, introducing them into the research on image segmentation would be promising.
- **Enlarging the Scope of Applications:** Though no general theory for segmentation exists, researches on segmenting different particular images from numerous applications have made much progress. As a lot of new applications still call for segmentation, developing the suitable algorithms for those new areas would have great potential, either from the point of view technique developments or from the point of view of image applications.

CONCLUSION

An overview of the development of image and video segmentation in the last 40 years is provided with emphasis on

showing the number of segmentation algorithms already developed, on describing the techniques for classifying these algorithms and on analyzing the survey papers for image segmentation. With such an expansive overview, readers should perceive a general idea about the 40 years' progresses of research and application on image segmentation.

KEY TERMS

Active Contour Model: Active contour model is a sequential technique for image segmentation. Given an approximation of the boundary of an object in an image, an active contour model can be used to find the *actual* boundary by deforming the initial boundary to lock onto features of interest within this image.

Clustering: Clustering is also called unsupervised learning and is a powerful technique for pattern classification. It is a process to group, based on some defined criteria, two or more terms together to form a large collection In the context of image segmentation, it is often considered as the multi-dimensional extension of the thresholding technique.

Edge Detection: Edge detection is the most common approach for detecting discontinuities in images, and is the fundamental step in edge-based parallel process for segmentation. An edge is a local concept. To form a complete boundary of an object, edge detection should be followed by edge linking or connection.

Gradient Operator: Gradient operator is the first type of operator used for edge detection. The gradient of an image is a vector consisting of the first order derivatives (including the magnitude and direction) of an image.

Graph Search: Graph search is a particular type of segmentation technique which combines edge detection and linking together. It represents edge segments in the form of a graph and searches the graph for low-cost paths that correspond to significant edges or boundaries of objects.

Image Engineering: Image engineering is an integrated discipline/subject comprising the study of all the different branches of image and video techniques. It mainly consists of three levels: image processing, image analysis, and image understanding.

Image Segmentation: A process consists of subdividing an image into its constituent parts and extracting these parts of interest (objects) from the image.

Region Growing: Region growing is a region-based sequential technique for image segmentation by assembling pixels into larger regions based on predefined seed pixels, growing criteria, and stop conditions.

Thresholding: Thresholding techniques are the most popularly used segmentation techniques. A set of suitable thresholds need to be first determined, and then the image can be segmented by comparing the pixel properties with these thresholds.

Watersheds: Watershed technique is inspired from the topographic interpretation of image segmentation by watersheds embodies many concepts of edge detection, thresholding and region processing techniques, and often produces stable and continuous results.

Imaging Advances of the Cardiopulmonary System

INTRODUCTION

A technological explosion has been revolutionizing imaging technology of the heart and lungs over the last decade. These advances have been transforming the health care industry, both preventative and acute care medicine. Ultrasound, nuclear medicine, computed tomography (CT), and magnetic resonance imaging (MRI) are examples of radiological techniques which have allowed for more accurate diagnosis and staging (determination of severity of disease). The most notable advances have occurred in CT and MRI. Most medical subspecialties rely on CT and MRI as the dominant diagnostic tools an exception being cardiology. CT and MRI are able to provide a detailed image of any organ or tissue in the body without the necessity of invasive or painful procedures. Virtually any individual could be tested as long as they are able to remain immobile for the duration of the study.

Image generation traditionally has been limited by the perpetual motion of the human body. For example, the human heart is continually contracting and relaxing without a stationary moment during which an image could be obtained. Lung imaging has been more successful than cardiac imaging, but studies were limited to the length of time an ill person is able to hold his or her breath.

Historically, imaging technology was limited by inability to take a picture fast enough of a moving object while maintaining a clinically useful level of resolution. Recent technologic innovation, resulting in high speed electrocardiogram-gated CT and MRI imaging, now allows the use of these imaging modalities for evaluation of the heart and lungs. These novel innovations provide clinicians with new tools for diagnosis and treatment of disease, but there are still unresolved issues, most notably radiation exposure. Ultrasound and MRI studies are the safest of the imaging modalities and subjects receive no radiation exposure. Nuclear studies give an approximate radiation dose of 10mSv and as high as 27mSv (Conti, 2005). In CT imaging, radiation dose can vary depending on the organ system being imaged and the type of scanner being used. The average radiation dose for pulmonary studies is 4.2mSv (Conti, 2005). The use of multi-detector CT (MDCT) to evaluate the heart can range from 6.7—13mSv. To put it into perspective, according to the National Institute of Health, an average individual will receive a radiation dose of 360mSv per year from the ambient environment. It is unlikely that the radiation doses received in routine imaging techniques will lead to adverse reactions such as cancer, but patients should be informed of the risks and benefits of each procedure so that they can make informed decisions. It is especially important that patients be informed when radioactive material is to be injected into their bodies. The reasons for this will be discussed later on in the chapter.

BACKGROUND

Coronary artery disease (CAD) is the leading cause of death in the U.S.. It is also the most common cause of the most costly heart disease in the U.S.—heart failure (Thomas & Rich, 2007). With a prevalence of almost 13,000,000, it carries an estimated cost of US$130 billion per year (Sanz & Poon, 2004). The American Heart Association calculates the cost of caring for those with cardiovascular disease at $300 billion per year (Raggi, 2006). According to the American Lung Association, lung disease is the third most common cause of death in America, responsible for one in seven deaths every year. Infections, particularly those of the lungs, are the number one killer of infants. An estimated 35 million Americans are currently living with lung disease such as emphysema, asthma, or chronic bronchitis. Even small technological advancement can lead to dramatic improvements in health care**.** Raggi (2006), the American Heart Association/American College of Cardiology and the

National Cholesterol Education program III have describe simple screening tools to risk stratify patients (group patients into prognostic categories). These stratification tools involve assessment of lifestyle factors, genetic factors, and simple blood tests. For example, patients who smoke, are obese, inactive, have high cholesterol, and a family history of heart disease are more likely to have heart disease than people who lack these risk factors. Based on the results of the screening, recommendations can be made for further diagnostical procedures, treatments, and lifestyle interventions. Some of the more advanced diagnostic procedures include echocardiography, nuclear medicine (NM) scans, CT, and MRI.

ECHOCARDIOGRAPHY

Echocardiography uses the principle of ultrasound (sound wave) reflection off cardiac structures to generate images of the heart just as it does in producing images of an unborn baby in a pregnant woman. In the past three decades, echocardiography has rapidly become a fundamental component of the cardiac evaluation. Measuring the same feature from different angles (windows) with different types of sound wave detectors (transducer) is done to produce an image. The entire heart and its major blood vessels can be displayed in real time and in various 2-D planes. Transthoracic echocardiogram (TTE) imaging is performed with a handheld transducer placed directly on the chest wall. In select situations in which a more direct image needs to be taken without the interference of the chest wall, chest muscles, and chest fat, a transesophageal echocardiogram (TEE) may be performed. In TEE, an ultrasound transducer is mounted on the tip of an endoscope and placed into the esophagus of a patient. The transducer is directed toward the heart so that high-resolution images can be attained with minimal interference. TEE is a riskier and more invasive procedure but is able to provide details on the parts of the heart distant from the transducer on TEE.

Newer echocardiographic machines have the advantage of being lightweight and portable (Figure 1). Some machines weigh less than 6 pounds and can be carried like a briefcase. The benefit of these advances is the ability to immediately assess heart function without the risk of having to move unstable patients (Beaulieu, 2007). This will soon become an essential part of the physical examination both hospitals and the outpatient setting. The echocardiograph permits quantification of the overall ability of the heart to supply blood to the body, description of the appropriate opening and closing of the heart valves, determination of leaks within the heart valves, visualization of abnormal fluid around the heart, visualization fluid trapped in the lungs and detection of structural abnormalities that disturb the blood flow through the heart (Figure 2). Although one of the older modalities in cardiopulmonary imaging, it still is the test of choice for certain conditions. TTE is advantageous in emergency situations when time is limited and a patient may be too unstable to transport (Shiga, Wajima, Apfel, Inoue, & Ohe, 2006). The most significant limitation is in the quality of the image that TTE delivers. A large amount of information can be generated from TTE, but the images may be particularly limited in obese individuals or those severe lung disease. In addition echocardiography is highly operator dependant for generating and interpreting images.

Doppler echocardiography is a newer modality in heart imaging. It uses ultrasound reflecting off moving red blood

Figure 1. Portable echocardiogram machine (Sonosite MicroMaxx, product photographs reprinted with permission from SonoSite; Sonosite trademarks owned by SonoSite, Inc.)

Figure 2. Echocardiogram of the heart (product photographs reprinted with permission from SonoSite)

cells to measure the velocity of blood flow across several different parts of the heart. Normal and abnormal blood flow patterns can be assessed and by adding color. Blood flow can be evaluated for smoothness or turbulence. The addition of color to Doppler echoes is an important advancement yielding more accurate readings.

NUCLEAR MEDICINE

NM techniques consist of the injection of a radioactive isotope into the blood stream of an individual. This isotope emits a photon (usually a gamma ray) generated during radioactive decay as the nucleus of one isotope changes to a lower energy level. Special cameras are placed over the chest of the individual and capture the photons released.

Nuclear studies of the heart and lungs have numerous applications. One can assess blood flow to specific areas of the heart. Blood provides a fresh supply of oxygen and nutrients required for the proper cardiac function. NM scans occurs in two parts, one while the patient is at rest and the second after the heart has been exercised. While at rest, the isotope is injected into the blood stream while the individual lies flat. A specialized camera rests over the heart capturing the emitted photons. The second phase of the test occurs just after the heart rate has been increased, either by medication or exercise. The camera then captures the photons emitted during increased cardiac stress and a comparison is made between the two studies. In a healthy heart, the photons emitted during both tests should be equal creating identical pictures. If any region of the heart that has poor circulation an image produced from the nuclear scan shows a black area from which few or no photons are emitted. This signifies that there is a reduced blood flow to that area of the heart and allows treatment to be initiate before the decreased blood flow leads to a heart attack.

Similar techniques are used when examining the lungs. A lung scan is most commonly used to detect a blood clot obstructing normal blood flow to part of a lung (pulmonary embolism). The test is broken down into two parts—a ventilation scan (V) and a perfusion scan (Q)—which combined comprise the V/Q scan. The ventilation scan involves inhaling of a known amount of radioactive tracer by an individual. Cameras are then placed over the chest to detect the emitted photons. An image representative of the movement of air through the lung is generated. Areas with inadequate ventilation appear dark because few photons arrive to those areas. Conversely, areas of the lung containing too much air emit an increased number of photons. The perfusion scan works in a similar fashion to that of the NM heart scan. The radioactive tracer is injected into the bloodstream as the blood passes through to the lungs. The scan will show areas of the lungs that are not receiving enough blood. Normally the tracer should be evenly distributed throughout the lung. When both tests are completed, a comparison of the images is done and any mismatch may indicate a that not enough blood is arriving or not enough air is arriving to a specific region of the lung.

A newer modality in nuclear medicine is positron emission tomography (PET). A PET scan is a diagnostic examination that involves the acquisition of physiologic images based on the detection of radiation from the emission of positrons. Positrons are tiny particles emitted from a radioactive substance injected into a patient's blood stream. PET scans of the heart and lungs can be done to examine blood flow to the heart, viability of the heart muscle, detect cancer in the lungs, and determine the effectiveness of cancer therapy using chemotherapeutics. Unlike the previous tests, which are only able to describe structure, PET scans are able to relay information on the functionality of the tissues being studied. Current research is investigating the possibility of using PET scan to routinely measure cardiac blood flow (deKemp, Yoshinaga & Beanlands, 2007; Di Carli, Dorbala, Meserve, El Fakhri, Sitek, & Moore, 2007).

One major problem in generating images from this technique is that the photons are emitted in a random array of directions from the origin. False readings can occur if the cameras are not placed correctly. A second problem occurs when tissues other than those targeted absorb photons. When this occurs insufficient numbers of photos reach the camera to create an interpretable image. The use of higher energy isotopes, most commonly technetium 99m (99m Tc) and thallium 201 (201 Tl) helps avoid these difficulties (Hoheisel, 2006). Both isotopes are frequently used and many times choices of isotope are made solely on the cost or experience of the operator.

COMPUTED TOMOGRAPHY

CT has emerged as a cutting edge technique able to evaluate the structure and function of both the heart and lungs. Often, both lung and heart imaging can be done simultaneously with no added patient inconvenience. Advancements in imaging speed have allowed for more accurate evaluation of both relatively stationary structures, such as large arteries as well as rapidly moving structures, such as the heart. Traditional mechanical CT scanners produce images by rotating an x-ray tube around a circular gantry through which the patient advances on a moving bed. The basic principle of CT is that a fan-shaped, thin x-ray beam passes through the body at many angles providing cross-sectional images. The corresponding x-ray transmission measurements are collected by a detector array. Information entering the detector array and x-ray beam itself is collimated to produce thin sections and avoid unnecessary photon scatter. The transmission measurements recorded by the detector array are digitized into picture elements with known dimensions and are reconstructed. What

this provides is a 3-D 360 degree examination of not only the heart, lungs, and its arteries, but also the lumen and walls of the arteries and airways. These images can provide detailed information on the size of the blood vessels lumen (the hole through the blood vessel). If the lumen of the blood vessels of the heart are significantly reduced and the individual is at high risk for a heart attack and may already be having chest pain resulting from decreased blood flow to the heart. In some institutions, cardiac CT is replacing cardiac catheterization for the diagnosis of coronary artery disease.

Although x-ray angiography remains the "gold standard" in diagnosing changes in artery lumen size, it is an invasive procedure. Non-invasive modalities such as CT and MRI are becoming routine in the diagnostic examination of patients with vascular disease (Dowe, 2007; Raff & Goldstein, 2007). Conventional CT scanners have been modified and now use a different approach to gather data. Spiral (helical) CT and now MDCT are now replacing older scanners providing detailed information in one sweep. Since spiral CT became a part of the routine diagnostic imaging in the early 1990's, CT as a whole has matured. In spiral CT scanners, the x-ray tube rotates continuously around the patient as the bed moves through the scanner eliminating stops in between traditional shots. This prevents data misread and reduces the time needed to acquire images. The recent development and refinement of MDCT systems is a pivotal advance in CT technology (Chartland-Lefebvere et al., 2007). MDCT can take a complete 3-D picture of the heart within one heartbeat simultaneously imaging pulmonary structures.

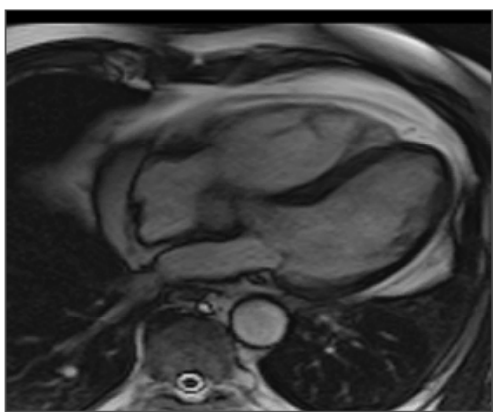
Many researchers now consider CT angiography/CT venography the test of choice when evaluating lungs for pulmonary embolism (blood clots) (Garcia, Lessick, & Hoffmann, 2006; Stein et al., 2006). As with cardiac CT imaging, the test involves placing a patient on the bed of the scanner. The bed moves through the doughnut-shaped scanner. In a cardiac CT, the patient is attached to a cardiac monitor so that it can follow the heart rate. An optimal study occurs if the heart rate remains regular and kept a maximal rate of 65 beats per minute (Poon, 2006). Many times a short acting medication is given to slow the heart rate. An iodinated contrast is injected into the blood stream of the patient, and the scanner is set on a timer. The timer predicts when the contrast will most likely reach the heart and images are recorded accordingly. Mis-timing can lead to poor images and an uninterpretable test. The patient is asked to hold his or her breath for 15 to 20 seconds as the scan is being done. The breath hold prevents the heart from moving as the chest rises and falls. Finally, the images are reconstructed able to be reviewed. Not only have these advancements changed how heart disease is measured, but have also substantially improved the quality of CT angiography of extracranial, thoracic, abdominal, pulmonary, and peripheral vasculature.

MAGNETIC RESONANCE IMAGING

MRI is a technique based on the magnetic properties of hydrogen protons present in water molecules. A large magnetic field can be used to induce, nuclear spin transitions from the ground state to excited states. As the nuclei lose energy, they return to their ground state, releasing energy in the form of electromagnetic radiation, which can be detected and processed into an image. Different tissues have a different concentration of water protons and molecular environments, therefore generating signals with different characteristics, which is the basis of the high quality tissue-contrast resolution of MRI (Sanz & Poon, 2004). The development of cardiac MRI has been particularly challenging because of motion of the heart and coronary arteries. Long scanning times needed in old MRI techniques made it technically difficult to get interpretable results.

Figure 3. MRI system (reprinted with permission from Siemens)

Figure 4. MRI of the heart (reprinted with permission from Siemens)



Much like the CT, an individual is placed on a sliding table and positioned in the MRI scanner. It also is doughnut-shaped with the table sliding back in forth through the hole (Figure 3). Depending on the number of images needed, the scan time can take 15 to 45 minutes. Contrast material can be injected into the blood stream but unlike CT contrast or nuclear medicine scans, there is no radiation or radioactive isotopes used.

The high-resolution 3-D images without the use of radiation of cardiac MRI sets it apart from other imaging modalities, but it also had its limitations (Figure 4). Disadvantages included long scanning times preventing acutely ill individuals and those who suffer from claustrophobia from tolerating the test. Also, anyone with metallic foreign bodies embedded in their bodies such as pacemakers, surgical clips, or bullet fragments are typically unable to undergo MRIs. Despite the advantages, MRI is rarely used as the initial imaging technique because of lack of availability, time delay, incompatibility with implanted metal devices, and monitoring difficulties during the study (Shiga et al., 2006). The most common patient complaint is remaining still during the study, which can last 30 minutes or more.

FUTURE TRENDS

Ultrasound and nuclear medicine have undergone technological breakthroughs, and newer devices provide more accurate and detailed results, which manufactures and researchers continue to focus on developing improved MDCT and MRI scanners. MDCT scanners will become faster with greater precision and detail allowing for improved diagnostic accuracy and reproducibility (Sanz & Poon, 2004). Similar advances are taking place with MRI. Scanners are being designed utilizing stronger magnetic fields, improving data acquisition technology, and improving contrast agents to produce higher quality images. The use of CT may decline as MRI becomes better, faster, and cheaper. The advancements of all these imaging modalities will change the field of medicine for the better.

CONCLUSION

Each imaging modality provides a specific type of information and when used appropriately can aid physicians in making rapid diagnoses, and each also has its limitations. At present it may appear as multi-slice CT imagers are taking center stage especially with the development of 16-slice, 32-slice, 64-slice, and 256-slice imagers now available. Presently, MR is the imaging modality of choice for peripheral vasculature and is more suited for elective diagnosis rather than clinical emergencies. CT plays a large role for pulmonary and cardiac imaging. Since technological advances and clinical research continue to improve all modalities, it is impossible to know which will be of most utility in the future. Whatever the future of cardiopulmonary imaging brings, there will always be a need to understand basic principles of ultrasound technology, nuclear medicine, CT, and MRI.

KEY TERMS

Atherosclerosis: A condition in which fatty material collects along the walls of arteries. This fatty material thickens, hardens, and may eventually block the arteries.

Computed Tomography: An imaging technology completed with the use of a 360-degree x-ray beam and computer production of images. These scans allow for cross-sectional views of body organs and tissues.

Coronary Heart Disease: A narrowing of the small blood vessels that supply blood and oxygen to the heart. CHD is also called coronary artery disease (CAD).

Echocardiography: A procedure that evaluates the structure and function of the heart by using sound waves recorded on an electronic sensor producing a moving image of the heart and heart valves.

Magnetic Resonance Imaging: The use of a nuclear magnetic resonance spectrometer to produce electronic images of specific atoms and molecular structures in solids, especially human cells, tissues, and organs.

Multidetector Computed Tomography: An imaging system which incorporates approximately 1,500 solid-state ceramic X-ray detector elements, each approximately 1 mm wide, arranged in rows. This detector array has been combined with improved X-ray tube design, allowing faster, multilevel scanning with high spatial resolution.

Nuclear Medicine Scan: The use of a camera to image certain tissue in the body after a radioactive tracer accumulates in the tissue.

Spiral (Helical) Compute Tomography: A newer version of CT scanning which is continuous in motion and allows for three-dimensional image generation.

The Impact of Network-Based Parameters on Gamer Experience

INTRODUCTION

Most of the existent games consist of multiple players, connected over a network, collaborating and competing in a virtual world. In this world, each player typically controls a single virtual entity. Communication between players can be achieved by sharing entity state information, such as positioning using synchronisation messages. These messages are periodically transmitted across the connecting network, and update the remote state of the virtual entity, which is the state replicated on other players' computers. If the games are using the Internet as a connecting network, latency, jitter, and packet loss, can have a significant impact upon the service experienced by application user (end-user). More specifically, latency or delay can by introduced by various types of delays, such as propagation, serialisation, and queuing delays.

Jitter is the variation in latency experienced by consecutive packets. Not all of the packets in a given flow will take the same path through the network. The time taken to traverse different routes is likely to vary due to factors such as their different physical distance, the number of hops, or physical link properties. On lower bandwidth links, which have a greater serialization delay, variation in packet lengths can introduce jitter. The size distribution and arrival patterns of other traffic flows on shared links may influence the queuing delay experienced by packets in one particular flow and is, in itself, a source of jitter. There are a number of different points on the network where packets may be lost. At the physical layer, all links experience some rate of data corruption, known as the bit error rate (BER). This may be caused by a high signal-to-noise ratio (SNR) during digital to analog conversion processes, which causes erroneous encoding or decoding of data, or it may be caused by faulty hardware. Forward error correction (FEC) is sometimes used at the link layer to recover from one- or two-bit errors. A cyclic redundancy check (CRC) may be applied to detect whether or not errors are included in the frame. Occasionally, transient congestion, with the subsequent queuing of packets, is so severe that it causes the routing queue buffer to overflow. When this occurs, newly arriving packets will be dropped until there is sufficient space in the buffer to place new packets. On other occasions, dynamic routing changes or route flapping may result in a temporarily incomplete network path, which causes losses.

BACKGROUND

The current Internet model provides only a single level of service, known as best effort (BE) delivery of data. In this model, the network will attempt to route traffic as quickly as possible to its destination, but provides no guarantees that those packets will traverse the same path across the network, arrive in the same order, or even arrive at all. Streaming and interactive applications (often referred to as *nonelastic* applications) require upper bounds to be placed on delay and jitter to facilitate smooth delivery. Packet loss and corruption must be also bounded to ensure adequate subjective quality, as it may not be possible to retransmit packets within the required time frame. How the required level of service might best be provided to the multitude of applications in use on the Internet has been the subject of extensive study for over a decade. When discussing the motivation for quality of service (QoS) in communications networks, it is important to define the term "quality of service." The International Telecommunication Union (ITU) Telecommunication Standardization Sector (ITU-T) describes the term "quality of service" as "The collective effect of service performance which determines the degree of satisfaction of a user of the service" (ITU-T, 1994). When this definition is used, it can be clearly seen that QoS is something that can only be correctly determined by the user of a service, as it relates to the user's expectation of service quality.

The quality of a voice/video telephony call, or a multiplayer game can be assessed using objective and subjective

methods. For voice/video, objective methods allow subjective quality to be predicted on the basis of psychoacoustic modeling (Hollier & Cosier, 1996). Similar applications are very much in their infancy for gaming. Subjective methods of assessment involve playing sample stimuli to a target audience in order to gather opinion data. The primary difficulty with subjective assessment is that of eliciting useful objective information when a user expresses their satisfaction or otherwise with a service. Quantifying what is meant by "good" is difficult without contextual information about the user's previous experiences and context. This points to the inherent complexity of measuring subjective quality and the difficultly involved in trying to obtain uniform answers from a diverse population of users. On the other hand, objective methodology, though often preferred because it is easier to measure and gather data for, is not without problems.

Subjective Measures of Mean Opinion Score (MOS)

Assessment measures that are based on ratings by human listeners are called subjective measures. When used for telecommunications systems, these tests seek to quantify the range of opinions that listeners express when they hear speech transmission of systems that are under test. Properly designed subjective tests provide the most accurate way of assessing speech quality. However, the results of subjective tests are influenced by the conditions of the tests, and great care must be taken of a number of factors in order to obtain reliable and reproducible results.

Although subjective assessment of speech quality requires substantial efforts, it is indispensable as a reference for evaluating the performance of objective speech quality

Table 1. Listening-quality scale

Quality of speech	Score
Excellent	5
Good	4
Fair	3
Poor	2
Bad	1

Table 2. Listening-effort scale

Effort required to understand the meaning of sentence	Score
Complete relaxation possible; no effort required	5
Attention necessary; no appreciable effort required	4
Moderate effort required	3
Considerable effort required	2
No meaning understood with any feasible effort	1

Table 3. Listening-effort scale

Loudness preference	Score
Much louder than preferred	5
Louder than preferred	4
Preferred	3
Quieter than preferred	2
Much quieter than preferred	1

measures. All subjective methods involve the use of large numbers of human listeners to produce statistically valid subjective quality indicator. The indicator is usually expressed as a *mean opinion score (MOS)*, which is the average value of all the rating scores registered by the subjects. For rating, the following opinion scales are approved and recommended by ITU-T:

Listening-Quality Scale

Listening-quality scale is a five-point category-judgment scale representing perceptual impression to speech quality as shown in Table 1.

The arithmetic mean of the listening-quality scale accumulated from all the subjects is known as the mean listening-quality opinion score, or simply mean opinion score, and is represented by the symbol MOS.

Listening-Effort Scale

Typical layout and wording of the listening effort scale is given in Table 2. The quantity evaluated from the scores accumulated (mean listening-effort opinion score) is represented by the symbol MOS_{LE}.

Loudness-Preference Scale

The layout and wording of the loudness-preference scale is given in Table 3. The quantity evaluated from the scores (mean loudness-preference opinion score) is represented by the symbol MOS_{LP}.

Amongst all the scales presented, the most used one is "listening–quality scale," as shown in Table 1, where the arithmetic mean of the listening quality scale accumulated is represented by MOS.

Objective Measures of MOS

Objective methods attempt to extract and catalog the motivations behind a user's decisions during an interaction. They are particularly applicable in the early stages of research or experiment design to establish a framework in which to operate. However, such methods should always be used in conjunction with subjective data to enable users to properly evaluate their experiences.

The E-model is a mathematical model of objective measurements, detailed in ITU-T Recommendation G.107 (ITU-T, 1995). The basic principle of the model is that "Psychological factors on the psychological scale are additive." It estimates the user satisfaction of a narrowband handset conversation, as perceived by the listener. The transmission rating factor *R* is obtained using a series of network impairment factors. Once computed, this R-value can be converted to an MOS score. The basic equation for the model is given by

$$R = Ro - Is - Id - Ie + A$$

where:

Ro = *S/N* at 0 dBr point
Is = Impairments simultaneous to voice signal
Id = Impairments delayed after voice signal
Ie = Impairments of special equipment such as codecs
A = Advantage factor which takes account of user advantages such as mobility

Another technique for estimating the effect of network impairments on Quake 3 clients is proposed by Ubicom (2005). The Quake 3 G-model is based on the ITU-T recommended E-model (ITU-T, 1995), as described previously. The impairment factor R is determined by:

$$R = (WL * L + WJ * J)(1 + E)$$

where

- *WL* is the latency weighting factor
- *WJ* is the jitter weighting factor
- *E* is the packet loss ratio
- *L* is the latency (one-way) in ms
- *J* is the jitter in ms as defined in Request for Comment (RFC) 1889

Some metrics used are based on work by Zander and Armitage (2004), and are correlated to average player performance, as defined by average player frags per minute. Obviously such a performance measure will not be applicable to all gaming genres, hence, the use of the more generic OPScore value. The measure has received criticism in some quarters for failing to account for other causes of lag, such as server and client processing delays, and the accuracy of the measure has been questioned on some forums.

Work by Wattimena (2006) is successive and focused on developing a similar model for QuakeIV. Data is taken from subjective tests on user samples, where network impairments are introduced, before applying multidimensional linear regression analysis to determine the appropriate mapping function. This function is given by

$$MOS = -0.00000587X^3 + 0.00139X^2 - 0.114X + 4.37$$

where the network impairment *X* is given by function:

$$X = 0.104 * ping_{average} + jitter_{average}$$

This mapping function displays very high correlation (R = 0.98) with subjectively determined MOS scores. It also displays high correlation with user gaming performance.

Analysis of impairment factors across a broader range of applications can be found in Dick et al., (Dick, Wellnitz, & Wolf, 2005). Here, the influence of latency, jitter, and overall skill level on player perception and performance for four separate multiplayer games is evaluated. One of the interesting things about this study is that it did not concentrate solely on FPS games, though two of the games studied are this genre, namely Counter Strike and Unreal Tournament 2004. There is also a car racing game, Need for Speed Underground 2, and an RTS title, World of Warcraft III. Both a subjective MOS and an objective normalized game score metric is determined for all titles. Multidimensional linear regression analysis was used to show coherences between the results. The analysis determined that not only do different multiplayer games behave differently under the same networking conditions, but also that even titles in the same genre behaved differently. This difference likely arises from the varying degrees of success with which compensatory techniques are employed by games developers.

NEW OBJECTIVE GAME QUALITY ASSESSMENT

Most existent game quality assessment techniques described take into consideration only network impairments, therefore, the measured games quality is only correlated with the network impairments (delay, jitter, and packet loss). To estimate the player's overall perception of games quality, the proposed objective game quality assessment extends the traditional objective game quality methods by introducing the end-user experience/knowledge. As shown in Figure 1, the proposed objective game quality assessment takes into consideration the following parameters:

a. end-user experience
b. distortions introduced by game client equipment (memory, graphic card) and I/O devices (screen, keyboard, and joystick)
c. distortions introduced by the network (end-to-end delay, jitter, packet loss)
d. distortions introduced by game server (number of users, game type, game capability to adapt to network distortions)

Using these parameters, a "game rating factor" (*GRF*) is proposed. The *GRF* is inspired from an ITU-T recommended computational model (E-Model) successfully used to assess the combined effects of variation in several parameters that may affect end-user perception of speech quality. The computation of the *GRF* can be described as follows: a maximum value that reflects a high level of game quality will be reduced in proportion with the distortions caused by various impairment parameters. The following equation is proposed for *GRF* calculation:

$$GRF = GRFMAX - IGCD - IN - IGS + A$$

where:
GRFMAX is the maximum Game Rating Factor
IGCD: impairment factor representing all impairments due to Game Client and I/O device
IN: impairment factor representing all impairments due to network connection between the game server and game client

Figure 1. Proposed game quality assessment

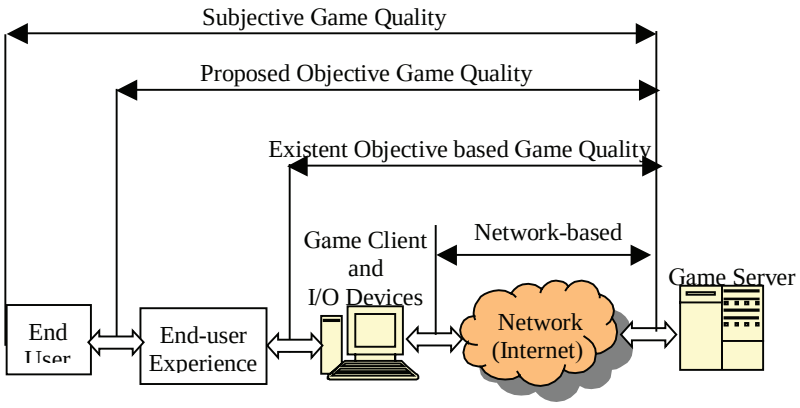

Table 4. Relation between the GRF, MOS_{GQE} and user satisfaction

GRF **(lower limit)**	$\mathbf{MOS_{GQE}}$ **(lower limit)**	**User satisfaction**
90	4.34	Very satisfied
80	4.03	Satisfied
70	3.60	Some users dissatisfied
60	3.10	Many users dissatisfied
50	2.58	Nearly all users dissatisfied

IGS: impairment factor representing all impairments due to Game Server
A: represents the end-user experience with online games.

The *GRF* can lie in the range from 0 to 100, where *GRF*=0 represents an extremely bad game quality and *GRG*=100 represents a very high game quality. The maximum value of 100 is in line with the ITU-T Recommendation G.107 (ITU-T, 1995). These parameters (excepting *GRFMAX*) will be individually calibrated and their effect on user perception will be measured directly using subjective assessment (MOS_{GPE}). An estimated MOS_{GQE} for an online game situation in the scale 1-5 can be obtained from the GRF using the following mapping function:

For $GRF < 0$: $MOS_{GQE}=1$
For $0 < GRF < 100$:
$MOS_{GQE}=1+0.035GRF+GRF(GRF-60)(100-GRF)7*10-6$
For $GRF > 100$: $MOS_{GQE}=5$

Table 4 shows the provisional guide for the relation between the *GRF*, $MOS_{GQE,}$ and user satisfaction.

MULTIPLAYER GAMING

Multiplayer gaming is becoming an increasingly important component of the Internet traffic mix, as evidenced by traffic measurements on Internet backbones (Joyce, 2000, McCreary, 2000). McCreary (2000) estimates that somewhere between 3% and 4% of traffic on one Internet backbone could be associated with just six popular gaming applications. Even this data might be drastically understated, as much like P2P traffic, multiplayer games traffic is difficult to identify based on simple port number mapping (Zander, Williams, & Armitage, 2006).

In an extensive survey of UK broadband subscribers, 48% of those surveyed listed "playing games" as a task for which they regularly use their Internet connection. This is only slightly less than the percentage who use their connections to download or listen to music, and greater than those who regularly use their connections for the purposes of online banking and downloading or watching videos. In a 10-month study of traffic at major Internet peering exchanges, games accounted for 14 of the 25 largest identifiable UDP applications (McCreary, 2000).

Wireless games are already considered to be a popular application globally, according to ITU-T (2002), with the wireless gaming market set to be worth in excess of $20 billion annually by 2010 (GIA, 2007). Europe is the world's largest wireless gaming market, and is estimated to account for approximately 43% of the global market in 2007. The remainder of the global market, comprising Canada, Asia-Pacific, Middle East, and Latin American regions, is projected to be the fastest growing wireless gaming market, with a compounded annual growth rate of circa 77% over a 10-year analysis period. The hosted server platform, offered by Vollee, allows for potentially any game to be played on a 3G handset by streaming a video of the game screen to the mobile. This vastly expands the range of available games without the difficulty of porting existing games or placing undue processing demands on the handset. It has been reported that the market for wireless gaming is developing in a manner similar to that of the games console market in the early nineties (Ward, 2005).

INTERNET AND ONLINE MULTIPLAYER GAMES

The most popular activities on the Internet today include e-mail, search, surfing, shopping, travel bookings, instant

messaging, listening to and downloading music, and playing games (Dutton, Gennaro, & Millwood 2005). Thus, it can be said that of the nine most popular things to do on the Internet, playing games is the only one where it is not possible to use a buffer to mitigate transient delay. Despite evidence that the demand for games grows alongside resource capacity and the high cost associated with providing sufficient bandwidth, many developers consider customer service to be the primary concern of games providers (Dutton et al., 2005). As defined by Veilleux (2002):

"The degree to which those companies need bandwidth is staggering. When a single server can host around 3,000 players at any time, and keeping in mind most of these online games often have many servers on which you can play, the cost must be sky high ... [but] the customer service issue is what the developers consider to be the most costly, and potentially the issue that could mean the difference between a loss and a profit ..."

The availability of Internet has provided an extensive infrastructure with global connectivity for the games industry to develop and deploy online games. Over the last 5 years, existent research reports revealed that online games have more severe requirements that are not fulfilled by the Internet's best effort model when compared with bi-dimensional Internet interfaces such as World Wide Web (WWW).

As indicated by Henderson (2003), multiplayer gaming on the Internet has proved enormously popular in spite of the lack of QoS guarantees. The many comments and discussions about "ping times" and "lag" on online gaming forums would suggest it is unlikely, but the hypothesis that users may actually be insensitive to network delays is subjectively evaluated by Henderson and Bhatti (2003). They monitored, over a 2-week period, user reactions to an advertised server latency of between 0 and 250ms, as well as introducing delays in this range, during the game, on a server with low advertised delay. The results revealed that delay had a significant impact upon a user's decision to join a server, but much less influence on a player's decision to leave a server. This occurred even though players indicated the delay was noticeable and their performance, as measured by frags per minute, decreased correspondingly.

Ward (2005) investigates the effects of both loss and delay on user performance in Unreal Tournament 2003 games. The main findings establish some bounds on typical values for loss and delay through analysis of public UT2003 servers. Loss was quite low, with a maximum reported loss of 3% and 80% of public servers reported no loss during the analysis period. Latency was less than 140ms for more than 80% of all servers measured. These values were then applied in a controlled experiment that demonstrated that packet losses in this range have no observable effect on player's performance. Latency however, of between 75ms and 100ms, resulted in significantly decreased player performance, as measured by observing shooting accuracy and the total number of frags. Users reported that once latency exceeded 75ms, the game developed a "sluggish" feel.

Evaluation of a car game by Pantel and Wolf (2002), finds that delays in excess of 100ms deteriorate gameplay and should be avoided. Results based on an evaluation of Counter Strike data (Farber, 2004) relating game lag (which includes nonnetworking delay) to subjective user data. These data are given in Table 5.

FUTURE TRENDS

The growth of gaming is a reflection of a worldwide trend, as many now predict that revenue from the games industry will soon exceed that of the US movie industry excluding DVD sales and foreign film rights. Combined video and computer games sales exceeded $7 billion in 2005. Research, conducted in 2006 by the US Entertainment Software Association (ESA), revealed that some 42% of all Americans had purchased or planned to purchase a game in 2006 (ESA, 2006). The same survey also demonstrated that 44% of frequent gamers play online, a figure which has risen from 19% in 2000. Another report, conducted by Joyce (2001), has shown that networked gaming, where multiple

Table 5. FPS game lag and its effect on user opinion

Lag	User opinion
<50 ms	Excellent gameplay
50ms-100ms	Good gameplay
100ms-150ms	Noticeably decreased gameplay
150ms-200ms	Significantly affected gameplay
>200ms	Intolerable gameplay

players play interactive games using network connections, are becoming an increasingly important component of the Internet traffic mix.

It is clear that, not only is the games industry undergoing substantial growth, but, within that industry, the importance of online gaming has been increasing. As broadband proliferation increases, and games development companies seek to extend the lifetime of their releases by encouraging online play, this trend seems likely to continue. This can be seen in the popularity of massively multiplayer online role playing games (MMORPG) like *World of Warcraft,* which has currently over 8.5 million subscribers. Worldwide software games sales are expected to reach $26 billion in 2010, with portable game sales due to hit $10 billion this year. The most popular first person shooter (FPS) game, *Counter Strike,* has, at any particular moment in time, an average of 85,000 concurrent players. In an extensive survey of UK broadband subscribers, 48% of those surveyed listed playing games as a task for which they regularly use their Internet connection (Hutton, 2005). This was only slightly less than the percentage using their connections to download or listen to music, and greater than those who used their connection for online banking and downloading or watching videos. It was nearly four times the percentage of those who used their Internet connections to make phone calls.

CONCLUSIONS

Interactive applications, such as online games, have certain requirements with respect to latency, jitter, and packet loss; usually referred to as quality of service (QoS) requirements. If the network cannot meet these service requirements, such impairments will impact negatively on the application user's experience. Over the last decade, game quality of service (QoS) has been, and still is, a challenging research area. Although there have been several standards and approaches published, the deployment of these technologies has been lacking.

This chapter detailed the network-based parameters mentioned (latency, jitter, and packet loss) and their impact on end user's experience. Measurement techniques for measuring these parameters were also given. A detailed review of existent standards and research advances into this research were presented. A new objective method for game quality assessment that could be used by both end-users and game providers was also presented.

KEY TERMS

Best Effort (BE): BE denotes "best effort" service delivery, the prevalent level of service offered by the Internet. It is analogous to the postal system and does not provide guarantees for timeliness, order or delivery itself.

First Person Shooter (FPS): An FPS game is a type of action game where the player views everything from a first-person perspective. Such video games are typically characterized by a high level of violence, and a focus on the use of handheld ranged weapons. The objective is to shoot and destroy objects or other players. Examples include Quake, Counter Strike and Unreal Tournament.

ITU-T E-Model: A mathematical model recommended by ITU-T to be used in assessing the speech/voice quality.

Jitter: Jitter is an unwanted variation of one or more characteristics. Jitter may be seen in characteristics such as the interval between successive moments, or the amplitude, frequency, or phase of successive cycles.

Latency: A time delay between the moment something is initiated and the moment its first effect begins.

Mean Opinion Score (MOS): MOS provides a numerical indication of the perceived quality of received media after compression and/or transmission. The MOS is expressed as a single number in the range 1 to 5, where 1 is lowest perceived quality and 5 is the highest perceived quality.

Packet-Loss: Packet loss occurs when one or more packets of data travelling across a computer network fail to reach their destination.

Quality of Experience (QoE): QoE is a higher-layer more abstract term than QoS. It is used in reference to the user's perception of QoS, which may differ greatly depending on a vast number of subjective criteria.

Quality of Service (QoS): A term used to describe performance criteria within a network. The criteria is quite varied, ranging from a loss rate below a given percentage or a bounded delay. BE is generally the term used when there is no specified QoS.

The Impact of Risks and Challenges in E-Commerce Adoption Among SMEs

Pauline Ratnasingam
University of Central Missouri, USA

INTRODUCTION

E-commerce provides different opportunities to small businesses as it overcomes part of their technical, environmental, organizational, and managerial inadequacies (Bergeron, Raymond, & Rivard, 2001; Hussin, King, & Cragg, 2002). According to Forrester Research, e-commerce in the US will grow at 19% reaching $230 billion by 2008. Further, the Internal Revenue Service (IRS) estimated that in 2003, there were 27 million small business tax returns. Small businesses are an important and integral part of every nation's economy (Hambrick & Crozier, 1985). The US Small Business Administration (SBA) defines a small business as "an independent business having fewer than 500 employees or is independently owned and not dominant in its field of operation." Small firms play an increasingly crucial role in US economy. They employ more than one half of the US private sector work force, are responsible for about one-half of the GDP, and generate more than one half of all sales in the US create 60%-80% of net new jobs annually (Ibrahim, Angelidids, J. & Parsa, 2004).

Alternatively, small businesses are often more challenged than larger firms by resource constraints, such as lack of financial capital, and technical or managerial skills, knowledge and expertise that significantly reduce the number and types of options available to management (Hodgetts & Kuratko, 2001). Previous research suggests that although most small businesses were connected to the Internet, the potential use of the Internet in their business was rarely explored. Security concerns has a direct impact on every critical part of the small business including reputation, productivity, and business continuity, as they need to adhere to the legal requirement for information management. The research question thus designed for this study is what factors inhibit or pose challenges for e-commerce adoption among small businesses? We discuss the findings of an exploratory case study with four firms, across a section of different industries, on the risks and challenges they encountered when adopting e-commerce. The study contributes to managerial and theoretical implications by increasing the importance and awareness of small businesses in e-commerce adoption.

BACKGROUND

The rapid growth of the Web, and its importance to the US economy, make it imperative to develop a greater understanding about the challenges and barriers experienced by small businesses. Small businesses use the Internet mainly to send electronic mail messages, and to conduct e-commerce, including financial transactions. Other uses include communicating internally and externally, thereby sharing data; providing customer service and vendor support; purchasing and selling products and services; and collaborating with other businesses (Schneider & Perry, 2001; Turban, Lee, King, Chung, 2006).

Small businesses are typically characterized by a flat organizational hierarchy and close proximity to coworkers, thereby contributing to effective communication practices comprised of informal channels (Vinten, 1999; Wickert & Herschel, 2001). Their communications are typically carried out face-to-face as the need arises, rather than applying a formal standard operating procedure. Small businesses lack human resources and budgets allocated for information security management. Many small businesses think they are not at risk because of the size of their business information. They display the "if it's not broke, don't fix it attitude." Due to the lack of IT, staff leads to no one thinking about the IT security of small businesses, thereby leading to the lack of IT security policies. Further, they are often pressured by their large manufacturers to adopt e-commerce. Their systems are often vulnerable, and are related to unpatched systems that are improperly configured. The next section discusses factors that inhibit small business adoption.

Factors Inhibiting E-Commerce Adoption

The factors that inhibit e-commerce adoption stem from two perspectives, namely, technology-related factors and relationship-related factors. Risks refer to the possibility of an adverse outcome and uncertainty. Risks can be derived both internally and externally, thereby causing a concern to the smooth flow of e-commerce operations.

Technology-Related Factors

Technology related factors are derived from misuse of IT, viruses, and the lack of confidentiality, integrity, and availability mechanisms. Some of the risks include viruses, worms, spy ware, spam, phishing scams, hackers, and bot networks. They impact the compatibility, infrastructure, complexity, and uncertainties of e-commerce systems and operations.

Preadoption Negotiation and Integration Challenges

E-commerce adoption, unlike traditional information systems adoption, demands high levels of negotiation, cooperation, and commitment from participating organizations. Selecting transaction sets, negotiating legal matters, and defining performance expectations can burn up hours of employees' time and demand financial and technological resources (Senn, 2000). This becomes even more challenging for small businesses, as they lack the technical skills and knowledge to negotiate effectively. Previous studies suggest an internal fear of opening their organization's systems to suppliers, as implementing e-commerce could affect critical business processes including procurement, inventory management, manufacturing, order fulfillment, shipping, invoicing, payments, and accounting, as in difficult to measure success (Nath, Akmanligil, Hjelm, Sakaguch, & Schultz, 1998; Senn, 2000; Storresten, 1998).

High Implementation Costs

Startup costs for implementing e-commerce applications can be high. These include connection costs, hardware, software, set up, and maintenance (Iacovou, Benbasat, & Dexter, 1995; Nath et al., 1998). Implementation costs may also include conducting an initial search costs, costs of writing contracts, and paying staff to update and maintain electronic databases.

Lack of Standards and Policies

Due to the small size and physical environment, most small businesses operate with a lack of formal standards and best-known practices, which can lead to potential compromises in network controls, maintenance, data ownership, internal and external security, and permissions (Riggins & Rhee, 1998; Senn, 2000). For example, current methods of standardization for structuring data exchanged in extranet applications totally ignore how e-commerce applications were designed to operate. Most small businesses do not know what policies to set and many do not even have a complete security policy in place (Marcella, Stone, & Sampias, 1998). Lack of established standards, regulatory policies, and best business practices can impact effective business operations in e-commerce.

Technology Uncertainties and Security Concerns

The proliferation of e-commerce applications has left most small businesses uncertain of e-commerce operations and unaware of the full potential of e-commerce technology (Ghosh, 1998). Uncertainties arise when small businesses encounter barriers in communication (such as incompatible e-commerce systems, or lack of uniform standards) that may lead to conflicts.

Relationship-Related Factors

Relationship-related risks are derived from mistrust among small business partners. Trust is defined as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party" (Mayer, Davis, & Schoorman, 1995).They arise from a lack of experience, training, and a lack of technical knowledge about the security concerns, task uncertainties, environment uncertainties, false impressions of unreliability, and concerns about the enforceability of transaction records in the electronic trade area. They examine opportunistic behavior, conflicting attitudes, poor reputation, lack of training, and reluctance to change in business partners.

Competitive Market Pressure

Small businesses that form electronic partnerships between buyers and suppliers or manufacturers and distributors are subjected to competitive pressures in the global environment that demand quality. Iacovou et al. (1995) suggest that external pressures and organizational readiness may affect e-commerce adoption. For most organizations, the biggest challenge is not if or when to consider an Internet commerce solution, but rather how to select the best Internet commerce strategies to develop and sustain competitive advantage.

Lack of Trust

Security is one barrier, but the real underlying factor is insufficient trust in the reliability of e-commerce systems to absorb the rapid increase in use (Keen, 2000). Despite the opportunities of Internet commerce, many small businesses

are reluctant to go online because they perceive the Internet as an intrinsically uncertain insecure environment (Bhimani, 1996; Cavalli, 1995; Jarvenpaa et al 2002; Storrosten, 1998). Small businesses fear that their business transactions and operations may be hacked and disrupted from confidentiality, integrity, and availability security concerns.

Lack of Top Management Support

With poor internal management and the lack of top management commitment, small businesses, implementing e-commerce, experience challenges. If management is unwilling to provide adequate financial resources, poor business practices might follow. For example, without full support a small business might neglect the need for a paper audit trail that would ensure the reliability of electronic certification and business continuity. Further, the lack of top management involvement and commitment impacts the extent of participation, extent of coordination with employees, and their strategic rationale for e-commerce adoption (Alavi & Leidner, 2001; Chatterjee & Segars, 2001).

Lack of Technical Skills, Knowledge, and Expertise

E-commerce was in its formative stages in the mid 1990s (Norlan and Norlan, KPMG, 1999). Many small businesses lacked the necessary IT skills, resources, and technical know-how to implement policies and strategies for secure e-commerce. This is consistent with previous empirical research that suggests the lack of technical knowledge, expertise, and resources hindered e-commerce adoption among small businesses (Heck & Ribbers, 1998; Iacovou et al., 1995; Reekers & Smithson, 1996).

Findings

An exploratory multiple case study approach was applied to examine the factors in four small business firms. According to Yin (1994), a research design should incorporate research questions including "how" and "why" types of questions.

The interviews were conducted applying a semistructured questionnaire for implementing and maintaining the security of the e-commerce system. The interviews lasted for 90 minutes, and two visits per firm were made. Four small businesses from a cross section of different industries, namely, a retail import-export firm, transportation firm, manufacturer, and a real estate firm participated in this study. Brief background information of each firm is given followed by Table 1, which summarizes the demographic information of the firms.

Firm A

Firm A is an import/export trading firm that conducts its business on a Web site developed in Nov 2003. They sell unique accessories including jewelries, artwork, handbags, and unique children books in Spanish and English. They aim to cater the needs of the women, gay, and young children in the Spanish and African American communities.

There have two full-time employees and their main business transactions include e-mail, fax, and telephone. They use QuickBooks, which takes in the orders and manages the shopping cart outsourced and managed by an IT solutions provider. The firm selects their suppliers for the variety of products via word of mouth.

Firm B

Firm is a transportation broker located in the town of Warsaw in Missouri with five employees in their branch office, paid on commission basis. They match trucks with freight that load goods across the US, in particular, the southeastern states of Mississippi (head office), Alabama, and Georgia. The Gulf States Paper or Georgia Pacific papers are their main shippers. The firm applies a data-entry software, called "Expressions," that records each order and matches a truck for it. They use e-mail extensively and have six phone lines. They also use the Internet to choose their truckers and offer low freight rates in order to stay competitive. They have 6,000 trucking companies in their database and use between 200-400 on a regular basis. Further, they have 20 shippers who use extranets. Some of their truckers use a special system, called Qual.com, that helps them to track where the truck is and when the goods will be expected to be delivered. Firm B mainly communicates via e-mail, fax, and telephones. They also do have a few shippers that use extranets. Their revenue each year is between $1-$10 million annually, and they spend about $5,000 on their IT computer systems as they have brand new computers.

Firm C

Firm C is an equipment supply and plastic packaging manufacturer located in Harrisonville (Missiouri). They have 15 full-time employees and sell equipment to global customers via their B2C Web site implemented in 2001. They manufacture and distribute equipment and plastic bottles on the requested size, shape, and color for their customers. They have 10 customers for the plastic bottles business and 50 customers each year on their B2C Web site, which sells specialized equipment. Their main business is conducted via the phone, fax, and e-mail for the plastic business and

the Internet for the equipment business. Their business documents include purchase order, invoices, quotations, and e-mail acknowledgements.

Firm D

Firm D is a real estate broker who has been in business for 25 years and owned this company for 20 years. They sell residential houses, farms, and commercial property primarily to the local area and to national customers who are mostly in the military. They have nine full-time employees. Their business transactions include closing agreement and foreclosure agreement. Most of the other documents are between the buyer and the bank. They rely on the lending institutions to take care of the financial process. Once the loan is approved, they order the title insurance and conduct a termite inspection. Their e-commerce system includes the multiple listing service system, implemented since 1990, that has all the information about the property, and is used by all realtors to network. It is crucial to their business strategy. In addition, they use the e-mail, fax, and telephone extensively. Through their MLS system, they have the voyager processor, which is the electronic tool used to facilitate the preparation of electronic contracts.

Table 1 presents the demographic information of the four firms.

Technology-Related Factors

Download delays and search problems from incompatible systems or lack of system functionality was not an issue for most of the firms, as they had an IT person who would fix their system if they had problems. Further, they had other ways of communicating with their customers such as the telephone and fax to do business if their network was down. Firm A spends nearly $40,000 for the initial IT implementation costs. Their annual maintenance costs of the Web site vary from $2,000-$5,000.

The manager of Firm A stated that the functionality of the Web site nor the user friendliness was important as they were able to observe the Web traffic as to how many customers visited their Web site. Firm B's computer does crash and they will call their IT service provider to come and fix it. The manager of Firm B noted: "In this business the better the tools are they make you the money because the system is able to provide you with timely accurate information that in turn enables you to make profit. Further, knowing our providers was important as we know our shippers very well in terms of what products they want us to transport. We need to know what the product is as we need special licenses and the driver needs special licenses." Firm B indicated that it was difficult to measure the success of their IT implementation as they moved from the old to the new system. The old

Table 1. Demographic information of the four firms

Characteristics	Firm A	Firm B	Firm C	Firm D
Type of Industry	Retail Marketing	Transport Freight	Plastic Packaging and Equipment Manufacturer	Real Estate broker
Number of Employees	2	15	15	7
Years Using IT/E-Commerce solution	Since November 2003	2001	2001	1990
Type of IT system	Internet B2C shopping cart	Internet, E-mail	B2C, Phone, fax and e-mail	Internet E-mail
Types of business transactions	Purchase order, Invoices, shipping notices	Purchase order, Invoices Shipping Notices Bills of Lading Payment Info	Purchase order, Invoices Quotations E-mail acknowledgments	Closing agreement, Foreclosure
Product Focus	Accessories – jewelries, artwork, handbags		Plastic bottles & Specialized equipment	Residential houses, farms, and commercial properties
Organizational Reach	Global National	National	National Global	Regional National

system had the complete database and 6,000 filters not in the new system. They are working on it.

Firm D's business partners include four local lenders and bankers. Their Web site was shared by the MLS (Mortgage Listing Service) as all can see it. Further, security was not a concern because each user is required to use a log-on user id and a password to get into the MLS system. Firm D spends about $2,000 to $5,000 each year to upgrade and maintain our IT systems.

The manager of Firm D noted: "In the past we had an MLS but it had a lot of redundant information. For example 5 different realtors will list the same house in the listing. It was a nightmare for the seller to keep track of who had listed and who did not. Firm D indicated that everything is legal and looks the same no matter which realto the seller or the buyer goes to."

Competition from traditional brick and mortar firms going online was not a concern as most of the firms sold specialized goods and services that served their customers locally and regionally. Complexity costs, training, and implementation costs was a concern for Firm B. The manager stated: "The main challenges that the firms experienced included; was the lack of IT skills as they had to rely on an IT solution provider to customize their systems when it was down."

Firms C and D had customized software and solutions that were not connected to the Internet but rather to intranets that had various log-in authorizations for their different employees.

Relationship-Related Factors

The impact of top management support for all firms was low as most of the firms were family owned business; hence, this was not a concern. The manager of Firm A indicated: "When you open a Web site business it is difficult for suppliers to know the size of your firm. Our suppliers thought that our business was big. A large image was impressive although in reality there were only two partners."

Issues pertaining to trust and uncertainties were not a concern for Firms C and D, as they maintained a long-term relationship with their business partners. Firm B indicated that most of their business partners are derived from word of mouth and is based on past reputations. They adopted the e-mail system in 1995 and found that it was crucial to their business strategy.

In order for Firm B to stay competitive, they had to provide good freight rates, sign contracts, thereby, providing customer satisfaction. Demands from larger trading partners related to timely delivery pickups. Firm B manager indicated: "We do not charge them if the shipper delays on the product. If they cancel on us and do not pick up the load there is nothing we can do. A bad experience like that will affect

Table 2

Factors that Inhibit IT/EC Adoption ***Technology-related Factors***	**Firm A**	**Firm B**	**Firm C**	**Firm D**
Competitors have also adopted new IT	L-3	M-4	M-3	L-4
Limited flexibility due to resource constraints	L-2	M-4	M-3	L-3

Inability to sustain e-initiatives	L-2	M-4	M-4	L-3
IT sophistication–resistance to change	L-2	M-2	M-4	L-3
Functionality of the Web site–difficult and not user friendly	L-2	M-3	L-2	L-3
Concerns over security and reliability of the system and the stakeholders	L-3	L-2	L-3	L-1
Difficult to integrate	L-3	L-3	L-3	L-3
Incompatible systems	L-2	L-3	L-2	L-2
Increased implementation costs	M-5	M-4	L-3	L-3
Relationship Factors				
Complexity costs, costs of training	L-2	L-2	L-3	L-2
Lack of financial resources	L-3	M-4	M-5	L-2
Lack of IT/IS skills	L-3	M-4	M-5	L-3
Lack of trust from external IT sources	L-3	L-2	L-3	L-2
Level of top management support	L-2	M-4	L-2	L-3
Market pressure	L-2	M-5	L-3	M-5

our business and usually give three chances. For example, when the trucker loads with the wrong product to the wrong place. We have to correct any mistake even if we have to spend more. It could be the drivers fault, shippers fault or the guy who loaded it. Papers can go spoilt if the van has a leakage. Usually the shipper will find a way to sell it as scrap so that the entire load is not wasted."

Market pressure was a concern for Firm C as the manager mentioned that although China and India could provide the specialized machinery items cheaper, it was seen as our weakness. Firm C has established a very strong relationship with their regular customers and hence, were able to compete effectively with the overseas market. Firm D encourages a team concept and so, hires only seven employees. We work really hard as a leader and discourage interoffice competition.

Impact of security risks and challenges experienced by the four firms were measured using a Likert scale where Low (L= 0-3), Medium (M=4-6), and High (H=7-10). Table 2 presents the summary findings based on the impact on factors that inhibit small businesses e-commerce adoption via a Likert scale.

FUTURE TRENDS

In this section, we discuss the observations of the findings as lessons learned and future trends of this study. Although most of the firms that participated in this study were not established and matured in the use of the e-commerce systems, as in an active shopping cart, it was found that most of the small businesses were operating using e-mails, extensively, to circulate documents, notes, attach invoices, financial reports, design documents, purchase order acknowledgments, and other business documents.

The firms did not undertake an evolutionary process when implementing their e-commerce systems but rather, implemented them as the need and demand arose, that is, they took a reactionary approach. This is because small businesses do not have the necessary financial, technical IT skills, knowledge, and strategic resources to build their system in an evolutionary fashion. Rather, most of them have outsourced their IT business operations to Web developers, IT consultants, or even subcontracted part of their IT operations to another firm. This indicates their resistance to change, to expand, educate, and increase their awareness of the full potential of the e-commerce technologies.

Further, small businesses were very cautious of sustaining their revenue in order to meet their ongoing overhead expenses such as utilities, wages, salaries for their current employees, cost of purchasing inventory, and other current operating expenses. In essence, they were not big risk takers. The Internet assists small businesses globally, but a physical store helps to build reputation and trust locally, and within suppliers and future trends of most small businesses is to maintain and upgrade their Web sites, which, in turn, will be reflected in their business operations.

CONCLUSIONS

In this study, we examined the factors that inhibit and pose risks and challenges to e-commerce adoption among small businesses. We tested an exploratory case study questionnaire with four small business firms from a cross section of different industries. The findings suggest the importance of adopting e-commerce to maintain a competitive and strategic advantage. It increased the awareness and importance of e-commerce adoption among small businesses. Future research should aim to examine these factors extensively. Small businesses need to have a brick and mortar office to do e-commerce because there are so many scamps going on.

KEY TERMS

E-Commerce: Refers to buying and selling over the Internet

Relationship-Related Factors: Refer to risks derived from mistrust among business partners.

Risks: Refer to possibility of an adverse outcome and uncertainty.

Small Business: Refers to an independent business having fewer than 500 employees or is independently owned and not dominant in its field of operation and the lack of confidentiality, integrity, and availability mechanisms

Trust: The willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party.

Impediments for Knowledge Sharing in Professional Service Firms

Georg Disterer
University of Applied Sciences and Arts, Germany

INTRODUCTION

Professional service firms (PSFs), where professionals (consultants, lawyers, accountants, tax advisors, etc.) work, are interested in knowledge management because their businesses are heavily dependent on the knowledge of their employees. A core asset is their ability to solve complex problems through creative and innovative solutions, and the basis for this is their employees' knowledge. The "product" that PSFs offer their clients is knowledge (Kay, 2002; Ofek & Sarvary, 2001; Chait, 1999).

Sharing knowledge between colleagues improves the economical benefits a firm can realize from the knowledge of employees. This is especially true for PSFs (Huang, 1998; Quinn, Anderson, & Finkelstein, 1996), where broad ranges of knowledge must be kept to provide intellectual services, and real-life experiences with certain questions and situations are an important asset. The organizations and its members are spread over various offices across the country or the world. The necessity for sharing grows because the network of professionals in most cases can offer significantly better professional advice than any individual. "We sell knowledge…the most valuable thing we can offer is the collective, institutional knowledge of our firm" (Roger Siboni, KPMG executive, in Alavi, 1997, p. 1). Working together openly without holding back or protecting vital pieces of knowledge will result in more productivity and innovation than could be reached individually.

BACKGROUND

No professional is denying the worth of using working documents and materials produced by others. All PSFs are trying to set up collections of knowledge acquired in projects in order to share it and conserve it for reuse. Knowledge databases can address what is sometimes called the traditional weakness of PSF: "…narrow specialists who see only their own solutions, self-centered egoists unwilling or unable to collaborate with colleagues" (Liedtka, Haskins, Rosenblum, & Weber, 1997, p. 58). Many authors signal that sharing knowledge seems to be "unnatural" (Quinn et al., 1996; Barua & Ravindran, 1996; Holloway, 2000).

However, attempts to use knowledge databases often fail. Only a few databases are accepted as up to date. The special fields of expertise are covered only in fragments. The access is laborious and uncomfortable. Heterogeneous sources (text, internal and external databases, journals, books, comments, codes of law, and so forth) cannot be integrated. The lack of actuality and completeness causes quality risks if dealt with thoughtlessly and if not reflected upon.

People issues are meant to be critical for successful knowledge sharing. According to Ruggles (1998), "In fact, if the people issues do not arise, the effort underway is probably not knowledge management. If technology solves the problem, yours was not a knowledge problem" (p. 88). Therefore, we analyze the reasons why knowledge sharing needs dedicated efforts and describe possible actions to foster knowledge sharing. Through our research (Disterer, 2000, 2001, 2002a) and analyses drawn from literature, we categorize and discuss the various impediments encountered by people sharing knowledge (see Figure 1). There are some empirical results that confirm these impediments (APQC, 1996; Ruggles, 1998; KPMG, 2003; Govindarajan & Gupta, 2001M; Hooff & Ridder, 2004; Lee, Kim, & Kim, 2006). Then we show various approaches to overcome these impediments.

IMPEDIMENTS TO KNOWLEDGE SHARING

Loss of Power

Knowledge can be used to take action and to enforce spheres of influence. Passing knowledge to colleagues might grant some of this potential. Those who do not have this knowledge are deprived of the capacity to act or to influence. That applies for knowledge about customers, competitors, suppliers, procedures, recipes, methods, formulas, and so forth. In this sense, someone who passes on knowledge to a colleague loses the exclusiveness of his or her influence, which might have suggested some professional respect and job security. "Knowledge is power" is the well-known citation to describe situations in which experts with rare knowledge have the highest reputation, and monopolies of knowledge causes knowledge hoarding instead of knowledge sharing (Reimus, 1997; Andrews, 2001; Kankanhalli, Tab, & Wei, 2005).

In industries like professional services, employees are competing directly with each other through their special

knowledge, gifts, and talents. It might be part of the individual culture of high-performing employees that they voluntarily enter into the competition for scarce seats on their career paths because they like to compete and excel (Quinn et al., 1996). But, the drawbacks of competition are obvious: knowledge workers would be cautious to share their knowledge, because they could possibly give up an individual lead.

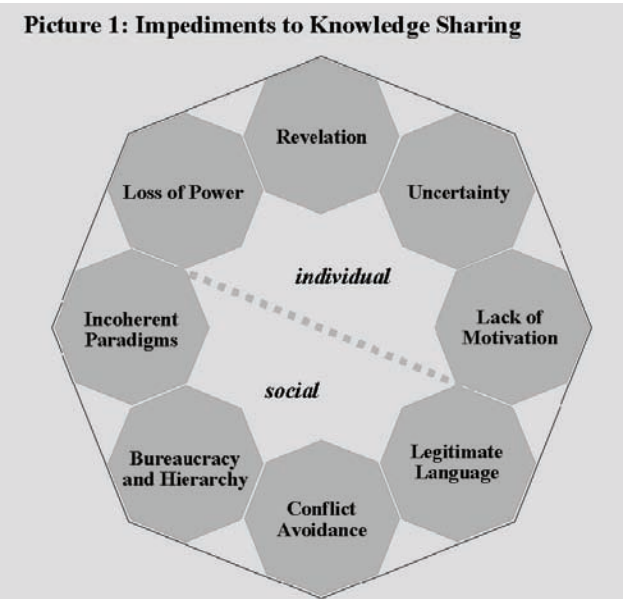
Revelation

Passing on knowledge to colleagues or entering working results into a knowledge database may be considered a revelation because it proclaims that this knowledge has a certain value and rarity. If this assessment is not shared by others, embarrassment may result (Rodwell & Humphries, 1998). Additionally, hasty colleagues rush to suggest "necessary" improvements to emphasize their expertise. For an individual, knowledge justified as "true belief" is not of particular concern. But in situations of knowledge sharing, more than one individual is involved. At this point, "…justification becomes public. Each individual is faced with the challenge of justifying his true beliefs in presence of [an]other" (Krogh, 1998, p. 35).

Uncertainty

Less-experienced colleagues may feel uncertain, because they cannot judge if their working results and experiences represent valuable knowledge for others. They cannot estimate if their knowledge is too general or too well known or, on the other side, that some results are too specific for a special situation and therefore useless for colleagues in other situations. Positioning on the scale of "general" to "specific" is not trivial and thus results in uncertainty.

Figure 1. Impediments to knowledge sharing



Lack of Motivation

Sharing knowledge is often seen as additional work because of the time necessary for reflection, documentation, communication, and so forth. Time is scarce, especially if the performance of an organization is measured by billable hours only. Reflection of work and sharing experiences are more an investment for future work than a billable action in the present. As stated in Dixon (2000), "In an organization with a bias for action, the time for reflection may be hard to come by" (p. 18; Hunter, Beaumont, & Lee, 2002).

Some employees do not expect reciprocal benefits from sharing, because they do not believe in these benefits or they did not experience it. Benefits of contributing to a knowledge database are gotten by a different stakeholder later on—the benefits will not be earned by the provider but by others (Nissen, Kamel, & Sengupta, 2000). Therefore, one precondition for contributing is the assumption of an equilibrium—a balanced give and take between colleagues. The insight that knowledge sharing can only be beneficial if everybody provides knowledge unselfishly may have charm only theoretically. In day-to-day practice, the benefit is too uncertain, and payback is not going to be immediate; therefore, the individual's commitment to share knowledge fails.

Legitimate Language

Some organizations lack a legitimate language (Krogh, 1998) that is known and accepted by all colleagues and can carry individual knowledge. This covers the need for a common language to communicate analogies and metaphors to externalize tacit knowledge hidden in individual mental models, viewpoints, working models, schemata, paradigms, and beliefs (Nelson & Cooprider, 1996; Nonaka, 1994; Haldin-Herrgard, 2000).

Conflict Avoidance

Attitudes of conflict avoidance and some conservative habits may prevent knowledge sharing, if the knowledge contains some new thoughts or innovative ideas. If most executives of an organization are not comfortable with change and are not willing to take risks, new ideas may be covered up easily. Different views and perspectives would be hidden, and knowledge not culturally legitimated may be suppressed ("do not rock the boat" attitude).

Bureaucracy and Hierarchy

Bureaucratic and hierarchical organizations show formal and administrative procedures that prevent the sharing of knowledge and new ideas. Strong hierarchical organizations prevent cross-functional communication, cooperation, and knowledge sharing.

Incoherent Paradigms

A lack of alignment between the personal intents of the individuals and the paradigms of the organization (strategic intent, vision, mission, strategies, values, etc.) can cause difficulties in articulating and justifying personal beliefs that do not fit with the ruling paradigms of the firm (Krogh, 1998).

ACTIONS TO FOSTER KNOWLEDGE SHARING

There is no complete methodology and no set of procedures and policies to address systematically all of the above impediments to knowledge sharing. Various approaches should be discussed further. Some of them sound like common sense but need to be emphasized because of their importance.

Concern and Trust

A precondition for knowledge sharing within organizations is an attitude of concern and trust among members of the organizations. Krogh (1998) called this "care" and defined it as serious attention, a feeling of concern and interest within an organization. His concept includes phenomena like trust among the people, interest in different viewpoints and experiences, access to help, lenience in judgment, courage to voice opinions, courage to allow experiments, and courage to take risks.

Organizations must strive for a culture of accepting mistakes (Soliman & Spooner, 2000). They should not penalize errors to foster a climate of constructive conflicts, giving members the chance to "fall forward." Organizational development processes should build and establish a common set of ethical standards and values for an organization and should achieve a consensus of accepted working practices and habits.

Leadership

Knowledge sharing is based on the consistent, reliable, and plausible behavior of management. Members of management must positively communicate that they are thoroughly convinced that knowledge needs to be "nurtured, supported, enhanced, and cared for" (Nonaka & Konno, 1998, p. 53) and that they financially support knowledge management initiatives. Management must afford time for communication and reflection. There must be organizational slack that permits time for employees to network (Krogh, 1998; Wiig, 1997).

To openly share knowledge, mutual trust is necessary among all organization members. Trust results in common expectations of reliability, consistency, and plausibility. Trust reduces the fear that others will act opportunistically. Likewise, management must act as examples for knowledge sharing. They have to walk-the-talk and give up knowledge hoarding first. Members of a profession or a community accept standards of behavior and working habits from their peers (Quinn et al., 1996); therefore, management must act as peers to be an example in knowledge sharing (McDermott & O'Dell, 2001).

Rewards and Incentives

Special rewards and incentive methods can act as extrinsic motivation for employees willing to share knowledge. Organizations are successful with the provision of personal recognition and reputation when people have contributed to knowledge databases or actively participated in knowledge sharing (Hunter et al., 2002).

Some examples for direct rewards and how to provide chances to build reputation and fame include the following: Texas Instruments created an annual award named "Not Invented Here, But I Did It Anyway Award" (Dixon, 2000, p. 57) to reward usage of other employees' knowledge. Buckman Labs rewards the top 150 "knowledge sharers" (judged by knowledge managers) with a laptop and an incentive trip to a resort (Davenport, Long, & Beers, 1998). AMS honors contributors to the knowledge center with a bronze plaque at the headquarters and regularly publishes a top 10 list of most frequently used contributions (King, 1998). Forum, a consultancy in Boston, Massachusetts, holds a "World Cup Capture" to encourage its consultants to make explicit and sharable what they have learned from their latest engagements (Botkin, 1999). An Australian law firm honors individuals who contributed the most by having a star named after them (Robertson, 1999).

Contrary to this, there might be professions with different views: "A major concern of software engineers…is the fear of being known as an expert" (Desouza, 2003, p. 100). They fear being staffed to projects based on their past experience instead of being allocated more challenging tasks with room for learning. In this situation, the brand-like identity of a software engineer works to his or her disadvantage and builds a barrier to individual professional development.

Many organizations incorporate issues of knowledge sharing into their compensation plans and promotion policies. The big consulting and accounting firms commonly base their personal evaluations partly on how many contributions are

made to knowledge databases, how many new employees people have tutored, and how many training courses have been designed (Quinn et al., 1996; Whiting, 1999).

Tutoring and Mentoring

Administrative actions may define responsibilities for tutoring and mentoring in an organization. Ongoing programs that systematically develop employees can foster common habits and attitudes and can support communication among the members of the organization.

Project Experiences

At the end of bigger projects and transactions, time and effort for explicit debriefing should be provided to learn systematically by experience. The lessons learned could be systematically analyzed and stored for access by other employees. In other actions, it can help to use knowledge and experiences gained in projects (Disterer, 2002b).

Communities of Practice

A popular approach for fostering knowledge sharing is to develop communities of practice. These groups of professionals enhance the ability of their members to think together, to stay in touch with each other, and to share ideas with each other. These informal networks, sometimes also called knowledge fairs or clubs, competence centers, or creativity centers, consist of groups of professionals, informally bound to one another through a common class of interests and problems and a common pursuit of solutions. People who are exposed to a common class of interests and problems often develop a common language with which to communicate and develop a sense of mutual obligation to help each other (Manville & Foote, 1996; McDermott, 1999). These phenomena can be used to overcome some of the individual and social barriers to knowledge sharing within communities of practice.

Focus on Codification or Personalization

In PSFs, the knowledge of experts is a core asset, and therefore, careful management of this asset is important. Management is responsible for ensuring that the organization is as independent as possible from individuals. At the same time, these companies are operating in a "people business," where the personal and individual link between clients and professionals is critical (Morris & Empson, 1998). This special situation requires special approaches to manage knowledge. Quite popular are two approaches that consulting firms apply that address cultural issues differently (Hansen, Nohria, & Tierney, 1999).

One strategy ("codification") centers on information technology (IT): the knowledge is carefully codified and stored in knowledge databases and can be accessed and used by others. With the other strategy ("personalization"), knowledge is tied to the person who developed it and is shared mainly through direct person-to-person contact (Hansen et al., 1999). With a codification strategy, knowledge is extracted from the person who developed it, is made independent from the individual, and is stored in the form of interview guides, work schedules, checklists, and so forth. Knowledge is then searched and retrieved and used by other employees. Personalization focuses on dialogue between individuals; knowledge is shared primarily in personal meetings and in one-on-one conversations.

Individual barriers are significantly lower with a personalization strategy, because professionals keep control through the whole knowledge management cycle. The individual is recognized as an expert and is cared for. In fact, focusing on personalization could be called a communication strategy, because the main objective is to foster personal communication between people. Core IT systems are yellow pages (directories of experts, who-knows-what systems, people finders) that show people with whom they should discuss special topics or problems.

Organizational Design

Some organizational designs can foster intra-organizational collaboration. Partnerships and other forms of ownership by employees can be utilized to produce involvement and commitment (Hildebrand, 1994; Miles, Miles, Perrone, & Edvinssen, 1998). Moreover, these organizational forms address the hesitation of professionals with specialized knowledge to work within strong hierarchies and in working environments with strong regulations (Quinn et al., 1996).

Office Design and Construction

To lower the disadvantages of bureaucracy and formal communications, modern office layouts reduce the distance between colleagues to foster ad hoc, informal, and face-to-face communication.

FUTURE TRENDS

Further research will be necessary to understand barriers to knowledge sharing, because cultural barriers are dominant over technical problems while implementing knowledge management initiatives. The connections between corporate culture and corporate climate and knowledge sharing within firms need more research for better understanding. Today, appropriate reward and incentive systems and well-established communities of practice are the most promising ways to overcome the barriers.

Inter-organizational knowledge sharing will become more important when larger and more complex projects will be distributed among several professional service firms. Sharing knowledge across organizational boundaries will raise questions of exchanging important knowledge while keeping business secrets.

CONCLUSION

Ways to support knowledge management with IT are manifold, but certain cultural aspects of knowledge sharing must be addressed. We describe some possible actions to overcome typical resistance often articulated with phrases like "this is client confidential," "only I know how to use it," "what's in it for me?" and "I have no time to document my experiences." The descriptions of the impediments and the possible actions make clear that knowledge management in professional service firms could not be seen as a technical field, as it is deeply social in nature. Corporate culture and corporate climate are important factors to foster—or hinder—knowledge sharing. Till now, there is no complete methodology and no set of procedures and policies to address all issues systematically, therefore managerial actions are described that can lower impediments of knowledge sharing.

KEY TERMS

Community of Practice: A group of people in an organization who are (somehow) held together by common interest in their work topic, purpose, and activities.

Culture: Covers the pattern of basic assumptions accepted and used about behaviors, norms, and values within an organization.

Knowledge Management: The systematic, explicit, and deliberate approach to creating, sharing, and using knowledge in order to enhance organizational performance.

Knowledge Sharing: The processes of transforming and transferring knowledge through an organization are designated by knowledge sharing.

Implementation Management of an E-Commerce-Enabled Enterprise Information System

Joseph Sarkis
Clark University, USA

R.P. Sundarraj
University of Waterloo, USA

INTRODUCTION

The integration of enterprise systems and the supply chain to an organization is becoming more critical in an ever-changing, globally competitive environment. Quick response will require close relationships, especially communications and information sharing among integrated internal functional groups as well as the suppliers and customers of an organization. Texas Instruments (TI), headquartered in Dallas, Texas, has come to realize this requirement for building and maintaining its competitive edge. Thus, it sought to implement an enterprise resource planning (ERP) system with a focus on linking it with a global electronic commerce (e-commerce) setting, an innovative and current issue (Weston, 2003).

There were a number of major players, including project management direction from Andersen Consulting Services, software vendors such as SAP and i2 Technologies, hardware vendors such as Sun Microsystems, and various suppliers and customers of TI.

The purpose of this case is to provide some aspects of implementation of strategic systems that provide valuable lessons for success. We begin and rely on the foundation of a strategic systems implementation model, which is initially described. A description of the case follows, with the various stages as related to strategic systems implementation described. We complete our discussion with implications and conclusions.

BACKGROUND

A process-oriented framework for ERP management is presented to help guide the discussion of this case (see Cliffe, 1998; Davenport, 1999; Miranda, 2002; Sarkis & Sundarraj, 2000).

The elements include the following:

- Strategy formulation and integration—One of the results of this step in the process is determination of an organization's core competencies that need specific technology support.
- Process planning and systems design—Also known as the reengineering phase, three studies are usually undertaken at this stage, and they are named AS-IS, SHOULD-BE, and TO-BE.
- System evaluation and justification—Here, analysis focuses on the economic, technical, and operational feasibility and justification of the system.
- System configuration—As a packaged software system, there are likely to be discrepancies (at the detailed level) between the needs of an organization and the features of the software. Hence, a significant amount of effort can be expected to configure the system or the organizational processes in order to produce an alignment between them.
- System implementation—The implementation stage can be classified into startup, project management, and a migration handing the switch over from the old to the new system.
- Postimplementation audit—This last "feedback" stage, although very important from a continuous-improvement perspective, is one of the more neglected steps.

As can be seen, the process suggested above can be arduous, but this necessary effort must be anticipated for the successful integration of complex and strategic systems into an organization.

IMPLEMENTING A GLOBAL ERP SYSTEM AT TI

Company Background

Texas Instruments Incorporated (TI) is a global semiconductor company and the world's leading designer and supplier of digital signal processing (DSP) solutions and analog

technologies (semiconductors represent 84% of TI's revenue base). The company has manufacturing or sales operations in more than 25 countries and, in 1999, derived in excess of 67% of its revenues from sales to locations outside the United States. Prior to the implementation of ERP, TI had a complex suite of stand-alone nonintegrated marketing, sales, logistics, and planning systems consisting of thousands of programs that were based on many independent databases and were running on proprietary mainframe systems.

OVERVIEW

Since the 1980s, TI had used a highly centralized infrastructure utilizing proprietary mainframe computers for meeting its IT requirement. As the first step toward global business processes, certain planning processes and systems were standardized in 1989. Starting in 1996, TI underwent a company-wide reengineering effort that led to the implementation of a 4-year, $250 million ERP system using Sun Microsystems' hardware platform, SAP AG's ERP software, i2's advanced planning tools, and Andersen Consulting's implementation process. In 1998, Texas Instruments implemented the first release of the ERP system, which primarily consisted of a prototype implementation of the i2 system running on a Sun E10000 platform. In early 1999, TI began rolling out the second release. In the middle of 1999, TI completed the i2 Technologies software implementation as part of the third release. Finally, TI turned on the remaining financials, and new field sales, sales, and distribution modules. A high-level architecture of TI's pioneering ERP implementation consists of SAP and the i2 system for advanced planning and optimization. The system is a pioneering large-scale global single-instance implementation of seven modules (finance, procurement and materials management, logistics, planning, field sales, sales, and marketing) for all of TI's divisions, and it is in use by 10,000 TI employees to handle 45,000 semiconductor devices and 120,000 orders per month. This solution also enabled global Web access to information for TI's 3,000 external users at customer, distributor, and supplier sites.

STAGES IN MANAGING THE GLOBAL ERP SYSTEM IMPLEMENTATION

Strategy Formulation

Traditionally, TI was primarily running what was called a "commodity" business, wherein orders were received, manufactured, and shipped as a batch. Mass customization combined with the maturity of TI's business caused it to reexamine its goals and strategies. TI started its shift toward a more customized product environment.

Within this new customized product environment, TI had a number of customer needs that could not be met easily. Thus, the goal was to determine the appropriate processes and information systems that must be put in place in order to support such agile design and manufacturing strategies. Another goal was a move toward supplier-managed inventory and customer-managed orders. Finally, standardizing systems was another integrative corporate goal. TI made extensive use of metrics. Strategic goals are translated into tactical and operational quantifiable objectives.

Process Planning and Systems Design

TI conducted a massive reengineering effort for the whole organization, with the goal of setting standard processes globally. The major result of this effort was to declare that all inventory and manufacturing management be done globally.

TI decided to implement a single-instance ERP system so as to fully leverage the system's capabilities to support the flexibility and standardization demanded by global processes. After site visits by major ERP vendors, TI selected SAP mostly because of its scalability to handle voluminous amounts of data.

System Justification

A budget of approximately $250 million was set for the implementation. The justification of the system was done using a combination of tangible and intangible factors at both the enterprise and business-unit levels. Standard hard-justification measures such as ROI and IRR were used to ensure the financial viability of the project.

Through this business case justification, acceptable financial returns, along with strategic factors such as competing effectively within a given niche market, and operational factors, such as global inventory management, all played roles in ERP's justification at TI.

System Configuration

The goals and processes entailed numerous and significant changes to all aspects of the business process design of the system.

Implementation

In this phase, concepts and goals were translated into tangible action, and as a result, it is perhaps one of most difficult phases of the project. General principles such as global

processes and standard systems need to be backed up by convincing and deploying the right people to implement the processes.

Startup

A number of key personnel, along with their families, were expatriated to the United States and stationed in Dallas, Texas, for a few years. About 250 people were transitioned from TI to Andersen Consulting that became the main provisioner of services with respect to the ERP system. IT outsourcing in this case involved Andersen Consulting taking over the employment and management of former TI people.

Project Management

Change management played a large role in this stage. The roles of training, planning, and communicating were of equal importance. All management levels were involved in this process as well as various vendors and suppliers. Some of the practices included the following:

- On-site experts were made available to new users of the system.
- A help desk was set up to handle problems that could not be addressed by these experts.
- A ticketing system for managing and prioritizing problems was also established (e.g., a system stop was a high-priority ticket that would get round-the-clock attention).

Handling Go-Live

To get prepared for "go-live," the key managers who were stationed in Dallas were sent back to their territories for educating the next level of users. Using selected experts, user-acceptance scripts were defined and tested, with problems, if any, being resolved as per one of the schemes outlined above. Daily conference calls were set up for 30 days prior to go-live to obtain status checks on progress and on the tickets.

Based on the results of these checks, a risk analysis was conducted weekly to determine the effects of various potential failures. The implementation plan was to have a few go-live dates one after another, but in relatively quick succession. Except for the planning system, in all the other stages, in this case, a direct conversion was employed. That is, with a downtime of about 2 to 3 hours during a weekend, the old system was turned off and the new one turned on.

Postimplementation Status

The system met most of its goals 9 months after the complete implementation. There are around 13,000 users on the system, with concurrent users ranging from 300 to 1,700. Some of the key performance measures and parameters evaluated were as follows:

- Productivity dip
- Ontime delivery
- Single-instance, global system
- Better response
- Inventory reduction

FUTURE TRENDS—MANAGERIAL IMPLICATIONS

The following lessons are summarized:

- Conduct a thorough strategic plan—The case illustrated how market forces had compelled the company to make radical shifts in its organizational environment and culture.
- Align IT plans with business plans—Conduct reengineering studies and develop strategic IT plans to align key IT needs with those of the business (Barker & Frolick, 2003).
- Get top management support—The prescription of top management support has been made ever since early IT implementations to the present (Mabert et al., 2001).
- Change management—Set realistic user expectations, such as the initial productivity dips. User involvement is critical. Andersen Consulting's process helped to ensure that such was the case. Make sure that the user was supported to help improve user satisfaction (Lee et al., 2003; Legare, 2002).
- Strong champion characteristics (Dean, 1987)—In TI's situation, the manager of the ERP project had over two decades of experience in various levels of the organization. This manager had broad knowledge of corporate operations. Previously, he was a vice president of one of TI's divisions.
- Rationalize business models and processes—Make sure the business models and processes fit within the strategic direction and goals of the organization. Time, mass customization, and flexibility concerns led to a global model (Gardiner et al., 2002). Global cultural issues were also a concern and needed to be managed (Davison, 2002).
- Manage external enterprises—Appropriate and well-planned involvement of consultants is important for

keeping the project on a tight schedule. Further, with the advent of e-commerce, companies are more likely to ship and order goods on the basis of Web-based inputs.

- Manage using metrics (Skok et al., 2001; Hitt et al., 2002)—TI and Andersen Consulting have a corporate culture and policy that require the stringent and formal use of metrics in the management and evaluation of projects. They attribute this policy adherence as one of the key reasons for success of the ERP implementation. Key performance indicators included such issues as reduction in inventory, percentage of suppliers linked, and productivity of outputs.

CONCLUSION

TI's ERP implementation with an e-commerce perspective required a significant amount of features that added issues to its management:

- It is a single-instance system, providing access to the same data, irrespective of the geographic location of the user.
- It provides access to 3,000 external users (customers and suppliers), thereby enabling 70% of the transactions to be conducted electronically.

Management saw some problems in this implementation process and tried to address the issues. Some of the major problems included the following:

1. The software for supply chain management (Red Pepper) that was initially chosen did not meet expectations of TI. This system had to be scrapped, and this resulted in a multimillion dollar cost.
2. A productivity dip occurred, and the implementation had to address this issue for all managers throughout the organization who had some stake in the performance of the system. The expectations that this would occur were communicated through newsletters and messages. Consistent and continuous communication helped to mitigate a situation that could have caused a major project failure.
3. Getting buy-in from internal functions not directly associated with the implementation process was difficult. This occurred with the marketing function.

Future extension of developing appropriate infrastructure is another issue that needs to be faced (Kovacs & Paganelli, 2003). Lessons learned here may be appropriate for small or large organizations, but some differences appear in the practices of what is successful and not for ERP implementations in different size organizations. One of the major issues is that small companies get greater operational benefits from ERP, while larger companies get more financial benefits (Mabert et al., 2003).

KEY TERMS

Audit: Reviewing and monitoring the performance of a system.

Enterprise Resource Planning (ERP) System: An information system that spans organizational boundaries with various organizational functional modules and systems integrated and managed by one system application.

Go-Live: The actual operation of an information system.

Mass Customization: Producing basically standardized goods but incorporating some degree of differentiation and customization.

Reengineering: Activities that seek to radically change business processes and support systems in an organization.

Single Instance: A one-time full-fledged company-wide initial operation of a system, as opposed to incremental (functionally or organizationally) or modular implementations.

Strategic Justification: The process of evaluating and selecting systems based on tangible (financial) and intangible factors that have implications for long-term and broad management of the organization.

Implementation of ERP in Human Resource Management

Harbin Institute of Technology, China

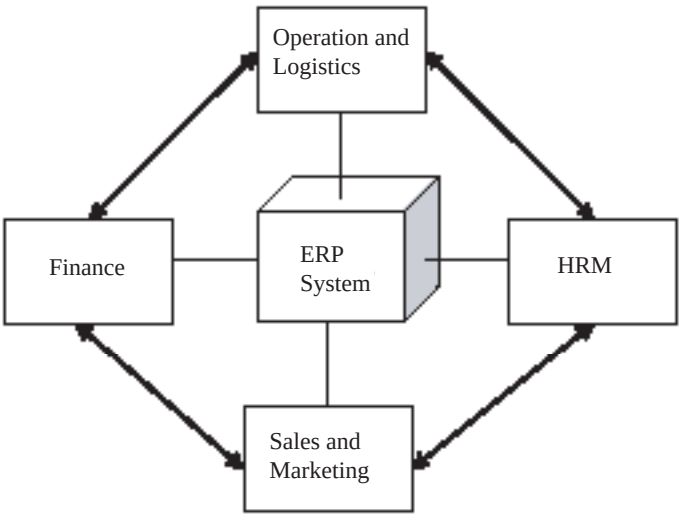
INTRODUCTION

In 1999, Peter Drucker said: "A new Information Revolution is well under way. It is not a revolution in technology, machinery, techniques, software or speed. It is a revolution in concepts." As a result of information technology (IT) innovation and reorganization, enterprise resource planning (ERP) was proposed by the Gartner Group in the early 1990s. It is a successor to manufacturing resource planning (MRP II) and attempts to unify all departmental systems together into a single, integrated software program that runs off a single database so that the various departments can more easily share information and communicate with each other (Koch, 2002). Over 60% of the U.S Fortune 500 had adopted ERP by 2000 (Kumar, & Hillegersberg, 2000; Siau, 2004), and it was projected that organizations' total spending on ERP adoptions was an estimated $72.63 billion in 2002 (Al-Marshari, 2002).

Many scholars have recognized the importance of people in organizations, and this viewpoint is the central focus of the human resource management (HRM) perspective (Pfeffer, 1995). In this perspective, HRM has the potential to be one of the key components of overall enterprise strategy. Additionally, HRM may provide significant competitive advantage opportunities when they are used to create a unique (i.e., difficult to imitate) organizational culture that institutionalizes organizational competencies throughout the organization (Bowen & Ostroff, 2004).

Typically, an ERP system supports HRM, operation and logistics, finance, and sales and marketing functions (Daven-

Figure 1. Function modules of an ERP system



port, 1998) (see Figure 1). But the early development stage of ERP in enterprises was all along with the center of production and sales course. Until recently, research has empirically supported the positive relationship between corporate financial performance and HRM function, and managers have also realized that HRM can deliver organizational excellence and competitive advantage for enterprises (Boudreau & Ramstad, 1997; Huselid, 1995; Wright, McMahan, Snell, & Gerhart, 2001). The HRM module was introduced into ERP, forming a highly integrated and efficient resource system with the other function modules of ERP. However, there are still many HRM-related problems that may result in the failure of ERP projects arising. So, there have been regular appeals to scholars for more research about the implementation of ERP systems in the HRM perspective in the last few years (Barrett & Mayson, 2006).

This article introduces the functions of an HRM module in ERP systems from the fields of human resource planning, recruitment management, training management, time management, performance management, compensation management, and business trip arrangement. Then it analyzes five HRM-related problems that may block the enterprises from implementing ERP successfully, and it provides reasonable recommendations. Finally, the article discusses future trends and suggests emerging research opportunities within the domain of the topic.

BACKGROUND

ERP, a term coined by the Gartner Group, is not simply a tool that provides singular outputs, but rather an infrastructure that supports the capabilities of all other IT-based tools and processes utilized by a firm (Enslow, 1996). Shang and Seddon (2000) classified the different types of ERP benefits as: IT infrastructure benefits, operational benefits, managerial benefits, strategic benefits, and organizational benefits. Palaniswamy (2002) pointed out that the failures of ERP projects were not because the software were coded incorrectly, rather the companies failed to understand the real organizational needs and systems required to solve their problems to improve performance. Lynne, Axline, Petrie, and Cornelis (2000) analyzed the adopters' problems with ERP including project phase problems, problems with product and implementation consultants, shakedown phase problems, underestimating data quality problems and reporting needs, and so on.

Within the managerial literatures, a coherent approach provides a conceptual basis for asserting that human resource is a key source of competitive advantages, since it offers a unique contribution to value creation, rarity, imperfect imitability, and non-substitutability of a firm's strategic resources (Bellini & Canonico, 2007). Stone (2007) considered the past, present, and future of HRM theory and research. He concluded that HRM theory and research has considerable potential to enhance organizational efficiency and effectiveness. Ashbaugh and Rowan (2002) summarized the technology features of a modern HRM system (see Table 1).

In addition, some scholars have already studied the relationship or connection of ERP implementation with HRM. For instance, Ashbaugh and Rowan (2002) argued that the major difference between ERP and its predecessors (e.g., MRP II) is the linkage of financial and HRM applications through a single database in a software application that is both rigid and flexible. Wright and Wright (2002) listed two of the most-cited HRM risks in an ERP system: lack of user involvement and inadequate training. Hsu, Sylvestre, and Sayed (2006) supplied another often-overlooked HRM factor when implementing an ERP system—that is, the result of high stress levels on the staff, particularly in the finance or accounting departments, which are already under stress from the heavy workload in a legacy system. Li (2001) studied the HRM function module in an ERP system. He insisted that the practical HRM system should be built up to improve incentive mechanism and to strengthen the training of employees while applying ERP.

Table 1. Technology features of modern HRM system

Integration	User friendliness
Common relational database	Enhanced reporting and analysis
Flexible and scalable technology	Process standardization and malleability
Audit trail and drill down capabilities	Internet and capabilities
Robust security	Document management and imaging
Workflow	

IMPLEMENTATION OF ERP RELATED TO HRM

Functions of the HRM Module in ERP System

We have studied the necessity and essentiality of HRM to the implementation of ERP in the preceding part of this article. The adoption of ERP also greatly impacts HRM by extending its functions to the all-direction management category (see Figure 2). The functions of HRM have developed from simple compensation calculating and personnel management to the fields of human resource planning, recruitment management, training management, time management, performance management, compensation management, and business trip arrangement (Ahmad & Schroeder, 2003; Li, 2001; Stone, 2007). Data from all function systems will be collected into a central database, and the database can further supply data needed for all function systems by integration.

Human Resource Planning

Based on the requirements of enterprises, managers can use the HRM module of an ERP system to establish human resource planning conveniently. The ERP system assists the decision making of managers by simulating the performance of human resource planning and comparing the data. Additionally, the ERP system is also able to analyze or forecast the human resource planning costs by integrating relevant information.

Recruitment Management

Recruitment should be taken as a significant investment because human resources are the foundational assets of an enterprise. To keep advantages in competition, the human resources department must have a reasonable recruitment system to select talents for enterprise. The ERP system can support recruitment management in three ways. First, it optimizes the recruitment process to reduce the workload. Second, it offers scientific management to recruitment costs. Third, it provides useful information for the decision making on recruitment management.

Training Management

Training in the use of multiple skills including process improvement skills, which can provide long-term work-life security rather than job security (Schonberger, 1994). The implementation of ERP can help train employees to acquire technical, interpersonal, and business skills required to become fully participating team members in the early stage of team development (Pasmore & Mlot, 1994). In other team development stages, by giving support to the human resource department to make an appropriate training plan, the ERP system can also help train team members to accept new skills, improved management regulations, and so on.

Time Management

Time management may support the planning, controlling, and management processes of HRM. It means to arrange the time table for the enterprises and staff flexibly according to the local calendar. The ERP system can record the attendance rate and other relevant information by using a Telematics Control Unit (TCU). For example, data related to the compensation will be further processed in the compensation management system.

Performance Management

Performance evaluation might consider the following issues: How are the facilitative and operational activities allocated to individuals in an organization, and how does the facilitative content of a task vary in an organization (Nilakant, 1994). The human resource department can establish an evaluation index system according to these issues. By integrating the performance management system with the time management system, the ERP system will record data in a central database and keep relevant data timely for each evaluation index. These data will be useful to the decision making of managers on corporate strategy, too.

Compensation Management

A reasonable compensation system should be able to apply proper calculation methods in terms of different regions, departments, positions, and so forth. The implementation of ERP will achieve this objective by integrating the compensation management system with other systems (e.g., timing management system, performance management system) so that it can update relevant data in a timely fashion so as to establish a dynamic compensation calculation system. The human resource department can simulate the performance of the calculation system to forecast compensation information needed and to adjust the structure of the compensation management system. This is an excellent improvement because it decreases management costs as well as problems caused by the intervention of manpower. Compensation management also includes other functions such as salary payments, loans for staff, and so forth.

Business Trip Arrangement

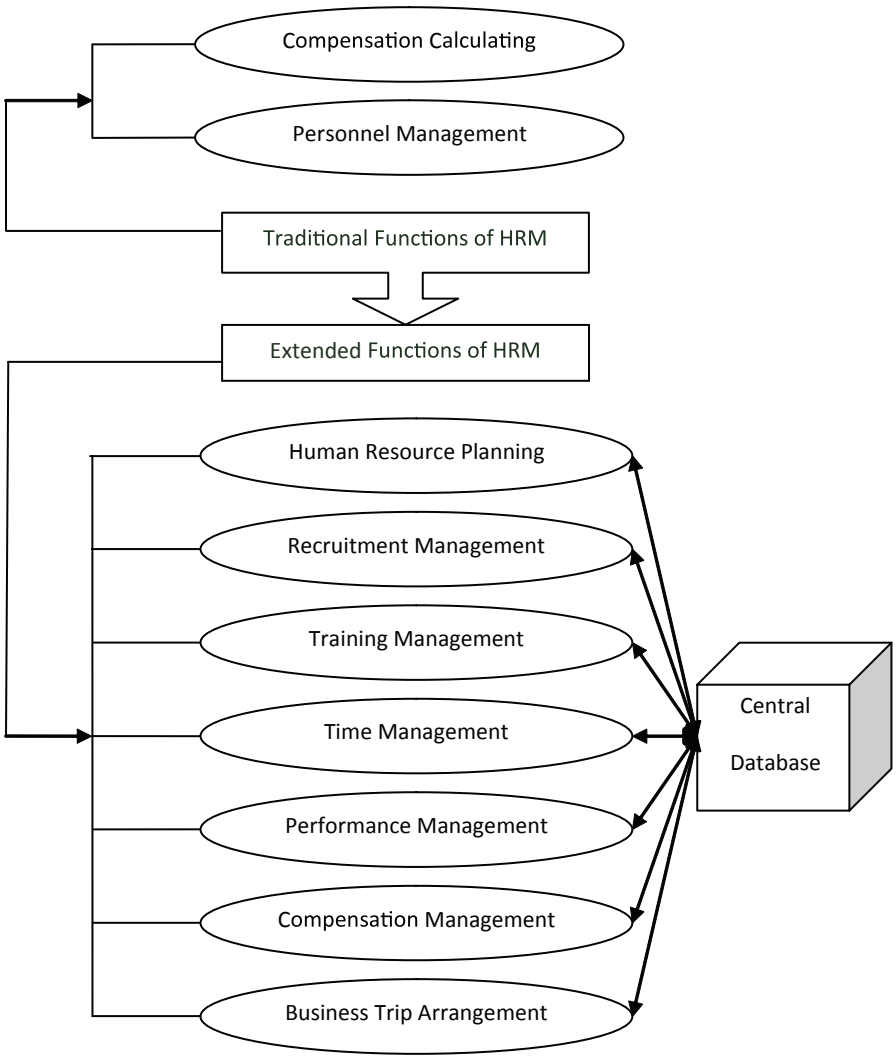
A business trip arrangement system can control the whole flow of a business trip from application to ratification and

reimbursement. These data will be further processed in other function modules of ERP (e.g., finance module) through systems integration.

Main HRM-Related Problems of ERP Implementation in Enterprises

ERP has been broadly applied in enterprises for nearly 20 years because of the enormous potential economic benefits. However, 53% of the ERP projects in U.S. firms were failed by 1996, and the success rate of ERP projects in Chinese enterprises was only less than 20% by 2002 (Edwards, 1999; Yang & Zhao, 2003). Hsu et al. (2006) pointed out that HRM factors played a significant role in almost all failed information systems. This article analyzes five main HRM-related problems that may block the success of ERP projects in enterprises (Lynne et al., 2000; Wright & Wright, 2002; Hsu et al., 2006; Sun, & Xu, 2006).

Figure 2. Traditional and extended functions of HRM



First is the shortage of professionals, especially the inter-disciplinary talents who are expert at both IT and management. ERP is not just an advanced technique, it is also an advanced management concept. Therefore, the inter-disciplinary professionals are crucial to the success of ERP. This problem is especially serious in the small and medium-sized enterprises because of the weakness of strength and management level.

Second is the deficient talent introduction mechanism. Employees who take charge of the ERP project of an enterprise are under high pressure because they take great responsibilities for the success of the implementation. If an enterprise does not have an effective talent introduction mechanism to attract talented people who are needed, it will be hard to start the ERP project at all, not to mention the successful application.

Third is the insufficient education and training for employees. The cultivation of talents is a process that needs much time investment as well as money, while some enterprises do not want to pay much investment to the education and training of employees due to lack of an in-depth understanding of ERP.

Fourth is the poor incentive mechanism for employees. Above all, the compensation mechanisms of enterprises may not be attractive enough. A competitive compensation mechanism cannot only attract applicants, but it also prevents the job hopping of employees. Still, the ERP projects have not been supported enough by superior administration departments. For example, the application of ERP needs the support of all involved departments, while managers hesitate to place departmental backbones on the ERP implementation. It may also influence the working enthusiasm of employees and kill more innovations if superiors interfere too much with the implementation.

Fifth is the lack of exterior consultation or a supervision system. An enterprise must pass the scientific verification of experts if it wants to adopt ERP. The implementation must be carried out under the direction of exterior professional organizations and the supervision of a special system. Enterprises may neglect the necessity and importance of these functions.

RECOMMENDATIONS

To implement ERP successfully, enterprises must pay attention to such tasks of HRM as follows (Lynne et al., 2000; Ashbaugh & Rowan, 2002; Sun & Xu, 2006):

- *Enterprises should realize the importance of human resources.* An ERP system is a production of IT, while human resources are part of the essential power of the invention or improvement of IT. The idea that HRM is just a secondary function must be updated.
- *Enterprises should redesign the functions of HRM.* ERP extends the traditional functions of HRM greatly. The simple compensation calculating or personnel management cannot meet the requirements of an ERP system. The extended functions of HRM are more favorable for inter-departmental cooperation, because they can conveniently provide the decision making with information needed.
- *Enterprises should establish an effective talent introduction mechanism and an effective incentive mechanism for employees.* An attractive compensation mechanism can provide useful market competitive advantage for enterprises to hold talents. On the other hand, enterprises should supply employees with reasonable freedom to make decisions within position responsibilities. This can enhance the working initiative as well as the sense of responsibility of employees.
- *Enterprises should place great emphasis on personnel education and training.* The human resource department can carry an ideological education that involves both senior managers and common staff to arouse their concerns about ERP implementation. The frequency and quality of personnel training should be strengthened as well.
- *Enterprises should enhance exterior consultation as well as the supervision function for the adoption of ERP.* It is a good idea to invite exterior experts to enterprises to make practical guidance. The human resource department can also organize staff to visit the enterprises that implement ERP successfully to draw on experience. Additionally, the human resource department should be in charge of the supervision function or help your enterprise establish a supervision department, made up of interior managers and exterior experts.

FUTURE TRENDS

Enterprise resource planning is a new concept introduced by the Gartner Group in 2000 to label the latest extensions to ERP (Classe, 2001). The new concept is that, having successfully integrated internal business applications such as finance, sales, and marketing to increase efficiency and create a total overview of the business, ERP II can be used to integrate external applications with collaborative commerce arrangements, e-business, and the supply chain (Payne, 2002). Traditional ERP is the main component in an ERP II system, but for the purposes of the collaboration, an ERP II system is opened to inflow and outflow of information (Moller, 2003). On the other hand, during the last decade, a new wave of human resource technology known as electronic human resource management (e-HRM) has emerged with the advent of intranet- and Internet-based technologies. E-HRM is mainly connecting staff and managers with the

human resource department electronically through the human resource portal (Lai, 2006). The basic expectations are that using *e-HRM* will decrease costs, will improve the human resource service level, and will give the human resource department space to become a strategic partner (Rual, Bondarouk, & Velde, 2007).

When we combine the ERP II concept with e-HRM technology, we find a valuable issue to study—that is, the research about the implementation of ERP II based on e-HRM. Additionally, we can also study other details of this issue according to different countries, cultures, industries, and so forth.

CONCLUSION

As IT continues to development, there will be more and more enterprises adopting ERP systems. ERP can extend the traditional functions of HRM greatly and also heighten the importance of HRM in enterprises. Enterprises that implement ERP must perfect the functions of HRM to raise the success rate, so to enhance the whole management level of enterprises. A poignant hope is that this article will be helpful to both scholars and practitioners who wish to improve the current situation of ERP implementation.

KEY TERMS

Electronic Human Resource Management (e-HRM): The planning, implementation, and application of information technology for both networking and supporting at least two individual or collective actors in their shared performing of HR activities.

Enterprise Resource Planning (ERP): An approach to the provision of business support software that enables companies to combine the computer systems of different areas of the business—production, sales, marketing, finance, human resources, and so forth—and run them off a single database. Also defined as an application and deployment strategy to integrate all things enterprise-centric.

Human Resource: The people that staff and operate an organization.

Human Resource Management (HRM): The function within an organization that focuses on recruitment of, management of, and providing direction for the people who work in the organization.

Information Technology (IT): The collection of technologies that deal specifically with processing, storing, and communicating information, including all types of computer and communications systems as well as reprographics methodologies.

Manufacturing Resource Planning (MRP II): A method for the effective planning of all resources of a manufacturing company, including functions of business planning, production planning and scheduling, capacity requirement planning, job costing, financial management, forecasting, and so forth.

Implementation of Programming Languages Syntax and Semantics

INTRODUCTION

Unlike natural languages, programming languages are strictly stylized entities created to facilitate human communication with computers. In order to make programming languages recognizable by computers, one of the key challenges is to describe and implement language syntax and semantics such that the program can be translated into machine-readable code. This process is normally considered as the **front-end** of a compiler, which is mainly related to the programming language, but not the target machine.

This article will address the most important aspects in building a compiler front-end; that is, syntax and semantic analysis, including related theories, technologies and tools, as well as existing problems and future trends. As the main focus, formal syntax and semantic specifications will be discussed in detail. The article provides the reader with a high-level overview of the language implementation process, as well as some commonly used terms and development practices.

BACKGROUND

The task of describing the syntax and semantics of a programming language in a precise but comprehensible manner is critical to the language's success (Sebesta, 2008). The **syntax** of a programming language is the *representation* of its programmable entities, for example, expressions, declarations and commands. The **semantics** is the actual *meaning* of the syntax entities. Since the 1960s (Sebesta, 2008), intensive research efforts have been made to formalize the language implementation process. Great success has been made in the syntax analysis domain. Context-free grammars are widely used to describe the syntax of programming languages, as well as notations for automatic parser generation (Slonneger & Kurtz, 1995). Formal specifications are also useful in describing semantics in a precise and logical manner, which is helpful for compiler implementation and program correctness proofs (Slonneger & Kurtz, 1995). However, there is no universally accepted formal method for semantic description (Sebesta, 2008), due to the fact that the semantics of programming languages are quite diverse, and it is difficult to invent a simple notation to satisfy all the computation needs of various kinds of programming languages. Overall, compiler development is still generally considered as one of the most appropriate software applications that can be implemented systematically using formal specifications.

Context-free grammar, BNF and EBNF. In the 1950s, Noam Chomsky invented four levels of grammars to formally describe different kinds of languages (Chomsky, 1959). These grammars, from Type-0 to Type-3, are rated by their expressive power in decreasing order, which is known as the **Chomsky hierarchy.** The two weaker grammar types (i.e., regular grammars, Type-3; and **context-free grammars**, Type-2) are well-suited to describe the lexemes (i.e., the atomic-level syntactic units) and the syntactic grammar of programming languages, respectively. **Backus-Naur Form** (BNF) was introduced shortly after the Chomsky hierarchy. BNF has the same expressive power as context-free grammar and it was first used in describing ALGOL 60 (Naur, 1960). BNF has an extended version called **Extended BNF**, or simply EBNF, where a set of operators are added to facilitate the expression of production rules.

LL, LR and GLR parsing. Based on context-free grammars and BNF, a number of parsing algorithms have been developed. The two main categories among them are called **top-down parsing** and **bottom-up parsing**. Top-

down parsing recursively expands a nonterminal (initially the start symbol) according to its corresponding productions and matches the expanded sentences against the input program. Because it parses the input from **L**eft to right, and constructs a **L**eft parse (i.e., left-most derivation) of the program, a top-down parser is also called an LL parser. A typical implementation of an LL parser is to use recursive descent function calls for the expansion of each nonterminal, which are easy to develop by hand. Bottom-up parsing, on the other hand, identifies terminal symbols from the input stream first, and combines them successively to reduce to nonterminals. Bottom-up parsing also parses the input from **L**eft to right, but it constructs a **R**ight parse (i.e., reverse of a right-most derivation) of the program. Therefore, a bottom-up parser is also called an LR parser. LR parsers are typically implemented by a pushdown automaton with actions to shift (i.e., push an input token into the stack) or reduce (i.e., replace a production right-hand side at the top of the stack by the nonterminal which derives it), which are difficult to code by hand. The table size of a canonical LR parser is generally considered too large to use in practice. Consequently, an optimized form of it, the LALR (Look Ahead LR) parser is widely used instead, which significantly reduces the table size (Aho, Lam, Sethi, & Ullman, 2007).

The grammars recognized by LL and LR parsers are called LL and LR grammars, respectively. They are both subsets of context-free grammars. LL grammars cannot have left-recursive references (i.e., a nonterminal has a derivation with itself as the leftmost symbol) and LR grammars cannot create action conflicts (i.e., shift-reduce conflicts, reduce-reduce conflicts). Any LL grammar can be rewritten as an LR grammar, but not vice versa. Both LL and LR parsers can be extended by using *k* tokens of lookahead. The associated parsers are called LL(k) parsers and LR(k) parsers, respectively. Lookahead can eliminate most of the action conflicts existing in an LR grammar, unless the grammar contains ambiguity. To resolve action conflicts in a generic way, an extension of the LR parsing algorithm, called **GLR (Generalized LR) parsing** (Tomita, 1986), has been invented to handle any context-free grammar, including ambiguous ones. The basic strategy of the algorithm is, once a conflict occurs, the GLR parser will process all of the available actions in parallel. Hence, GLR parsers are also named parallel parsers. Due to its breadth-first search nature, the GLR parsing suffers from its time and space complexity. Various attempts have been made to optimize its performance (e.g., McPeak & Necula, 2004). Currently, GLR is still not widely used in programming language implementation, but its popularity is growing. There are a number of tools available to automatically generate LL, LR and GLR parsers from grammars[1]. These tools are generally referred to as parser generators or compiler-compilers (Aho, Lam, Sethi, & Ullman, 2007).

Figure 1. Attribute grammar of the Robot language for location calculation

Production	Semantic Rules
Program → begin Moves end	Program.out_x = Moves.out_x; Program.out_y = Moves.out_y; Moves.in_x = 0; Moves.in_y = 0;
$Moves_0$ → Move $Moves_1$	$Moves_0$.out_x = $Moves_1$.out_x; $Moves_0$.out_y = $Moves_1$.out_y; Move.in_x = $Moves_0$.in_x; Move.in_y = $Moves_0$.in_y; $Moves_1$.in_x = Move.out_x; $Moves_1$.in_y = Move.out_y;
Moves → ε	Moves.out_x = Moves.in_x; Moves.out_y = Moves.in_y;
Move → left	Move.out_x = Move.in_x - 1; Move.out_y = Move.in_y;
Move → right	Move.out_x = Move.in_x + 1; Move.out_y = Move.in_y;
Move → up	Move.out_x = Move.in_x; Move.out_y = Move.in_y + 1;
Move → down	Move.out_x = Move.in_x; Move.out_y = Move.in_y - 1;

Attribute Grammar: Semantic analysis is usually embedded into syntax analysis. **Attribute grammars** (Knuth, 1968) were invented to specify the static semantics of programming languages (those properties that can be acquired from the source program directly) as an extension of context-free grammars. Each symbol has an associated set of attributes that carry semantic information, and each production has a set of semantic rules associated with attribute computation. The attributes are divided into two groups: synthesized attributes and inherited attributes. The synthesized attributes are used to pass the semantic information up the parse tree and the inherited attributes are passed down from parent nodes. An evaluation scheme traverses the tree one or more times to compute all the attributes. Figure 1 shows an attribute grammar of a simple Robot language. In this language, a robot can move in four directions from the initial position (0, 0). The attribute grammar uses two synthesized attributes *out_x* and *out_y*, as well as two inherited attributes *in_x* and *in_y*, to compute the final result location.

Denotational Semantics: Although an attribute grammar can provide a formal description of the static semantics of a programming language, it is still not powerful enough to express dynamic semantics, which are those properties that "reflect the history of program execution or user interactions with the programming environment" (Kaiser, 1989, p. 169). A number of formal methods have been created to define the full semantics of programming languages such as operational semantics, axiomatic semantics and denotational semantics (Slonneger & Kurtz, 1995). Among these approaches, **denotational semantics** is the most researched. The denotational semantics of a programming language map a program in that language directly to its meaning represented as a mathematical value called its denotation. The primary components of a denotational semantics specification are the semantic algebras and evaluation functions. The semantic algebras define a collection of semantic domains and the valuation functions map syntax domains into functions over semantic domains. The denotational semantics for the simple Robot language is shown in Figure 2. Denotational semantics is very suitable for mathematical reasoning, but it is rarely used for practical implementation due to the fact that it cannot be used to derive an efficient compiler implementation. For more details about denotational semantics and other formal methods for semantic description, please refer to Slonneger and Kurtz (1995).

LANGUAGE IMPLEMENTATION IN PRACTICE

There are various approaches to develop a compiler front-end, such as handcrafting a compiler from scratch, fully implementing the language with formal specifications, or utilizing parser generators to describe syntax and using a programming language to code semantics. Depending on the nature of the language and available environment, different development strategies can be selected. In the following paragraphs, two of the most commonly used strategies are introduced.

Figure 2. Denotational semantics of the Robot language

Abstract Syntax
P ∈ Program
M ∈ Move
P ::= begin M end
M ::= left | right | down | up | M_1 M_2

Semantic algebra
Point = Integer × Integer

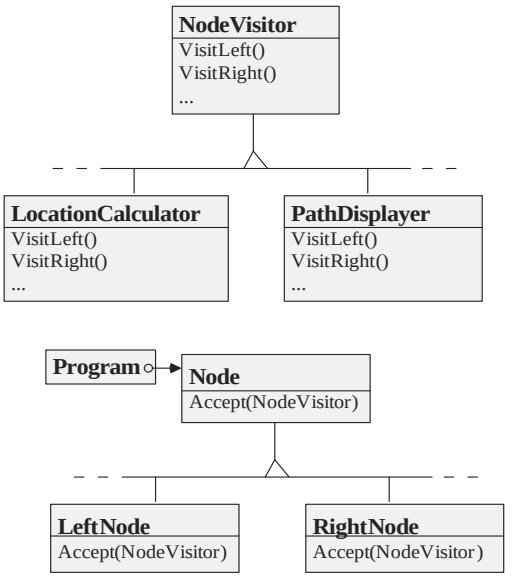
Semantic evaluation functions
P : Program → Point
M : Move → Point → Point
P ⟦begin M end⟧ = M ⟦M⟧(0,0)
M ⟦left ⟧ = λ(x,y). (x-1, y)
M ⟦right ⟧ = λ(x,y). (x+1, y)
M ⟦up⟧ = λ(x,y). (x, y+1)
M ⟦down ⟧ = λ(x,y). (x, y-1)
M ⟦M_1 M_2 ⟧ = λ(x,y). M ⟦M_2⟧(M ⟦M_1⟧(x,y))

Scenario I: Parser Generator + Visitor Pattern

In this scenario, syntax and semantics are implemented separately (i.e., language syntax is described by a formal specification and semantics is implemented by a general purpose programming language). For syntax analysis, the language is fully specified with a context-free grammar, which serves as input to a parser generator such as Yacc (Johnson, 1975). Most parser generators allow attaching semantic code with each grammar rule in the parser specification, but the mixed grammar and code fragments generally make the overall specification hard to read and debug (Wu, 2007). In reality, as long as a representation of the program (i.e., an Abstract Syntax Tree -AST) is built after parsing, the semantic code can be factored out to later phases as AST traversing logic. Therefore, ideally the attached code fragment should only contain code related to AST construction. To support polymorphism and inheritance, these tree nodes are generally implemented using object-orientation (i.e., each node is represented by a class).

After the tree is successfully built, the remaining phases of the front-end can be implemented by using the Visitor pattern (Gamma, Helm, Johnson, & Vlissides, 1995), which is an object-oriented pattern used to separate functional operations with object structure. In applying this pattern, all the methods pertaining to one semantic pass are encapsulated inside a visitor class. Each AST node class has a general *accept* method, which can redirect a semantic evaluation request to the appropriate method in the provided visitor class. The benefit of using this pattern is that each tree traversal phase is isolated as a class, which is independent of other node classes and can be freely modified or extended. Figure 3 provides an illustration of the Visitor pattern in implementing two analysis phases for the Robot language. The visitor *LocationCalculator* contains the same semantics as described in Figures 1 and 2. The second visitor *PathDisplayer* contains printing actions to display the path of the robot.

Figure 3. Illustration of the Visitor pattern



Scenario II: Attribute Grammar Implementation

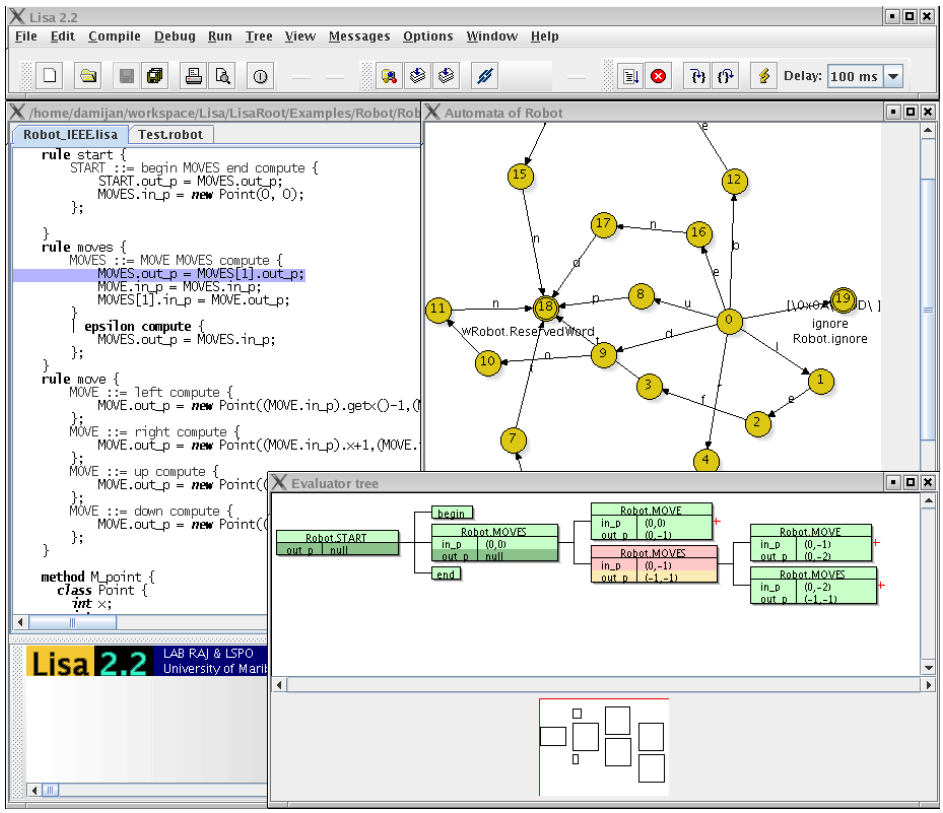
In this scenario, both syntax and semantics are described by formal specifications. Specifically, syntax is described by a variant of BNF, while semantics are described with attribute grammars where specialized languages can be used for semantic rules (e.g., FNC-2 [Jourdan, Parigot, Julie, Durin, & Le Bellec, 1990]) or assignment statements from general-purpose programming languages are employed (e.g., LISA-Language Implementation System based on Attribute grammars [Mernik & Žumer, 2005]). An important distinction for parser generators, where semantic actions are mixed with productions, is that attribute grammars are declarative. Hence, the semantic part can be separated from the syntax. Moreover, the order of evaluation of semantic rules does not need to be specified when describing the language. It is automatically obtained from an attribute dependency graph, which alleviates the burden from the language implementer.

Various compiler generators based on attribute grammars exist (e.g., FNC-2 and LISA) where systems are differentiated by their AST representation (e.g., structured, modular, or object-oriented), traversal logic (e.g., L-attributed or ordered attribute grammars) and the power of semantic rules (e.g., logic, functional, parallel, incremental). Overall, the whole front-end is automatically generated from such specifications and often used in implementation of domain-specific languages (Mernik, Heering, & Sloane, 2005). An informative description of attribute grammars as a programming language implementation methodology is given in Paakki (1995).

The development of the Robot language in LISA is shown in Figure 4. LISA moves toward modular, reusable and extensible language specifications. Different parts of language specifications (e.g., lexical definitions, generalized syntax rules that encapsulate semantic rules, and operations on semantic domains) can be inherited, specialized or overridden from ancestor specifications. Due to space limitations these features are not present in Figure 4. Interested readers can find more information in Mernik and Žumer (2005).

From the above two scenarios, it can be seen that language implementation has been greatly facilitated by automatic generation tools. However, being generative is not enough. The key challenge of language development resides in

Figure 4. LISA integrated development environment



providing high-quality modularity of the implementation (Mernik, Wu, & Bryant, 2004), which helps the developer to divide-and-conquer the complexity of constructing a complex language. Large grammars may well run into several hundred or even thousands of productions (e.g., the GOLD grammar of COBOL 85 is 2500 lines[2]). Developers sometimes are forced to put a fair amount of production rules inside one module and develop the parser as a whole, which results in a system that is hard to develop and maintain. This is an obstacle that neither of the two scenarios introduced above can overcome. Moreover, although the use of object-oriented techniques and concepts greatly improves language specification toward better modularity, there are still incidents where object-orientation is not a natural specification for semantic actions that crosscut AST node classes. For instance, since object-orientation describes a system by a collection of objects rather than a collection of operations, the complicated implementation of the Visitor pattern introduces a lot of side-effects (Wu et al., 2006), despite the fact that it brings advantages in separation of concerns.

FUTURE TRENDS

It can be foreseen that, for syntax description and implementation, context-free grammar and its variants will still be the mainstream specification for syntax analysis. Sophisticated parser generators will be used as the main method for developing a parser, while hand-coded parsers will only exist in legacy systems. GLR parsing and its equivalent technologies will gain more attention when the implementation becomes more mature.

Due to the diversity of language semantics, describing semantics using formal specifications will remain an intricate problem. The current available formal specification methods will be enhanced in terms of the comprehensibility and automatic generation ability. But the ideal solution, that a language designer can easily use a specification language to produce an efficient compiler implementation without using any general purpose programming language, is less likely to appear in forthcoming years (e.g., attribute grammar-based systems like LISA use general-purpose languages for semantic rules).

To achieve modularity, extensibility and reusability to the fullest extent, it can be expected that more state-of-the-art techniques will be brought into language development. For example, component-based development technology (Szyperski, 2002) could help decompose the workload of developing a large language into developing a number of smaller languages such as languages for expression and commands, which can be developed and tested individually (Wu, 2007). Instead of generating a single parser for a complex language, the future parser generator should be able to generate a set of parsers based on well-defined specification modules. These parser components should be composed in an organic way to deliver the parsing functionality. Moreover, due to the crosscutting nature of semantic phases, aspect-oriented programming (Kiczales et al., 1997) should be utilized for developing semantics, which is already being investigated, as described in de Moor, Peyton-Jones, and Van Wyk (2000), Hedin and Magnusson (2003) and Wu et al. (2006).

CONCLUSION

The article provides background knowledge to help the reader understand the current state and future direction in language development technologies. It first describes the roles of syntax and semantics in implementing a programming language, followed by the introduction of formal syntax and semantic specifications. Some theory of syntax analysis is highlighted by describing grammar classes and their associated parsing algorithms such as LR(k), LL(k) and GLR. Practical information on compiler construction is the main part of this article, where two most widely used development scenarios are presented. Some of the current difficulties in language implementation are also presented, with a special focus on the modularity problem of a compiler system. Various research directions are suggested at the end, including using the state-of-the-art programming technologies such as aspect-oriented programming and component-based development to help modularize language implementations. Due to space restrictions, some topics such as component-based compiler development and aspect-oriented semantic implementation are not covered in depth in the article. Interested readers may refer to the Web site (http://www.cis.uab.edu/wuxi/research/) for more details.

KEY TERMS

Aspect-Oriented Programming: Aspect-oriented Programming (AOP) provides special language constructs called aspects that modularize crosscutting concerns in conventional program structures (e.g., a concern that is spread across class hierarchies of object-oriented programs). A translator called a weaver is responsible for merging the additional code specified in an aspect language into the base language at compile time.

Attribute Grammar: Attribute grammar is an extension of context-free grammars in which each symbol has an associated set of attributes that carry semantic information, and each production has a set of semantic rules associated with attribute computation.

Bottom-Up Parsing: Bottom-up parsing is a parsing strategy that identifies terminal symbols from the input stream first, and combines them successively in a rightmost way to reduce to nonterminals, until the start symbol is reduced.

Compiler-Compiler: Compiler-compilers are tools that can automatically generate compilers or interpreters from programming language descriptions.

Context-Free Grammar: A context-free grammar is a quadruple (N, T, P, S), where N is a set of nonterminal symbols; T is a set of terminal symbols with $T \cap N = \varnothing$; the relation $P \subseteq N \times (N \cup T)^*$ is a finite set of production rules and S is the start symbol with $S \in N$. The production of the form $A \rightarrow \alpha$ means A derives α, where $A \in N$ and $\alpha \in (N \cup T)^*$.

Denotational Semantics: The denotational semantics of a programming language map a program in that language directly to its meaning represented as a mathematical value called its denotation. Its primary components are the semantic algebras that define a collection of semantic domains and evaluation functions that map syntax domains into functions over semantic domains.

Front-End: Among all the compiler phases, those mainly related to the programming language but not the target machine are normally considered as the front-end of a compiler.

Semantics: The semantics of a programming language is the actual meaning of the syntax entities. It describes what the programs written in this language can achieve.

Syntax: The syntax of a programming language is the representation of its programmable entities, for example, expressions, declarations and commands. It describes the appearance of programs written in this language.

Top-Down Parsing: Top-down parsing is a parsing strategy that iteratively expands the leftmost nonterminal (initially, the start symbol) according to its corresponding productions and matches the expanded sentences against the input program from left to right.

Implementation of Web Accessibility Related Laws

Holly Yu
California State University, Los Angeles, USA

INTRODUCTION

In the past three decades, the general method of delivering and receiving information has shifted from paper-based, typewriter-generated, hand-edited, and printing-press-produced publications to more technology-mediated, intelligent, WYSIWYG software-generated forms and interactive design. The Web has expanded its horizon as a gateway in carrying and delivering information to include audio and video formats. Further, the advent of the *Web 2.0*, or social networking/virtual community via the Web has changed the nature of the Web not only as an information carrier, but also a tool for all to use, share, and participate. Consequently, the concept of delivery of, access to, and interaction with information has changed to reflect this phenomenon. The new forms of utilizing the Web that have made it easier for non-disabled people have often created barriers for people with disabilities because, in a large part, the standard methods of access and delivery are inaccessible for people with disabilities.

The disability rights movement in the United States originated during the post World War II era when large numbers of veterans who were disabled in the war joined the efforts of parents seeking education and independent living options for their children with disabilities (Slatin & Rush, 2003). The notion of access to information involving the civil rights of people with or without disabilities arises from the fact that access to information through technology has increasingly become a necessary tool for success and a source of opportunity in education and employment. With the unprecedented opportunities they created for people with and without disabilities, it has become apparent that information technologies have a tremendous potential for allowing people with disabilities to participate in mainstream activities and to support their ability to live independently. The legal foundation for protecting the right to access for persons with disabilities has been established through a series of federal and state laws, and court decisions. These laws provide a legal ground on Web accessibility implementation.

BACKGROUND

A person with a disability is defined in the *Americans with Disabilities Act (ADA)* as "someone who has a physical or mental impairment that substantially limits one or more major life activities, a person who has a record of such impairment, or a person who is regarded as having such impairment" (ADA, 1990). It is estimated by the American Foundation for the Blind (AFB) that approximately 10 million blind and visually impaired people in the United States, and 1.3 million Americans, are legally blind (AFB, 2007). In defining Web accessibility, Hackett and Parmanto (2005) state that accessibility may be direct or through the use of *assistive technologies*, hardware or software that aids a person in accessing the information. Section 508 of the Rehabilitation Act of 1973, as amended in 1998, documents that "Web sites are accessible when individuals with disabilities can access and use them as effectively as people who don't have disabilities." (Section 508, 1998).

Disabled people who benefit the most from accessible design and assistive technology in interacting with the Web, are those who are blind, visually impaired, people with hearing impairment, physical impairment, and learning difficulty such as dyslexia. Recently, we have seen a growing body of significant laws, regulations, and standards concerning Web accessibility that impact people with disabilities and their ability to fully overcome digital barriers and participate in the Web environment.

LAWS, REGULATIONS, STANDARDS, AND GUIDELINES

Under the provisions of laws, some of the legal milestones that have direct impact on Web accessibility are Section 504 of the Rehabilitation Act of 1973, Americans with Disabilities Act (ADA) of 1990, and Section 508 of the Rehabilitation Act of 1973, as amended in 1998.

Section 504, Rehabilitation Act, 1973

Signed on October 1, 1973, Section 504 of the Rehabilitation Act is regarded as landmark legislation and the first civil rights law prohibiting recipients of federal funds from discriminatory practices on the basis of disability.

Core areas of the legislation consist of the prohibition of such activities as discriminatory employment practices,

and discrimination in the delivery of educational offerings, health, welfare and social services, or any other type of programs benefit, or service supported in whole or in part by federal funds.

Section 504 is currently applied to all entities that receive federal government funds, including states, counties, cities, towns, villages, and their political subdivisions, public and private institutions, public and private agencies, and other entities that receive federal money. Each Federal agency has its own set of Section 504 regulations that guide its own programs. Over the years, the Rehabilitation Act has been amended several times to address the constant changes in technology and its impact on society. The amendments most relevant to the access to information technology are those made to *Section 508*. The significance of Section 504 lies not only in that it was the first statute applying civil rights protections to people with disabilities, but that it also "furnished the model for major subsequent enactments, including the ADA" (NCD, 2001). Section 504 was legislated too early to specifically address the issue of access to services and programs provided over the Web.

Americans with Disabilities Act (ADA), 1990

Signed by President George H.W. Bush on July 26, 1990, the ADA establishes a clear and comprehensive prohibition of discrimination on the basis of disability. While Section 504 applies to federal government agencies and those that receive federal funds, the ADA extends the rights of equal treatment for people with disabilities to the private area, to all places of public accommodation, employers, and entities that deliver government services. The core sections of the law are found in the first three titles: Employment, State and Local Government Activities, and Public Accommodation. Title II of the ADA requires that state and local governments give people with disabilities an equal opportunity to benefit from all of their programs, services, and activities, such as public education, employment, transportation, recreation, health care, social services, courts, voting, and town meetings. Section 202, Title II indicates that "no qualified individual with a disability shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subjected to discrimination by such entity" (ADA, 1990). Title II recognizes the special importance of communication, which includes access to information in its implementing regulation at 28 CFR Section 35.160(a). The regulation requires that a public entity must take appropriate steps to ensure that communications with persons with disabilities are as effective as communications with persons without disabilities. The ADA mandates for "effective communication, reasonable accommodations, and auxiliary aides and services" (ADA, 1990).

However, Web accessibility did not become prominent until 1996 when the Department of Justice (DOJ) responded to Senator Tom Harkin (D-Iowa), the author of the ADA, when he inquired on behalf of one of his constituents on Web page compatibility for the blind and other people with disabilities. In response, DOJ stated that ADA Title II and III do indeed require covered entities to provide "effective communication" regardless of the media used, and that information offered through digital media must be offered through "accessible means" as well. The Internet is an excellent source of information and, of course, people with disabilities should have access to it as effective as people without disabilities (DOJ, 1996). This response involves understanding to what extent the ADA requires Web pages to be accessible to people with disabilities. The DOJ's ruling explains how the mandate for "effective communication" in ADA should apply to Web pages and Web design.

Section 508, Rehabilitation Act, 1998

Signed into law on August 7, 1998 as part of the Workforce Investment Act, Congress revised Section 508, an amendment to the Rehabilitation Act of 1973. The core area of this amendment is to ensure that all Americans have access to information technology. The law applied specifically to all U.S. government agencies, but it also affects anyone who works with the U.S. government. The law requires that when federal departments or agencies develop, procure, maintain, or use Electronic and Information Technology (EIT), they should ensure that the EIT allows federal employees with disabilities to have access to and use of information and data that is comparable to the access to and use of information and data by other federal employees (Section 508, 1998).

Section 508 charges the Architectural and Transportation Barriers Compliance Board (Access Board) with the task of producing accessibility standards for all electronic and information technologies used, produced, purchased, or maintained by the federal government. On December 21, 2000, the Access Board finalized and issued the Standards. With its publication, the federal government for the first time set specific access standards for information presented over the Web. According to the law, federal agencies were permitted a six-month period after the Standards were issued to demonstrate that their information technology systems met the Standards. Federal agencies become subject to civil rights litigation for noncompliance under Section 508 after June 21, 2001. These Standards have been folded into the federal government's procurement regulations, namely the Federal Acquisition Regulations (FAR) to which most agencies are subject. The Standards define means of disseminating information, including computers, software, and electronic office equipment. They provide criteria that make these products accessible to people with disabilities, including those with vision, hearing, and mobility impairments. The

scope of Section 508 and the Access Board's Standards are limited to the federal sector. It does not explicitly apply to the private sector, or to state and local governments unless a site is provided under contract to a federal agency, in which case only that Web site or portion covered by the contract would have to comply (Section 508 Standards, 2001).

The statements issued by the US Department of Education and the Access Board support a concept of state government obligations wherein they abide by Section 508 by virtue of their linkage with funding supplied to state governments through the Assistive Technology Act (29 USC 3001)**.** There is a statement in the US Department of Education's enforcing regulations to the Assistive Technology Act at 34 CFR Part 345, requiring "compliance with Section 508 of the Rehabilitation Act of 1973" (34 CFR 345.31, 2002).

Web Content Accessibility Guidelines (WCAG)

Founded in 1994, the World Wide Web Consortium (W3C) was originally organized by the European Center for Nuclear Research (CERN) and by the Massachusetts Institute of Technology (MIT). The W3C launched the Web Accessibility Initiative (WAI) in April 1997 specifically to address the question of how to expand access to the Web for people with disabilities with a goal of providing a single shared standard for Web content accessibility that meets the needs of individuals, organizations, and governments worldwide. The WAI published the Web Content Accessibility Guidelines 1.0 (WCAG) in May 1999, and Authoring Tool Accessibility Guidelines 1.0 (ATAG) in February 2000, and the User Agent Accessibility Guideline 1.0 (UAAG) in December 2002.

The WCAG establishes three priority checkpoints for Web content developers to meet. The Guidelines includes 64 checkpoints arranged under 14 separate guidelines within the three priorities.

Priority I -- Developers MUST satisfy Priority I checkpoints in order to attain a minimum degree of accessibility. Otherwise, one or more groups will find it impossible to access some part of the information.

Priority II – Developers SHOULD satisfy Priority II checkpoints for a higher degree of accessibility.

Priority III – Developers MAY address Priority III checkpoints for maximum accessibility and usability (WAI, 2000).

Topics of the Guidelines include images, programming scripts, navigation, multimedia, forms, frames, and tables. The Guidelines are detailed and prioritized with an associated checklist. WCAG 1.0 has become the basis for accessibility standards adopted by the international community.

Currently, WCAG 2.0 is being developed to apply to more advanced Web technologies, and be more precisely testable with a combination of automated testing and human evaluation. Specifically, the WCAG2.0 is developed to address many unanswered questions in WCAG 1.0 on how to implement, how to evaluate and reasons behind its requirements to reflect the diverse needs of a broad community including industry, disability organizations, accessibility researchers, government, and others interested in Web accessibility (WCAG 2 FAQ, 2007).

Web standards developed by the Web Accessibility Initiative (WAI) of W3C are called W3C Recommendations, and they encompass guidelines and technical reports. The milestones that a technical report goes through on its way to becoming a W3C Recommendation are working draft, last call working draft, candidate recommendation, proposed recommendation and W3C Recommendation (Web Standard).

Different from WCAG 1.0, WCAG 2.0 is organized around four design principles of Web accessibility. Each principle has guidelines, and each guideline has success criteria at level A, AA, or AAA. The basis for determining conformance to the WCAG 2.0 Working Draft are the success criteria (Overview of WCAG 2.0 Documents, 2007).

The Four Principles are stated in the Working Draft of Web Content Accessibility Guidelines 2.0 issued in May 2007:

- Perceivable – Information and user interface components must be perceivable by users;
- Operable – User interface components must be operable by users;
- Understandable – Information and operation of user interface much be understandable by users;
- Robust – Content must be robust enough that it can be interpreted reliable by a wide variety of user agents, including assistive technologies (Web Content Accessibility Guidelines 2.0, 2007).

WCAG 2.0 ensures accessible Web design, development, evaluation, and implementation**.** Key differences between WCAG 1.0 and WCAG 2.0 lie in that WCAG 2.0 applies more broadly to different Web technologies and is designed to apply as technologies develop in the future (Overview of WCAG 2.0 Documents, 2007).

Laws, Regulations and Policies in Other Countries

World Wide Web has no boundaries, therefore, "nations everywhere are developing policies and standards to enhance the accessibility of electronics and information technology" (Paciello, 2000). These nations include European countries (Belgium, France, Greece, Norway, Portugal, Sweden, and United Kingdom), Canada, Australia, and Japan. Davies finds that the drivers that underpin appropriate and adequate provision to visually impaired people include legislation,

international conventions and codes of practice (Davies, 2007). In many countries and the international community, accommodating visually impaired people are made mandatory in legislations. For instance, there are Standard Rules on the Equalization of Opportunities for Persons with Disabilities issued by the United Nations in 1993, and in the United Kingdom, there is the Disability Discrimination Act (1995) and the Special Educational Needs and Disability Act (2001). Australia and Canada have also enacted legislations. Prominent Australia legal standards include the Disability Discrimination Act (DDA) of 1992, and the Anti-Discrimination Act of New South Wales of 1977. Australia's Human Rights and Equal Opportunity Commission, a government agency, is responsible for creating and establishing legal decrees mandating equality of access for the disabled. In Canada, the Equity and Diversity Directorate of the Public Service Commission of Canada (PSC), "was the first government institution in any country to create a series of Web accessibility guidelines used to evaluate Web pages" (Paciello, 2000). The Common Look and Feel Working Group created in 1998 by the Treasury Board Secretariat's Internet Advisory Committee is charged to establish standards and guidelines as a base for official government policy. There are practical methods based on research and evaluation to achieve desirable results for people with disabilities. As a founding contributor, the European Community provides financial support to the WAI. European Union (EU) Web Accessibility Benchmarking (WAB) cluster of three EU-funded projects --the European Internet Accessibility Observatory (EIAO), SupportEAM, and BenToWeb, working in liaison with the W3C/WAI to develop a harmonized European methodology for evaluation and benchmarking of Web sites, the Unified Web Accessibility Methodology, or UWEM (Brophy & Craven, 2007).

ISSUES RELATED TO WEB ACCESSIBILITY

The current concerns encountered in the implementation of accessible Web design do not only stem from design issues, nor are they because of a lack of laws, regulations and government-related standards, although there are unanswered questions in that laws create difficulty in the implementation process. And, among these concerns are that the current legal framework for electronic and information technology accessibility is actually a patchwork of laws covering certain categories of technology in some settings, other categories in other settings, but nowhere reflecting an overview or comprehensive assessment of either the issues or the solutions (NCD, 2001). We have not seen that this situation has been improved since the statement was made by the National Council on Disability (NCD) in 2001.

There is a tendency that most Web designers either unaware of the laws and regulations, or ignore the accessibility requirements, or only pay attention to them as part of legal requirements. This situation is resulted from the absence of an obligation to fulfill legal requirements and not being aware that ensuring resource accessibility is a legal mandate. In many cases, the absence of obligations is because of the unfamiliarity with the legal responsibility for creating accessible Web sites. This is the reason why so many institutions are still in the beginning stage of applying accessible Web design techniques.

Compounding these problems have been the conflicting views between minimum compliance and maximum accessibility.

Technically, stand-alone workstations utilizing assistive technology software solutions are no longer sufficient because in the Web environment, the linkage between an individual and the Internet community as a whole is addressed, and access to the Web cannot be handled on a case-by-case basis using workstations with assistive technology. When approaching the issue of accessibility, John Mueller, the author of *Accessibility for Everyone: Understanding the Section 508 Accessibility Requirements*, points out that the issue should be approached from the viewpoint of universal design. "The application you create should work equally well with any hardware the user might have attached to the machine" (2003). Assistive technology alone cannot overcome the barriers that are created at a more basic level, the format in which content is presented (Schmetzke, 2001). Access barriers created by inaccessible design cannot be overcome even with the most sophisticated assistive technology. In defining the concept of accessible design, Brophy and Craven state that "the information provided on screen must be presented in a way that can be interpreted by any kind of access technology, "which can be assistive, adaptive, or enabling technology that enables a visually impaired user to access on-screen information receiving output in a way that is appropriate to their needs" (Brophy & Craven, 2007). Therefore, good Web interface design and the use of assistive technology are two fundamental methods to improve the accessibility of Web-based information access, delivery and interaction.

Further, *assistive technology* may also give rise to issues of incompatibility, and different types of *assistive technologies* present different problems to accessing Web sites. Training of both the user and the service provider adds another layer to the complexity of the issues surrounding the successful use of assistive technologies.

Design issues revealed by usability studies are also primary factors to impacting people with disabilities interacting with Web sites. Such issues include navigation structure, and content organization, form design, etc. In their studies, Brophy and Craven (2007) and others (Hackett & Parmanto,

2005**,** Pilling, Barrett, & Floyd, 2004) indicate the following issues in addition to those major concerns stated above:

- Higher education Web sites become progressively inaccessible as complexity increases
- Lack of support and training in the use of assistive technologies
- Disabled people cannot afford, or are not motivated, to upgrade their assistive software to the latest version
- Web pages with cluttered contents, graphics and links
- Poor accessibility for voice recognition system users
- Lack of ALT text or poor use of ALT text

Technical issues are deeply rooted in the lack of legal obligations in accessible Web design, and the accessible design is still an afterthought. Compounding these are cost in time and resources and conflicts with aesthetic and other design considerations.

IMPLEMENTATION

The overwhelming benefits of creating universally accessible Web pages can hardly be disputed. However, *accessibility barriers* are usually systematic. There are practical and legal reasons for addressing accessibility issues in our policy, education and design. As the rapid development of new Web applications continues, particularly Web 2.0 or social networking applications, it is necessary to ensure that barriers themselves will not continue to expand. Awareness, policy, education, and assessment are primary aspects to ensure Web sites designed with maximum accessibility. We have seen tremendous efforts being made in these processes.

To increase awareness of Web accessibility issues, understanding the laws related to accessibility, and the consequences of major disparities in our society is the first step. Lacking of knowledge in legal obligations and applications in making Web sites accessible can be resolved through systematical training. It is crucial that people with disabilities be involved in the procurement and/or development of accessibility solutions. Thus, issues of compatibility and accessibility can be anticipated and addressed during strategic planning stage. Identifying problems and implementing repairs are two integral elements of Web site accessibility assessment. One way to ensure the assessment can be carried out is to recommend its inclusion into the institution's Web planning and design process. Another is for the institution to develop its own checklists or follow the most up-to-date guidelines published by the W3C. The assessment should indicate the areas of violations and content that is inaccessible. Based on the assessment, a plan should be made to integrate the findings and recommendations for change. Developing tools to facilitate accessible Web design is a key to the ultimate success of an accessible Web site. Brophy & Craven point out that, the three assessment methodologies include semi-automatic and automatic testing using validation tools, manual evaluation using relevant criteria for assessment such as WCAG 1.0/2.0 guidelines and success criteria, and user testing of specific features of a Web site. Using guidelines and automated testing tools are not enough to assess the accessibility of Web sites and that involving users—and in particular disabled people—in the design and testing process will help improve accessibility usability (2007). Principles of universal design should be achieved, and the view of depending heavily on the tool – the assistive devices to mediate and decode should be utilized as a last result. Conducting usability studies with the understanding that the accessibility is an integral part of usability will assist in promoting inclusion.

FUTURE TRENDS

Discussions about the "digital divide" problem, needs for accessible Web design, and practical tips for designing barrier-free Web sites found in literature in recent years have demonstrated awareness-raising efforts (Brophy & Craven, 2007; Casey, 1999; Clapper & Burke, 2005; Hackett & Parmanto, 2005; Jobe, 2000, & Valenza, 2000; Loiacono & McCay, 2004; Pilling, Bannett, & Floyd, 2004; Rouse, 1999).

The ultimate goal for Web sites is universal design, or pervasive accessibility-interfaces that adapt to the user, regardless of ability. It is so often that with each release of new technology, there will be fixes to accessibility problems. "Subsequently, that technology that increases access to people with disabilities is termed assistive and adaptive as opposed to being a technology that is in inherently accessible" (Paciello, 2000). As we observed, while much of today's technology designed lacking in accessibility, recent awareness of laws and guidelines, and advances in promoting accessibility give rise to hope for achieving the ultimate goal for accessibility. The "design for all" concept – a single version of the Web site which is accessible to everyone regardless of abilities, is changing the way of the provision of a parallel text-only version. The benefits resulting from the implementation of universal Web design principles, which allow pages to be accessible to the largest number of segments of the population, have been emerging.

Needless to say, the progress in designing more accessible Web pages has been made. However many problems cited in this article five years ago are still in existence.

CONCLUSION

The concept of accessible design or universal design is increasingly becoming an important component of Web design. Today, public and private entities are subject to the requirements of the ADA, Section 504, and Section 508. According to the definition of the law, denial of access resulting from the inaccessibility of mainstream information technology is considered to be discrimination. Barriers mostly resulting from the absence of obligations to fulfill legal requirements should be eliminated as the awareness of the importance of accessibility increases. Functionalities found in assistive technology can streamline our digital architecture, and the very functionality required in Web design by people with disabilities can meet dynamic requirements for Web-based transactions. A universal Web design will greatly reduce the cost for assistive technology geared specifically to individual computer workstations, and allow universal access for users from anywhere at anytime. A universal Web design allows the disability community to benefit as a whole rather than achieving accessibility through a segregated, compartmentalized, and ad hoc approach. The benefits and value for overcoming these barriers for the community of people with disabilities cannot be disputed, and maximum accessibility is a goal for us to achieve.

KEY TERMS

ALT-Text: Stands for Alternative Text, primarily used to render graphics when the image is not being displayed.

Assistive Technology (AT): A term includes assistive, adaptive, enabling and rehabilitative devices and the process used in selecting, locating, and using them to access information. AT promotes greater independence for people with disabilities by enabling them to perform tasks that they are normally unable to accomplish, or have great difficulty accomplishing.

Americans with Disabilities Act (ADA): U.S. public law enacted 1990 ensuring rights for people with disabilities. This legislation mandates reasonable accommodation and effective communication.

Section 508: Section 508 of the Rehabilitation Act is U.S. legislation that establishes requirements for electronic and information technology developed, maintained, procured or used by the federal government.

W3C: The World Wide Web Consortium (W3C) develops interoperable technologies such as: specifications, guidelines, software, and tools to lead the Web to its full potential. W3C is a forum for information, commerce, communication, and collective understanding.

Web Accessibility Initiative (WAI): Established by W3C and the Yuri Rubinsky Insight Foundation in 1997, the WAI works with organizations around the world to promote Web accessibility in five key areas: technology, guidelines, tools, education and outreach, and research and development.

Web Content Accessibility Guidelines 1.0 (WCAG 1.0): The official set of guidelines published by the W3C to assist Web content developers in the creation of accessible Web sites. The guidelines established three priority levels with 64 checkpoints for Web developers to meet.

Web Content Accessibility Guidelines 2.0 (WCAG 2.0): WCAG 2.0 is organized around four design principles of Web accessibility. Each principle has guidelines, and each guideline has success criteria at level A, AA, or AAA. The basis for determining conformance to the WCAG 2.0 are the success criteria. Currently the WCAG 2.0 is still at its Working Draft stage. It is expected to become W3C Recommendation (Web Standard) in early 2008.

Improving Data Quality in Health Care

Karolyn Kerr
Simpl, New Zealand

Tony Norris
Massey University, New Zealand

INTRODUCTION

The increasingly information intensive nature of health care demands a proactive and strategic approach to data quality to ensure the right information is available to the right person at the right time in the right format. The approach must also encompass the rights of the patient to have their health data protected and used in an ethical way. This article describes the principles to establish good practice and overcome practical barriers that define and control data quality in health data collections and the mechanisms and frameworks that can be developed to achieve and sustain quality. The experience of a national health data quality project in New Zealand is used to illustrate the issues.

BACKGROUND

Tayi and Ballou (1998) define data as "the raw material for the information age." English (1999) builds on the idea of information as being data in context, with knowledge being information in context, where you know the significance of the information. Translating information into knowledge requires experience and reflection.

Klein and Rossin (1999) note there is no *single* definition of data quality accepted by researchers and those working in the discipline. Data quality takes a consumer-focused view (consumers being people or groups who have experience in using organisational data to make business decisions) that quality data are "data that are fit for use" (Loshin, 2001; Redman, 2001; Wang, Strong, & Guarascio, 1996). Data quality is 'contextual'; the user defines what is good data quality for each proposed use of the data, within its context of use (Pringle, Wilson, & Grol, 2002; Strong, Lee, & Wang, 1997). Therefore:

Data are of high quality if they are fit for their intended uses in operations, decision-making, and planning. Data are fit for use if they are free of defects and possess desired features (Redman, 2001).

Data quality is now emerging as a discipline, with specific research programmes underway within universities, the most significant being that of the Sloan School of Management Information Quality Programme at the Massachusetts Institute of Technology (MIT)[1]. The field is based upon the well-established Quality Discipline, drawing on the work of Deming (1982) and the adaptation of the "*plan-do-check-ac*" cycle (the Deming Cycle). It also draws upon the "*quality is free*" concept of Crosby (1980) arising from the notion that doing things wrong is costly, and imports the ideas behind the Six Sigma approach and Total Quality Management (Juran & Godfrey, 1999) adapted to Total Data Quality Management (TDQM) and the management of information as a product (Wang, Lee, Pipino, & Strong, 1998).

The research programmes are developing ways to combine TDQM with the strategic direction of the organization, aligning the data quality requirements with overall goals. At present, there is little research published in this area, although some organizations do have data quality programmes with some strategic alignment to the business requirements.

Data quality is also becoming an increasingly important issue for health care providers, managers and government departments. The movement towards total quality management in health care to improve patient safety and health care efficiency is demanding high quality information. Further, evidenced based care requires the assimilation of large amounts of relevant and reliable research data available at the point of clinical decision making. Strategic prevention, national consistency of improvement practices, evolving data standards, and targeted improvements with increasing consumer involvement are all moving health care towards a TDQM model of data quality management.

Using the TDQM model, many of the methods developed in other industries can be useful for improving health care data. However, health data differ from data that arise in other fields in several ways. For example, the complex and multidisciplinary nature of medicine means that, unlike other sciences, health care data have no internationally standardized terminologies. This lack of standardization produces many homonyms, where the same term can mean different things depending on context, and synonyms, where there are several ways of expressing the same meaning. Added to these sources of ambiguity is the plethora of healthcare abbreviations which have no agreed format. The required longevity, privacy, and confidentiality concerns associated

with health data are also distinguishing characteristics. Combine these inherent features with the need to share and integrate the data across distributed and disparate entities such as the Ministry or Department of Health, regional health boards, hospitals, general practices, and individual specialists, and it is hardly surprising that the improvement of healthcare data quality is multifaceted and more involved than in many other domains.

THE DEVELOPMENT OF A DATA QUALITY EVALUATION FRAMEWORK

A common imperative in the health sector is the need to structure and improve the management of data quality within regional or national health data collections that aggregate patient health data and use the combined data for epidemiological and service planning purposes. Clinicians and managers recognize the need for assessment tools that indicate the level of data quality, identify where the problems are, and who should be accountable. This information can then be used to construct a strategy for quality improvement. This was recently the situation in New Zealand where previous work to develop the Ministry of Health information systems strategic plan, and a current state analysis of data quality, provided further support for the commencement of a programme of data quality improvement.

The starting point for any Data Quality Evaluation Framework (DQEF) in the health sector is the pioneering work of the Canadian Institute for Health Information (CIHI) (2003a, 2003b) The CIHI has developed a comprehensive data quality framework based on a hierarchy of quality attributes ranging from criteria at the base level that are grouped into characteristics, and then further reduced into a small number of high-level dimensions[2]. The CIHI framework is of course developed for Canadian conditions and must be adapted for local circumstances to ensure applicability. This can be done by engaging data custodians and stakeholders in an iterative sequence of focus group, interviews, and discussions that modify the data attributes at each level to reflect existing organizational structures and practice. The iterative process is most readily facilitated by action research using grounded theory (Strauss & Corbin, 1998) to structure the analysis of qualitative data through inductive coding and comparison.

In the New Zealand project, for example, analysis confirmed the utility of the Canadian quality dimensions of accuracy, relevancy, timeliness, usability, and comparability, but found it necessary to add a dimension of privacy and security to ensure that this aspect is explicitly managed to meet New Zealander's expectations for national data collections. The project also revealed that New Zealand's unique patient identifier, the National Health Index (NHI), is a powerful tool for the location of poor quality (e.g., redundant or incorrect) database entries.

The New Zealand project also revealed the advantages of the action research approach. Discussion and feedback, coupled with rigorous analysis, raises awareness of the importance of data quality, an issue which is frequently underrated at all levels by data users and managers. The approach similarly creates a common understanding of terminology and recognition of the importance that quality improvement is an ongoing venture needing continued support and clear lines of accountability. Thus, in developing and applying a data quality evaluation framework, it is important to:

- define the underpinning data quality criteria carefully involving all stakeholders to ensure common understanding and direction;
- consider the critical quality dimensions that reflect how the organization uses data and how data flow throughout the business processes;
- document business processes identifying data sources and their reliability;
- appreciate that the framework requires practical supporting tools, for example, documentation, to make it effective;
- customize the language of user guidelines or manuals with regard to the level and experience of the intended users;
- be aware of the importance of both education and training at all necessary stages and levels – training is essential to affect the culture change that must accompany the realization of the importance of data quality; and
- be aware that application of the framework is an iterative, on-going process – the required outcomes cannot be achieved in a single-pass.

THE DEVELOPMENT OF A DATA QUALITY IMPROVEMENT STRATEGY

Porter (1991) states that the function of a strategy is to integrate the activities of diverse functional departments to ensure consistency within an organization with explicit, reinforcing goals and policies when senior management cannot participate or monitor all decisions directly. It will be apparent from the above discussion that a Data Quality Evaluation Framework will not, by itself, automatically lead to required improvements and that a strategy, as defined by Porter, is critical to its successful implementation. Robson (1997) also notes that a successful strategy "exploits opportunities and fits the circumstances at the time" with a requirement, therefore, to undertake a systematic, skillful, accurate and realistic assessment of the opportunities and to re-evaluate them. The design and execution of a Data Quality Improvement Strategy (DQIS) in health care therefore begins with a current state analysis followed by an assess-

ment of the capability and maturity of the relevant health care organizations to effect the necessary improvements and understand the implications. Benchmarking against international organizations and other business sectors also helps to root the strategy so that it identifies local priorities and exploits current capabilities.

As is typical of many health systems at the present time, an extensive analysis of practices in New Zealand found that data quality management is entirely initiated through "bottom up" processes, in general through information services or information technology teams. Management has not yet taken responsibility, and indeed does not understand their role in the data quality process. Data quality improvement tends to occur when staff become frustrated with their inability to use the data for its intended purpose and there is no one else in the organization responsible for overall data quality management. This bottom up approach introduces silos of data quality improvements that can lead to even more quality issues by increasing discrepancies and producing conflicting reports from the same source. The New Zealand analysis shows that this situation is evident in all types of health sector organizations. It confirms that TDQM and the strategic management of data quality are relatively new phenomena, still rarely found across organizations in either New Zealand or overseas. New Zealand health care is certainly not lagging behind in the management of data quality but its political system, national public sector provision, structured assessment tool, and the NHI suggest that it has the infrastructure and capability to become a world leader in the implementation of a strategic data quality programme based on TDQM principles.

The New Zealand DQIS thus provides the Ministry of Health and the sector with detailed guidelines on how to develop and implement TDQM at all levels of the health sector. Roles and responsibilities are clearly defined, along with data ownership. A series of projects provides the required development for "business as usual" initiatives that institutionalize data quality into every day practice and make use of existing sector knowledge through the development and dissemination of best practice guidelines. For a data quality improvement strategy, it is important therefore to:

- derive and impose standards that facilitate data and information transfer whilst preserving quality;
- re-engineer the business processes to deliver the quality data needed for efficient service planning and the effective practice of integrated patient care;
- identify and disseminate best practice to reduce the development time needed to improve data quality;
- ensure data quality levels are not unnecessarily rigorous to maintain user ownership and workloads at reasonable levels;
- define user accountabilities for data quality and the mechanisms to enforce them; and
- seek to embed the search for data quality in normal working practices and recognize its achievement in appropriate ways such as accreditation.

As these requirements suggest, the strategic management of data quality requires wide ranging skills from practitioners with experience in many different areas. The challenge is, therefore, to encourage these practitioners to develop an interest and ownership in data quality and then to undertake further study to apply their skills to the development of the necessary strategic programmes.

There is considerable theory available in disciplines outside of data quality to support the New Zealand findings that organization wide teams enhance the learning and innovation of those who participate leading to improvements throughout the organization as a whole. Encouraging staff to develop solutions themselves helps to institutionalize data quality in the organization, through the development of emergent strategy. Data quality practitioners are empowered to implement "business as usual" initiatives that they themselves believe work. This emergent strategy is guided by the overarching organizational or national strategy that provides the simple rules that encourage the seeds of innovation and maintain momentum towards the defined vision.

Whilst comparison with data quality initiatives in other sectors is important, the development of a data quality framework and strategy for health care must always recognize the inherent complexity of the "business" of health. Plsek and Greenhalgh (2001) introduce the science of Complex Adaptive Systems (CAS) to help understand and bring about change in the health care environment. A complex system is defined as "a system with many independent agents, each of which can interact with others" (Penchas, 2003), that can behave very sensitively and be influenced by small initial differences (Champagne, 2002). Health care systems are just such systems creating complex adaptive interactions that contain emergent learning and change potential (Penchas, 2003).

In summary, the management and improvement of data quality in health care relies on an action research approach through collaborative groups to understand the relevant issues, an organization wide data quality team to develop the maturity capability of the organization, and an awareness of the inherent complexity of health care that demands multidisciplinary solutions to multidisciplinary problems.

CONCLUSION AND FUTURE DIRECTIONS

The development of a Data Quality Evaluation Framework and a Data Quality Improvement Strategy as described in this article provide clear direction for a holistic and "whole of health sector" way of viewing data quality, enabling

organizations to implement local innovations through locally developed strategies and data quality improvement programmes. Simple rules, such as the TDQM process and the data quality dimensions guide the change, leaving room for innovation. With these essential features in place, practitioners can use a range of other devices to embed data quality awareness and accountability in normal practice and facilitate further change.

For example, experience in using the DQEF and the benefits of better data quality information will help to generate appropriate data quality metrics. Suitable metrics are paramount to the success of the DQEF and to provide data suppliers with applicable key performance indicators for expected levels of data quality. The New Zealand research referred to provided an embryonic methodology for metrics development via its ethnicity data collections but the methodology needs further refinement and validation through empirical testing.

Organizationally, data quality practitioners should have a pivotal role in the development and implementation of new systems, including ongoing training of data collection staff on the impact of errors and the downstream uses of the data. Further, the importance of data quality, and the staff who work in this area, needs to be recognized by management teams. Recruitment of staff should include those with the skills of strategic thinking and analysis. Providing such a team with a structured programme of data quality management, with clear roles and responsibilities for the organization to manage their data from a whole of system view, will enable data quality practitioners to concentrate on improvement initiatives.

Other valuable approaches include change management theories such as appreciative enquiry (Fry, 2002), which can help to encourage the utilization of existing organizational knowledge and enact change with a minimum period of diminished performance (Elrod, 2002). The theory of "complex systems of adjustment" (Champagne, 2002; Stacey, 1993) can be instilled in the organization to encourage change through the constant interaction of people throughout the organization. Champagne (2002) notes the similarities between complexity and learning theories. Both see change in a global, integrated way as forming part of the routine life of organizations, with the change process a collective one.

This research that underpins this article was undertaken in New Zealand, but the many similarities between international health care systems and the correspondence in data quality capabilities suggest strongly that the results are generally applicable. This raises the possibility of external benchmarking (Hamel & Prahalad, 1994) between international healthcare organizations to compare performance, develop best practice, and identify key challenges. Even so, the health sector environment has some way to go before reaching second and third generation data quality management as discussed by Redman (2001). Continued research into the prevention of poor quality data through process management could lead to a health sector where all data quality is managed through prevention rather than "find and fix." This may be a difficult, even elusive, goal but its pursuit will bring benefits to all citizens.

KEY TERMS

Complex Adaptive System: A system with many independent agents, each of which can interact with others.

Data Quality Dimensions: Quality properties or attributes of data; a set of data quality attributes that most data consumers react to in a fairly consistent way.

Data Quality Framework: A tool for the assessment of data quality within an organization; a vehicle that an organization can use to define a model of its data environment, identify relevant data quality attributes, analyse data quality attributes in their current or future context, and provide guidance for data quality improvement.

Data Quality Improvement Strategy: A cluster of decisions centered on organizational data quality goals that determine the data processes to improve, solutions to implement, and people to engage.

Datum: A fact or value assigned to a variable; single observational point that characterises a relationship. Data is the plural noun of datum

Emergent Strategy: A series of actions converges into patterns that become deliberate when the pattern is recognized and legitimized by senior management.

Grounded Theory: A method of extracting meaning and theories from data by systematically and intensively analysing and coding the data, sentence-by-sentence, or phrase-by-phrase.

Total Data Quality Management: An approach that manages data proactively as the outcome of a process, a valuable asset rather than the traditional view of data as an incidental by-product.

ENDNOTES

1 http://mitiq.mit.edu

2 Each familiar, high-level, dimension is defined in context by appropriate characteristics that answer "what is/are?" questions such as "what is the level of error?". Underpinning these characteristics are "criteria" that define processes and metrics used to assess the presence of potential data quality issues, for example, "Is the error within acceptable limits?"

Improving Public Sector Service Delivery through Knowledge Sharing

Gillian H. Wright
Manchester Metropolitan University Business School, UK

W. Andrew Taylor
University of Bradford, UK

INTRODUCTION

Since the publication of the first knowledge management article in *Harvard Business Review* (Nonaka, 1991), the world has witnessed a revolution in management practice. While the origins of knowledge management extend further back in history (see Prusak, 2001; Wiig, 1997), it is certainly true that in the last decade the creation, sharing and application of knowledge are increasingly seen as a source of competitive advantage. However, knowledge management is largely a private sector innovation at the present time, although gradually moving towards the public service sector (Bate & Robert, 2002; Hartley & Allison, 2002). The implementation of knowledge management places an emphasis on organizational factors such as learning capability, culture and leadership as well as renewed focus on the importance of information quality (Alavi & Leidner, 2001). The ability to manage the sharing of information (and hence knowledge) effectively remains one of the most important but still least understood activities in modern organizations, no less so in public services.

BACKGROUND: KNOWLEDGE SHARING IN CONTEMPORARY PARTNERSHIP ORGANIZATIONS

Public services represent a significant economic sector in most countries and public demands on services are increasingly consumerist. This has led to escalating scrutiny of the performance of public services. Consequently, the strategic use of information and knowledge to improve service delivery and financial performance has become a key skill for managers in this sector. Partnership working represents a formal departure from the traditional compartmentalized approach to public service delivery. Often referred to as joined-up thinking, partnership working challenges existing hierarchies, encouraging the partner organizations to work together at all levels, including strategy, service planning and service delivery to enhance efficiency and improve user experience and satisfaction. For partners to work effectively together, knowledge of best practices must be shared and utilized towards the common goal of improving the overall quality of service delivery.

Our research has focused on health and social care as an area of public service in which organizations responsible for commissioning and delivering all aspects of care are increasingly expected to work together, to reduce fragmentation of access to the user. Management of the provision of high quality public services continues to be a major social and political issue in many countries. Our research was conducted in the context of UK national policies for performance management (DETR, 2001a), partnership working (DETR, 2000, 2001b; Fordham, 1998), the reduction of health inequalities (DoH, 1998a, 1999), and overall improvements in service quality (DoH, 1998b, 2000). We have concentrated particularly on the issue of making public service partnerships work effectively, to achieve strategic objectives, that is, to improve individual health and personal well being as well as to achieve gains in public health. Specifically, our research questions relate to assessing the readiness of the partners to work together, and to share knowledge that each possesses about their part in the overall service delivery process. By understanding the factors that influence effective knowledge sharing, managers can take practical steps toward improving these antecedent preconditions.

MANAGING THE ANTECEDENTS TO KNOWLEDGE SHARING

The key to partnerships is a focus on the creation of an explicit understanding of what needs to be done to meet strategic objectives –akin to Choo's concept of a "knowing organization" (Choo, 1988). We conceptualize the role of knowledge in the partnership process (Figure 1) in terms of two core aspects, viz:

- The effective management of information to support the vertical deployment of organizational strategy in terms of communication and development of meaningful performance measures, and
- The wider organizational culture to support attitudes conducive to new ways of working.

Figure 1. The public service partnership: The knowing organization

Figure 1.
The public service partnership:
The knowing organization

We have identified six key factors that are associated with successful knowledge sharing in public sector partnerships (Wright & Taylor, 2003), namely:

- Innovative culture
- Change readiness
- Information quality
- Clarity of responsibility
- Strategy formulation and deployment
- Accountability

Innovative Culture

An innovative culture is one where people are receptive, rather than resistant to, new ideas, and where they are motivated to embrace and develop these ideas and shape them into improved working practices. Such cultures provide people with time to reflect, to learn from both success and failure, providing supporting systems to facilitate reflection and capture lessons learned. Finally, innovation is focused on the user or customer, whereby people actively search for new ways of improving service delivery. The legal and political constraints on public service managers and persistent demands for strict oversight can lead to rigidity and bureaucracy in public sector organizations that counter the development of an open and inclusive culture (Scott & Falcone, 1998).

Change Readiness

Change and innovation are closely linked. An innovative culture needs to be able to implement changes to working practices and behaviors generated by innovation. This requires a positive attitude to doing things differently, rather than seeking to maintain the status quo. Change requires leadership, to proactively seek opinions and listen to views whilst engendering an atmosphere where ideas are freely expressed and there is no perception of a need for staff to cover their backs to protect themselves from criticism and retribution. Involvement and commitment will decline and the organization's innovative potential will be diminished if there is a culture of reluctance to challenge current ways of working. High levels of media scrutiny of public sector organizations (Perry & Rainey, 1988) and the top-down nature of government-imposed changes (Collier, Fishwick & Johnson, 2001) can reduce public sector employees' receptivity to change (Halachmi & Bovaird, 1997). Being ready to change implies a concomitant sensing of the need to change. Information about performance gaps, that highlights the need for change, must be communicated throughout an organization. If people feel that managers pay little attention to performance statistics, they too will ignore them and continue working in ways that maintain the status quo. The nature of the change and the benefits that it will bring need to be understood.

Quality of Information

Good quality information facilitates performance review, and reflection on service delivery. It supports people in their work tasks and it provides a medium for the capture and dissemination of lessons learned. If timely and meaningful information is not provided, people will find it difficult to know how well they are performing, and they will spend extra time searching for the information they really need. Public sector organizations often place less importance on the quality of information and perceive less need to invest in information systems (Rocheleau & Wu, 2002). Unless there is clarity about the basis of performance measurement, information systems will not be perceived as providing appropriate support.

Clarity of Responsibility

It is important for people to understand their specific roles and responsibilities and to know whom to contact elsewhere in the service value chain. People need to see clearly how their jobs fit into the bigger picture, to have their responsibilities delineated clearly in relation to the organizational strategy, and to see how their roles contribute to its achievement. Thus clarity of responsibility is concerned with the effectiveness of strategy delivery. Managers must ensure that people can grasp the significance of strategy in relation to their own responsibilities, and that the performance measures that derive from the strategic process (see Figure 1) are useable for managing service delivery. All too often, public sector performance measures are regarded by employees as vague and of limited utility (Townley, 2002). To achieve clarity of responsibility in partnerships there needs to be:

- A joint strategy developed, and owned by all partners
- Re-definition of the service value chain and its business processes
- Re-examination of roles and responsibilities within the value chain
- Development of partnership-based performance measures
- Logical and explicit derivation of performance measures from the joint strategy

Strategic Connections

This factor addresses communication gaps in the strategy formulation and deployment process. Public sector managers must ensure that people feel involved in the strategy formulation process and do not feel that strategy is imposed from on high, as is often the case in public services. Staff need to understand the meaning of strategy in their own situations. Strategic plans need to be living documents, owned by all, rather than uninspiring rhetoric that gathers dust on a shelf in the strategist's office. In public service partnerships, strategy must be communicated in terms of improved relationships and outcomes for service users, rather than a structural end in itself.

Accountability

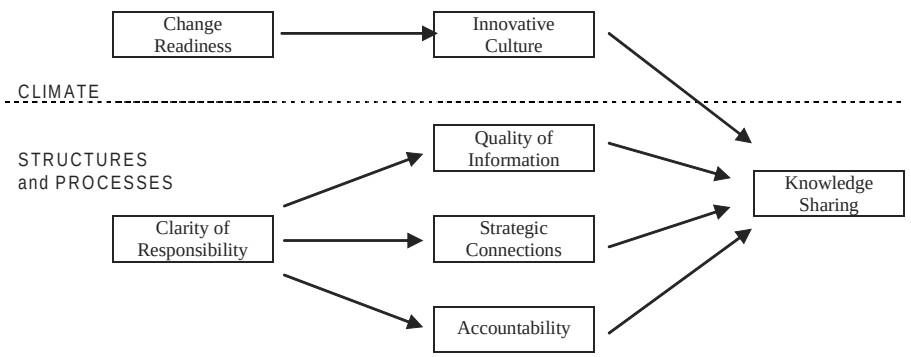
People need to know where the buck stops. In an integrated service delivery chain that crosses organizational boundaries, it must be made clear who is ultimately accountable for performance. Poor redefinition of accountability is symptomatic of, and consistent with, top-down imposition of strategy with little staff involvement, and poor deployment of strategies into meaningful processes and activities.

FUTURE TRENDS: MANAGING KNOWLEDGE SHARING

Six antecedents to successful knowledge sharing are illustrated in Figure 2, and these form a basis for the management of knowledge sharing. Increasingly, organizations will move from simply practicing knowledge management and knowledge sharing, toward an emphasis on evaluating its effectiveness. Using this model as a basis for diagnosing an organizational climate that is supportive of knowledge sharing, a targeted, proactive approach can be developed for implementing and maintaining effective knowledge sharing.

Figure 2. Predictors of knowledge sharing

Figure 2. The predictors of knowledge sharing



This empirically validated model indicates that these six factors are important precursors in the development of an effective knowledge sharing process and can give guidance to managers about where they should focus their efforts. We have found that an innovative culture is the strongest factor in explaining knowledge sharing, with acceptance of new ideas being the strongest element within this factor.

Our research identified the issues of trust and power as being underpinning and tacit impacts on knowledge sharing and our factors include items that embody trust and power (Dirks & Ferrin, 2001). For example, trust can result in higher levels of co-operation, increased willingness to take risks (Mayer, Davis & Schoorman, 1995), increased involvement of employees in decision making (Spreitzer & Mishra, 1999), increased sharing of information and greater satisfaction with organizational change programs (Rousseau & Tijoriwala, 1999). Thus this model incorporates the effects of trust and power in the ways in which they are experienced in a knowledge sharing environment.

CONCLUSION: A MANAGEMENT AGENDA FOR KNOWLEDGE SHARING AND INNOVATION

There are some clear antecedents to the management of effective knowledge sharing in partnerships developed to enhance public services. The change implications of knowledge sharing are very important, and are represented strongly in the innovative culture and change readiness factors. These factors are well established as key strategic management challenges and underline that knowledge sharing is a key strategic issue, rather than an IT-centred initiative, as it is often portrayed. While public policy usually addresses structural and process issues, our research suggests that this may inadvertently be misguided and that the key to improved service delivery lies in changes to the underlying culture, particularly with regard to an innovative orientation and change readiness. Applying structural solutions to behavioral problems is not recommended.

This model of knowledge sharing suggests a management agenda to improve service delivery through knowledge sharing. To develop an innovative culture, there must be a climate where both motivation to innovate and acceptance of new ideas are equally strong, and further, there must be appropriate systems in place to facilitate learning and reflection. To generate a shared understanding of best practices and a sharing of knowledge about lessons learned, staff in such partnerships need to be given time and opportunities to engage in socialisation processes that facilitate learning (Nonaka & Takeuchi, 1995). Organizations need to take on board Garvin's assertion that while much knowledge can be generated from reflecting upon success, there is even more to be gained from reflection on failure (Garvin, 1993). The changes needed to move from a departmental focus to an inter-organizational one point very forcibly to the organizational culture and especially the role of senior management.

Public services are embedded in an environment wherein government requirements for performance reporting and accountability often seem to have little relevance for informing staff about what needs to be improved. The intangibility of public services means that public service managers rely very much on knowledge – insight, understanding and empathy. Extant studies of knowledge have generally focussed on the private sector. However, the prominence of a knowledge sharing culture is clearly a key element in achieving a partnership-based, user-focused public service.

KEY TERMS

Accountability: Transparency of responsibility for performance, the management of performance and resulting implications for the deployment of future resources.

Change Readiness: An organizational mindset that welcomes challenges to established structures and processes and administrative orthodoxies.

Clarity of Responsibility: An understanding of the roles and responsibilities of individuals and business units working together to deliver a holistic service proposition.

Information Quality: The accuracy, completeness, timeliness and utility of performance related information that is used as the basis of management decision making.

Innovative Culture: An organizational climate that fosters new ideas and reflection on learning from experiences.

Knowledge Sharing: Formal, deliberate and systematic activities of transferring or disseminating knowledge from one person, group or organization to another.

Partnership Working: A network of organizations working together to provide a total service offering to a targeted group of users.

Public Services: Social infrastructure services, delivered wholly or partly with the benefit of public funds and strategically driven through national or regional administrations.

Strategic Connections: The relationships between the strategy formulation process and the deployment of resources to achieve it.

Improving the Usability in Learning and Course Materials

Maria Elizabeth Sucupira Furtado
University of Fortaleza and Estadual of Ceara, Brazil

INTRODUCTION

Human-computer interaction (HCI) is a discipline concerned with the study, design, and development of high-usability interactive systems (ISs) focusing on users' needs and their experiences with technologies, among others. In a simplified way, the usability of an IS refers to how easy it is to use and to learn. HCI is a very broad discipline that encompasses different specialties with different concerns regarding computer development: software engineering (SE) is concerned with the design and development of high-quality ISs focusing on schedule, budget, communication, and productivity. The quality of an IS refers to how satisfied the system clients and/or users are, verifying whether the system is performing exactly what was requested.

In order to achieve both IS usability and quality, it is necessary to go beyond designing user interfaces (UIs) and that they are easier to use and learn. It is important to define methods and use techniques (as ethnographic, semiotic, prototypes), which help designers to understand HCI concepts and build better interactive artifacts (as widgets) and to understand the effects that systems will have on humans (Cooper & Reimann, 2003). Some HCI concepts are characteristics of users (such as their preferences, language, culture, and system experience) and their contexts of use (such as great familiarity with a device, easy accessibility, and good luminosity of the environment).

In the interactive learning context, it is necessary to consider HCI concepts into an interactive learning system development method. The pedagogic usability of an interactive learning system is related to how easy and effective it is for a student to learn something using multiple devices (such as palm, camera, cell phone) to interact with the system. For these reasons, it is important not only to think about the IS quality, but about its usability as well. In this text, an interactive learning system is composed of a virtual learning environment (VLE), with tools to support a collaborative learning and interactive course materials available for the users through this environment. So, it is important not only to think about the VLE usability, but also about the interactive course material usability.

We have identified some problems to achieve a successful deployment of interactive learning systems (Furtado, Mattos, Furtado, & Vanderdonckt, 2003):

- **Lack of learning quality:** Many academic staffs are worried about the learning process quality through the course materials available in VLE. However, the material of a face-to-face course is hardly ever adapted to the students' needs and experiences. This way, it is expected that a VLE allow students exploring possibilities brought by new technologies in order to participate in the elaboration of this material.
- **Lack of adaptive tools:** Learning systems are very useful, but most of them are not adaptive and neither consider the user experiences with technology. Interactivity and personalization are factors that help for allowing a user participating in the community, which he or she makes part of (McCarthy & Wright, 2004).
- **Lack of training in modern and collaborative technologies:** Any academic staff (such as a teacher), as part of his/her professional development, needs continuous and sophisticated training. Such training should help overcoming the limits found by this community in accessing to digital technologies for the creation of interactive information and multimedia content, in a collaborative way with their own students. It is necessary to fulfill these needs by adopting an integrated pedagogical-technological content (Perrenoud, 2001).

All of these issues have a critical impact on the usability and quality of interactive learning systems. Thus, we developed a general architecture for such systems, which aims to show the concepts that must be considered to increase the quality of the learning process and to increase their UIs usability.

The remainder of this article is structured as follows: in the next section, we explain the main concepts that helped us to develop such general architecture. Then, we provide the best practices used in a development cycle of an IS, focusing on the usability issue. Finally, we summarize the main points of this text.

BACKGROUND

There is a trend about technological convergence, which companies are thinking in providing users common access to content by using any device in any place. It involves dif-

ferent technologies such as mobile phones interconnected with other surrounding interfaces (e.g., i-TV, PCs, PDAs, in-car-navigators, smart-house appliances, etc.) (Roibás, Geerts, Furtado, & Calvi, 2006). This technological convergence will be decisive in the creation of pervasive virtual learning environments. Many HCI researchers focus on the interaction design process in order to build UIs to these environments with which the users (students) can interact with no usability problem. In this process, several design decisions are made concerning the system navigation, the feedback mechanism, and the information organization and by taking into account the users' device and their context of use. However, it is important to point out that the user controls a VLE for the purpose of learning the content (course material). Then improving the usability of these systems is also to improve the usability of the multimedia content. A system UI should ideally be designed to be an integral part of the content (Garrett, 2003). It means that the UI design paradigm involving the task efficiency concepts (such as response time, errors control, task completion) must be extended to involve the content efficiency concepts (such as to allow users to read a content again, to stop of seeing it and to return when they want, to show someone an interesting content, to add a comment, etc). By combining these efficiency concepts, users can have more control of the systems and consequently, they can change their posture of passive learner to a more active one. In Chorianopoulos and Spinellis (2006), a UI evaluation approach was described in which the content quality is a relevant part to the quality of interactive television systems. Mattos (2005) described an approach, which can be used by teachers to persuade and motivate their learners to define their own contents.

VLE AND INTERACTIVE COURSE MATERIAL BACKGROUND

As we have mentioned before, an interactive learning system is composed of a VLE and tools for creation in a collaborative way of interactive course instructional materials.

A VLE has to provide students with spatial freedom and time flexibility. It has to be flexible enough so that every student may profit from his or her own skills and abilities, use his or her previously developed idiosyncratic characteristics (cognitive, social, or emotional), and apply his or her previously gained experience and expertise (Karoulis & Pombortsis, 2003). Some tools available in a VLE are links to tutorials and course materials, collaborative tools (as blog, skype), evaluation tools, and administrative tools.

There are some authoring tools, which users (students and teachers) can use to develop their own contents and make them available and accessible in various devices (such as palmtop, digital television, kiosks, and mobile phones) (Maia & Furtado, 2006). The user of this system follows a flow of activities to edit and update the Web content and to design the UIs of these contents. During UI design, HCI patterns are made available in order to assure the consistence between user interface objects of different devices. We can define HCI patterns as a tested solution for a usability problem (such as lack of orientation, difficulty in finding information) that happens in a certain context (search, visualization, etc.). Other tools, such as those for specific programming languages (HTML, FLASH, SVG), are only used by specialized teams.

BASIC CONCEPTS RELATED TO USABILITY IN INTERACTIVE LEARNING SYSTEMS

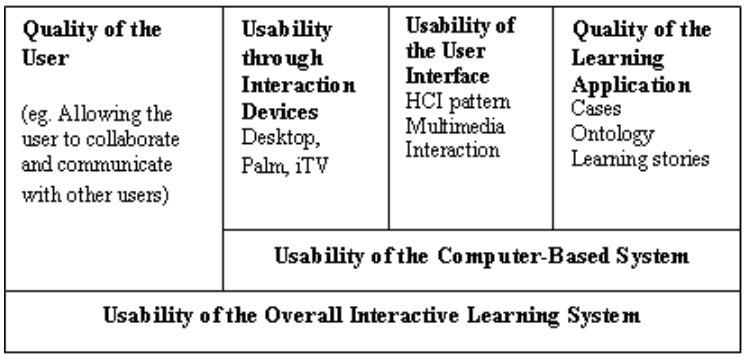
The general architecture initially proposed in Furtado et al. (2003) but updated here in Figure 1 aims at the development of VLE and interactive materials, taking into account some concepts studied in different areas (human-computer interaction, cognitive sciences, ergonomic, artificial intelligence, and pedagogy).

According to Figure 1, an interactive learning system's usability can be assured when its components have been built with quality and when users' needs have been taken into account. Quality of a component means: (1) quality in the application that corresponds to content, which refers to the information and knowledge involved in the system. Information (such as learning stories and objects) is related to the development of instructional materials, and knowledge (such as cases) is especially related to the collaborative practices; (2) usability in the UI, which refers to a good specification of the interactive information of the system (its windows, its buttons, etc.); and (3) usability through interaction devices, which makes the interaction with different media (sound, text, image) possible through different interaction resources as pen for palmtops, cameras and microphones, remote control for iTV, and so on. The quality of the user refers to his or her ability to use new interaction devices and technologies, experience with technologies, and acquaintance of the domain in question.

The concepts related to usability in an interactive learning system are:

- Utilization of ontology to assure the flexibility in modeling learning applications. The ontology notion comes from the artificial intelligence area where it is identified as the set of formal terms with one knowledge representation, since the representation completely determines what "exists" in the system (Guarino, 1995). During an application modeling, models (such as the user model), knowledge (such as cases studies), and

Figure 1. The general architecture proposed



learning stories and their learning objects associated to an instructional material can be represented using ontology. The advantage of using this representation is that the ontology can be defined once and used as many times as necessary (evolutionary approach). In addition, the ontology is useful to create learning objects and reuse them when a new course is initialized.

- Utilization of human factors and HCI patterns to assure effective interaction, maximum performance, and flexibility (multiplicity of ways the user and the system exchange information). Human factors such as the teachers' beliefs and guidelines related to graphic aspects and characteristics of the users and their context of use must be considered. Guidelines are suggestions about the ergonomic aspects of the interfaces such as showing only the necessary information or letting the user control the system dialog. Many HCI patterns are associated to guidelines, in order to help the designer to determine the best way in which the information is to be provided to users and to ensure optimal accessibility of the system (Appleton, 2000).
- Convergence of various devices and resources to improve interaction. The use of different interaction devices makes it possible to explore the possibilities brought by mobile and iTV technologies, in order to bring more facilities of access to information. As consequence, special attention should be given to issues such as sociability, creativity, and context awareness. It implies in developing systems that employ appropriate mechanisms of feedback, and content sharing and creation.
- Utilization of collaboration and communication mechanisms to assure the quality of the user and the continuous usability of the learning system. Some VLEs implement the collaborative aspect by allowing users to share an application (such as TELE (Neto, Raimir, Bezerra, & Sarquis, 2001)) and/or by using forums and chats. It allows users to share knowledge, when they are motivated to collaborate through principles of participation, for instance, in problem definition practical situations. There is a need to continuously assure usability of a system due to technological changes and to the evolution of users' needs. We believe instructional materials of a course should evolve from human interactions between students and teachers occurring within an interactive discussion forum (Mattos, Maia, & Furtado, 2003). Hence, we believe in a collaborative process between users and designers to adjust accessibility, acceptability, and usability criteria of a system.

USABILITY OF INTERACTIVE LEARNING SYSTEMS: THE BEST PRACTICES OF REQUIREMENTS ENGINEERING

In this section, the concept of usability (learnability, flexibility, and robustness) is related to some best practices of the requirements modeling and validation of an IS (see Table 1).

An IS must be developed with the participation of users throughout the development process because it is easier for developers to define and evaluate the functional and nonfunctional (usability) requirements. The functional requirements of a VLE are related to the tasks that the user wants to perform (user tasks), for instance, to interact with other students and tutors, and to access the rules and regulations of the course. Usability requirements are related to users' satisfaction and the performance of the system. These requirements directly influence aspects of the system quality of use (e.g., never lose sight of navigational functions).

Sutcliffe (2002) gives practical guidance for requirements modeling and validation based on scenarios. A scenario represents a story or example of events taken from real-world

experience. These stories are close to the common sense use of the word and may include details of the context of use for a system. These representations help users think about how the system would support their tasks.

During the material design, users must be able to inform their learning requirements, which are related to content (students must perform the study tasks for a particular unit). These requirements are usually represented in storyboard sketch or animated sequences. A storyboard represents a future vision of a designed material with sequences of behavior and possibly contextual description. These representations serve as a starting point in determining the information that should have a specific material.

However, a single scenario or storyboard shows only some possible sequences of events among many possible sequences permitted during the interaction of a user with an IS. Interactive prototype is an interactive medium that allows the users to explore all alternative paths, and it gives a look and feel overview of the IS. To do a prototype, the designers should take into account HCI patterns. During a session of requirements validation, it is necessary to actively engage users in checking that the designed IS actually does what they want. If the IS developed is accepted by the user, we can say that its development process was user centered, according to their needs and suggestions. As we mentioned, the usability of an interactive learning system is not just the UI. The focus must also be on the support that the VLE or instructional material provides for its interactive students.

As requirements are so volatile, it is important to examine how they can be specified so software can evolve and adapt to the users´ needs. The evolutionary process involves continuous requirement adjustments in two points of view: (1) of the user—when using the system, his or her practices and working methods can be adapted to satisfy the evolving needs individually and/or collectively; and (2) of the system—the system's behavior can be adapted. The evolution of users' needs can involve modifying a system's characteristics related to its design options, for instance. In order for an IS to be considered evolutionary, its quality must be continuously verified. In VLEs, this means that its functionalities must be changed (for instance, to realize that students would like to publish their work to be viewed by any of their tutors other than themselves). In course materials, the changes can require a definition of a new learning object from an existing one.

To develop an adaptive IS, the UI designer must consider guidelines that must conform to usability requirements defined previously and users' characteristics and their context of use. It is usual to gather users sharing the same value for a given set of characteristics into stereotype. The problem is there is no predefined information on the users to ensure that an IS has high quality of interaction to a stereotype of all users (Furtado et al., 2001). In case of difficulties, it is better to design the best interaction possible for the most representative users, who are the intermediates (Cooper et al., 2003). They establish the functions that they use with regularity and those that they only use rarely.

Ontology can be used to represent a variety of parameters that are not necessarily identified nor truly considered in the requirements analysis. The notion of ontology allows the definition of the meta-models, which define the specification language with which any model can be specified. This resource makes it easier to consider new information in models (Vanderdonckt et al., 2004). In interactive adaptive learning systems, a flexible user modeling approach is very important. The ontology of a user model can be updated accordingly to consider more information.

So the success of an IS will depend on a complex trade-off between the classic view of requirements being satisfied by a design, but evolving, and the desired degree of satisfaction in acquiring the desired product (Sutcliffe, 2002).

These practices and the HCI concepts described here are more detailed in Sousa, Mendonça, & Furtado, 2005). It provides the developers and users a framework, including the activities that must be performed using these HCI concepts and artifacts.

FUTURE TRENDS

The multidisciplinary dimension of this work is characterized by the studies done in diverse areas of knowledge,

Table 1. A summary of requirements engineering practices to have usability

Usability of VLEs	Usability of course instructional materials
Participatory design of users	Participatory design of students and teachers
User-centered design	Student-centered design
Focuses on the UI and pedagogical functions of the VLE	Focuses on the UI and pedagogical content of the material
Requirements are represented in scenarios and prototypes	Requirements are represented in storyboards and prototypes
Convergence of various devices and resources of interaction	Authoring tool assuring the content sharing and creation using various media (photo, video, and text).

from human-computer interaction and software engineering to pedagogy. Distance learning adheres to a vision where interactive learning applications are developed for the widest population of users in the most varied contexts of use by taking into account individual differences. This population of users is being called "interactive community." To create an interactive community-centered design will be the best practice of the requirements engineering for developing the applications, which will be able to better support the collaborative learning. In addition, it will be possible to develop applications with adaptive user interfaces. These interfaces must be able to adapt themselves to the community and contexts of use characteristics.

CONCLUSION

From our experience with the community of students and teachers in the interactive learning systems and with the development of interactive systems, it was possible to establish the following conclusion about how to obtain more usable ISs: the main question for the success of learning processes for users through the different technologies does not lie exclusively on the choice of pedagogical methodology and techniques. It lies, fundamentally, on three factors: (1) the understanding of the needs of both teachers and students though a participatory design, (2) the transformation of such needs in a consistent UI and adaptive functions of a VLE and its available course materials; (3) the need to continuously assure usability of a system through an extensible representation of requirements, and (4) the technological convergence.

ACKNOWLEDGMENT

I thank the CAPES for the financial support given to this research.

KEY TERMS

Evolutionary System: Involves continuous adjustments of its functionalities and UI according to the user and/or technological changes.

Extensible Representations of Requirements: Ways to represent easy requirements that were not necessarily identified nor truly considered in the requirements analysis.

HCI Pattern: A representation (graphical, textual and so on) about a tested solution for a usability problem (such as lack of orientation, difficulty in finding information) that happens in a certain context (search, visualization, etc.).

Pedagogic Usability of an Interactive Learning System: Related to how easy and effective it is for a student to learn something using the system.

Requirements Engineering: The human acts of identifying and understanding what people want from an IS.

Usability of an IS: Refers to how easy it is to use and learn the system.

Usability Requirements: Related to users' satisfaction and the performance of the system.

Improving Virtual Teams through Creativity

Teresa Torres-Coronas
Universitat Rovira i Virgili, Spain

Mila Gascó-Hernández
Open University of Catalonia, Spain

INTRODUCTION

Many studies have already shown how a team can become more creative, and therefore more efficient, but only a few researchers have focused on how a virtual team can use creativity techniques to perform better. In this article, we study what differences there are (both in terms of processes and in terms of results) when creativity techniques are used in the management of traditional and virtual teams. To do this, we discuss three main elements: the definition of creativity and its relationships with team performance, the variables that enhance creativity in a virtual team, and the most suitable creativity techniques for a virtual environment.

BACKGROUND

Most researchers and practitioners believe that the key to organizational success lies in developing intellectual capital and acquiring a new set of thinking: the creativity to produce an idea and the innovation to translate the idea into a novel result (Roffe, 1999). Explaining the meaning of creativity is not straightforward; there are thousands of definitions of the term. So, for the purpose of this article, we will understand creativity as the shortest way to search for unconventional wisdom and to produce paradigm-breaking ideas and innovation. This unconventional wisdom through the generation and use of creative knowledge is the key to building sustainable competitive advantages (Carr, 1994).

In order to develop more innovative products, services, or processes, organizations must encourage their employees to become more creative. During the last few decades, several researchers (Andriopoulous, 2001; Nemiro & Runco, 2001; McFadzean, 1998; Amabile, Conti, Coon, Lazenby & Herron, 1996) tried to describe contextual factors largely under the control of managers that influence creativity, though as creativity is a multidimensional concept, there is not a universal theory yet (Walton, 2003). This section focus on how managers and/or team leaders can improve creative climate within virtual structures.

The literature review conducted by Andriopoulous (2001) highlights five major organizational factors that enhance creativity in a traditional work environment: 1) organizational climate, or designing a working atmosphere that fosters participation and freedom of expression; 2) a democratic and participative leadership style; 3) an organizational culture that nourishes innovative ways of solving problems; 4) new resources and skills through the development of human resources creative talent; and 5) a structure and systems that include building flat structures, and rewards, recognition, and career systems that emphasize people creative thinking. Scholars argue that these factors create conditions that enhance creativity both at the team and individual levels.

From a study of the social psychology of creativity, Amabile (1996) cites the three main origins of creative performance as: task motivation, domain-relevant skills, and creativity-relevant skills. She differentiates between intrinsic and extrinsic motivation, proposing that the intrinsic motivation enhances creativity. In Amabile's research, the work team environment is also considered to exert a powerful impact on creativity by influencing the employee's intrinsic motivation. Management practices indicate that performance can be fostered by allowing freedom and autonomy to conduct one's work, matching individuals to work assignments, and building effective work teams that represent a diversity of skills and are made up of individuals who trust and communicate well with each other, challenge each other's ideas, are mutually supportive, and are committed to the work they are doing (Amabile & Gryskiewicz, 1987). Creativity is best achieved in open climates (Feurer, Chaharbaghi & Wargin, 1996).

These studies have not specifically addressed dimensions that may be necessary when groups no longer interact in traditional structures (Nemiro, 2001). In fact, so far, the only research that has been seriously conducted about this issue is that by Nemiro (2001), who identifies several key elements that influence creativity in virtual teams and therefore result in effectiveness and high levels of performance. Table 1 summarizes some of these factors as described by Nemiro (2001, p. 94).

A creativity-based management aimed at fostering virtual team creativity and performance must manage the above environmental variables in order to enhance employees' internal drive to perceive every project as a new creative challenge (Andriopoulos & Lowe, 2000).

A quick analysis of the variables shown in Table 1 gives rise to the conclusion that there are no meaningful differences

between the factors that affect creativity in traditional environments and those that affect creativity in virtual contexts. On the other hand, most of the factors that influence creativity (such as work characteristics and situational constraints) are also considered as factors that impact team performance, as the conceptual model of Prasad and Akhilesh (2002) shows. Nevertheless, due to the particular way virtual teams work, there is a need to consider some elements related to the previous variables. Thus, communication and trust become very relevant issues.

In this sense, Henry and Hartzler (1998) find that keeping the synergy and creativity flowing, without frequent face-to-face interaction, is the greatest challenge a virtual team has. Virtual teams lose non-verbal communication and, as has been argued, electronic communication increases the level of social isolation. Schein (1993) points out that most communication workshops emphasize active listening, which means paying attention to the spoken words, the body language, the tone of voice, or the emotional content. Virtual teams that want to communicate successfully cannot actively listen in this sense. Other tools must therefore be explored¾for example, the use of multiple media or several communication technologies (Bal & Teo, 2001). However, as Van der Smagt (2000) showed, it is crucial to ensure that dialogue is the primary form of interaction between team members and that two-way monologues are avoided. Rich media—those that transmit nonverbal cues—are not the solution.

"In a dialogue, the difficult part is to make one's own assumptions manifest, not the exchange of insights with others. The attitude in relation to other actors is one of openness, which makes it relatively easy to get behind the position and possibilities of actors." (Van der Smagt, 2000, p. 155)

Collaborative work also requires a level of personal familiarity and trust. Without trust, building a true team is almost impossible (Duarte & Snyder, 1999). For most newly forming virtual teams, achieving an effective level of trust is not an easy task. Increasingly, virtual teams will form without the advantage of prior face-to-face team building opportunities, but with the added challenges of geographic isolation, time zone differentials, and cultural diversity (Holton, 2001). With virtual team heterogeneity there is a high probability that team members are confronted with mistrust (Prasad & Akhilesh, 2002), though such diversity within a team has the potential to increase opportunities to be innovative and creative (Lipnack & Stamps, 1997), if trust can be established (Dyer, 1995). But how can trust be built? The qualitative research project of Holton (2001) concludes that standard team-building tools can be used to enhance collaboration and trust in a virtual team. The book of Simon Priest (2001) is full of examples for virtual team building. But, as with all team building, there is no quick fix for virtual teams.

These difficulties related to communication and trust are only an example that illustrates the need to conduct in-

Table 1. A summary of factors that can foster creativity in a team context

Autonomy and Freedom. Allowing individuals responsibility for initiating new ideas and making decisions; a sense of control over one's work.
Challenge. Work that is stimulating, engaging, and meaningful; a sense of having to work hard on challenging and important tasks.
Clear Direction. Goals that facilitate creativity are clear, negotiated, attainable, shared, and valued.
Diversity/Flexibility/Tension. Diversity, both in terms of the work assignments offered and the people one interacts with, and a tolerance of differences. In order to be tolerant of differences, flexibility is needed. Both diversity and flexibility can lead to creative tension.
Support for Creativity. An organizational focus on support for or encouragement of creativity.
Trust and Participative Safety. Especially crucial for group creativity is trust and participative safety. The emphasis is on encouraging participation in a non-threatening, non-evaluative environment.

depth studies on the rest of environmental factors that, in non-virtual contexts, have been proven to directly impact teamwork creativity.

TOOLS AND TECHNIQUES TO IMPROVE CREATIVE PERFORMANCE

How can team creativity be encouraged? Until now no serious research has been conducted into which creativity techniques are the most suitable in a virtual environment. In traditional environments, one method of achieving this is to encourage teams to utilize creative problem-solving (CPS) techniques such as synectics, brainwriting, or wishful thinking.

In this context, McFadzean (2000, 1999, 1998) explores creative problem solving and presents a model that helps facilitators and team members choose appropriate techniques. McFadzean (1996a, 1996b) classifies creative problem solving (CPS) techniques into three categories: paradigm preserving, paradigm stretching, and paradigm breaking. Paradigm preserving techniques do not tend to change a participant's perspective. Paradigm stretching techniques encourage users to stretch the boundaries of the problem space. Paradigm breaking techniques allow participants to completely break down the boundaries of the problem space and to look at something entirely new.

In a virtual environment, three variables must also be considered when selecting a technique (Gascó-Hernández & Torres-Coronas, 2004): 1) the effectiveness of the method in finding innovative solutions, considering that quality solutions require the right balance between knowledge of the business issue and novelty (Kim, 1990); 2) the technological context or support system through which the technique can be implemented; and 3) the level of interaction that the technique requires. It is also important that the virtual facilitator has experience in running virtual creative sessions. Team members must also be taught about the dynamics of virtual interactions and about the use of technological tools, such as chats, e-mail, video conferencing, or interactive whiteboards.

Next, McFadzean's creativity continuum (1996a, 2000) will be used to summarize how virtual teams can choose among different techniques, which will be briefly described, to generate ideas. To make valuation accessible, the techniques will be classified according to the above three criteria. They will be rated as well (low, medium, and high). Finally, common technological tools by which each technique can be used will be shown.

It is a fact that there is a remaining need for in-depth research studies that help clarify which is the best creative problem-solving tool in terms of virtual team creative performance. Table 2 intends to be the basis to start evaluating the creativity continuum in a virtual context.

The use of these techniques will only be effective if the organization has a creative culture (McFadzean, 1998). Environmental factors that help managers to build a creative climate within virtual communities and creative problem-solving tools are two sides of the same coin.

FUTURE TRENDS

Virtual teams can use creativity in order to perform better. Nevertheless, there is a need to adapt those tools and techniques to a virtual environment. In this article, we have approached some of the issues that must be considered when studying the relationship between teams that work online and creativity. Nevertheless, several questions still remain unanswered and, in this sense, further research is required. In particular, three important issues need further development. First, the relationship between creativity and virtual team performance needs to be thoroughly explored. Successful studies will determine how structural and environmental factors influence team creativity. Second, although virtual teams are already using idea-generation techniques, their strengths and weaknesses need to be carefully and academically explored. Finally, it is also important to consider the effects of technology on both individual and team creativity. Technology has risks that can sometimes outweigh its benefits. When applying creativity techniques, people need to focus on the creative process, not on the technology being used. Technology must be easy to use, it must be effortless and unsophisticated—the simpler the technology, the better.

CONCLUSION

The emergence of tools based on the new information and communication technologies is currently affecting team creative processes. Nowadays, achieving high levels of creative performance is still an unresolved problem within virtual teams. Only a few researchers have focused on how a virtual team can use creativity techniques to perform better or how to build a creative virtual environment to foster creativity. The critical issues discussed in this article summarize many challenges to implement creative management within both virtual teams and organizations. With greater emphasis being placed on creative thinking and processes, team creative performance will increase day by day, allowing organizations to succeed and to become more innovative and adaptable.

KEY TERMS

Autonomy and Freedom: Allowing individuals responsibility for initiating new ideas and making decisions; a sense of control over one's work.

Challenge: Work that is stimulating, engaging, and meaningful; a sense of having to work hard on challenging and important tasks.

Clear Direction: Goals that facilitate creativity are clear, negotiated, attainable, shared, and valued.

Converging Thinking Techniques: Tools used during the convergent phases of the CPS to improve the evaluation and selection of the most relevant ideas, thoughts, or data. Pluses, potentials, and concerns (PPC); highlighting; and the evaluation matrix are some of the most common converging thinking techniques.

Creative Performance: High level of capability in an idea or solution, applied to solve a problem in an imaginative way, resulting in effective action. Environmental factors such as autonomy and freedom, challenge, clear direction, diversity/flexibility/tension, support for creativity, trust, and

participative safety directly affect the creative performance within work teams.

Creative Problem Solving (CPS): A systematic process model to solve problems and to harness creativity. Its six steps include objective-finding, data-finding, problem-finding, idea-finding, solution-finding, and acceptance-finding. Each step has a divergent and convergent phase. During the divergent phase, a free flow of ideas is elicited. Convergent phases involve the evaluation and selection of the ideas with the greatest potential or relevancy. The defer-judgment rule separates idea generation from idea evaluation.

Creativity: The production of something new or original that is useful; the act of creating recombining ideas or seeing new relationships among them. Creativity is usually defined in terms of either a process or a product and at times has also been defined in terms of a kind of personality or environmental press. These are four Ps of creativity: process, product, person, and press.

Divergent Thinking Techniques: Tools used during the divergent phases of the CPS to improve the generation of ideas, thoughts, or data without evaluation. These tools are classified according to their primary use of related or unrelated problem stimuli. Brainstorming, brainwriting, forced connections, analogies, and metaphors are some of the most used divergent thinking techniques.

Diversity/Flexibility/Tension: Diversity, both in terms of the work assignments offered and the people one interacts with, and a tolerance of differences. In order to be tolerant of differences, flexibility is needed. Both diversity and flexibility can lead to creative tension.

Support for Creativity: An organizational focus on support for or encouragement of creativity.

Trust and Participative Safety: Especially crucial for group creativity is trust and participative safety. The emphasis is on encouraging participation in a non-threatening, non-evaluative environment.

Virtual Team: A group of people who are geographically separated and who work across boundaries of space and time by utilizing computer-driven technologies such as desktop video conferencing, collaborative software, and Internet/intranet systems. How these teams interact defines them as "virtual."

An Inclusive IS&T Work Climate

Debra A. Major
Old Dominion University, USA

Valerie L. Morganson
Old Dominion University, USA

INTRODUCTION

Employees develop perceptions regarding which behaviors are expected, supported, and rewarded in their organization through a series of workplace events, practices, and procedures; these beliefs comprise a workplace climate (Schneider, Wheeler, & Cox, 1992). An inclusive workplace climate is one in which everyone has a sense of belonging, is invited to participate in decisions, and feels that their input matters (Hayes, Bartle, & Major, 2002; Major, Davis, Sanchez-Hucles, Germano, & Mann, 2006). For an inclusive climate to exist, all organizational members should feel equally welcome in the IT work environment and feel free to make suggestions regardless of their gender or ethnicity. Moreover, all organizational members should feel that their contributions have an impact (Major et al., 2006). Rather than simply tolerating diversity, organizations with an inclusive climate embrace it and capitalize upon it. In an IT sample, inclusive climate was positively associated with job satisfaction, organizational and career commitment, and intentions to remain with one's employer (Major et al., 2003). In contrast, exclusion is associated with turnover, reduced organizational commitment and decreased job satisfaction (Greenhaus, Parasuraman, & Wormley, 1990). Research has highlighted the role of three contributors to inclusive climate: (1) strong supervisor/subordinate relationships, (2) supportive coworkers, and (3) a supportive culture (Margolis & Fisher, 2003; Major, Davis, Sanchez-Hucles, & Mann, 2003). The current article briefly reviews social factors that have hindered the realization of a gender and minority inclusive IT climate and draws upon these three contributors to identify strategic levers to guide managers and researchers toward fostering inclusion in the IT workforce.

BACKGROUND

Women's underrepresentation in IT education and careers has been recognized as a global problem (Huyer, 2005; Rosser, 2005). In addition, certain U.S. ethnic minority groups, including African Americans, Hispanic Americans, and Native Americans, are underrepresented in programs preparing people for IT careers (Tapia, Kvasny, & Trauth, 2004). Researchers refer metaphorically to a "leaky pipeline" to describe the attrition of women and minorities from pathways leading to participation and success in IT education and careers. From childhood to adulthood, a variety of experiences, such as limited access and exposure to computers, and the unappealing portrayal of the IT industry (e.g., depictions of individuals working in solitude and the stereotypical IT "geek image"), discourage female and minority interest in IT (see Rosenblum, Ash, Coder, & Dupont, 2006, Splender, 1997; Tapia et al., 2004).

Barriers persist in the IT workplace. Women encounter a "glass ceiling," a situation in which men hold top-level positions and women are limited in their ability to move up due to barriers that are not readily obvious or overt (Martin, 2005). In fact, U.S. women hold fewer than 5% of IT executive positions, such as chief information officer (Gingras, 1999). Instead, they are more likely to hold support positions such as help desk operator or support center staff (Belt, 2002). The nature of IT work can be a barrier, requiring long and irregular hours and, in some positions, the flexibility to travel. These job demands infringe upon family life and women are frequently less willing or able to sacrifice their home and childcare duties (Panteli, Stack, & Ramsay, 1999; Roldan, Soe, & Yakura, 2004).

Populated primarily by white males, the IT work climate can be "chilly" because of characteristics that make it unfriendly and inhospitable to women and minorities (Roldan et al., 2004). An inclusive climate is

warm and inviting to all regardless of their demographic characteristics. This review considers key factors that research has shown to contribute to an inclusive climate and to the success of a diverse workforce. We begin with a discussion of self-fulfilling prophecy as a mechanism through which workforce inclusion disparities function. Mentoring, leadership and coworker relationships are each discussed as levers for social change.

SELF-FULFILLING PROPHECY

Based on experience and perceptions, people develop expectations about what behaviors to anticipate from other individuals. Expectations, in turn, can realize themselves through the actions of the perceiver and subsequent reactions of the perceptual target. Social scientists refer to the tendency of others' assumptions to evoke behavior as *self-fulfilling prophecy* and have highlighted its influence in the professional development and success of women and minorities. Expectations are particularly influential when they are held by powerful individuals. Through the process of self-fulfilling prophecy, managers form expectations of employees and behave according to their expectations by either providing or withholding emotional and social support. In turn, subordinates exposed to high expectations and greater support gain experience, confidence, and ultimately perform better, whereas those confronted with low expectations and a lack of support are less likely to be high performers, given a relative lack of opportunity to bolster confidence and experience (Eden, 1997).

Self-fulfilling prophecy can be either negative or positive and can operate on an individual level or pertain to entire social groups. In IT, women often feel that they need to outperform men to be viewed equally. When they act upon this expectation, the quality of their work may be adversely affected, and they appear less competent as a result (Valian, 1998). Along the same lines, members of underrepresented groups feel extra pressure because they fear confirming and reinforcing negative stereotypes about their group. *Stereotype threat* is the circumstance when this extra pressure reduces performance and persistence (Steele, 1997).

Organizational development experts have recognized the power of positive expectations as an instrument to change work climates for the better. They advocate *appreciative inquiry* or emphasis upon optimism, positive expectations, and challenge (Srivasta & Cooperrider, 1990). By focusing on what the organization does well, rather than what it does poorly, and acknowledging individual contribution, organizations become better aligned and equipped to achieve inclusive climate. Holding positive expectations can be especially transforming in situations where low expectations are usually held (McNatt, 2000) and when gender and racial stereotypes tend to influence expectations (Jussim & Eccles, 1992).

MENTORING

Mentoring is a process by which a more experienced employee (e.g., a supervisor) guides, advises, counsels and otherwise enhances the professional development of another employee. Mentors act as role models, provide social support, and serve as sources of information, especially early in an employee's organizational tenure. Mentors can be instrumental in the new employee's career development (Scandura, 1992). For example, mentoring is associated with higher performance ratings, more frequent promotions, greater job satisfaction and higher income (e.g. Allen, Eby, Poteet, Lentz, & Lima, 2004; Ragins & Cotton, 1999).

Developing an effective mentor-protégé relationship can be challenging for minority and female employees. Although women and minorities may prefer a mentor who is demographically similar to themselves (Murrell, Crosby, & Ely, 1999), they are in short supply given the composition of the IT workforce. Compared to white males, incumbent women and minorities in the IT workforce are more likely to be in the junior stages of their careers. At early career stages, professionals have more limited social networks, and less access to information, and therefore may have limited effectiveness as mentors (Benishek, Bieschke, Park, & Slattery, 2004). White males may be better mentoring resources to the extent that they have greater social status and power in the organization (Dreher & Cox, 1996; Ragins & Cotton, 1999).

However, mixed-gender mentoring relationships also have obstacles. In the case of a male mentor and a female protégé, concern that others will make sexual attributions about the nature of their relationship can make both parties reluctant to pursue a mentoring relationship (Ragins & Cotton, 1999). When mixed-gender mentoring relationships do develop, they may offer

less support than same-sex mentoring relationships. Female protégés are sometimes viewed by the mentor as not taking their professional goals seriously, and may be mentored in a qualitatively different way than male protégés (Schwiebert, Deck, Bradshaw, Scott, & Harper, 1999). Moreover, in mixed-gender mentorships, the female protégé is less likely to be included in informal networking activities than her male counterpart (Ragins & McFarlin, 1990).

To equitably disperse the many benefits of mentoring relationships, organizations should be active in fostering collaboration among junior and senior employees. Organizations profit from formal mentorship programs, although informal mentorships are associated with even greater benefit, especially for women (Ragins & Cotton, 1999). As an effective strategy, organizations may identify a pool of potential mentors and protégés, provide training, and allow dyads to form according to individual preference (Forret, Turban, & Dourghty, 1996).

LEADERSHIP

IS&T work requires effective leaders to maintain a balance of technical/task-oriented and interpersonal skills (Major et al., 2007). Yet, the technical aspects of the IS&T profession have historically been emphasized while interpersonal requisites have been downplayed. This emphasis may disadvantage females whose strengths are often relationships, understanding, communication and other interpersonal aspects of IT (Nielsen, von Hellens, Greenhill, & Pringle, 1997). This is not to infer that females are weak at technical aspects of IT work. Indeed, there is no evidence to support such a conjecture. Instead, our intent is to recognize the contribution that research shows interpersonal skills make to IT leadership effectiveness.

Major et al. (2007) found that IT professionals appreciate supervisors with effective interpersonal and relationship building skills. Some research suggests that female IS&T supervisors are better able to develop high-quality working relationships with their subordinates than male supervisors (Major et al., 2006). Mayo (1982) offers a plausible explanation for this finding. She described a condition of positive marginality, whereby minorities and women develop strong leadership skills because they have observed effective and ineffective practices from the sidelines. Promoting women and minorities to positions of leadership may act as a catalyst for inclusive climate by synergistically changing norms to welcome diversity and by providing female and minority subordinates with role models.

In addition to recognizing the value of a relational approach to IT leadership, IT professionals should be aware of how gender stereotypes can hinder inclusive climate. Women attempting to lead, especially in male-dominated environments, may face a double-standard (Gherardi, 1995). Women who lead with an instrumental and assertive style (i.e., a stereotypically masculine style) may be rejected and labeled as overly "pushy" and are likely to be viewed as behaving inconsistently with female gender role expectations. IT professionals should be mindful of the influence of their own gender socialization and expectations in order to prevent the manifestation of such double standards.

COWORKER RELATIONSHIPS

The expression "the people make the place" is sometimes used to emphasize human capital as an organizational asset (see Schneider, 1987). This holds true for creating inclusive climate. Through effective coworker relationships, individuals are better able to adjust and are more likely to feel anchored in their environment. Indeed, coworker support is associated with a variety of positive work outcomes, including reduced stress, greater organizational commitment, higher job satisfaction and reduced intentions to turnover (Baruch-Feldman, Brondolo, Ben-Dayan, & Schwartz, 2002; Ducharme & Martin, 2000; Lee, 2004). Among IT professionals, men and women reported equal satisfaction with the IT social environment and both felt equal emotional support from their coworkers (Major et al., 2006). In addition to affective ties, social networks contribute to well-being and career progress (Podolny & Baron, 1997; Seibert, Kraimer, & Liden, 2001) and provide women in IT with a means of coping (Pegher, Quesenberry, & Trauth, 2006). However, compared to men, women report being less able to employ social networks to make career moves (Sumner & Werner, 2001). This finding illustrates a distinction between participation and influence. To truly realize an inclusive climate, individuals should be equally able to realize results and benefits from their participation (Major et al., 2006).

FUTURE TRENDS

Research has identified several levers to increase inclusive climate. To warm the "chilly" climate, policies and norms should be set in place to welcome diverse lifestyles. For example, women value working for organizations that promote child care, maternity leave, equal opportunity, sexual harassment laws, and training (Trauth, 2002). In addition, efforts should be made to promote minorities and women and to develop their careers so that they are present to mentor subordinates. Inclusive relationships enhance mentoring and advising, and increase retention of women and minority IT professionals (Gürer & Camp, 2002). Finally, it is essential that IT professionals experience a sense of influence rather than simply being allowed to participate. In one study of IT professionals, women, particularly minority women, reported feeling included in a relational sense only; they felt their contributions had less of an impact than those of their male counterparts (Major et al., 2006). It is important to note that organizational policies and practices aimed at increasing the inclusion of women and minorities do not exclude majority group members (e.g., white males). Instead, the levers we have discussed here promote the inclusion of all.

Minority status can be especially stressful due to reduced access to mentors and to information (Jackson, Stone, & Alvarez, 1992). Just as organizational polices and practices can promote inclusion, there are also steps that individuals can take to improve inclusion. Active coping is defined as taking steps to overcome these stressors and mitigate their effects. Individuals practicing active coping (1) *plan* or think about how to cope with a stressor, (2) *seek social support* for instrumental and emotional reasons, (3) *suppress competing activities* to allow focus on the stressor at hand, and (4) *restrain action* until the appropriate time (Carver, Scheier, & Weintraub, 1989). Through active coping individuals can capitalize on a constellation of positive outcomes, including increased optimism, control, self-esteem, and resilience and decreased anxiety. Teaching active coping has great potential as an intervention to increase inclusive climate in the field of IT.

CONCLUSION

Inclusive climate is essential for recruiting and retaining a diverse workforce in IT organizations. Inclusion offers the benefit of diverse viewpoints and promotes race and gender equity. Effective IT management practices include embracing participation, providing support for individual lifestyle accommodations, and taking an individual interest in each employee (Major et al., 2007). Inclusive practices, such as sourcing from hiring agencies that specialize in providing female and minority applicants and promoting family-friendly polices and procedures (e.g., relaxed environment, flexible work arrangements, child care services and telecommuting) are associated with success in the IT industry (Agarwal & Ferratt, 2002). Individuals and organizations should be proactive in creating an inclusive environment because failing to actively encourage women and minorities may have the same effect as actively discouraging them (Leggon, 2003).

KEY TERMS

Active Coping: Directly seeking to overcome stressors and reduce their impact by (a) planning, (b) suppressing competing activities (i.e., focusing on

the stressor at hand), (c) restraint coping (i.e., waiting for an appropriate time to act), and (d) seeking social support (Carver et al., 1989).

Appreciative Inquiry: An intervention that focuses on an organization's positive aspects and uniting individuals under a single positive view.

Glass Ceiling: The condition in which men hold top-level positions and women are limited in their ability to move up due to barriers that are not readily apparent.

Inclusive Climate: Workers' perception of a workplace atmosphere where everyone has a sense of belonging, is invited to participate in decisions, and feels that their input matters (Major et al., 2006).

Mentoring: A process by which a more experienced employee (a mentor) guides, advises, counsels and otherwise enhances the professional development of another employee (a protégé).

Positive Marginality: The constructive and positive use of one's minority experiences of exclusion.

Self-Fulfilling Prophecy: A phenomenon that begins with an assumption about a person or group, and evokes behavior that makes the original conception become reality.

Stereotype Threat: The fear that an underrepresented group member experiences about confirming or reinforcing a negative stereotype about their group; it leads to impaired performance.

Increasing the Accuracy of Predictive Algorithms: A Review of Ensembles of Classifiers

INTRODUCTION

In classification learning, the learning scheme is presented with a set of classified examples from which it is expected tone can learn a way of classifying unseen examples (see Table 1).

Formally, the problem can be stated as follows: Given training data $\{(x_1, y_1)\ldots(x_n, y_n)\}$, produce a classifier h: X->Y that maps an object x ϵ X to its classification label y ϵ Y. A large number of classification techniques have been developed based on artificial intelligence (logic-based techniques, perception-based techniques) and statistics (Bayesian networks, instance-based techniques). No single learning algorithm can uniformly outperform other algorithms over all data sets.

The concept of combining classifiers is proposed as a new direction for the improvement of the performance of individual machine learning algorithms. Numerous methods have been suggested for the creation of ensembles of classifiers (Dietterich, 2000). Although, or perhaps because, many methods of ensemble creation have been proposed, there is as yet no clear picture of which method is best.

Table 1. Instances with known labels (the corresponding correct outputs)

Data in standard format					
case	Feature 1	Feature 2	...	Feature n	Class
1	xxx	x		xx	good
2	xxx	x		xx	good
3	xxx	x		xx	bad
...					...

BACKGROUND

Generally, support vector machines (SVMs; Scholkopf, Burges, & Smola, 1999) and artificial neural networks (ANNs; Mitchell, 1997) tend to perform much better when dealing with multidimensions and continuous features. In contrast, logic-based systems (e.g., decision trees [Murthy, 1998] and rule learners [Furnkranz, 1999]) tend to perform better when dealing with discrete or categorical features. For neural-network models and SVMs, a large sample size is required in order to achieve the maximum prediction accuracy whereas the naive Bayes model (Jensen, 1996) may need a relatively small data set. Most decision-tree algorithms cannot perform well with problems that require diagonal partitioning. The division of the instance space is orthogonal to the axis of one variable and parallel to all other axes. Therefore, the resulting regions after partitioning are all hyperrectangles. The ANNs and the SVMs perform well when multicolinearity is present and a nonlinear relationship exists between the input and output features.

Although training time varies according to the nature of the application task and data set, specialists generally agree on a partial ordering of the major classes of learning algorithms. For instance, lazy learning methods require zero training time because the training instance is simply stored (Aha, 1997). Naive Bayes methods also train very quickly since they require only a single pass on the data either to count frequencies (for discrete variables) or to compute the normal probability density function (for continuous variables under normality assumptions). Univariate decision trees are also reputed to be quite fast—at any rate, several orders of magnitude faster than neural networks and SVMs.

Naive Bayes methods require little storage space during both the training and classification stages: The strict minimum is the memory needed to store the prior and conditional probabilities. The basic *k*-nearest-neighbor (k-NN) algorithm

(Aha, 1997) uses a great deal of storage space for the training phase, and its execution space is at least as big as its training space. On the contrary, for all nonlazy learners, the execution space is usually much smaller than the training space since the resulting classifier is usually a highly condensed summary of the data.

There is general agreement that k-NN is very sensitive to irrelevant features: This characteristic can be explained by the way the algorithm works. In addition, the presence of irrelevant features can make neural-network training very inefficient and even impractical. Logic-based algorithms are all considered very easy to interpret, whereas neural networks and SVMs have notoriously poor interpretability. k-NN is also considered to have very poor interpretability because an unstructured collection of training instances is far from readable, especially if there are many of them.

While interpretability concerns the typical classifier generated by a learning algorithm, transparency refers to whether the principle of the method is easily understood. A particularly eloquent case is that of k-NN; while the resulting classifier is not quite interpretable, the method itself is very transparent because it appeals to the intuition of human users, who spontaneously reason in a similar manner. Similarly, naive Bayes methods are very transparent as they are easily grasped by users, like physicians, who find that probabilistic explanations replicate their way of diagnosing. Moreover, decision trees and rules are credited with high transparency.

MAIN FOCUS OF THE ARTICLE

Mechanisms that are used to build ensembles of classifiers include (a) using different subsets of training data with a single learning method, (b) using different training parameters with a single training method (e.g., using different initial weights for each neural network in an ensemble), and (c) using different learning methods.

Bagging is a method for building ensembles that uses different subsets of training data with a single learning method (Breiman, 1996). Given a training set of size *t*, bagging draws *t* random instances from the data set with replacement (i.e., using a uniform distribution). These *t* instances are learned, and this process is repeated several times. Since the draw is with replacement, usually the instances drawn will contain some duplicates and some omissions as compared to the original training set. Each cycle through the process results in one classifier. After the construction of several classifiers, taking a vote of the predictions of each classifier produces the final prediction. Another method that uses different subsets of training data with a single learning method is the boosting approach (Freund & Schapire, 1997). Boosting is similar in overall structure to bagging except that it keeps track of the performance of the learning algorithm and concentrates on instances that have not been correctly learned. Instead of choosing the *t* training instances randomly using a uniform distribution, it chooses the training instances in such a manner as to favor the instances that have not been accurately learned. After several cycles, the prediction is performed by taking a weighted vote of the predictions of each classifier, with the weights being proportional to each classifier's accuracy on the training set. AdaBoost is a practical version of the boosting approach (Freund & Schapire). A number of studies that compare AdaBoost and bagging suggest that AdaBoost and bagging have quite different operational profiles (Bauer & Kohavi, 1999; Opitz & Maclin, 1999). In general, it appears that bagging is more consistent, increasing the error of the base learner less frequently than does AdaBoost. However, AdaBoost appears to have greater average effect, leading to substantially larger error reductions than bagging on average. A number of recent studies have shown that the decomposition of a classifier's error into bias and variance terms can provide considerable insight into the prediction performance of the classifier (Bauer & Kohavi). Bias measures the contribution to error of the central tendency of the classifier when trained on different data. Variance is a measure of the contribution to error of deviations from the central tendency. Generally, bagging tends to decrease variance without unduly affecting bias (Breiman; Bauer & Kohavi). On the contrary, in empirical studies, AdaBoost appears to reduce both bias and variance (Breiman; Bauer & Kohavi). Thus, AdaBoost is more effective at reducing bias than bagging, but bagging is more effective than AdaBoost at reducing variance. The decision on limiting the number of subclassifiers is important for practical applications. To be competitive, it is important that the algorithms run in reasonable time. Quinlan (1996) used only 10 replications, while Bauer and Kohavi used 25 replications, Breiman used 50, and Freund and Schapire used 100. For both bagging and boosting, much of the reduction in error appears to have occurred after 10 to 15 classifiers. However, AdaBoost continues to measurably improve test-set error until around 25 classifiers for decision trees (Opitz & Maclin, 1999). As mentioned in Bauer and Kohavi, the main problem with boosting seems to be robustness to noise. On the contrary, they pointed out that bagging improves the accuracy in all data sets used in the experimental evaluation. MultiBoosting (Webb, 2000) is another method of the same category. It can be conceptualized as wagging committees formed by AdaBoost. Wagging is a variant of bagging: Bagging uses resampling to get the data sets for training and producing a weak hypothesis, whereas wagging uses reweighting for each training instance, pursuing the effect of bagging in a different way. Webb, in a number of experiments, showed that MultiBoost achieved greater mean error reductions than AdaBoost or bagging decision trees in both committee sizes

that were investigated (10 and 100). Another metalearner, DECORATE (diverse ensemble creation by oppositional relabeling of artificial training examples), was presented by Melville and Mooney (2003). This method uses a learner (one that provides high accuracy on the training data) to build a diverse committee. This is accomplished by adding different randomly constructed examples to the training set when building new committee members. These artificially constructed examples are given category labels that disagree with the current decision of the committee, thereby directly increasing diversity when a new classifier is trained on the augmented data and added to the committee.

There are also methods for creating ensembles that produce classifiers that disagree on their predictions. Generally, these methods focus on altering the training process in the hope that the resulting classifiers will produce different predictions. For example, neural-network techniques that have been employed include methods for training with different topologies, different initial weights, and different parameters (Mitchell, 1997). Another effective approach for the generation of a set of base classifiers is ensemble feature selection. Ensemble feature selection involves finding a set of feature subsets for the generation of the base classifiers for an ensemble with one learning algorithm. Ho (1998) has shown that the simple random selection of feature subsets may be an effective technique for ensemble feature selection. This technique is called the random subspace method (RSM). In RSM, one randomly selects $N^*<N$ features from the N-dimensional data set. By this, one obtains the N^*-dimensional random subspace of the original N-dimensional feature space. This is repeated S times so as to get S feature subsets for constructing the base classifiers. Then, one constructs classifiers in the random subspaces and aggregates them in the final integration procedure. An experiment with a systematic partition of the feature space, using nine different combination schemes, was performed by Kuncheva and Whitaker (2001), showing that there is no best combination for all situations and that there is no assurance that in all cases a classifier team will outperform the single best individual.

Voting denotes the simplest method of combining predictions from multiple classifiers (Roli, Giacinto, & Vernazza, 2001). In its simplest form, called plurality or majority voting, each classification model contributes a single vote. The collective prediction is decided by the majority of the votes; that is, the class with the most votes is the final prediction. In weighted voting, on the other hand, the classifiers have varying degrees of influence on the collective prediction, which is relative to their predictive accuracy. Each classifier is associated with a specific weight determined by its performance (e.g., accuracy, cost model) on a validation set. The final prediction is decided by summing up all weighted votes and by choosing the class with the highest aggregate. Kotsiantis and Pintelas (2004) combined the advantages of classifier fusion and dynamic selection. The algorithms that are initially used to build the ensemble are tested on a small subset of the training set and, if they have statistically worse accuracy than the most accurate algorithm, they do not participate in the final voting. Stacking (Ting & Witten, 1999) aims to improve efficiency and scalability by executing a number of learning processes and combining the collective results. The main difference between voting and stacking is that the latter combines base classifiers in a nonlinear fashion. The combining task, called a metalearner, integrates the independently computed base classifiers into a higher level classifier, a metaclassifier, by relearning the metalevel training set. This metalevel training set is created by using the base classifiers' predictions on the validation set as attribute values and the true class as the target. Ting and Witten have shown that successful stacked generalization requires the use of output class distributions rather than class predictions. In their experiments, only the MLR algorithm (a linear discriminant) was suitable for use as a Level 1 classifier. Cascade generalization (Gama & Brazdil, 2000) is another algorithm that belongs to the family of stacking algorithms. Cascade generalization uses the set of classifiers sequentially, at each step performing an extension of the original data by the insertion of new attributes. The new attributes are derived from the probability class distribution given by a base classifier. This constructive step extends the representational language for the high-level classifiers, reducing their bias. Todorovski and Dzeroski (2003) introduced meta-decision-trees (MDTs). Instead of giving a prediction, MDT leaves specify which classifier should be used to obtain a prediction. Each leaf of the MDT represents a part of the data set, which is a relative area of expertise of the base-level classifier in that leaf. MDTs can use the diversity of the base-level classifiers better than voting, thus outperforming voting schemes in terms of accuracy, especially in domains with a high diversity of errors made by base-level classifiers.

Another attempt to improve classification accuracy is the use of hybrid techniques. Lazkano and Sierra (2003) presented a hybrid classifier that combines the Bayesian network algorithm with the nearest-neighbor distance-based algorithm. The Bayesian network structure is obtained from the data and the nearest-neighbor algorithm is used in combination with the Bayesian network in the deduction phase. Wang, Yuan, Li, and Li (2004) presented flexible NBTree: a decision-tree learning algorithm in which nodes contain univariate splits as do regular decision trees, but the leaf nodes contain general naive Bayes classifiers, which is a variant of the standard naive Bayesian classifier. Zhou and Chen (2002) generated a binary hybrid decision tree according to the binary information gain ratio criterion. If attributes cannot further distinguish training examples fall-

ing into a leaf node whose diversity is beyond the diversity threshold, then the node is marked as a dummy node and a feed-forward neural network named FANNC is then trained in the instance space defined by the used attributes. Zheng and Webb (2000) proposed the application of lazy learning techniques to Bayesian induction and presented the resulting lazy Bayesian rule learning algorithm, called LBR. This algorithm can be justified by a variant of the Bayes model, which supports a weaker conditional attribute independence assumption than is required by naive Bayes. For each test example, it builds the most appropriate rule with a local naive Bayesian classifier as its consequent. Xie, Hsu, Liu, and Lee (2002) proposed a similar lazy learning algorithm: selective neighborhood-based naive Bayes (SNNB). SNNB computes different distance neighborhoods of the new input object, lazily learns multiple naive Bayes classifiers, and uses the classifier with the highest estimated accuracy to make the final decision. Domeniconi and Gunopulos (2001) combined local learning with SVMs. In this approach, an SVM is used to determine the weights of the local neighborhood instances.

FUTURE TRENDS

The key question when dealing with classification is not whether a learning algorithm is superior to others, but under which conditions a particular method can significantly outperform others on a given application problem. Metalearning is moving in this direction, trying to find functions that map data sets to algorithm performance (Kalousis & Gama, 2004). To this end, metalearning uses a set of attributes, called metaattributes, to represent the characteristics of learning tasks, and searches for the correlations between these attributes and the performance of learning algorithms. Some characteristics of learning tasks are the number of instances, the proportion of categorical attributes, the proportion of missing values, the entropy of classes, and so forth. Brazdil, Soares, and Da Costa (2003) provided an extensive list of information and statistical measures for a data set.

CONCLUSION

After a better understanding of the strengths and limitations of each method, the possibility of integrating two or more algorithms together to solve a problem should be investigated. The objective is to utilize the strengths of one method to complement the weaknesses of another. If we are only interested in the best possible classification accuracy, it might be difficult or impossible to find a single classifier that performs as well as a good ensemble of classifiers.

KEY TERMS

Artificial Neural Networks: They are nonlinear predictive models that learn through training and resemble biological neural networks in structure.

Bagging: Bagging uses different subsets of training data with a single learning method. After the construction of several classifiers, taking a vote of the predictions of each classifier produces the final prediction.

Boosting: It is similar in overall structure to bagging, except that it keeps track of the performance of the learning algorithm and concentrates on instances that have not been correctly learned.

Cascade Generalization: It uses the set of classifiers sequentially, at each step performing an extension of the original data by the insertion of new attributes.

Majority Voting: The collective prediction is decided by the majority of the votes of the classifiers; that is, the class with the most votes is the final prediction.

Rule Induction: It is the extraction of useful if-then rules from data based on statistical significance.

Stacking: Stacking integrates the independently computed base classifiers into a higher level classifier: a metaclassifier.

Indexing Techniques for Spatiotemporal Databases

INTRODUCTION

We can define as spatiotemporal any database that maintains objects with geometric properties that change over time, where usual geometric properties are the spatial position and spatial extent of an object in a specific *d*-dimensional space. The need to use spatiotemporal databases appears in a variety of applications such as intelligent transportation systems, cellular communications, and meteorology monitoring. This field of database research collaborates tightly with other research areas such as mobile telecommunications, and is harmonically integrated with other disciplines such as CAD/CAM, GIS, environmental science, and bioinformatics.

Spatiotemporal databases stand at the crossroad of two other database research areas: spatial databases (Güting, 1994; Gaede & Gunther, 1998) and temporal databases (Salzberg & Tsotras, 1999). The efficient implementation of spatiotemporal databases needs new data models and query languages and novel access structures for storing and accessing information. In Güting, Bohlen, Erwig, Jensen, Lorentzos, Schneider, and Vazirgiannis (2000) a data model and a query language capable of handling such time-dependent geometries, including those changing continuously that describe moving objects, were proposed; the basic idea was to represent time-dependent geometries as attribute data types and to provide an abstract data type extension to the traditional database data models and query languages. In that paper, it was also discussed how various temporal and spatial models could possibly be extended to be spatiotemporal models.

BASIC ALGORITHMIC TOOLS

The problem of spatiotemporal indexing is considered in the standard external memory model. In this model each disk access transfers a contiguous block of B data items in a single input/output operation (I/O). The space complexity of a data structure is measured in terms of the amount of disk blocks it uses, while the time complexity of its various operations is expressed with the number of needed I/Os. In the sequel, we let N denote the number of stored objects and let $n=N/B$ and $k=K/B$, where K denotes the size of the desired output.

R-Tree and Variants

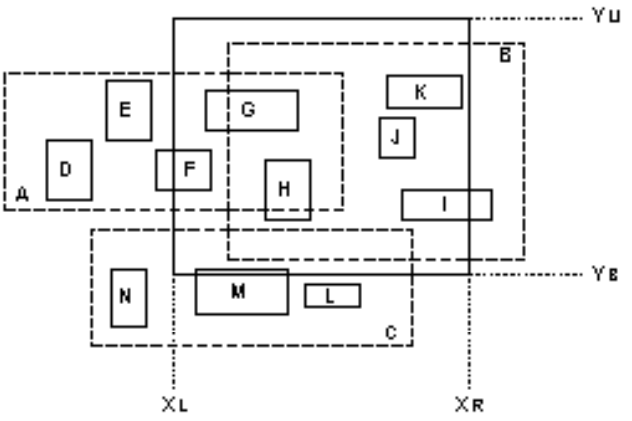
The R-tree (Guttman, 1984) is a spatial access method; it stores objects in R^d with a spatial position and extent and is able to answer various geometric queries. In a nutshell, it is an hierarchical structure, resembling a classical B-tree, where every node has size equal to the disk block size, all objects are stored at the leaves of the structure, and all leaves are at the same distance from the root. Each node v of the R-tree corresponds to a d-dimensional rectangle Rect(v); the rectangle corresponding to a leaf is the minimum rectangle that encloses the objects stored at the leaf, while the rectangle

corresponding to an internal node encloses all the rectangles corresponding to its children. Moreover, every node contains between m and M children where m, M are parameters whose value depends on the block size; this means that the height of an R-tree is $O(\log_m n)$. Searching in the R-tree is done in a similar way as in the B-tree, where for both point and region queries, the paths where rectangles intersect with the query object are followed. In contrast to the B-tree, the R-tree does not guarantee that traversing a path of the tree is enough when searching for an object, as the bounding rectangles of entries in the same nodes may overlap one another. In the worst case, the search algorithm may have to visit all nodes, in order to answer a query. See, for example, the 2-dimensional R-tree of Figure 1 that stores 11 rectangles (n=11) with block size B=4. For the given axis-parallel range query (x_L, x_R, y_B, y_U) of the figure below, the search algorithm may have to visit all nodes in order to determine the K=7 rectangles that are enclosed or intersected by the query rectangle.

The search efficiency of the R-tree could be improved if the spatial overlap between sibling nodes could be minimized. There exists a set of heuristics to achieve that, leading to two known variants of the R-tree: the R+-trees (Sellis, Roussopoulos, & Faloutsos, 1987) and the R*-trees (Beckmann, Kriegel, Schneider, & Seeger, 1990). R+-trees do not allow the subspaces of each internal node to overlap with the subspace of its sibling nodes. However, this clipping of the subspaces has, as an immediate consequence, the creation of much more subspaces and thus much more leaves. Also an object is assigned to more than one leaf causing a much larger tree structure. On the other hand, R*-trees embed maintenance algorithms that aim at minimizing the following penalty metrics: (i) the area and the perimeter of each bounding rectangles, (ii) the overlap between two sibling bounding rectangles, and (iii) the distance between the centroid of a bounding rectangle and that of the node containing it. As discussed in the original publication, the minimization of these metrics decreases the probability that a node is accessed by a range query. Experimental studies show that R*-trees can achieve 50% better query times from the common R-trees.

The interested reader should consult Gaede and Gunther (1998) and Manolopoulos, Theodoridis, and Tsotras (2000) for more information concerning the aforementioned structures.

Figure 1. An example of an R-tree



Partition Trees

Partition trees are data structures that can handle simplex range searching queries and are based on the idea of simplicial partitions. A simplicial partition for a set S of N points in R^d is a collection of pairs $P(S) = \{(S_1, s_1\}, (S_2, s_2), \ldots, (S_m, s_m)\}$ where the S_i's are disjoint subsets of S whose union is S and s_i is a simplex containing S_i. The crossing number of $P(S)$ is the maximum number of simplices in $\{s_1, \ldots, s_m\}$ that can be crossed by an arbitrary hyperplane. Matousek (1992) has proved that for any set S and given parameter r, $r \leq N$, it is possible to construct a simplicial partition of size r for S, whose crossing number is $O(r^{1-1/d})$, in $O(N^{1+\varepsilon})$ time, for any $\varepsilon>0$. Using this theorem recursively, it is possible to come up with a partition tree T for the set S. The root node has $O(r)$ children, which correspond to the simplices of the initial partition and are the roots of recursively defined partition trees for the simplicial partitions. A query with a given query simplex can be answered by starting at the root of T and descending towards the leaves, based on the relation between the query simplex and the simplices in the partitions of the various nodes. In Agarwal, Arge, Erickson, Franciosa, and Vitter (2000), they described an external memory version of static partition trees that needed $O(n)$ disk blocks, so that d-dimensional simplex queries could be answered in $O(n^{1-1/d+\varepsilon}+k)$ I/O s.

INDEXING TECHNIQUES

Research on spatiotemporal access methods has mainly focused on two aspects: (i) storage and retrieval of historical information concerning the positions of the moving points, and (ii) prediction of future positions. There are two kinds of spatiotemporal databases: those that deal with *discrete* and those that deal with *continuous* movements. In the sequel, we will briefly refer to discrete spatiotemporal databases, and we will mainly focus our presentation on continuous spatiotemporal databases.

A sequence of spatiotemporal movements in a discrete environment can be considered to be an ordered sequence of database snapshots of the object positions/extents taken at time instants $t_1<t_2<\ldots$, with each time instant denoting the moment where a change took place. By taking this point of view then it could be possible to handle the index-

ing problems in such environments by suitably extending indexing techniques from the area of temporal (Salzberg & Tsotras, 1999) and of spatial databases (Gaede & Gunther, 1998); in Manolopoulos, Theodoridis, and Tsotras (2000), it is elegantly exposed how these indexing techniques can be generalized in order to handle efficiently queries in a discrete spatiotemporal environment.

In the continuous spatiotemporal environment there exists a plethora of efficient data structures (Agarwal, Arge, & Erickson, 2003; Kollios, Gunopulos, & Tsotras, 1999; Patel, Chen, & Chakka, 2004; Saltenis, & Jensen, 2002; Saltenis, Jensen, Leutenegger, & Lopez , 2000; Tao, Papadias, & Sun, 2003). The common thrust behind these structures lies in the idea of abstracting each object's position as a continuous function *f(t)* of time and updating the database whenever the parameters of the function change; accordingly an object is modeled as a pair consisted of its extent at a reference time (design parameter) and of its motion vector.

The basic queries supported by these structures are: (Q_1) given an orthogonal range and a time stamp *t*, report the objects that lie in the query range at time *t*, (Q_2) given an orthogonal range and two time stamps t_1 , t_2 report all the objects that lie in the query range at any time instant between t_1, t_2, (Q_3) given a query point *q*, a constant δ>0 and a time stamp *t*, report a δ-approximate neighbor of *p* at this timestamp (δ designates the degree of the approximation).

We can partition the most prominent of the aforementioned indexing structures into two broad categories; those that are based on geometric duality and represent the stored objects in the dual space (Agarwal, Arge, & Erickson, 2003; Kollios, Gunopulos, & Tsotras, 1999; Patel, Chen, & Chakka, 2004) and those that leave the original representation intact indexing data in their native *d*-dimensional space (Saltenis, Jensen, Leutenegger, & Lopez, 2000; Saltenis, & Jensen, 2002; Tao, Papadias, & Sun, 2003). The geometric duality transformation is a tool heavily used in the computational geometry literature that maps hyper-planes in R^d to points and vice-versa. In general, the straightforward approach of representing an object moving on an 1-dimensional line is by plotting the trajectories as lines in the time-location (*t*,*y*) plane (same for (*t*,*x*) plane). The equation describing each line is $y(t)=ut+a$ where *u* is the slope (velocity vector in this case) and *a* is the intercept (initial position vector in this case), which is computed using the motion information (Figure 2). Based on this setting, the query is expressed as the 2-dimensional interval $[(y_{1q},y_{2q}),(t_{1q},t_{2q})]$, and it reports the objects that correspond to the lines intersecting the query rectangle.

For example, one dual transform for mapping the line with equation $y(t)=ut+a$ to a point in R^2 is by using the dual plane where one axis represents the slope of an object's trajectory (i.e. velocity) and the other axis its intercept. Thus we have the dual point *(u,a)*. Accordingly, the 1-d query $[(y_{1q},y_{2q}),(t_{1q},t_{2q})]$ becomes a polygon in the dual space (see Figure 3).

In Kollios, Gunopulos, and Tsotras (1999) a set of indexing techniques were presented supporting operations Q_1, Q_2 for objects in the one- and two-dimensional Euclidean space. For the one-dimensional case the application of duality transformation makes the problem of indexing moving objects equivalent to the simplex range searching problem in two dimensions which is solved by applying the external memory partition tree of Agarwal, Arge, Erickson, Franciosa, and Vitter (2000); this tree uses O(*n*) space, answers queries in $O(n^{1/2+\varepsilon}+k)$ I/Os and handles updates in O(log*N*) I/Os. Partition trees, though having a guaranteed worst case performance are generally considered non-practical since they entail large hidden factors. Hence, in (Kollios, Gunopulos, & Tsotras, 1999) two more structures are presented: one based on k-d-trees and a more complex one based on B+-trees. Both these structures use linear space and work well in the average case. Moreover they extend their results in the two-dimensional case for two distinct versions of the problem; in the first version the objects are allowed

Figure 2. Trajectories and query in (t,y) plane

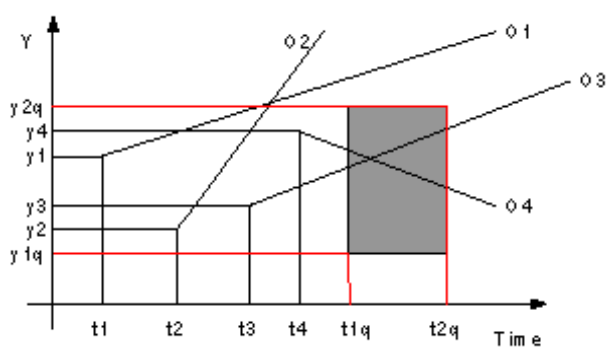


Figure 3. Query on the dual plane

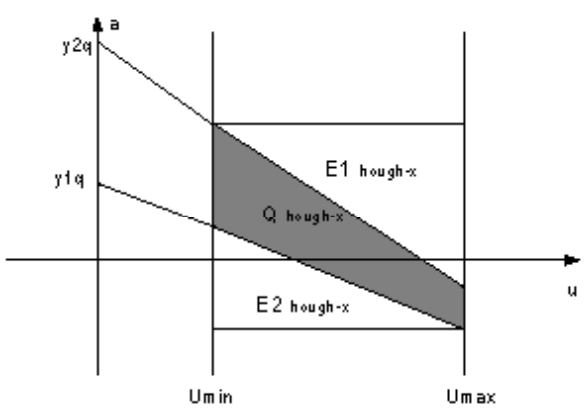

to move on a network of one-dimensional routes while the second version allows arbitrary movements. The first version, reduces to a number of one-dimensional subproblems that use the previously described structures, while the second is equivalent (through geometric duality) to simplex range queries in R^3, which can be solved in $O(n^{2/3}+k)$ I/Os with the use of external memory partition trees.

In Agarwal, Arge, Erickson, Franciosa, and Vitter (2000), results were refined and improved. In particular, a new version of partition tree was introduced that could handle questions Q_1, Q_2 for objects in the plane in $O(n)$ space, $O(n^{1/2+e}+k)$ query time, and $O(\log_B n)$ expected amortized update cost; the results apply also for higher dimensional spaces slowing down only the update time (it becomes $O(\log^2_B n)$ I/Os). If it is assumed that the queries arrive in chronological order then the query time for problem Q_1 can be further reduced to $O(\log^2_B n/\log_B \log_B n)$I/Os; this is achieved by employing the kinetic data structures framework (Basch, Guibas, & Hershberger, 1997) at external range trees. Moreover by combining multiversion kinetic data structures with partition trees, they develop an indexing scheme having a query time that is small for near-future queries and is increasing for queries that are far-away, without exceeding the bound of $O(n^{1/2+\varepsilon}+k)$ I/Os. Finally an indexing technique is described for handling δ-approximate queries; the query time is $Ï(n^{1/2+\varepsilon}/\sqrt{\delta})$, the expected update time is $O(\log^2_B n/\sqrt{\delta})$ and the space is $O(n/\sqrt{\delta})$ disk blocks.

The TPR tree was introduced in Saltenis, Jensen, Leutenegger, and Lopez (2000) and is basically a generalization of the R*-tree data structure in order to store and access linearly moving objects. The leaves of the structure store pairs with the position of the moving point and the moving point, while internal nodes store pointers to subtrees with associated rectangles that minimally bound all moving points or other rectangles in the subtree. The difference with the classical R*-tree lies in the fact that the bounding rectangles are time parameterized (their coordinates are functions of time), and it is considered that a time parameterized rectangle bounds all enclosed points or rectangles at all times not earlier than current time. The algorithms for search and update operations in the TPR tree are straightforward generalizations of the respective algorithms in the R*-tree, moreover the various kinds of spatiotemporal queries can be handled uniformly in one-, two-, and three-dimensional spaces.

The TPR-tree constituted the base structure for further developments in the area. Saltenis and Jensen in (Saltenis, & Jensen 2001) presented the R^{EXP}-tree, an R*-based access method that building on the TPR –tree handles efficiently moving objects that have the extra property that their positions may expire after specific time periods; the problem is adequately motivated from Internet-service scenarios, employed by standards such as WAP or Bluetooth, where objects that have not reported their position for a specific time period are considered to have been expired.

In Tao, Papadias, and Sun (2003), an extension to the TPR-tree was proposed, the so called TPR*-tree, that for some scientific publications (Tao, Faloutsos, Papadias, & Liu, 2004) is considered as the most efficient spatiotemporal structure. The crucial improvement (in comparison to the TPR-tree) is in the update operations, where it is shown that local optimization criteria (at each tree node) may degrade seriously the performance of the structure and more particularly in the use of update rules that are based on global optimization criteria. Moreover the authors propose a novel probabilistic cost model for validating the performance of a spatiotemporal index and analyze with this model the optimal performance for any data-partition index.

Finally, in Patel, Chen, and Chakka (2004), the STRIPES index is proposed. STRIPES is based on the application of the duality transformation and it employs disjoint regular space partitions (disk based quadtrees [Gaede, & Gunther, 1998]); the authors claim, though the use of a series of implementations, that STRIPES outperforms TPR*-trees for both update and query operations.

EXTENSIONS

The previously described methods have as common characteristic that the movement of the objects follows a linear function. While this assumption does not hold (obviously) for every movement that needs to be practically handled, this linear model is often justified in two ways: (i) its adoption avoids the complications arising from arbitrary motion patterns and permits the handling of several problems that otherwise could be intractable, and (ii) it is possible, through the effective use of piecewise linear segments to approximate (virtually, to arbitrary precision) any curve. These two arguments are however only partially true since it is possible to construct examples where stored objects follow motion patterns that cannot possibly be represented with the use of linear motion patterns. In order to overcome these problems, in Tao, Faloutsos, Papadias, and Liu (2004), a general framework was introduced, that can handle effectively arbitrary motion types. This general framework contains three important contributions to handle the specific problems: (i) a general client-server architecture for objects with unknown and possibly variable movement types, where a filter refinement mechanism is employed so that candidate objects are contacted for more refined information, (ii) an elegant technique, for expressing in a concise format, the so-called recursive motion function, a large number of movement types, and (iii) an access method, the STP-tree (spatiotemporal prediction tree), for indexing the expected trajectories (at the server). The STP-tree constitutes a generalization of the previously mentioned data structures in order to handle arbitrary polynomial functions; both construction and update algorithms follow closely their counterparts in

TPR and TPR* trees. Finally, the contributions of the presented framework are validated through an extensive set of experimental results.

FUTURE TRENDS

Concerning future trends, since partition trees are considered impractical (due to the large constant factors involved) then various research teams focus on presenting improved variants of the R-tree structure. However, R-trees, due to their overlapping nature, can cause backtracking in search, and they may not be best suited for every application so there is need for more efficient data structures. Finally, another interesting problem (Roddick, Egenhofer, Hoel, Papadias, & Salzberg, 2004) lies in the fact that in quite a few of the latest spatiotemporal applications (i.e., sensor networks) data arrive in the form of data streams; therefore in such applications the indexing techniques should aim at maintaining approximate summarized information, and handle queries effectively using as guide such approximations.

CONCLUSION

In this article, we have presented a set of indexing techniques for spatiotemporal databases; the various presented structures have various advantages and disadvantages and the choice of a particular structure depends on the application, the hardware configuration, and the range of required operations. The use of these structures is motivated by real-life applications such as intelligent transportation systems, meteorology monitoring, and mobile computing.

KEY TERMS

Bitemporal Databases: Temporal databases that support both the valid and the transaction time.

Database: A collection of interrelated persistent information stored and organized as a unit in order to serve a specific purpose and satisfy the demands of a set of users. A database can be considered to be an electronic filling system stored on mass-storage systems such as magnetic tape or disk. A database is one component of a database management system.

Data Structures: A collection of methods for storing and organizing sets of data in order to facilitate access to them. More formally data structures are concise implementations of abstract data types, where an abstract data type is a set of objects together with a collection of operations on the elements of the set.

Secondary Memory Algorithms: Algorithms for handling information on secondary media, like hard disks, CD-ROMs, and so forth, and trying to minimize the number of accesses on them.

Spatial Database: A database storing and handling objects that are equipped with spatial information (a position and an extent).

Spatiotemporal Database: A database that maintains objects with geometric properties that change over time, where usual geometric properties are the spatial position and spatial extent of the object in a specific d-dimensional space.

Temporal Database: A database that stores and handles objects that are equipped with built-in time information. These databases are components of database management systems that should offer a suitable temporal data model and a temporal version of a structured query language.

Transaction Time Databases: Temporal databases, the supported time dimension of which is the transaction time dimension that is the time when a fact is stored in the database. Transaction time is consistent with the transaction serialization order.

Valid Time Databases: Temporal databases, the supported time dimension of which is the valid time dimension that is the time when a fact becomes valid (effective) with respect to the real world.

INTRODUCTION

Information retrieval is the computational discipline that deals with the efficient representation, organization, and access to information objects that represent natural language texts (Baeza-Yates, & Ribeiro-Neto, 1999; Salton & McGill, 1983; Witten, Moûat, & Bell, 1999). A crucial subproblem in the information retrieval area is the design and implementation of efficient data structures and algorithms for indexing and searching information objects that are vaguely described. In this article, we are going to present the latest developments in the indexing area by giving special emphasis to: data structures and algorithmic techniques for string manipulation, space efficient implementations, and compression techniques for efficient storage of information objects.

The aforementioned problems appear in a series of applications as digital libraries, molecular sequence databases (DNA sequences, protein databases [Gusûeld, 1997)], implementation of Web search engines, web mining and information filtering.

BACKGROUND

Dictionary Data Structures

The dictionary data structure stores a set S of n elements in order to support the operations of insertion, deletion, and the test of membership. A basic criterion for categorizing dictionary data structures is whether only comparisons are used, or the representation of elements for guiding the search is also employed. Typical representatives of the former group are *search trees* and of the latter *tries* and *hashing*. Search trees need O(log$n$) update/search time and O(n) space and the most prominent examples of them are: AVL-trees, red-black trees, (α,b)-trees, BB[α]-trees and Weight Balanced B-trees (Arge, & Vitter, 1996; Cormen, Leiserson, & Rivest, 1990; Mehlhorn, 1984). On the other hand, *tries* and *hashing* structures (Cormen, Leiserson, & Rivest, 1990; Czegh, Havas, & Majewski, 1997; Pagh, 2002) try to use the representation (for example, the value of the element written as a string of digits or the value itself), to compute directly the element's position in system's memory. The time and space complexities of these structures generally vary; however, it should be mentioned that a lately developed structure (Anderson & Thorup, 2001) answers both search and update operations in $O(\sqrt{\log n / \log\log n})$ time. This structure is also able to retrieve the largest element in the stored set smaller than a *query* element (*predecessor* query).

Finding Occurrences of Patterns

The string matching (or pattern matching) problem is one of the most frequently encountered and studied problems in the area of system/algorithm design. In this problem, we are searching for the occurrences of a pattern P in a sequence of symbols T. The naive $O(|P||T|)$ algorithm aligns the pattern at each one of the O($|T|$) possible positions of the sequence and executes O($|P|$) comparisons; however, there exist elegant, though complex, algorithms whose overall time complexity is linear, that is, $O(|P|+ |T|)$. The most known linear time algorithms that achieve that are Knuth-Morris-Pratt (Knuth, Morris, & Pratt, 1977) and variants of the Boyer-Moore (Boyer & Moore, 1977) algorithm. For the case that we are searching for a set of patterns in the sequence, the Aho-Corasick automaton (Aho & Corasick, 1975) can be used. This automaton accepts all the patterns of the set and can be constructed in time linear to the sum of the lengths of them. Running the automaton with the characters of T, all the occurrences of the patterns are reported in $O(|T|)$ time.

On most of the modern applications, the patterns arrive in an on line manner and the $O(|T|+ |P|)$ computational

time is prohibitive; there is need for indexing structures (indices) that can perform the queries as closer as possible to $O(|P|)$ computational time, assuming that the text has been preprocessed *once*. The indices that try to satisfy this demand are divided in two categories: the *word-based* (or *keyword-based*) indices, which have been designed for sequences of symbols that can be divided in tokens/words, and the *full-text* (or *sequential scan*) indices, where the previous feature does not hold and the strings involved are non-tokenizable.

TEXT AND STRING DATA STRUCTURES

Word Based Indices

The most commonly used indexing structures in this category are *inverted files, signature files* and *bitmaps*. An inverted file consists of two parts: a structure for storing the set of all different words in the text and, for each such word, a list of the text positions where the word appearances are stored. Signature files are term-oriented structured based on hashing while bitmaps represent each document as a bit vector having length equal to the size of the lexicon. In typical applications compressed inverted files are considered to be superior to both signature files and bitmaps (Faloutsos, 1985; Zobel, Moffat, & Ramamohanarao, 1998).

More analytically, consider a document collection and a lexicon containing the terms that appear in the documents of the collection. An inverted file consists of a search structure containing all the distinct terms that appear in the lexicon and, for each distinct term, a list termed inverted (or postings) list storing the identifiers (usually integer numbers starting from 1) of the documents containing the term. The search structure can be implemented as a search tree or a hashing structure, and queries are evaluated by using the search structure to find the relevant terms, fetching the inverted lists for the corresponding terms, and then intersecting them for conjunctive queries or merging them for disjunctive queries. There are many algorithms for constructing inverted files while their performance can be significantly improved by employing compression techniques for representing the postings lists. The interested reader should find relevant material in Witten, Moffat, and Bell (1999) and Zobel, Moffat, and Ramamohanarao (1998).

On the other hand, in the signature file method, all the documents in the collection are stored sequentially; each document is hashed (mapped to) a distinct signature and all the signatures are stored in a signature file.

Finally, in bitmaps for every term in the lexicon a bit-vector is stored, each bit corresponding to a document, a bit with value 1 means that the term appears somewhere in the document; otherwise it has value 0.

Full Text Indices

In general, these indices are more powerful from word-based indices since they answer a wider range of queries like arbitrary substring queries, motifs, and repetitions selection queries, and they have the ability to index non-tokenizable strings like biological sequences. The price for these extra capabilities is larger space consumption. The common feature of full-text indices is that they organize in a proper order (frequently lexicographic), all the suffixes of the sequence.

Static Indices: For the setting that texts do not underlie on updates (insertions/deletions of characters), there are many classical confrontations coming quite a few years ago. The most famous data structure of this type is the *suffix tree*. A suffix tree of a string T is a compacted trie of all suffixes of T. The suffix tree has linear, to the length $|T|$ of the string, construction time. For bounded alphabets, there exist the algorithms of Weiner (1973), McCreight (1976) and Ukkonen (1995) and, for arbitrary large alphabets, the algorithm of Farach (1997). The main counterparts of suffix trees are *suffix arrays*. A suffix array of a string T is an array that indicates the lexicographic order of all suffixes of T. Suffix arrays were proposed in Manber, and Myers (1993), where they described an $O(|T|log|T|)$ construction time algorithm and how pattern matching queries can be performed in $O(|P|+log|T|)$ time, assuming that the longest common prefixes among each pair of adjacent suffixes in the array have been precomputed. Later on, there were proposed three linear time construction algorithms in Karkkainen and Sanders (2002); Ko, and Aluru (2003); Kim, Sim, Park, and Park (2003). Suffix arrays, though having a slowdown term, are usually preferable from suffix trees due to their smaller space requirements. The interested reader should refer to Grossi, and Italiano (1993) and Gusfield (1997) to familiarize with the numerous applications of the aforementioned structures.

Dynamic Indices: In many applications, for example, text editors, log files and so forth, the sequences that underlie pattern matching queries change dynamically by insertions or deletions of symbols in arbitrary places. For this setting, we would like to answer the queries as closer as possible to the desirable $O(|P|)$ time without preprocessing the whole sequence from the start and paying $O(|T|)$ computational time. The static structures from the previous subsection cannot achieve that since even a small change can modify all the suffixes and enforce a full reorganization of them. In Gu, Farach, and Pagli (1994), Ferragina (1994), Ferragina, and Grossi (1995a), Sahinalp, and Vishkin (1996), Ferragina and Grossi (1995b), Alstrup, Brodal, and Rauhe (2000), the researchers developed various indices, trying to keep the

update computation cost as closer to the size of the changed (in number of characters) text and the query time closer to the linear bound to the length of pattern. More specifically, the more efficient of these structures are described in Ferragina and Grossi (1995b); Alstrup, Brodal, and Rauhe (2000). Both solutions are quite complex and use a large number of algorithmic techniques from the areas of data structures and stringology. In Ferragina and Grossi, (1995b), an algorithm was presented than needed $O(x+\sqrt{|T|})$ time for inserting/deleting a string of length x in T and $O(|P|+\alpha)$ computational time for retrieving $O(a)$ occurrences. They propose a novel technique called *balanced partition* that keeps the indexed text in equal chunks. Also, they make heavy use of properties of the periods of a string to detect the occurrences of the pattern in the above bounds. In Alstrup, Brodal, and Rauhe (2000), another algorithm was proposed with $O(\log^2|T|\text{loglog}|T|\log^*|T|)$ time for insertions/deletions of characters and $O(|P|+\log|T|\text{loglog}|T|+\alpha)$ time for retrieving $O(a)$ occurrences. They combine a deterministic signature encoding technique originally described in Mehlhorn, K., Sundar R., and Uhrig Christian (1997), and a transformation of the pattern matching problem to the range searching problem to achieve the above bounds.

Another interesting problem in the dynamic setting is when we have a set of patterns that changes dynamically, when inserting or deleting a pattern. The solution of Aho-Corasik automaton is not efficient for this setting because it has to be reconstructed from the start. In Sahinalp and Vishkin (1996), an optimal solution was presented that needed $O(|P|)$ time for inserting/deleting a pattern P from the set and $O(|T|+\alpha)$ time for finding all $O(a)$ occurrences of the patterns in T.

SPACE EFFICIENT IMPLEMENTATIONS COMPRESSION

The design of efficient text compression algorithms is already a very rich area, and most text compression methods can be placed in one of two classes: *symbolwise* methods and *dictionary* methods. Symbolwise methods work by first estimating the probability of appearance of each symbol (character) in the text and then coding each symbol so that frequent characters take codewords with smaller length and rare characters take codewords with larger length. The prominent symbolwise compression algorithms are *Huffman coding* and *arithmetic coding*. On the other hand, dictionary methods achieve compression by replacing groups of consecutive characters by an index in a dictionary. The main such technique is Ziv Lempel coding and its various variants (LZ77, LZ78, LZW). For more details concerning text compression techniques, the interested reader should consult Bell, Cleary, and Witten (1990), Salomon (1992), and Witten, Moffat, and Bell (1999).

COMPRESSED STRING STRUCTURES

Full-text indices, although having a very wide repertoire of applications, fall short in space occupation issues. They are many times larger than inverted files that have sub-linear size. Towards improving the space consumption, there have been proposed structures with succinct representations and self-indexing structures. Self-indexing structures are indices that encapsulate in them the information so there is no need to have aside a copy of data. The first step towards compressed string structures was made by Grossi and Vitter in (2000), where they introduced the *compressed suffix arrays*. Compressed suffix arrays use $\Theta(|T|)$ bits and answer the pattern matching query in $O(|P|/\log|T| + \alpha\log^c|T|)$ time where α is the size of the answer and c is a constant. Sadakane (2003) made compressed suffix arrays self-indexed.

Known compressed string indices, besides the one reported in Grossi and Vitter (2000), are the *opportunistic data structures* and the *LZ-index*. The notion of an opportunistic data structure was introduced in Ferragina and Manzini (2000) (see also Ferragina & Manzini, 2005), it is based on the exploitation of an elegant transform, the Burrows Wheeler transform (Burrows & Wheeler, 1994) and the size of the proposed index depends on the entropy of the text. The LZ-index was proposed in Navarro (2004) and is based on a combination of Ziv-Lempel encoding techniques and tries and occupies $4|T|(1+o(1))$ bits, while answering pattern matching queries in $O(|P|^2\log(|P||\Sigma|)+(|P|+\alpha)\log|T|)$ time, where α is the size of the answer and Σ is the alphabet. Finally, more recent developments can be looked at in Cormode and Muthukrishnan (2005), Ferragina, Giancarlo, Manzini, and Sciortino (2005), and Ferragina, Manzini, Mäkinen, and Navarro (2004).

DATA STRUCTURES IN SECONDARY MEMORY

The most common data structure for handling the dictionary problem on disk is the B-tree (Bayer & McCreight, 1977) and its variants. The B-tree is a tree structure where the degree of each node is required to be $\Theta(B)$ with B being the size of the disk block. A quite powerful variant is the weight balanced B-tree (Arge & Vitter, 1996) that has the property that the weight (the number of nodes in its subtree) of any node at level h is $\Theta(c^h)$, where c denotes a fixed parameter. In a wide range of applications, the weight balanced B-tree can schedule the rebalancings in an amortized way with only

O(1) disk I/Os. The interested reader should refer to Vitter (2001) for a complete presentation of several kinds of data structures on secondary memory including spatial, graph, and hashing data structures.

Suffix trees and suffix arrays, when placed on secondary storage devices, perform very poorly. They need a large number of disk I/Os for their construction and a worst case number of $O(|P|)$ I/Os for answering the pattern matching query. This happens due to the unbalanced nature of the suffix tree, the possibility of large nodes when the alphabet is bigger than the disk block size *B,* and the need to make more access to disk when we cross an edge. The suffix arrays, which perform a binary search upon the array, perform poorly too because of the need for non-local movements.

There are two general methodologies to overcome these difficulties. The first one tries to stuff as much as possible information in main memory in order to perform a draft search in main memory and a more coarse in a small range of information in the secondary memory. This methodology has been followed in Baeza-Yates, Barbosa, and Ziviani (1996). The other one combines the classic B-tree with the plain full-text structures and every internal node is organized like a Patricia tree or a suffix array. Following this approach, Ferragina and Grossi (1999) managed to answer the pattern matching queries in $O(|P|/B+\log_B|T|)$ I/Os with a novel data structure the String *B*-tree.

FUTURE TRENDS

As the handling of large amounts of information come along with all modern applications, the algorithmic area exhibited in this article is going to be stimulated more and grow constructively in the coming years. There is a number of very interesting problems under theoretic and practical perspective to be solved yet. A listing of prospective research problems is the following: (1) more efficient processing of compressed sequences and of compressed text indexing and adaptation of the methods to biological sequences as well as semi structured data and general (hyper) linked data, (2) design of new succinct data structures and implicit data structures, and (3) provision of software for new types of compressed matching and corresponding methods of compression.

CONCLUSION

In this article, we presented the latest developments in the text indexing area by giving special emphasis to string algorithms, secondary memory indices, and space efficient implementations. The areas covered were: data structures and algorithmic techniques for string manipulation, space efficient implementations, and compression techniques. Especially the area of compressed indexing structures is expected to be the central focus for future research as the amount of data to be handled continuously increases, and it is related to the areas of large-scale processing, network communication, and multimedia. This article can hold as a survey for indexing techniques used in text manipulation that can be useful for both academic researchers and practitioners (software developers) that implement indexing structures for various kinds of information systems.

KEY TERMS

BioInformatics: A scientific field that stands at the crossroads of Biology and Informatics, and uses techniques from informatics, computer science, applied mathematics, and statistics to solve biological problems. A synonym term is computational biology, but whereas computational biology deals mainly with the scientific filled bioinformatics is usually used to indicate the infrastructure part.

Compression: The process of encoding information Maintain using fewer information units than a more obvious representation would use, by employing specific encoding schemes that try to exploit the inherent entropy and/or redundancy of the input.

Database: A collection of interrelated persistent information stored and organized as a unit in order to serve a specific purpose and satisfy the demands of a set of users. A database can be considered to be an electronic filling system stored on mass-storage systems such as magnetic tape or disk. A database is one component of a database management system.

Data Structures: A collection of methods for storing and organizing sets of data in order to facilitate access to them. More formally, data structures are concise implementations of abstract data types, where an abstract data type is a set of objects together with a collection of operations on the elements of the set.

Information Retrieval: The scientific discipline that deals with the representation, organization, storage, and maintenance of information objects and in particular textual objects. The representation and organization of the information items should provide the user with easy access to the relevant information and satisfy the user's various information needs.

Secondary Memory Algorithms: Algorithms for handling information on secondary media, like hard disks, CD-ROMs, etc., and try to minimize the number of page accesses in them.

String: A sequence of symbols drawn from an alphabet; differently, it is a series of alphanumeric characters or a series of keywords used to characterize an information object.

World Wide Web: A distributed hypertext-based information system that operates over the Internet and permits the easy access to available information by employing a special software called a "Web browser".

Indicators and Measures of E-Government

Francesco Amoretti
University of Salerno, Italy

Fortunato Musella
University of Naples Federico II, Italy

INTRODUCTION

Although the question of measurement is crucial when defining any concept, little attention has been devoted to a comprehensive view of information and communication technologies (ICTs) applications, spanning qualitative and quantitative assessments.

Due to the lack of a clear definition of e-government, many differences can be noted in the way in which digital policies have been interpreted by academics and practitioners. Coined by the U.S. programme for reinventing government under the Clinton administration (*National Performance Review)*, the term e-government refers to a public sector reorganisation which aims at increasing the efficiency of the public administration and reducing its budget through the use of new technologies. In the words of Douglas Holmes (2001), e-government is "the use of information technology, in particular the Internet, to deliver public services in a much more convenient, customer oriented, cost effective and altogether different and better way. It affects an agency's dealing with citizens, business and other public agencies as well as its internal business processes and employees" (p. 2).

Yet many definitions go beyond the role of e-government in improving the provision of public services. Indeed, the label e-government supports other definitions, not necessarily limited to the computerisation of the public administration (Osborne & Gaebler, 1992). The concept of e-government seems to contain both the redesigning of public services system and a wider transformation of the relationship between private and public actors, so that the restructuring of public administration–influenced by the ideal of a new public management–is combined with the renewal of the democratic decision-making process. Digital policies are presumed to be a key element in improving online service quality and other factors, casting a new role for the citizen-costumer.

At the same time, although e-government is becoming a catch-all concept, from an analytical point of view, official reports produced by international actors show a significant convergence in the way in which this is evaluated and measured. Diffusion of e-government practices are often closely related, and limited, to features of public administration Web sites, with reference to dimensions of openness and interactivity (La Porte, Demchak, & De Jong, 2002). Other studies focus exclusively on how citizens and businesses *perceive* the quality of public e-service, with reference to customer satisfaction, benefits conceived in terms of value and utility of services offered and opportunity of use as strategic factors for performance efficacy and efficiency (Graafland-Essers & Ettedgui, 2003; Stowers, 2004). Only recently a new approach has taken shape, which concentrates more attention on socio-political aspects of the intensive use of new technologies.

BACKGROUND

It can be assumed that measurement is a relevant component of any form of rational decision-making, acting as a mechanism for improving allocative decisions and technical efficiency (Townley, 2005). However, only recently has performance evaluation become a central part of the activity of the public administration.

The increasing interest in the measurement of government activities goes back to the second half of the 20th century, and is strongly related to the growth of public sector expenditure. It was a product of the more general turn to "planning," a key element during the period in question (Boivard, 2005). In the 1980s, the introduction of market principles in public bureaucracies, the process of privatisation, the contracting out of public services and their management though performance contracts gave significant momentum to evaluation.

This move toward performance measurement represented one of the most important issues within the dominant management philosophy, which has sought to modernise the public administration over the last two decades in line with the so-called "new public management" (Schedler & Proeller, 2000). In its attempts to render public services more efficient and to downsize government activities, the resulting wave of public sector reforms has focused greater attention on the outcomes of public activity, emphasising output indicators in reporting administrative performance. Although technical devices have often been presented as a "transparent snapshot of activities," it is clear that they reflect a broader range of political considerations. The importance given to outcomes of government activity has accompanied state restructuring in favour of an increasing market component to public sector delivery.

As part of the "reinventing government" programme, strategic applications of new technologies for the renewal and innovation of public administration has produced several approaches to the evaluation of digital policies. As Jane Fountain (2001) puts it, "applying performance measures is essential to evaluate whether e-government is cost efficient, is serving stakeholders, and is being used effectively by government agencies, staff, citizens, and businesses" (p. 41).

This heightened attention to the question of measurement has led to the conclusion that e-government represents a very complex and multidimensional issue. At a first stage, e-government evaluation concerns the value of ICT investment, that is, the relationship between the costs incurred for the acquisition and introduction of new technologies and the gains made in terms of better management. Indeed, e-government assessments may consider a wide range of variables, including the type of technology, management, as well as organisational and legal issues (Eddowes, 2004; Gupta & Jana, 2003).

Studies on e-government evaluation may present different perspectives: For instance, a clear difference can be noted by comparing *Strategic Value Analysis* method, focusing on organisational issues, and *Cost-Benefit Analysis*, evaluating the impact of public programmes in terms of community well-being. A more articulated idea of performance evaluation is tied to diffusion of the category of governance, which leads to interpret public activity as a negotiated process among private and public actors, rather than a managerial question. Such developments have conducted to look to the social and environmental effects of public action, because it has attempted to measure the consequences of public activity on the whole community of stakeholders rather than on a restricted group of direct service users.

Despite the number of variables effectively involved (Gil-Garcıa & Pardo, 2005), official reports, especially at the international level, seem to encounter considerable difficulties in acknowledging this complex framework of e-government evaluation.

UNPACKING E-GOVERNMENT IN AMERICAN AND EUROPEAN REPORTS

Many efforts have been made to measure the progress and impact of e-government in several countries. The reports produced by international and supranational organisations seem to converge on the following three points:

- The Web site is adopted as the unit of analysis for evaluation of e-government experiences. The way in which information is organised and provided to the citizen-user is considered a key element (Wang, Bretschneider, & Gant, 2005), with specific reference to the possibility of creating interactive systems.
- The path of e-government development seems to follow pre-established stages. Most e-government evaluation is based on a "stages model," a metaphor based on organic growth (Lee, 2007, p. 33). In this deterministic view, countries belonging to different geo-political areas are presumed to be similar in the process of e-government implementation.
- Electronic democracy is not distinct from electronic government, because forms of citizenship involvement are fostered as a direct consequence of the process of administrative restructuring (Mayer-Schönberger & Lazer, 2007). It is often argued that participation will occur when a two-way flow of communication between citizens and political institutions is created. Information provision and transaction processing are used to measure governmental responsiveness to citizens' demands.

Taking such three observations as our point of departure, common elements can be identified in a range of different official documents. A report published by the American Society for Public Administration on behalf of the United Nations, the *Global E-Government Readiness Report* (2005), singles out four goals for electronic government. As outlined in Table 1, the evolutionary relationship between electronic government and electronic democracy is presented through strictly interrelated developmental stages.

The evaluation of digital policies attempts to unify measurement of online services quality and other factors, enabling a participative relationship between citizens and political institutions. An *index of e-readiness* for the performance of public agencies is combined with an *index of e-participation* focusing on citizens' involvement. The participation framework includes several important dimensions: the quantity and quality of information on programmes, budgets, laws and regulation, and other materials dealing with key issues of public interest; e-consultation tools and procedures that encourage citizen participation in public debates; a decision-making e-process to increase citizen input and feedback about specific government decisions.

The findings of a number of European research projects also support a similar approach, stressing the centrality of e-government within the broader family of digital policies, the weak autonomy of e-democracy and the identification of a developmental pattern. Electronic government is considered an essential premise for future experiments in electronic democracy, as shown particularly at the national level. In a study produced by the European University Institute and the University of Geneva (Trechsel, Kies, Mendez, & Schmitter, 2003), focused on the qualitative analysis of 26 recent national reports, e-government infrastructures are viewed as the foundation for future experiments in e-democracy. These reports aim at evaluating the use of ICTs within European

Table 3. E-government development stages according to European Commission (Capgemini, 2006)

- *information* – data necessary to launch the procedure aimed to make public services available online;
- *one-way interaction* – a publicly-accessible Web site providing access (by download) to the paper forms needed to activate the service procedure;
- *two-way interaction* – a publicly-accessible Web site providing access to official electronic forms to obtain certain services to be compiled directly online; and
- *full electronic-case handling* – a publicly-accessible Web site providing full service management within a single Web site, including processing and delivery. No additional paperwork or procedures are necessary.

parliaments and parties, addressing four areas (Trechsel et al., 2003, p. 14). Table 2 presents the e-government goals in such report.

The study concentrates on parliament and party Web sites and on the impact of ICTs on representative institutions, mostly considered in terms of the features of Web sites. Options such as usability and communication approach are considered the main components of a working definition of e-democracy, without addressing the effects of citizens' participation on the decision-making process.

Another authoritative study of electronic government, funded by the European Commission and edited by Capgemini, *Online availability of public services: How is Europe progressing?* (Capgemini, 2006), takes into account a selection of Web sites and provides case studies from all EU member states, evaluating the online services available and their overall structure. There are few references to the political implications of the introduction of new media. The application of new technologies is appraised through a measurement table identifying four developmental stages (Capgemini, 2006, p. 7). Table 3 presents four levels of e-government implementation:

From this point of view, the percentage of public services fully available online is considered a central point, as a consequence of the assumption of the public agencies' Web site as the only–or at least the most important–unit of analysis. Moreover, the meagre attention paid to political variables in assessments of e-government may be the result of the narrow focus of most e-government initiatives on service delivery: "Projects seem to focus on the role of citizens as consumers of public services, and less on the possibilities of ICT to improve the interaction with citizens to develop new policies" (Snijkers, Rotthier, & Janssen, 2007, p. 76).

Such consumer-centricity is also evident in those studies dedicated to understanding the perceptions, attitudes and intentions of citizens in their use of digital services. Despite official reports concentrating on the *provision* rather than *usage* of public services, an important field of the literature on technology adoption regards how digital policies are perceived by users, a question not less important than economic investments in determining the success or failure of e-government initiatives (Gilbert, Balestrini, Kolsaker, & Littleboy, 2007).

FUTURE TRENDS

Future trends are likely to reveal further convergence of e-government methodologies and indicators. A new articulation of evaluation techniques regarding digital policies can also be expected, so that other analytical dimensions may be included in action plans and other official reports. As recent developments suggest, more attention will be devoted to social and political variables, especially those relating to participation.

In the first stage, the overlap between e-government and e-democracy puts emphasis on technological dimensions, frequently using the Web sites of public agencies as a measure of the progress produced by ICT applications (La Porte et al., 2002). More recently, there has been a re-evaluation of political components: Terms like e-rulemaking, e-consultation and e-participation express new conceptions and directions. The potential of new technologies is being investigated not only for boosting the efficiency of the public administration, but also in terms of their effect on democratic regimes. The category of e-governance may be considered an idea that expresses the aim of stimulating the involvement of public and private actors in a networked and horizontal political system, as well as the related and widespread concept of "good governance." This expression has begun to refer to new and more participative processes of coordination made possible or even necessary by the diffusion of online activities.

A report by the OECD (2003a, 2003b) argues that the dilemma of early thinking about e-government was that most Internet enthusiasts did not understand or care very much about political democracy. This is a position echoed too by Chadwick (2007), according to whom democratisation has represented the forgotten promise of e-government. Although online consultations integrating groups based within civil society with bureaucracies and legislatures, internal democratisation of the public sector itself, involvement of users in the design and delivery of public services and diffusion of open-source collaboration in public organisations constitute the main areas of convergence between technological revolution and the objective of improving democratic mechanisms.

During the period of 2000-2003, front office presence of e-government in the form of online service delivery was considered the most important variable for the evaluation of ICT applications. By contrast, more attention is now being paid to back-office strategies and to wider impact of digital policies on society (Albright, 2005; Kunstelij & Vintar, 2004). The "second generation e-government paradigm" furthers the thin objective of achieving improvements in service delivery, increasingly looking toward e-government-as-a-whole concept. In this way, the focus has shifted from the provision of services to the use of ICTs for increasing the value of services, as such a new paradigm "maintains that genuine cost savings and quality improvements will occur only if there is a re-engineering of the internal structures and processes of the administration" (United Nations, 2008, p. 5). As a strategic tool and as an enabler for public service innovation, technology is presumed to lead to a connected or networked governance, which engages the creative efforts of all of society. Indeed, recent trends have moved toward considering the most sophisticated level of online e-govern-

Table 4. Families of e-government indicators

ment initiatives characterized by an integrated back-office infrastructure and more citizen engagement supported and encouraged by governments in the decision-making process (United Nations, 2008, p. 16).

An articulated set of indicators have been used in a significant report produced by *The Conference of European Regional Legislative Assemblies* (2005), composed by the chairman of regional and local parliaments, whose e-democracy working group is in charge of evaluating the experiences of European local and regional institutions in applying new ICTs. The mission of this project is to identify e-democracy practices based on two categories: transparency and participation. Some indicators are intended to capture the quality and nature of service accessibility, along with changes in the internal organisation and administration of regional or local authorities.

Other indicators are intended to highlight the kinds of activities promoting effective citizen participation through digital communication and to measure the level of citizen satisfaction when using services specifically designed and implemented to promote participation. At the same time, as the following table shows, some indicators locate information on education and training activities offered to citizens, as well as issues related to democratic values and ICTs.

A greater awareness of the political implications of ICTs has been achieved as a result of these recent experiences. E-government initiatives preserve a strong link to democratic values such as transparency, inclusion, participation. Although digital experiments have often been accompanied by the rhetoric of democratic participation–depicted as their only source of justification–many difficulties in e-government implementation can be identified. E-government initiatives continue to appear rather immature, especially those regarding provision of services for citizens. Indeed, the most recent benchmarking report on online services provided in Europe (Capgemini, 2006) reveals that the degree of advancement of business-oriented services vastly exceeds those directed toward citizens. The former are included in the "two-way interaction" category in many countries, while the latter remain confined within the "one-way interaction" mode (Capgemini, 2006, p. 9).

Leaving aside these considerations of quality, other differences are noticeable in relation to delivery: business-oriented and citizen-oriented services cover, respectively, two thirds and one third of the overall distribution (Capgemini, 2006, p. 10). Moreover, a recent report by Darrel West (2007) shows that countries vary enormously in their overall e-government performance. Only 28% of the 1,687 Web sites examined around the world present services that are fully executable online. If the political potential of new technologies is often taken for granted, empirical analyses call into doubt the effectiveness of ICT applications for democratic purposes.

CONCLUSION

The analysis of evaluation systems for e-government policy has revealed an overlapping set of indicators for the development of new technologies. American and European reports seem to make reference to a common interpretative platform, intended to blur the borders between e-government and e-democracy. Although high aspirations are tied to new technologies—a remedy for the evils of "poor communication between general public and decision-makers in the political system; a lack of political participation, either caused by structural or functional deficits in the political system; and a negative effect of mass media both on the political system in general and on political participation in particular" (Hagen, 2003)—reports tend to concentrate attention on the modernisation of the administrative machinery through new tools, and on the delivery of public services in a more efficient and customer-oriented approach. In addition to this, they mostly focus on the technical features of Web sites, limiting themselves to the electronic façade of online services, with little or no reference to redesigning back-office administrative procedures or wider political implications. The evaluation of e-government mainly refers to output indicators, as initiatives are typically ranked on the basis of the amount of services that are brought online.

The same vision is embraced by a report produced by the World Bank for the Information for Development Program (infoDev), under a very meaningful title, *The Handbook of E-government* (World Bank, 2002). This document is an implementation guide, a practical tool underlining key resources and best practices when establishing e-government plans. The democratisation process is presumed to conform to a similar path in countries with very different traditions and history. The first stage involves the use of new technologies in order "to expand government information access" (World Bank, 2002, p. 3). If the public administration of modern states produce a huge amount of documents, data management possibilities enable the distribution of "government information to an audience as wide as possible" (World Bank, 2002, p. 3). The second stage involves a larger impact of technologies on the quality of democracy, by activating greater citizen involvement and interaction with political institutions. A two-way information flow enables citizens to receive answers to their questions directly from policy makers. Finally, in the third phase of digital policy development, known as the "transaction stage," citizens can access public services directly online. Once again, it is difficult here to differentiate between e-government and e-democracy, because the first is defined as a tool to implement better government.

More recently, the association between objectives of participative governance and the restructuring of administrative design has been confirmed. As the last United Nations *Global*

E-Government Survey (2008) put it, in the movement from e-government to connected governance, "efforts are aimed at an improved cooperation between governmental agencies, allowing for an enhanced, active and effective consultation and engagement with citizens, and a greater involvement with multi-stakeholders regionally and internationally." Thus, new developments of e-government paradigm show more consciousness on socio-political aspects of the introduction of information technologies.

However, the central role of technical variables in methodologies used to measure e-government can be underlined, as well as the consequent fading of the distinction between e-government and e-democracy. The World Wide Web is becoming a vehicle for the evaluation of the openness of public organisations, so that measuring the diffusion and quality of modern networked information technologies is often considered a way to measure the spread of administrative arrangements that are vital to emerging forms of democratic governance.

KEY TERMS

Benchmarking: An interactive process by which the activities of an actor are evaluated in relation to best practices.

E-Consultation: The use of the Internet to disseminate the developments in a policy field to the wider public, experts and interest groups, and to invite them to respond.

E-Democracy: The use of the ICTs for increasing the transparency of the political process, for enhancing the direct involvement and participation of citizens and for improving the quality of opinion formation by opening new spaces of information and deliberation.

E-Rulemaking: A "notice and comment" method, following three steps: announcement, comment and publication. The agency publishes a notice containing a proposed law and the interested public is invited to send comments and proposals via e-mail during a fixed time period, so that the agency can analyse and consider these comments in its final version of the law.

E-Governance: A concept and emerging practice, seeking to realise processes and structures for harnessing the potentialities of information and communication technologies at various levels of government and the public sector and beyond, for the purposes of enhancing good governance.

E-Participation: The use of information and communication technologies to broaden and deepen political participation by enabling citizens to connect with one another and with their elected representatives.

Good Governance: The processes and structures that guide political and socio-economic relationships, with particular reference to a set of eight major characteristics: participation, consensus, accountability, transparency, responsiveness, effectiveness and efficiency, inclusiveness and the rule of law.

Governmental Openness: A governmental strategy leading citizens to play a stronger role in interacting with government and in controlling its activities, making decision-making more transparent. It may also be considered a measure of government accountability, in that government agencies can be continuously assessed by citizens through everyday interactions.

Monitoring: The systematic collection of information to provide indications on how a programme or service is performing.

ICTs: Acronym for information and communications technologies. It is a general term that describes any technology that helps to produce, manipulate, store, communicate, or disseminate information.

Performance Measures: Benchmarks which indicate the economy, efficiency and effectiveness of a current or past activity, unit or organisation.

Individual-Based Modeling of Bacterial Genetic Elements

Venetia A. Saunders

Richard Gregory
University of Liverpool, UK

Jon R. Saunders
University of Liverpool, UK

INTRODUCTION

Individual-based computational modeling of biological systems is an important complement to experimental research. The individual-based model (IbM) is a bottom-up approach that considers the fate of individuals, their properties and interactions, and the influence of these interactions, holistically, on properties of the system. This contrasts with population-based models dependent on averaged behaviour of the whole system (DeAngelis & Gross, 1992; Huston, DeAngelis, & Post, 1988). IbMs can track individuals in time so that unusual events can be captured. They are particularly suited to biological simulations, where individuals might represent virtual plants, animals, or microorganisms in differing ecosystems. Lower complexity, coupled with the wealth of genetic knowledge about bacteria, allow for more realistic simulations compared with higher organisms. Accordingly, a lineage of IbMs, including Bacteria Simulator (BacSim) (Kreft, Booth, & Wimpenny, 1998; Kreft, Picioreanu, Wimpenny, & van Loosdrecht, 2001), INDividual DIScrete SIMulation (INDISIM) (Ginovart, Lopez, & Gras, 2005; Ginovart, Lopez, & Valls, 2002; Prats, Lopez, Giro, Ferrer, & Valls, 2006), COmputing Systems of Microbial Interactions and Communications (COSMIC) (Gregory, Paton, Saunders, & Wu, 2004; Paton, Gregory, Vlachos, Saunders, & Wu, 2004), RUle-based BActerial Modeling (RUBAM) (Paton, Vlachos, Wu, & Saunders, 2006; Vlachos, Paton, Saunders, & Wu, 2006) and COSMIC-Rules (Gregory, Saunders, & Saunders, 2006, 2008b), based on COSMIC and RUBAM, has been developed for bacterial simulations.

Although all these models are individual-based, underlying simulation mechanisms and aims vary. BacSim was the first to use IbM in a recognizable biological context (Kreft *et al*., 1998, 2001) aiming to model growth and cell division, quantitatively, at the population level, using a pseudocontinuous 2-dimensional world with restricted nutrients. INDISIM is based on stronger mathematical foundations, and is a discrete space and time stochastic simulation of colony growth, largely based on random variables (Ginovart *et al*., 2002). Each cell is a set of parameters existing at a discrete location. COSMIC uses pseudocontinuous space and discrete time to model evolution of cells (Gregory *et al*., 2004). Each cell contains a bit string genome that interacts with itself and the environment. This model is largely deterministic, although random events do have a role. It can run in a parallel machine, though any random effects this creates have been removed. RUBAM is a simplification of COSMIC, with pseudocontinuous space, discrete time, and a much more simplified genome. It aims to model adaptation (Vlachos *et al*., 2006). The simplified genome allows for comparatively rapid simulations that show adaptation and acquired resistance to antibiotics. COSMIC-Rules is a culmination of IbM modeling design, having an effective balance of modeling detail while being computationally tractable (Gregory *et al*., 2006, 2008b). Like COSMIC, it is a parallel simulation with pseudocontinuous space and discrete time. It uses a genome abstraction to represent the conditions and outputs of complex biochemical pathways, while incorporating an element of specificity and means of simulating evolution. Like the other IbMs considered here, each individual has its own parameters and state. Unlike the other IbMs, the scope of COSMIC-Rules covers vertical and horizontal gene transfer using populations of millions of cells.

BACKGROUND

IbMs describe behaviour in a system, acknowledging the uniqueness of the individual, its characteristics and interactions with other individuals. Individuals are only considered together as a population or community when analysed. The majority of IbM approaches to bacterial simulations have focussed on growth and metabolism from ecological and evolutionary perspectives. However, COSMIC-Rules (Gregory *et al*., 2006, 2008b), the IbM described here, has been designed to simulate genetic interactions in bacteria

within a framework that allows adaptation and evolutionary processes to be observed. An advantage of the IbM in these simulations is that bacterial evolution becomes open-ended: emergence, growth, and death of individual bacteria, their interactions with other bacteria, and any infection events can be monitored over time. Such an approach permits questions about impact of individual variability on adaptive evolution to be addressed. Genetic elements, such as plasmids and viruses, can spread within bacterial populations mediating genetic exchange (Sørensen, Bailey, Hansen, Kroer, & Wuertz, 2005) and, coupled with mutation, provide raw materials for adaptive evolution (Marri, Hao, & Golding, 2007). By acquiring new or mutated genes, bacteria can adapt and survive in changing environments. Some plasmids are conjugative (self-transmissible), transferring by the horizontal gene transfer process of conjugation. This requires cell-to-cell contact involving a conjugation ligand, encoded by the donor, and a receptor on the recipient (Manning & Achtman, 1979).

Bacteriophages (phages) are viruses that infect bacteria (Carter & Saunders, 2007). The infective cycle is initiated by attachment of phages to susceptible bacteria through specificity of phage ligand-host cell receptor interactions. Phages may be temperate or virulent. A temperate phage is capable of operating in lytic (host killing) or lysogenic (without harming the host) modes. Phage replication occurs in the lytic cycle, culminating in cell lysis and release of progeny phages. For lysogeny, an inactive phage genome is stably inherited; there is neither bacterial lysis nor production of progeny phages. Phages that lysogenize the host (lysogen) confer immunity to superinfecting, homologous phages, and may effect changes to host properties by lysogenic conversion (Brussow, Canchaya, & Hardt, 2004). Furthermore, lysogeny promotes adaptation to survival in poor/unstable environments where resources are limited, as well as providing a potential reservoir of progeny phages.

MODELING GENETIC ELEMENTS IN BACTERIA

The Model: COSMIC-Rules

COSMIC-Rules (Gregory *et al*., 2006, 2008b) incorporates three levels using IbM philosophy: the genome, the cell, and an environment populated by such cells. Organisms possess individually defined physical locations, size, cell division status, and genomes including extrachromosomal elements (*e.g.*, plasmids and phages). The virtual environment consists of multiple, individual substances (substrates and toxic agents *e.g.*, antibiotics) whose relative nutrient status and/or toxicity is specified by the make-up of particular bacterial genomes. Individuals have specific, mutable genotypes and phenotypes evolving in a medium of initially defined, though changeable, composition. The environment is a 3-dimensional space, with the third dimension being of one cell diameter, so that cells effectively move in two dimensions.

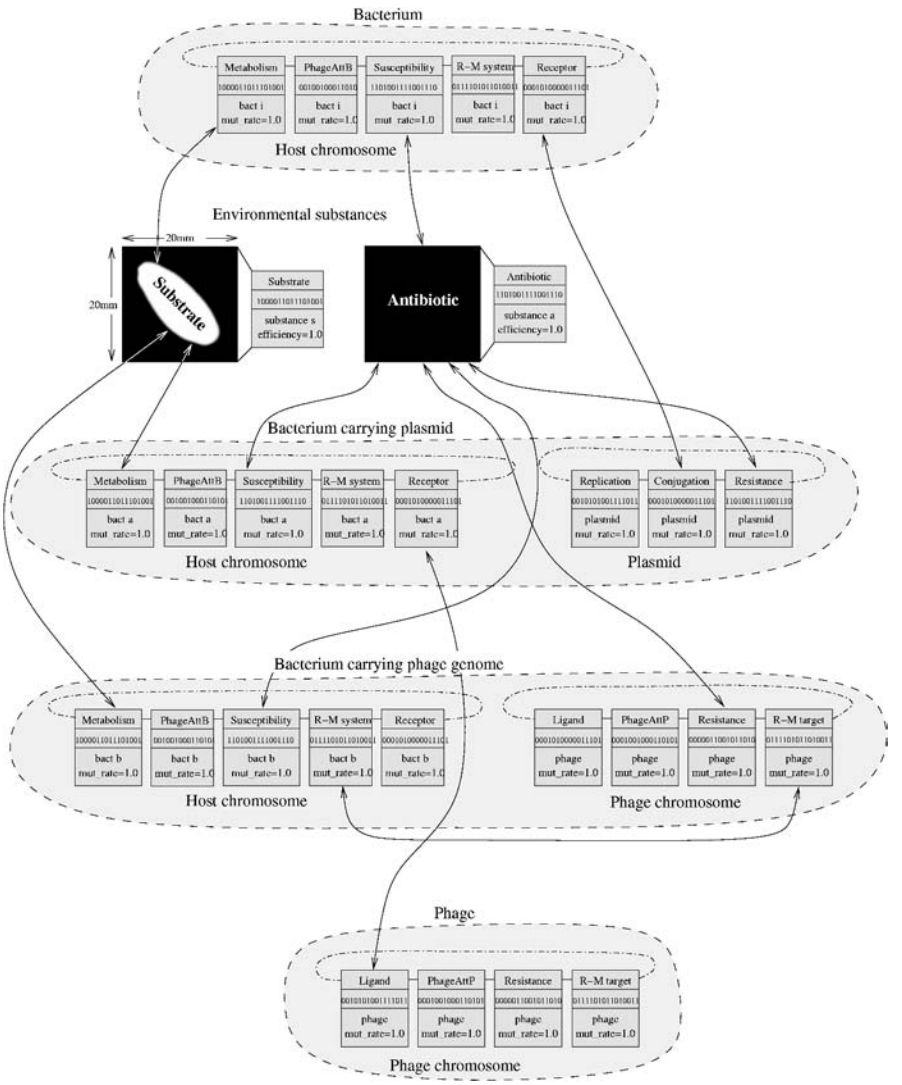
Central to the model are novel features for representing genotypes and phenotypes in a compressed manner (genome compression). Each gene/gene set is represented by a unique tagged bit string that defines coding capacity and mediates specific genotypic and phenotypic interactions through bit string matching (Figure 1). This allows modeling of ligand-receptor interactions required, for example, for bacterial cell contact and conjugation or phage infection, metabolism-substance (substrate) interactions for cell growth, and susceptibility-substance (antibiotic/toxic agent) interactions for antibiotic action and cell death. If there is interaction with a resistance tag, probability of death is reduced to zero. A successful outcome demands that tagged bit strings match, and matching depends on them being no more than two bits different. The degree of similarity for matching varies with events under consideration. There are multiple metabolism, susceptibility, and resistance tags for each individual, together with multiple substances, and the best match is used in each case. "Best" refers to an outcome that produces either highest growth rate or highest probability of cell death. Collectively, bit strings form the genome and only genes directly involved in a particular simulation are considered; other required functions are assumed to be provided by covert gene sets to reduce computational load. However, flexibility of the model allows additional bit strings to be incorporated to increase genome complexity as necessary.

COSMIC-Rules models simplifications of real-world situations, aiming to reproduce biologically realistic conditions, by applying a series of rules, informed by physical laws and principles of bacterial genetics. Simulation parameters reflect biological values, as determined experimentally. Rules govern behavior of individuals in simulations and are varied for different scenarios.

The model is built for parallel execution utilizing a development cluster and scales to large HPC systems. To achieve parallelism, the environment is partitioned into demes, each containing individuals that move and interact with other individuals, and for one time step, the deme is isolated from other demes. Individuals then move and may migrate to another deme. Isolating demes in this way facilitates computability, since cell-to-cell synchronization between demes is not required.

The simulation treats each bacterium or free phage as an object instance, with its own associated parameters and genome. Genomes are also handled as objects. Within each genome are tagged bit strings representing compressed genes that make this approach tractable. Individual bacteria or free phages are subject to mutation, and soon each individual has its own unique bit strings associated with each tag. Once parallel synchronization has been achieved, a typical cycle

Figure 1. Genomes of individuals and their interactions. Compressed genomes comprise keywords plus bit string pairs that specify overall function (consequences of a successful interaction). Examples of interactions are shown by connecting arrows. mut_rate, mutation rate associated with bit strings; R-M system, restriction-modification system; R-M target, site for action of restriction-modification system; PhageAttB, phage attachment site on bacterial genome; PhageAttP, attachment site on phage genome.



of the simulation involves randomly iterating over all tags in all individual bacteria and free phages. For each matching tag, a rule is "triggered" (see Figure 1 for instances of matching).

Triggered rules invoke some combination of time delay and probabilistic or deterministic action, the exact outcome depending on the tag involved, the bit string, and possibly position of individuals in the environment. These rules implement, for example, substrate uptake, antibiotic-induced death, plasmid transfer, phage infection, and cellular decay, some involving several rules triggered in succession.

Case Studies

COSMIC-Rules has been validated by modeling case studies including antibiotic action and resistance in bacterial populations (Gregory *et al*., 2008b), conjugative plasmid transfer (Gregory *et al*., 2008a), and phage infection. The simulations illustrate adaptation and survival of bacteria in changing environments through genetic events (mutation and gene transfer) that alter phenotype and can confer selection benefits on the host.

A. Emergence of Antibiotic Resistance in Bacteria

The simulation in Figure 2 demonstrates the action of a bactericidal antibiotic that kills sensitive bacteria. A few resistant mutants survive after exposure to the antibiotic. Growth of mutants is promoted by nutrients released from dead cells. Thus, the model incorporates the influence of the organism on the environment and the reverse.

B. Plasmid Transfer in Bacteria

Plasmids are responsible for a large proportion of resistance to antibiotics, and their transmission through bacterial populations renders individual bacteria resistant. Figure 3 simulates spread of a virtual antibiotic resistance (R) plasmid through an antibiotic-sensitive bacterial population.

A substrate is provided for growth and an antibiotic that overlaps part of the substrate zone is present. Bacteria grow around the antibiotic zone, but do not survive in it, so the initial level of substrate is maintained here. When R plasmid-

Figure 2. Simulation of antibiotic action and emergence of antibiotic resistance in a bacterial population. (a) Snapshots of key moments in the simulation. Panels 1-7 show growth of the antibiotic-sensitive bacteria. A substrate (dashed oval area, panel 1) supports the population. Addition of antibiotic kills most cells. Panel 8 shows growth of the few antibiotic-resistant mutants. (b) Graphical representation of simulation in (a). Antibiotic-resistant mutants (whose "susceptibility" bit string has mutated sufficiently to avoid death) survive, supported by nutrients released from dead cells.

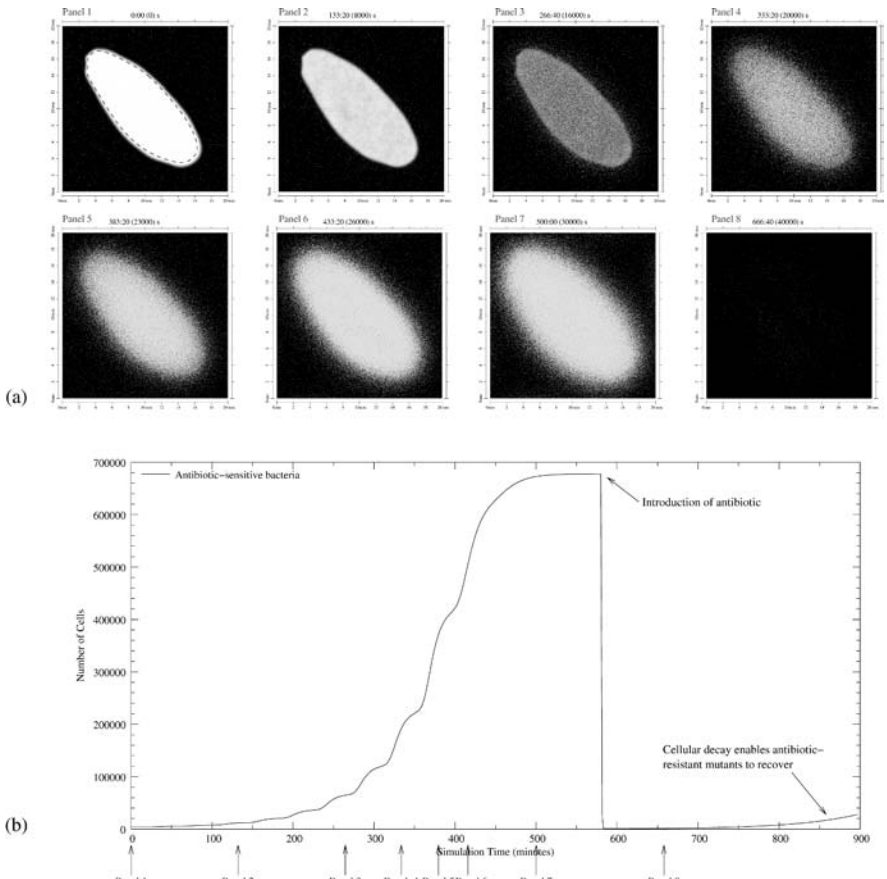


Figure 3. Simulation of plasmid spread in a bacterial population. (a) Snapshots of key moments in simulation using an antibiotic to monitor plasmid transfer. Panel 1 shows an oval area of substrate (dashed outline) and a circular area of antibiotic (dotted outline); (a) is the region of overlap of substrate and antibiotic. Sensitive bacteria only grow in the area with substrate and no antibiotic (panel 2). Plasmid-containing bacteria are added at "R" (white dashed outline, panel 3). Panels 4-8 show spread of the resistance plasmid. (b) Graphical representation of simulation in (a).

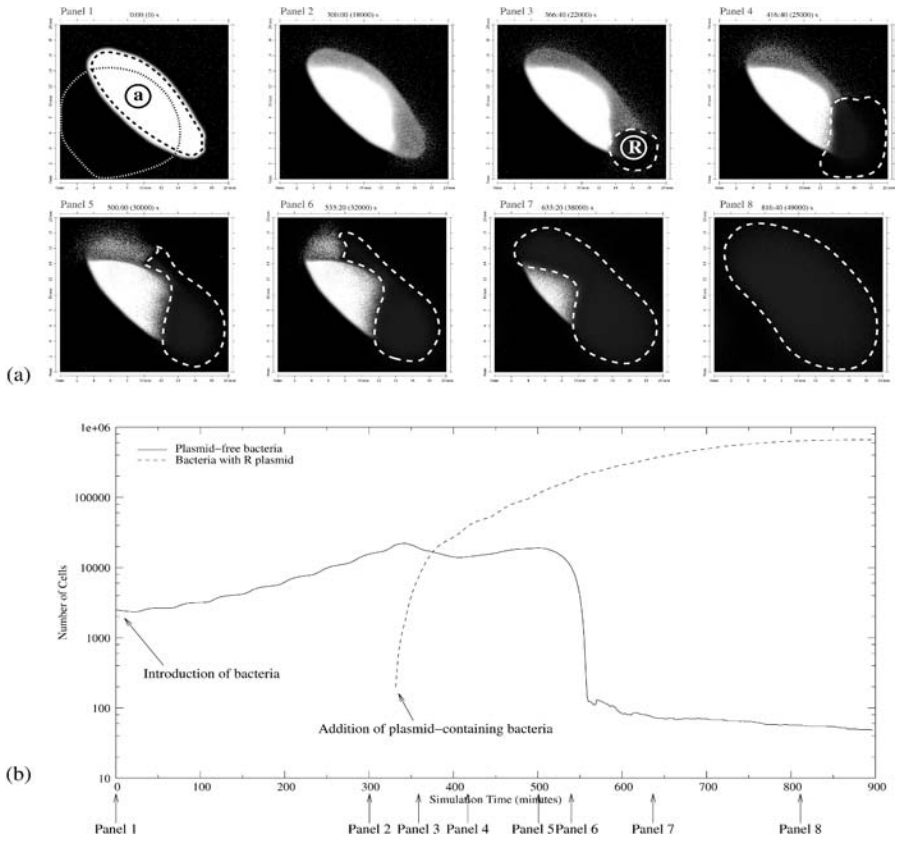


containing bacteria, resistant to the antibiotic, are added, the plasmid transfers to plasmid-free recipients, rendering them resistant. Such recipients are now able to colonize the zone of overlap of substrate and antibiotic. With further plasmid transfer there is rapid spread of antibiotic-resistance throughout the population. This mimics the emergence and spread of antibiotic-resistance, for example, amongst clinically important bacteria.

C. Phage Infection

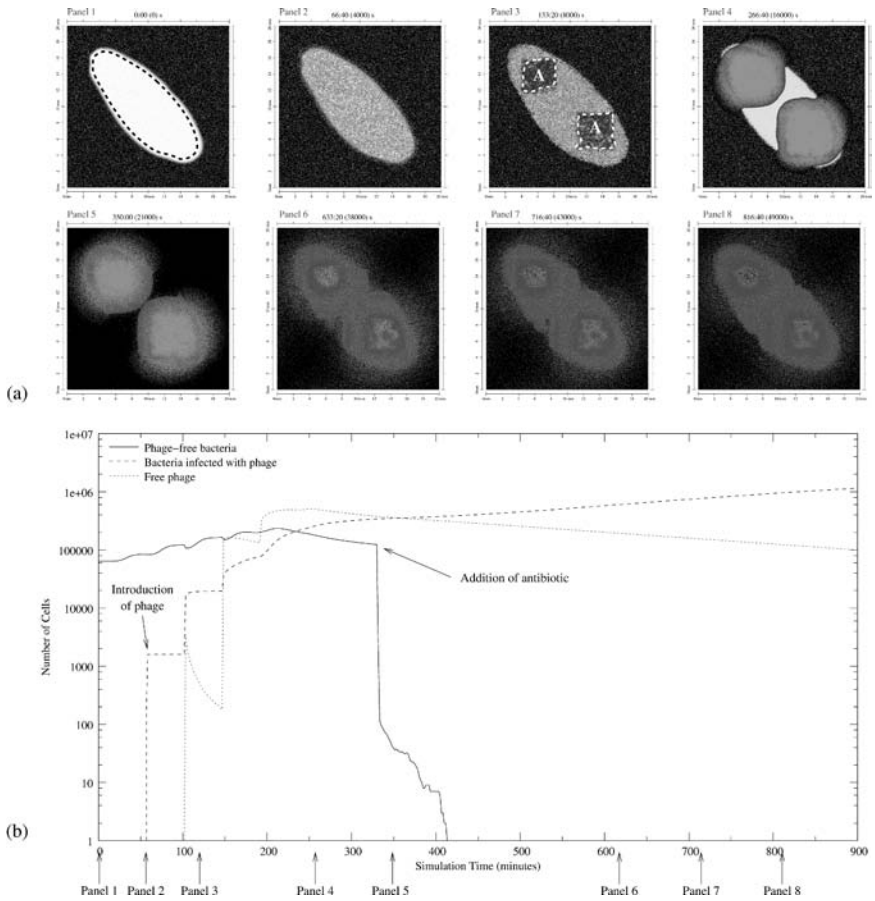
Phages, which are ubiquitous in nature, have a crucial role in controlling abundance of bacteria by infecting and killing susceptible cells. Figure 4 describes the spread of a virtual temperate phage through a susceptible population. The phage genome carries a gene, encoding resistance to an antibiotic to facilitate selection of lysogens, upon exposure to antibiotic. Addition of phages results in infection of phage-free cells. Phages either enter the lytic cycle, killing host cells and releasing progeny phages, or establish lysogeny and confer an antibiotic-resistance phenotype on resultant lysogens. Such lysogens, which exhibit superinfection immunity, continue to grow, despite the presence of free phages. Addition of antibiotic kills uninfected bacteria, with the exception of a few resistant mutants, but lysogens survive due to the antibiotic-resistance gene. Growth of surviving cells is encouraged by nutrients released from dead bacteria. Free phages, having a finite half-life, gradually decline through lack of susceptible host cells. This is reflected in natural populations that fre-

quently comprise bacteria that are multiply lysogenized by different phages. Moreover, the genomes of extant bacteria contain evidence of extensive lysogenization during bacterial evolution (Brussow *et al*., 2004; Williamson, Radosevich, Smith, & Wommack, 2007).

FUTURE TRENDS

COSMIC-Rules has been used here to examine some simple case studies involving virtual transmission of plasmids and phages, and demonstrates the applicability of the model to studying the role of genetic elements in bacterial populations. It is a highly flexible model, and provides a springboard for generating more complex simulations involving multiple genetic transactions by, for example, combining plasmids and phages in bacteria subject to natural and anthropogenic environmental change. Extending the model, using larger scale Grid technology, should allow simulations more representative of mixed populations in natural environments. Accordingly, the model should inform studies on bacterial adaptation and evolution, including gene transfer and spread of antibiotic-resistance in bacteria, and behaviour of pathogenic bacteria and their viruses. It is also applicable

Figure 4. Simulation of phage infection of a susceptible bacterial population. (a) Snapshots of key moments in simulation of phage infecting bacteria. Panel 1 shows an oval area of substrate (dashed outline) supporting growth of the bacterial population. The population increases as substrate is consumed. Phages are introduced (at "A," panel 3). Panel 4 shows phages spreading through uninfected bacteria: the lighter areas represent phage-free bacteria, the darker areas phage-infected bacteria/free phages. Addition of antibiotic kills uninfected bacteria (antibiotic-sensitive), except for a few resistant mutants. Panels 6-8 show phage-infected bacteria that express antibiotic resistance and free phages. Surviving bacteria grow on nutrients released from dead bacteria. (b) Graphical representation of simulation in (a).



to modeling the epidemiology of infectious diseases. More widely, the approach would have applications in other areas of information science and technology, where an evolutionary dimension is involved.

CONCLUSION

COSMIC-Rules has been developed and validated using scenarios involving virtual bacteria, their plasmids, and phages in environments varying between supportive (with added nutrients) and inhibitory (with antimicrobial agents). The simulations reinforce our basic notion (Gregory *et al*., 2008b) that compressing the representation of the genome is justified and retains biological realism. The model has demonstrated the utility of IbM philosophy to simulating plasmid transfer and phage infection in bacteria. A rule-based approach thus provides a valuable tool for predicting behaviour of bacterial populations in response to past and future episodes of environmental change.

KEY TERMS

Antibiotic: A natural or artificial substance that can kill or inhibit growth of microorganisms.

Bacterial Conjugation: A naturally occurring horizontal gene transfer process in which donor and recipient cells come into direct contact for exchange of genetic material in bacteria.

Bacterial Plasmid: A self-replicating, extrachromosomal genetic element found in bacteria. Plasmids may carry genes for various functions, including antibiotic resistance and virulence.

Bacteriophage (Phage): A virus that specifically infects bacteria. Broadly, there are two types: virulent (or lytic) and temperate (or lysogenic). Upon infection, a virulent phage replicates and releases progeny phages. A temperate phage may enter the lytic cycle or lysogenize the host, with the phage genome remaining dormant. The genome may later become active, directing the synthesis of progeny phages and destruction of the host.

Bit String Matching: Method by which bits in a tagged bit string are compared with bits in another tagged bit string to determine if they are acceptably similar. COSMIC-Rules uses the fast exclusive-or operation followed by counting the number of set bits.

COSMIC-Rules: Model and modeling framework simulating bacterial adaptation using IbM philosophy and genome compression to achieve realistic and qualitatively accurate simulations of, for example, substance affinity, plasmid transfer, phage spread, and cellular decay.

Genome Compression: An abstraction that reduces the complexity of pathways into single components. Each "gene" can represent an otherwise intractable pathway if its external overall effect, behaviour, or input/output relationship can be characterised by probability, mathematical formula, lookup table, logical expression, or a combination of any of these methods.

Individual-Based Model (IbM): Modeling philosophy in which numerical quantities, representing the size of some population, are replaced by individuals that make up the population. Each individual would have its own state, allowing analysis to include both population level crowd effects and individualism. The form of the individual is inherently open-ended and need not be tied to mathematical expressions. The IbM philosophy also allows use of nested levels of individuality.

Tagged Bit String: Consists of both a type and a bit string. The type specifies what pathway it abstracts, and what other tags must be present for this pathway abstraction to be active. A bit string provides specificity by adding another (mutable) condition to activation of a pathway. Both tag and bit string exist as an inseparable pair and are passed through both vertical and horizontal inheritance.

Influential Agile Software Parameters

INTRODUCTION

Successful software systems development is a delicate balance among several distinct factors (Jalote, 2002) such as enabling people to grow professionally; documenting processes representing the gained experiences and knowledge of the organization members; using *know how* to apply the suitable processes to similar circumstances; and refining processes based on achieved experience.

Software projects have two main dimensions: engineering and project management. The engineering dimension concerns the construction of a system, and focuses mainly on issues such as *how to* build a system. The project management dimension is in charge with properly planning and controlling the engineering activities to meet project goals for optimal cost, schedule, and quality.

For a project, the engineering processes specify how to perform activities such as requirement specification, design, testing, and so on. The project management processes, on the other hand, specify how to set milestones, organize personnel, manage risks, monitor progress, and so on (Jalote, 2002).

A software process may be defined as "a set of activities, methods, practices, and transformations that people use to develop and maintain software, and the associated products and artifacts."[1] This is pictorially depicted in Figure 1 (Donaldson & Siegel, 2000).

BACKGROUND

Premise of Agile Software Development

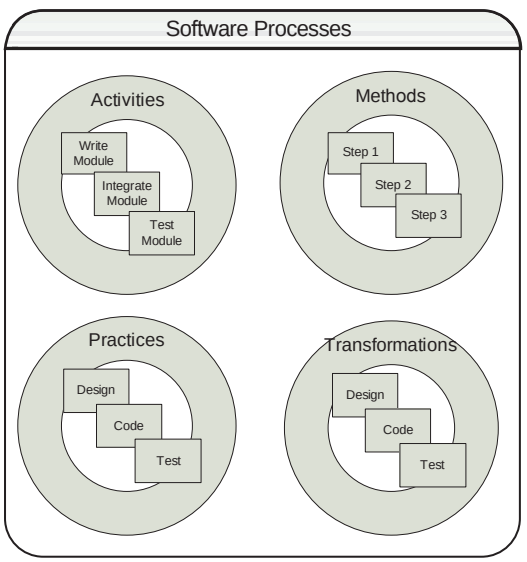
The professional goal of every development team is to deliver the highest possible value to the project and customers. Yet, projects fail, or fail to deliver value, at a frustrating rate due to an increase in process inflation. Plan-driven methods are those in which work begins with the elicitation and documentation of a *complete* set of requirements, followed by architectural and high-level design development and inspection. In this context, the concept of *agile* appeared where principles and values were shaped as a way to help teams avoid the cycle of process inflation and to focus on simple techniques for reaching their goals.

Agile processes allow adjustments of requirements during all phases of the development cycle and stress collaboration between software developers and customers and early product delivery (Donaldson & Siegel, 2000).

Key motivations of *agile methods* apparition are

- Iterative development is of lower risk than waterfall development (Larman, 2004).
- Early risk discovery and improvement.
- Promotes early change: consistent with new product development.
- Early partial product apparition.
- Satisfaction through early and repeated successes.
- Continuous testing activity.
- Final product matches client's desires better.

Figure 1. Software processes



Features Of Agile Software Development

The core of the "Manifesto for Agile Software Development" (n.d.) is as follows (Fowler, 2002; Fowler & Highsmith, 2001; Martin, 2001):

- individuals and interactions over processes and tools;
- working software over comprehensive documentation;
- customer collaboration over contract negotiation; and
- responding to change over following a plan.

The central aspects of agile methods are simplicity and speed. These goals can be achieved by software whose development is incremental, cooperative, straightforward, and adaptive.

The agile software development approach considers people the main resource of the development. In this context, its approach is collaborative considering that software development is, in fact, a collaborative team activity. In this way it steps away from the individualistic software engineering paradigm, and instead considers software development as a collaborative team activity. This enables agile software development teams to learn how to work together and thereby provides a mechanism for resolving the inevitable misunderstandings that occur during a project.

The set of consistent approaches that arise from agile software development processes are (Abrahamson, Salo, Ronkainen, & Warsta, 2002; Fowler & Highsmith, 2001; Larman 2004)

- human resource issues,
- amount of documentation to be as reduced as possible,
- communication is a critical issue, and
- modeling tools are not as useful as in other development processes.

Agile processes characteristics are stated as follows (Fowler & Highsmith, 2001):

- modularity is used on development process level;
- iterative activities with short cycles enable fast verifications and corrections;
- time spent with iteration cycles takes from 1 to 6 weeks;
- temperance in development process that removes all useless activities;
- adaptive;
- incremental; and
- collaborative and communicative working style.

There are many agile methods sharing common characteristics and starting from the same approach. Some of them are: *extreme programming, crystal family of methodologies, rational unified process, dynamic systems development method,* and *adaptive software development.* Each of them has its own processes, principles, practices, roles, and responsibilities, but they all have in common the agile approach.

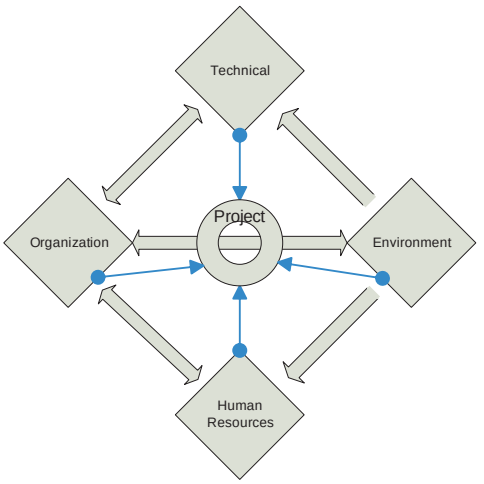
INFLUENCE PARAMETERS OF AGILE SOFTWARE DEVELOPMENT PROJECTS

In agile approach it is quite hard to distinguish between success and failure factors of projects. What was considered decisive for a project echoing success may be considered as a limit in another one. At the same time, a certain factor may influence not only a project, but may also persuade the rest of agile factors. In this context, it is difficult to draw a fixed and clear line between influence factors and how they act in agile software projects. Different factors[2] that influence the success or failure of software projects are shown in Figure 2 and are described hereafter.

Organizational Factors and Their Influences

- **Organization Culture:**
  1. A dynamic, agile organization will find agile methods extremely suitable for it (Abrahamson et al., 2002). Importance of customer feedback and control on an agile project requires an adaptive and collaborative working environment. In this working environment, which is, in fact, the organization, all its members, for example, management, developers, and testers must be in total agreement to use agile processes, because without organization commitment to being agile, failure may develop into a strong possibility (Smith & Pichler, 2005).
  2. In a bureaucratic organization where respecting plans, rules, and directives are a way of work, agile is inappropriate as a new path in creating value. A stagnant organization with a culture believing in efficiency, control, and process rigor tends to neglect the fact that success evolves from new successes, failures, and different alternatives used. The deeper these factors are grounded in the organizational culture, the more difficult they are to revolutionize, and the more easily they can became obstructions in adopting new approaches (Highsmith, 2000).

Figure 2. Main influence factors of agile projects



- **Team Dimension:**
  1. Team dimension is directly dependent on project size and influences communication between team members. The agile approach with face-to-face communication suits teams with less than 20-40 people.
  2. As team size grows, coordinating the interfaces becomes a dominant issue. The communication required in the agile approach breaks down and becomes increasingly difficult and complex with more than 20-40 people (Dyba, 2000). If more than 20-40 people are involved in an agile project, scaling strategies must be adopted, for example, breaking a large team into few smaller teams and applying agile for team coordination.
- **Team Distribution:**
  1. One of the factors that are likely to positively influence the success of an agile software development project is the centralized organization of the teams. Companies involved in distributed international projects will be affected by the cultural and political situations in those regions. For instance, if there are teams that are located in regions where the political and cultural environment supports collaborative work advocated by the agile approach, those teams are more likely to be successful over the ones that are located in regions where this is not the case.
  2. Directly dependant on project type and environment (especially for international projects), geographic distribution of teams may be an inconvenience for an agile project. In such a case, face-to-face communication is extremely difficult and documents apparitions are highly desirable.
- **Decision Time:**
  Teams using an agile approach are more likely to make decisions more quickly than other teams, relying on frequent informal communication.
- **Customer Commitment:**
  1. Close collaboration with customers provides a team following an agile approach the chance to react fast to adherence (or any change) in customer requirement. Customers have the opportunity of driving development along with the project managers (Lindvall et al., 2002). A project following the agile approach represents a partnership between customers and development teams, where each member has a specific role, responsibility, and authority. During the development effort, relationships between customers and developers must be collaborative.
  2. Software is not an ordinary commodity. Unlike other products, it cannot be ordered and received as a final product according to the specified requirements. A customer must describe its needs, and more than anything else time, budget, and resource constraints must be part of a contract. Such needs may change over time following interactions between the customers and the project team. Also, customer requirements may become a reason for failure of a system, if they are not "filtered" by the developers. The reason is that some of the requirements of the customers might be infeasible. Therefore, customer commitment becomes an important factor, the absence of which might negatively impact the project.

Human Resource Factors and Their Influences

The success of a software development project is often related to people factors (Turner & Boehm, 2003). Human resource factors are also hypothesized as important factors for the success of agile software development projects.

- **Competency:**
  One may be said to be competent for a software development project if one has real-world experience in the technology domain, has built similar systems in the past, and possesses good interpersonal and communication skills.
  1. One of Boehm's principles of top talent: "use better, and fewer people" is central to an agile process (Keith, 2002). Having high competency

members in a team is one of the most important requirements of the agile approach.

2. Even if a final product looks and works in the same manner, differences between competencies of the members influence all development phases. Too many slow workers either slow the pace of development of an entire team or end up being left behind by their faster colleagues (Cohn & Ford, 2003).

- **Personal quality:**
  1. Team members must not necessarily be extremely skilled and experienced people, but honest, collaborative, responsible, ready to learn, and work well with others. A team, where there are integrated distinct types of IT specialists (programmers, testers, analysts) will work well with such members.
  2. Just professional competencies are not enough anymore for a programmer. Agile's core principle: "Communication is critical" has secondary effects on the requirements of team members' qualities—without communication abilities and the desire to work in an agile team, even an expert may become a hindrance to the success of the process.
- **Percentage of experts in project:**
  1. A well-fabricated team, even without having various experiences in a specific field, will work efficiently, if for any success-critical issue at least one person has the time and expertise to resolve the issue. Davies's 131st principle "People are the key to success," combined with close team communication, allows to any team members to learn from his/her peer.
  2. For highly agile, tactical environments, as also for extremely specialized domains, external experts may be of limited help. If there is no such expert in an organization, it will take a long time to train one.

Technical Factors and Their Influences

- **Project Size:**
  1. A large project may influence other agile factors such as: team dimension, team distribution, and communication with a large number of customer representatives. Each of them has its own influence on the project.
- **Documentation:**
  1. An organization's goal should be to communicate effectively. As per the agile approach requirements, documentation should be given secondary importance. On the other hand, since documentation has important functions (Highsmith, 2004) in supporting project phases such as sustaining team collaboration and communication, preserving historical information and information evolution, and fulfilling requirements, documentation in agile projects must be concise and have the ability to respond to project specific needs, as per necessity. In other words, documentation should be strictly limited to what is optimal.
  2. "Good" products can be produced with or without documents; nevertheless, without a documented process it is difficult, for an organization to create products on time and within budget. Code is not the ideal medium for communicating the rationale and structure of a system. In this context, the team needs to produce human readable documents that describe the system and the rationale for their design decisions.

Environmental Factors and Their Influences

- **Culture:**
  1. As any other human activity, software development is highly influenced by regional (local) culture. A communicative, dynamic, progressive environment has a major influence on the members of a society. With such social values recognized, any individual may fit well in an agile team.
  2. On the other hand, an oppressive society, full of constraints has a bad influence on human behavior (considering agile set of values).
- **Cultural differences between team members:**
  1. As any new experience brings new values, encountering people with similar culture may have a positive influence on team communication and foster a willingness to work together.
  2. On the other hand, if there are extremely high differences between team members, it may take a long time until they are in fact able to work together efficiently.

FUTURE TRENDS

In addition to identifying the important factors influencing success, it is important to obtain empirical evidences from the industry. Similarly, most of the changes and challenges identified in the existing literature that are required for adopting agile processes in a traditional development organization are either based on experience of the developers, or are based on the opinions of agile experts without much empirical support. Additionally, different previous articles report long lists of such changes and challenges. However,

for an organization considering adopting agile processes, such long lists are of limited help. It is important to identify the critical factors responsible for the transition of traditional software development organizations into agile methods based on empirical survey-based evidences.

CONCLUSION

Agile software development methodologies have recently gained widespread popularity. The "Manifesto for Agile Software Development" (n.d.) states valuing "individuals, and interactions over processes, and tools, working software over comprehensive documentation, customer collaboration over contract negotiation, and responding to change over following a plan" (Fowler, 2002). However, little is known about how effective and efficient agile practices are over the traditional methodologies, and what their success factors are. There have been several disparate anecdotal evidences about the success of software development projects using agile methodologies.

In this article we introduced the concepts surrounding agile software development. We have also mentioned some of the important factors influencing the success or failure of agile software development projects. These factors are based on previously published literature. This article should help software development teams willing to adopt agile practices to be aware of the "what works and what does not" in agile projects.

We reviewed the parameters that affect the success of projects adopting agile software development methodologies based on previous anecdotal and practical experience stories. We also presented a conceptual framework showing the relationships between the success of agile software development and its predictors.

KEY TERMS

Agile: The quality of being quick.

Agile Manifesto: A public declaration of principles and intentions shared by a group of software developers who advocated the philosophy of software development.

Agile Methodologies: Methodologies that follow the manifesto, principles, and values of agile software development.

Agile Software Development: An approach for software development advocated by a group of software developers believing in developing software in shorter time boxes, faster communication, working closely with customers, and allowing changes to requirements even late in the software development process, among others.

Iterative Development: The art of developing software incrementally in versions by taking advantage of lessons learned from producing previous deliverables of software.

Process: A sequence of steps following which can lead to an outcome.

Project: A plan or proposal, which is undertaken, usually over a fixed time duration.

Information and Communication Technology for E-Regions

Koray Velibeyoglu
Izmir Institute of Technology, Turkey

Tan Yigitcanlar
Queensland University of Technology, Australia

INTRODUCTION

Information and communication technologies (ICTs) are essential components of the knowledge economy, and have an immense complementary role in innovation, education, knowledge creation, and relations with government, civil society, and business within city regions. The ability to create, distribute, and exploit knowledge has become a major source of competitive advantage, wealth creation, and improvements in the new regional policies. Growing impact of ICTs on the economy and society, rapid application of recent scientific advances in new products and processes, shifting to more knowledge-intensive industry and services, and rising skill requirements have become crucial concepts for urban and regional competitiveness. Therefore, harnessing ICTs for knowledge-based urban development (KBUD) has a significant impact on urban and regional growth (Yigitcanlar, 2005). In this sense, e-region is a novel concept utilizing ICTs for regional development.

Since the Helsinki European Council announced Turkey as a candidate for European Union (EU) membership in 1999, the candidacy has accelerated the speed of regional policy enhancements and adoption of the European regional policy standards. These enhancements and adoption include the generation of a new regional spatial division, NUTS-II statistical regions; a new legislation on the establishment of regional development agencies (RDAs); and new orientations in the field of high education, science, and technology within the framework of the EU's Lisbon Strategy and the Bologna Process. The European standards posed an ambitious new agenda in the development and application of contemporary regional policy in Turkey (Bilen, 2005). In this sense, novel regional policies in Turkey necessarily endeavor to include information society objectives through efficient use of new technologies such as ICTs. Such a development seeks to be based on tangible assets of the region (Friedmann, 2006) as well as the best practices deriving from grounding initiatives on urban and local levels. These assets provide the foundation of an e-region that harnesses regional development in an information society context.

With successful implementations, the Marmara region's local governments in Turkey are setting the benchmark for the country in the implementation of spatial information systems and e-governance, and moving toward an e-region. Therefore, this article aims to shed light on organizational and regional realities of recent practices of ICT applications and their supply instruments based on evidence from selected local government organizations in the Marmara region. This article also exemplifies challenges and opportunities of the region in moving toward an e-region and provides a concise review of different ICT applications and strategies in a broader urban and regional context.

The article is organized in three parts. The following section scrutinizes the e-region framework and the role of ICTs in regional development. Then, Marmara's opportunities and challenges in moving toward an e-region are discussed in the context of ICT applications and their supply instruments based on public-sector projects, policies, and initiatives. Subsequently, the last section discusses conclusions and prospective research.

BACKGROUND

New Regionalism and Information Society in Turkey

In the 1950s, Turkey was divided into seven geographic regions based on topographic and climatic conditions without paying attention to administrative aspects. In terms of territorial division, Turkey has a national administration, and 81 province, 873 district, and 3,227 local administrations. Provinces and districts are both administrative units of the national government and territorial units of local government. Representatives of the national government, governors of provinces, and heads of districts on the one hand, and local government bodies and provincial local governments on the other hand work in the same areas but carry out different duties (Sagbas, 2003). The administrative reorganization and spatial division of regions have been under review posed by

the new regulations covering the establishment of RDAs and NUTS-II statistical regions.

Adoption of EU's regional standards and information society objectives are challenging ambitions for Turkey. The EU's Lisbon agenda (2000) has also come up with a similar ambitious plan with a strategic vision to become the most competitive and dynamic knowledge economy in the world that is capable of sustainable economic growth with more jobs and greater social cohesion (Campano et al., 2004). To address these objectives, a comprehensive e-transformation program, e-Turkey, was prepared rapidly after Turkey participated in the e-Europe initiative in 2001. The main goals of this initiative include cheaper, faster, and secure Internet; investing in people and skills; stimulation of Internet use in European regions; and acceleration in forming information society foundations (Tuzun & Sezer, 2002). In conjunction with this initiative, the e-transformation Turkey project was launched in 2002. The information society department of the State Planning Organization (SPO) was assigned for the coordination of this project. The prime ministry, nongovernment organizations, and all public institutions are identified as affiliated organizations for the project (SPO, 2004).

Local governments play a key role in developing local ICT policies in order to coordinate with national-level policy implications, which are indexed to the e-Europe initiative (Akin, 2005). The e-Turkey initiatives, however, are undertaken by both national and local governments, where no coordinating regional authority is allotted with these initiatives. These regional policy initiatives focus on the promotion of wealth, welfare, and sustainability in a broader information society context. Therefore, focusing on the regional level would likely increase the success chance in the implementation of ICT applications within the e-Turkey initiatives.

E-Region and ICT

E-region can be considered as the set of innovative actions to achieve economic and social cohesion and to raise the technological level of regions through the use of information ICTs.

ICTs are the backbones of the knowledge economy and in recent years have been recognized as effective tools for promoting economic growth and sustainable development (Chen & Dahlman, 2005). According to Millard (2002), the five *E*s (entity, economy, equity, environment, e-technology) provide basic conditions to achieve sustainable regional development. For example, entity promotes territorial identity and integration; similarly, economy is the engine for growth and efficiency, equity resembles cohesion and inclusion in encountering the spatial digital divide and promoting welfare, and environment is an important tangible asset for regions inducing sustainability. E-technology or ICTs complement the other four dimensions and can widen the spectrum of innovativeness and creativity of a region.

Another emphasis for the development of the knowledge economy is to enhance regional governance. It is widely accepted that good governance and effective institutional structure are important sources of regional competitiveness. This requires the partnership of private-, public-, and voluntary-sector bodies aimed at driving forward a region's e-agenda.

The EU's regional approach and projects for the information society and urban technologies have a good framework toward understanding e-regions. These policies have been discussed under three major objectives: Support the provision of ICT infrastructure to reduce the digital divide and regional disparities, stimulate new electronic services and innovative ICT applications ranging from e-commerce to e-governance, and invest in people to ensure necessary skills and capabilities via distance learning and digital literacy (European Commission [EC], 2006). In this context, a variety of e-region initiatives in the European region has been under way: Kaunas E-Region (Latvia), E-Region Blagoevgrad (Bulgaria), E-Bourgogne Programme (France), Kuyavia and Pomerania E-Region (Poland), and E-Region Schleswig-Holstein (Germany). These initiatives are parts of the e-Europe region, which represents the information society at the service of regional development.

MARMARA: TOWARD AN E-REGION?

Marmara is the most developed region in Turkey, covering approximately 60% of the output of the Turkish manufacturing industry, 37% percent of the gross domestic product (GDP), and 26% of the total population. The region's dominant position also reflects the share of public investment (28.7%) and private investment incentives (46.3%; Karadag & Deliktas, 2004). On the other hand, Marmara has also been highly innovative in the implementation of cutting-edge ICT applications and associated public-sector (national and local governments) supply instruments, which is explored based on the categories posed by Heeks (2005).

Supply Environment (Policies, Strategies, and Legislations)

Grounding the national-level ICT policies such as e-Turkey to the urban and regional level is a major challenge that needs to be tackled. Within the frame of e-Turkey, Yalova province in Marmara is selected as a pilot city for the initiative. ICT projects of Yalova were presented as best practices in various national and international conferences, meetings, and platforms. In this context, various local ICT policies have been deployed in order to enhance public Internet access (public Internet kiosks), economic development (call centers), e-literacy (adult IT certification programs), and online

public services (local e-government). Macro factors such as economic instability and change, and the ever-changing local political context, however, lead to the sustainability failure of so-called IT City Yalova projects (Velibeyoglu, 2006).

On the strategic level, two recent developments are important in the implementation of ICT applications internal to local governments' structure. First, the strategic decision of Turkey to join the EU and the need to adopt EU principles in the field of local government have constituted a powerful driving force and accelerated local government reform in Turkey (Kosecik & Sagbas, 2004; Ozkaynak, 2005). In the new Local Government Act (2005) establishment of geographic and urban information systems (UIS) for intermunicipality tasks has become obligatory for all metropolitan municipalities. Second, through total quality management (TQM) strategies, some local governments (Bursa, Kocaeli, Yalova) in Marmara have reorganized their departmental structures and processes that allowed them to accommodate rational technical systems like GIS (geographic information system). In Yalova, for example, online local-government services are measured and evaluated through TQM principles (Velibeyoglu, 2006).

Supply of Resources (Infrastructure, Skills, and Other Resources)

Local governments in Turkey have experienced serious policy bottlenecks in governing and investing in their ICT infrastructures. Infrastructure provision is left for the national government and private sector. The detrimental effects of the Marmara earthquake (1999) had important influence on local governments in Marmara as well as Turkey in terms of recognition of the importance of telecommunications infrastructure and ICT-based services. For example, Yalova is selected as Turkish Telecom's pilot city for the provision of a natural-disaster-resistant Internet infrastructure. Another impact of the earthquake was the recognition of the vital importance of an information infrastructure that accelerated the development of spatial information systems in post-earthquake cities (Sakarya, Duzce, Yalova, Kocaeli, Bursa) in the region (Velibeyoglu & Saygin, 2005).

The availability of skilled personnel for information systems use is one of the biggest problems in public-sector organizations in Turkey including local governments. This was largely because of the problem of the public-sector employment policy that neither computer skills nor individual productivity was encouraged and rewarded by the administrative system (Tecim, 2004). However, some innovative and careful attempts can be observed in the local governments of Marmara. In the Bursa metropolitan municipality, for example, the UIS Division was founded to support the functioning of municipal services, in-house production and maintenance of information, and training of the staff in IS applications (Velibeyoglu, 2005).

As hubs of the knowledge economy, universities and research centers play a critical role in the creation of e-regions (Marceau & Martinez, 2005). In this sense, in Marmara there are a considerable number of universities and research centers (e.g., TUBITAK Marmara Research Center) that help to facilitate human resources and adoption capability in information systems and technologies. Bilisim Vadisi (Informatics Valley), for example, was designed in the Marmara region Istanbul to ensure development of Turkey among the regional countries as a center of production and operation for international IT corporations as well as to attract foreign direct investment in the domestic IT sector (SPO, 2006). In addition, new technology-park developments in Marmara have been planned to focus on R&D (research and development) firms in the automotive and telecommunication sectors in order to support the Specialization in Technology Development Zones objectives of the 2006-2010 Information Society Strategy Action Plan of Turkey (SPO).

Supply Mechanisms (Local and Global Organizations, Initiatives, and Networks)

Building strong partnerships in disseminating and sharing knowledge between institutions such as academia, the public sector, and the private sector has become a vital issue for KBUD and the transition to a knowledge economy (Yigitcanlar, 2005).

The information need of postdisaster management and recovery have provided some international and national donor aid in the establishment of UIS in post-earthquake cities in Marmara. The Sakarya governorship GIS center, for example, has developed several applications for emergency situations (e.g., to provide tents, prefabricated houses, food, and social activities) with the help of UNICEF-Turkey and the Ministry of Internal Affairs (Tecim, 2004).

On the European level, local governments in Marmara have affiliated regional information society initiatives in Europe. The Yalova municipality currently has the only Turkish member of the Telecities network, which is a regional institute that aims to bring together towns and cities for the development of urban ICT applications.

ICT Applications (Local E-Government and Urban Information Systems)

As aforementioned, new EU integration initiatives including e-Turkey have visible impacts on the implementation of ICT applications such as local e-government and UIS in local governments. The national and local e-government initiative lies at the heart of the e-Turkey project. It is seen as an essential part of government reform and restructuring (SPO, 2004). Within the framework of the e-government project, restructuring the state, raising the level of educa-

tion and health of the society, strengthening scientific and technological capability, developing new technologies, and improving physical infrastructure have been determined as critical. About 200 large, medium, and small e-government projects are now under way. Among them, local e-government projects in the provinces of Marmara (e.g., Istanbul, Bursa, Yalova) have dominated e-governance awards that promote the best projects and initiatives in ICT applications in Turkey (Velibeyoglu, 2006).

Initiatives supporting e-municipality and e-government, and transition from government to e-governance and then to e-democracy raised the importance of transparency, communication, public accountability, and participation issues (Yigitcanlar & Baum, 2006). In this sense, the concept of UIS began to be popular among the local governments. The UIS concept is used as an umbrella term encapsulating all the efforts for an information system, whether GIS or MIS (management information system), or information technologies like the Internet within an integrated system that is supposed to be performed in local-government operations in order to support organizational rationality (Velibeyoglu, 2005).

Although so-called UISs were being marketed by vendors as the panacea for all problems, the implementation of large-scale information systems generally ended in failure because ISs require large changes in an organization's existing structure. Implementation of UIS generally incorporates a significant set of rational structures, processes, culture, professional strategies, and involvement (Saygin, 2003).

In the Turkish case, although no local government has been able to complete the establishment of a citywide UIS so far, the most promising applications have come from the local governments in Marmara (e.g., Bursa UIS) because of several reasons. First, local governments in Marmara have relatively more experience with UIS (e.g., Istanbul since 1989, and Bursa since 1996). Second, there has been positive reception from local governments in the implementation of various technological systems and therefore some of them rearranged their organizational structure for better utilization of IS (e.g., TQM or semiautonomous UIS departments or centers). Third, financial resources have been available particularly as a part of large-scale infrastructure projects. In the Bursa UIS case, for example, funding for UIS was obtained through an international donation within the framework of the fresh-water infrastructure project (Velibeyoglu, 2005). Finally, the specific supply instruments outlined above have been influential in the development of UIS in the region.

FURTHER TRENDS

For future studies and research, regional-level indicators should be developed in relation to both supply and demand from businesses, government, and households. Similarly, the tangible assets of the region should be taken into account. The best-practice applications obtained from the Marmara region should be extended, updated, and shared with other public-sector organizations, yet only a few studies focus on the institutional dimension of the ICT applications and the context of supply instruments. The important and challenging task of researchers, then, is to demonstrate the multilevel evidence in recorded case studies and research.

CONCLUSION

The EU harmonization process has set the challenge of developing information society objectives in Turkey. In this context, there is an urgent need to find implementation paths to realize ICT policies not only at local and national levels, but also on the regional level as well. This concise review revealed that local governments in Marmara have already taken part in the European urban and ICT networks. With best-practice implementations, local governments in Marmara are accelerating the efforts of the country in terms of spatial IS and e-governance applications. Although there are some indicators of e-region and some short-term individual best practices from Marmara, the efforts moving toward an e-region is still embryonic and largely suffers from the uncoordinated nature of supply instruments.

As international relations have been intensified, and as common concerns have been shared, local governments in Marmara have required new networking mechanisms for interorganizational as well as international cooperation. Therefore, new ICT supply mechanisms should be introduced toward an e-region to support KBUD, allowing public and private partnership and community participation in decision-making processes, and also encouraging local economic development and social cohesion. This is to say that ICT applications need to be smoothly adopted for unstable, rapidly changing sociospatial circumstances and considered soft organizational realities of local organizations.

Supply mechanisms and ICT applications should be fully accommodated in the future developments of the region. For example, a coordinating autonomous or semiautonomous regional body for ICT policy and implementation needs to be established. Such a mechanism is less vulnerable to environmental changes and political instability, which are very important in a developing-country context.

KEY TERMS

E-Region: It is a set of policy actions to achieve economic and social cohesion and to raise the technological level of regions through the use of ICTs. It covers a wide range of ICT initiatives from the provision of ICT infrastructure to the promotion of new electronic services and innovative ICT applications.

Knowledge-Based Urban Development: This is a knowledge-intensive urban planning and development approach to nourish the transformation and renewal of cities into knowledge cities.

Local E-Government: Local e-government refers to information, services, or transactions that local governments provide online to citizens using the Internet and Web sites.

Nomenclature of Territorial Statistical Units: It is a system of the classification of regions across the EU used by the European Commission.

Regional Development Agency: This is a semiautonomous, regionally based body operating at arms length vis-à-vis its sponsoring political authority. It is a multifunctional and integrated agency, the level of which may be determined by the range of policy instruments it uses.

Total Quality Management: TQM is an organization-wide effort to improve quality and make it the responsibility of all employees.

Urban Information Systems: UISs are powerful means for governments in meeting long-term strategic planning and management challenges. They provide a heightened awareness of the interdependency among environmental, social, and economic health and the impact of decisions made by neighboring jurisdictions, government agencies, and private business.

Information Fusion of Multi-Sensor Images

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

The human perception to the outside world is the results of action among brain and many organs. For example, the intelligent robots that people currently investigate can have many sensors for sense of vision, sense of hearing, sense of taste, sense of smell, sense of touch, sense of pain, sense of heat, sense of force, sense of slide, sense of approach (Luo, 2002). All these sensors provide different profile information of scene in same environment. To use suitable techniques for assorting with various sensors and combining their obtained information, the theories and methods of multi-sensor fusion are required.

Multi-sensor information fusion is a basic ability of human beings. Single sensor can only provide incomplete, un-accurate, vague, uncertainty information. Sometimes, information obtained by different sensors can even be contradictory. Human beings have the ability to combine the information obtained by different organs and then make estimation and decision for environment and events. Using computer to perform multi-sensor information fusion can be considered as a simulation of the function of human brain for treating complex problems.

Multi-sensor information fusion consists of operating on the information data come from various sensors and obtaining more comprehensive, accurate, and robust results than that obtained from single sensor. Fusion can be defined as the process of combined treating of data acquired from multiple sensors, as well as assorting, optimizing and conforming of these data to increase the ability of extracting information and improving the decision capability. Fusion can extend the coverage for space and time information, reducing the fuzziness, increasing the reliability of making decision, and the robustness of systems.

Image fusion is a particular type of multi-sensor fusion, which takes images as operating objects. In a more general sense of image engineering (Zhang, 2006), the combination of multi-resolution images also can be counted as a fusion process. In this article, however, the emphasis is put on the information fusion of multi-sensor images.

BACKGROUND

There are many modalities for capture image and video, which use various sensors and techniques (Brakenhoff, 1979; Committee, 1996; Bertero, 1998), such as visible light sensor (CCD, CMOS), infrared sensor, depth sensor, con-focal scanning light microscopy (CSLM), a variety of computer tomography techniques (CT, ECT, SPECT), magnetic resonance imaging (SAR), synthesis aperture radar, millimeter wave radar (MMWR), etc.

Main Steps of Image Fusion

For image fusion, many image techniques can be used in three steps (Zhang, 2007).

Image Pre-Processing

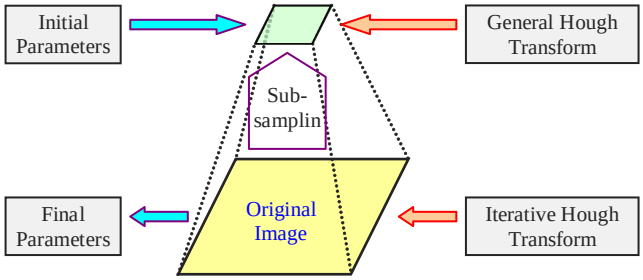
It includes image normalization (gray level equipoise, re-sampling, and interpolation), image filtering, color enhancement, edge sharpening, etc. Image fusion is carried out among images of different sizes, different resolutions, and different dynamic ranges of gray levels or colors. Image normalization is to normalize these parameters. Image filtering is to high pass filter the higher resolution image to obtain high frequency texture information, to keep it in fusion with lower resolution image. Image color enhancement is to increase the color contrast in lower resolution image, to reflect the spectrum information into the fused image. Edge sharpening is performed on high-resolution image for making the boundary clear and reducing noise, thus it fuses the space information from high-resolution image to low resolution image.

Image Registration

It is to align different images in space. In a more general sense, it is a special case of image matching, which has many existing techniques (Kropatsch, 2001; Shapiro, 2001; Buckley, 2003; Zhang, 2007). Image fusion has high requirement for accurate registration. If the registration error is higher than one pixel, then the fused results will show superposition effect and the visual quality of image will be greatly reduced.

Image registration can be classified as relative registration and absolute registration. The relative registration takes one image from many images of the same category as a reference image; other images will be aligned relatively to this reference image. Absolute registration takes the space

Figure 1. Framework for image registration using control point-based multi-scale Hough transform



coordinate system as the reference system; images to be fused will be aligned relative to this system.

Image registration can be classified also as region-based registration and feature-based registration. Control point (corresponding points in both images to be registrated) is a typical feature used in feature-based registration. Once the correspondence between control points was determined, the registration process can be carried out with determined parameters. The general Hough transform (GHT) is a commonly used technique. It can be considered as the evidence accumulation method. The global search space depends on the scale and rotation parameters, and can be very huge. To reduce the complexity of GHT, iterative Hough transform (IHT) can be used. However, IHT is influenced by the initial parameters and the range of parameter values, and often converged to local maximum. By using Hough transform in a multi-resolution decomposition environment, as shown in Figure 1, the robustness of GHT and computation efficiency of MIHT can be combined (Li, 2005).

In multi-resolution decomposition-based techniques, few control points are used in low-resolution layer in which GHT is used to obtain accurately the initial values of transform parameters. While in high resolution, IHT is used to accelerate the process.

Image Fusion

It is performed after image pre-processing and registration. The quantitative fusion is to fusion a group of data to obtain a consistent data, which is a conversion from data to data. The qualitative fusion is to fusion many single decisions to form a combined decision, which is a conversion from several uncertainty representations to a relative coherent representation. The quantitative fusion often treats information represented by numeric value while the qualitative fusion mainly treats information represented by non-numeric values.

Three Layers of Image Fusion

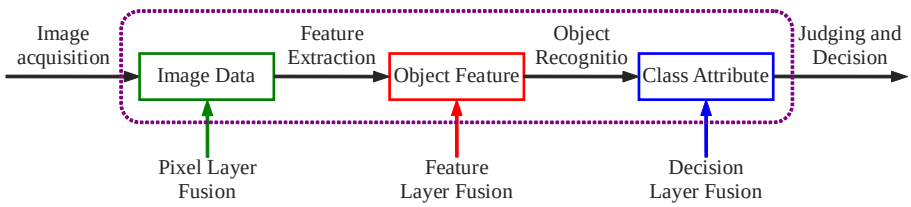
The multi-sensor image fusion can be split into three layers. They are, from low to high, pixel-based fusion layer, feature-based fusion layer, and decision-based fusion layer (Polhl, 1998). In recent years, the development tendency of fusion is going from pixel to region (Piella, 2003).

The flowchart of multi-sensor image fusion with three layers is illustrated in Figure 2. There are three steps from capturing scene image to making judgment and decision: feature extraction, object recognition, and decision creation. Three layers of image fusion are just corresponding to these three steps. The pixel-based fusion is made before the feature extraction step, the feature-based fusion is made before the object recognition step, and the decision-based fusion is made before the decision creation.

Pixel Layer Fusion

Pixel layer fusion is conducted in low layer, data layer. It operates directly on captured images and produces a single

Figure 2. Flowchart of multi-sensor image fusion



fused image. Pixel layer fusion provides the basis for high layer fusion. The advantages of pixel layer fusion is that it will keep as more as possible original information, so the precision obtained would be higher than that of other two fusions. The main disadvantages are the huge information to be treated and high computation cost. Moreover, pixel layer fusion often requires the data to be fused are captured by the same type or similar type sensors.

Feature Layer Fusion

Feature layer fusion is conducted in middle layer. It needs to extract features, obtain scene information, and integrate them to provide higher believable decision. Feature layer fusion not only keeps the important information, but also compresses the data volume. It is suitable for sensors of different types. The advantage of feature layer fusion is that it deals with less data than the pixel layer fusion, so it is more suitable for real time process. The main disadvantage of feature layer fusion is that its precision is worse than pixel layer fusion.

Decision Layer Fusion

Decision layer fusion is conducted in the highest layer, often performed with the help of symbolic computation. It makes directly the optimal decision according to the reliability of each decision, as each process unit has already finished the tasks of object classification and recognition. The advantage of decision layer fusion is that it has the properties of high tolerance, opening and real time. The main disadvantage of decision layer fusion is that the information has already had a lot of loss before fusion, so the precision, either in time of in space, would be inferior to other two fusions.

Principal properties of the three fusion modes are listed in Table 1.

Some typical techniques used in three fusion modes can be found in (Zhang 2007).

MAIN FOCUS OF THE CHAPTER

Techniques in pixel layer fusion will be illustrated with real examples. In pixel layer fusion, the original images to be fused have some different but complementary properties.

Basic Fusion Methods

In the following, by taking the fusion of TM (thematic map) multi-spectrum images captured by Landsat earth resource satellite and of complete spectrum images captured by SPOT remote sensing satellite as example, several basic methods are introduced. Currently, TM multi-spectrum images covers seven bands ranged from blue to infrared (with wave length 0.45 ~ 12.5 μm), and SPOT whole spectrum images cover five bands ranged from visible light to near infrared (with wave length 0.5 ~ 1.75 μm). The space resolution of SPOT image is higher than that of TM image, but the spectrum coverage of TM image is wider than that of SPOT image. Figures 3(a) and 3(b) show a TM image $f_t(x, y)$ in Band-5 (with wavelength 1.55 ~ 1.75 μm) and a SPOT image $f_s(x, y)$ with wavelength 0.5 ~ 0.73 μm, taken from same place.

Weighted Average Fusion

It is an intuitionistic method with the following steps:

(1) Select the region of interest in $f_t(x, y)$.
(2) Re-sample different wave band images in this region to extend $f_t(x, y)$ to a high-resolution image.
(3) Select the corresponding region of interest in $f_s(x, y)$, and match it with $f_t(x, y)$.
(4) Perform the following algebra operation to obtain weighted average fused image.

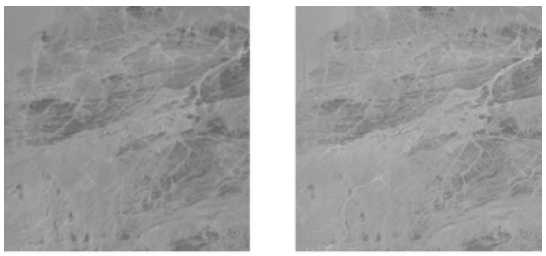
$$g(x, y) = w_s f_s(x, y) + w_t f_t(x, y) \quad (1)$$

where w_s and w_t are the weighting values for $f_s(x, y)$ and $f_t(x, y)$, respectively.

Table 1. Principal properties of three fusion modes

Fusion Layer	Fusion Level	Information Loss	Tolerance	Anti-disturb	Precision	Real Time	Computation Complexity
Pixel Layer	Low	Small	Bad	Bad	High	Poor	Big
Feature Layer	Middle	Moderate	Middle	Middle	Middle	Moderate	Middle
Decision Layer	High	Big	Good	Good	Low	Good	Small

Figure 3. Examples of TM image and SPOT image



(a) (b)

Pyramid Fusion

Pyramid is a common data structure to represent images in multi-scale. Pyramid fusion can be carried out by:

(1) Select the region of interest in $f_t(x, y)$.
(2) Re-sample different wave band images in this region to extend $f_t(x, y)$ to a high-resolution image.
(3) Decompose all $f_t(x, y)$ and $f_s(x, y)$ to be fused according to pyramid structure.
(4) Fuse the corresponding decomposition results of $f_t(x, y)$ and $f_s(x, y)$ in every layer of pyramid.
(5) Reconstruct the fused image from the fused pyramid by using inverse process for generating pyramid.

HSI Transform Fusion

HSI (hue, saturation, and intensity) transform converts the color image from RGB space to HSI space. HSI transform fusion performs fusion operation with the following steps:

(1) Select three bands of images from $f_t(x, y)$, take them as *R*, *G*, and *B* images, and transform them into *H*, *S*, and *I* images.
(2) Substitute *I* image after HSI transform (this image determine the details) by $f_s(x, y)$.
(3) Perform inverse HSI transform; take thus obtained RGB image as the fused image.

PCA-Based Fusion

PCA (principal component analysis) relies on KL transform. The main steps for PCA-based fusion are:

(1) Select three or more bands of images from $f_t(x, y)$ to perform PCA.
(2) Take the first principal component obtained by PCA operation, match it with $f_s(x, y)$ by using their histograms and make them having comparable mean and variance values.
(3) Substitute the first principal component by the above matched $f_s(x, y)$, perform inverse PCA, and take thus obtained image as the fused image.

Wavelet Transform Fusion

Wavelet transform decomposes an image into sub-images corresponding to different structures of the image. The main steps for wavelet transform fusion are (Pajares, 2004):

(1) Perform wavelet transform for both $f_t(x, y)$ and $f_s(x, y)$, obtain low frequency and high frequency sub-images for each image.
(2) Substitute the low frequency sub-images of $f_s(x, y)$ by those of $f_t(x, y)$.
(3) Combine substituted low frequency sub-images of $f_t(x, y)$ with the high frequency sub-images of $f_s(x, y)$; perform the inverse transform to obtain the fused image.

Combination of Fusion Methods

The above introduced fusion methods have their own particularity.

Weighted average fusion is simple and fast, but ineffective for anti-jamming and the quality of fused image is questionable. One typical problem is the blur caused by averaging.

Pyramid fusion is also simple to implement and can provide clearly fused image. However, the different layers in pyramid have correlation, so the images in different layers have redundancy. Besides, the reconstruction of pyramid has some instability, especially for distinct images.

HSI transform fusion, when used to fuse TM multi-spectrum image and SPOT whole spectrum image, can make the fused image having high definition to enhance the spatial detail information in image. However, if substitute all *I* component of TM image by SPOT image, the spectrum information will have a big loss and the resulted fusion image will have a large distortion.

PCA-based fusion produces fused image with high spatial definition and high spectrum definition, and the details for objects will be even clear. However, if substitute the first principal component of TM image by SPOT image, some useful information in the first principal component of TM image that related to the spectrum property will be lost. In this case, the spectrum definition of fused image will be affected.

Wavelet-transform fusion can effectively keep the spectrum information from multi-spectrum image and the detailed information from whole spectrum image, so the fused image would be better both in visual appearance and in statistics. However, the standard wavelet transform has two problems.

One is that it is equivalent to filter image with high-pass and low-pass filters, this filtering process will cause the loss of some original information. Another is that the gray levels of TM and SPOT images are quite different, the fusion would cause the change of TM image's spectrum information and induce the generation of noise.

To overcome the problems in using only one type of fusion methods, different fusion methods have been combined in practice.

Fusion by Combining HSI Transform and Wavelet Transform

It has the following steps:

(1) Select three bands from $f_t(x, y)$; perform the transform from RGB space to HSI space.
(2) Perform wavelet-transform for both $f_s(x, y)$ and I component.
(3) Substitute the high frequency coefficients obtained from the decomposition of I component by the high frequency coefficients obtained from the wavelet transform of $f_s(x, y)$.
(4) Perform inverse wavelet transform for all wavelet coefficients after substitution to obtain a new intensity component I'.
(5) Perform the transform from H, S and I' to R, G, B and obtain the fused image.

Figures 4(a) and (b) show the fused images obtained from fusing Figures 3(a) and (b) with HSI transform fusion and wavelet transform fusion, respectively (Bian, 2005). Figure 4(c) shows the fused images obtained by using the combined method. Since the new fused result not only keeps the high frequency information from SPOT image but also keeps a lot of texture information from TM image, it has clear details and provides better visual impression than either Figure 4(a) and Figure 4(b).

Fusion by Combining PCA and Wavelet Transform

It has the following steps:

(1) Perform PCA operation for all bands of $f_t(x, y)$.
(2) Take the first principal component obtained by PCA operation, match it with $f_s(x, y)$ by using their histograms and make them having comparable mean and variance values.
(3) Perform wavelet transform for matched two images.
(4) Substitute the high frequency coefficients obtained from the decomposition of $f_s(x, y)$ by the high frequency coefficients obtained from the first principal component of $f_s(x, y)$.
(5) Perform inverse wavelet transforms for all wavelet coefficients after substitution to obtain a new first principal component of $f_t(x, y)$.
(6) Perform the inverse PCA operation for the new first principal component and other components of $f_t(x, y)$ to obtain the fused image.

Figures 5(a) and (b) show the fused images obtained from fusing Figures 3(a) and (b) with PCA-based fusion and wavelet transform fusion, respectively (Bian, 2005). Figure 5(c) shows the fused images obtained by using the combined method. It is seen that the new fused result enhances the texture property, enriches the spectrum information, as well as makes the object contour more visible.

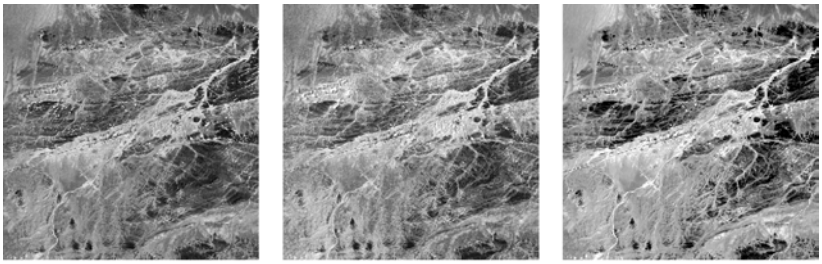
FUTURE TRENDS

The basic fusion techniques use only static images; such an analysis constitutes an ill-posed, under-determined problem. A new paradigm of "active, qualitative, purposive" vision has been introduced (Andreu, 2001). With the goal of effective fusion in mind, multiple moving images and suitable analysis

Figure 4. Fused image with the combination of HSI transform and wavelet trans

(a) (b) (c)

Figure 5. Fused image with the combination of PCA and wavelet transform



(a) (b) (c)

are employed. The uncertainty problem will be well defined. Further researches in this direction should be continued.

The sensor model plays an important role in multi-sensor image fusion. It should not only describe sensors' own properties, but also describe the influence of exterior conditions to sensor and the ability of cross actions among different sensors.

Finally, the scope of fusion can be further extended from the three layers described. For example, to the low end by considering the detection of signals, and to the high end by considering the situation state and tendency.

CONCLUSION

In the above, the principles of multi-sensor information fusion, especially of multi-sensor image fusion, are introduced. Some basic techniques used in multi-sensor image fusion are presented with real applications.

Multi-sensor information fusion is a basic ability of human beings. In mimicking such ability by computer, the fuzziness in perceiving environment could be reduced, the reliability of making decision could be increased, and much more completed problems could be solved. Except the examples for the fusion of remote sensing images here, the fusions of visible-light image and infrared image, CT image and PET image also have provided to be successful. It is expected that this technology will be applied in more application areas.

KEY TERMS

Bayesian fusion: A probabilistic method for fusing information from different sensors. It can be used for feature level fusion and decision level fusion.

Evidence reasoning fusion: A new method for fusing information from different sensors. It also called D-S theory. It can be used for feature level fusion and decision level fusion.

Fusion based on rough set theory: A fusion method for decision level. Instead of exact set, it uses rough set to manipulate sensor data. It can compress redundant information so avoid the composition exploitation problem during fusion procedure.

Image Engineering: An integrated discipline/subject comprising the study of all the different branches of image and video techniques. It mainly consists of three levels: Image Processing, Image analysis, Image understanding.

Information fusion: Combined process of information from the source of same object or scene to obtain more complex, reliable and accurate information.

Objective evaluation of image fusion results: To judge the quality of image fusion with some computable metrics based on fusion results.

Sensor model: An abstract representation of the physical sensors and its information manipulation process.

Subjective evaluation of image fusion results: To judge the quality of image fusion with subjects' perception on fusion results.

From Information Management to Knowledge Management

Călin Gurău
GSCM – Montpellier Business School, France

INTRODUCTION

The continuous evolution of theory and practice has modified the existing organizational paradigms and has introduced new models which attempt to explain how information is created, transmitted, used, and managed within various organizations. Many authors have outlined the fact that information no longer represents the most important asset of a firm. In the present competitive conditions, the managers must also consider knowledge and its relationship with enterprise information systems (Gray & Densten, 2005; Jorna, 2002; Nonaka & Takeuki, 1995).

Using both a theoretical and empirical approach, this study attempts to investigate the implication of a new paradigm of *knowledge management* on an organization's structure and functioning, considering knowledge management in direct relation with data management and information systems. This article shows, using two organizational examples, that the development of effective *knowledge management* systems requires a well-organized information system, as well as the clear identification of the main knowledge and decision-making centers within the business organization.

After briefly defining the concepts of *information management* and *knowledge management,* the article presents a comprehensive literature review of the academic and professional publications that investigate the inter-relationship between these two organizational functions. Based on this secondary information, we propose a model that integrates both information and knowledge management systems, and provides an analysis of two UK business firms in order to illustrate the integration between these elements.

BACKGROUND

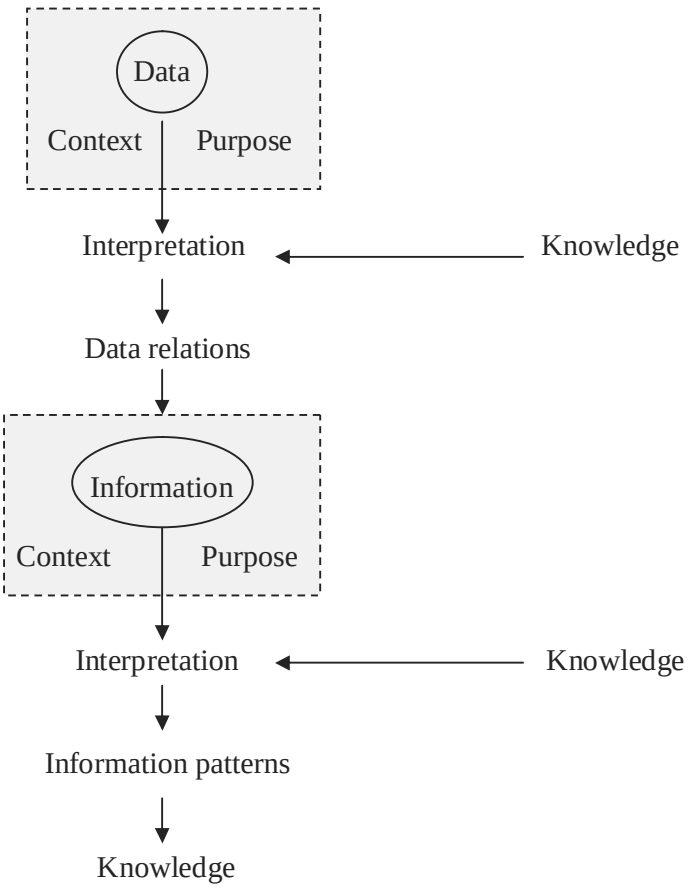
Before considering the research made on the relationship between *information management* and *knowledge management,* it is important to understand clearly the meaning of concepts such as data, information, and knowledge, and the progression from one to another within an organization.

A simple collection of data does not represent information, and equally, a simple collection of information cannot be considered as knowledge. An isolated datum has no meaning, and a collection of randomly combined isolated data is even more confusing (Schreiber et al., 2000). In order to transform a data collection into information, a person or a system must order the data, applying a specific interpretative pattern, which is determined by the context and the objectives of data analysis. Through the application of this interpretative pattern, specific relations among the collected data are discovered and defined, which transforms data in information, but only for a specific context and purpose (Bellinger, 2004). When the resulting information is ordered and interpreted in a specific context and with a specific purpose, patterns can be identified and defined as knowledge (Bellinger, 2004). Considering this transformation of data in information and then in knowledge, it is possible to draw a descriptive model (see Figure 1). It is interesting to note that in order to properly interpret the data and then the information, certain information patterns (knowledge) must be applied which create a dynamic cycle of knowledge creation and application within organizational systems.

However, this model is still too simplistic for several reasons. First of all, the knowledge used to define interpretation rules might not be created inside the organization, but rather acquired and transferred from outside (e.g., from a consulting firm), and it might be completely different from the knowledge resulting as an output of the entire process of interpretation.

Secondly, knowledge can be of different types (Wilson, 2002). Nonaka and Takeuki (1995) identify two types of knowledge—tacit and explicit knowledge—the first being derived from the second. On the other hand, Jorna (2002) defines three types of knowledge that are integrated into a dynamic model (van Heusden, & Jorna, 2001): (a) tacit or perceptual knowledge, (b) coded knowledge, and (c) theoretical knowledge. Perceptual knowledge is based on the perception of a specific difference in the environment, which allows one to identify and become aware of a specific situation or context (perceived as a pattern). Jorna (2002) considers this type of knowledge as uni-dimensional. The step towards coded knowledge is realized when the perceiver identifies a specific relation between recognized events or processes. This type of knowledge is defined as bi-dimensional. Coded knowledge is easier to communicate, because it can be represented and reproduced using specific signs (e.g., letters, mathematical operators, symbols, etc.). Finally, knowledge becomes theoretical when coded signs relate to the events represented not on a basis of a convention, but on the basis

Figure 1. The progressive transformation of data in information and information in knowledge



of formal or structural qualities (Jorna, 2002). At this level, abstract signs can be used as knowledge operators, in order to predict the development and evolution of real events or processes (e.g., scientific formulas).

Depending on the purpose and utility of knowledge, Zack (1999) classifies knowledge as:

a. *declarative knowledge* knowledge about something;
b. *procedural knowledge* knowledge of how something occurs or is performed; and
c. *causal knowledge* knowledge of why something occurs.

On the other hand, considering the specific subject/object or the form of knowledge, Lemken, Kaler, and Rittenbruch (2000) identify:

a. *tacit knowledge* you know it but you can't say it;
b. *experience-based knowledge* physical experience;
c. *coded knowledge* still available when people leave;
d. *conceptual knowledge* cognitive ability, abstraction;
e. *social knowledge* shared knowledge, culture, groups;
f. *event knowledge* events and trends; and
g. *process knowledge* operations and context.

Thirdly, the knowledge is mainly connected with people, and therefore human resource management is considered one of the main tracks of *knowledge management* (Parise, 2007; Sveiby, 2001), together with information systems. Choi and Lee (2003) make a clear distinction between a system-oriented and a human-oriented approach in knowledge management. System orientation emphasizes codified knowledge, focuses on codifying and storing knowledge via information technology, and attempts are made to share knowledge formally. On the other hand, human orientation emphasizes dialogue through social networks and person-

to-person contacts, focuses on acquiring knowledge via experienced and skilled people, and attempts are made to share knowledge informally (Sorge & Warner, 2001).

The management of various forms of knowledge within organizations is the subject of many recent studies (Gray & Densten, 2005; Jorna, 2002). One main area of research is the way in which knowledge can be created, managed, and distributed in complex business organizations.

Zack (1999) indicates four primary resources that are used for the management of explicit knowledge: (1) repositories of explicit knowledge; (2) refineries for accumulating, refining, managing, and distributing knowledge; (3) organization roles to execute and manage the refining process; and (4) information technologies to support these repositories and processes.

Although this research framework has its merits, allowing an analytical investigation of the various components of knowledge management systems, the approach neglects the role of the basic building blocks of knowledge: data and information. Considering the three main elements presented in Figure 1—data, information, and knowledge—it becomes obvious that a clear vision of the organizational knowledge system must also take into account the relationship among data, information, and knowledge, and consider the role of various employees in these three inter-related systems (Jorna, 2002).

Investigating Data Systems Inter-Relations within Business Organizations

In order to understand the relationship between data, information, and knowledge, two case studies of active UK-based companies have been investigated. The firms have been contacted as a result of previous collaborative work with the researcher, and invited to participate in this study. The first company (X) is a small business consulting firm, and the second one is a medium-sized biotechnology company (Y). Both firms are located in London and have more than 20 years of working experience. For confidentiality purposes, the names of the analyzed firms were not disclosed in this study.

The investigation of these organizational systems has been realized using both secondary and primary data. First of all, the public presentation of these companies, their annual reports and press releases, have been analyzed in order to understand organizational profiles of the firms, their portfolios of activities, and their main marketing strategies. Secondly, a series of face-to-face interviews, lasting between 45 and 90 minutes, have been conduced with the managers and the employees of these firms, regarding the organization and management of knowledge within the firm, as well as its connections with data and information systems. Finally, this information has been compared with the data collected during a direct observation of the internal functioning of these firms. The data collected was analyzed using simple qualitative techniques, such as the identification of the main representations and narratives of respondents about the organizational knowledge system.

The Relation Between Data, Information, and Knowledge Management

The analysis of these companies indicated both a number of common and specific elements concerning the relationship between data, information, and knowledge systems. In terms of common findings, both organizations used data, information, and knowledge systems, which they recognized as essential for the good functioning and the performance of the firm. The firms used a combination of internal and external data and information. Two types of knowledge have been identified as essential: routine organizational knowledge and creative organizational knowledge. *Routine knowledge* can be defined as knowledge with a high degree of stability which is applied repetitively for the good day-to-day functioning of the company. On the other hand, *creative knowledge* is applied to solve singular and/or unexpected situations that cannot be fully predicted and defined in advance.

There is no direct correspondence between routine knowledge and the coded knowledge defined by Jorna (2002), because in both companies the respondents recognized that some of the routine knowledge is implicit. Similarly, the creative knowledge is both codified and implicit, although the most substantial part is implicit, based on the personal professional experience and talent of employees.

Despite these common elements, the investigated companies present specific profiles in what concerns the predominance and the areas of application of routine and creative knowledge. Firms X collects or acquires both general market data and individual customer data, while the biotechnology firm focuses its data collection activities only on general market data. This approach is logical considering that the relation of the first firm with customers is direct and personal. On the other hand, company Y develops health therapies for a global consumer segment, and the clinical trials of its products are realized by a partner organization.

The routine knowledge is used by these organizations to process general market data and to interpret information in relation to a specific context and purpose. The resulting information is then transmitted to the centers of creative knowledge which develop and define the general strategy and the specific tactics of the firm. Sometimes, a drastic change in the market conditions determines a change of strategic orientation, which consequently has an impact on the routine knowledge (interpretation rules and objectives) used to process and interpret general market data and information.

Firm X

Figure 2 presents the relationship between data, information, and knowledge within company X. As can be seen, the main components of the company data system are the processes of data collection/acquisition, data archiving, and data processing—this last process being realized mainly using routine knowledge procedures.

The direct interaction between customers and consultants results also in data collection, which is processed in real time by a company's employees and transformed in information which is then interpreted using creative knowledge procedures, in order to provide customized and effective consulting solutions. On the other hand, the customer-consultant interaction enriches the professional experience of the company's personnel, enhancing the available creative knowledge.

At an organizational level, the information interpreted though routine and creative knowledge represents an input for the *strategic decision-making* center, which is using the received information to define the strategic orientation of the firm and the tactical day-to-day operations. These decisions are consequently enriching/modifying both the routine and the creative knowledge of the firm. The presence of various *double-loop connections* among data, information, and knowledge systems indicates the main *organizational learning* processes, which result in a dynamic evolution of company's knowledge (Antonacopoulou & Chiva, 2007; Engeström, 2007).

Firm Y

The connection among the three internal organizational systems is different in the case of firm Y (see Figure 3). The various information resulting from data processing represents an input for the operational block of the company, which is composed of three main departments: Research and Development (R&D), Production, and Commercialization. On the other hand, internal or external (outsourced) creative knowledge is also involved in the functioning of these departments. An exact representation of data, information, and knowledge systems for each of these three departments would present, in fact, a similar structure to the general model, with department-specific operations of data collection, archiving, and processing; with information processing mechanisms that apply department-specific routine and creative knowl-

Figure 2. The inter-relations among data system, information system, and knowledge system in company X

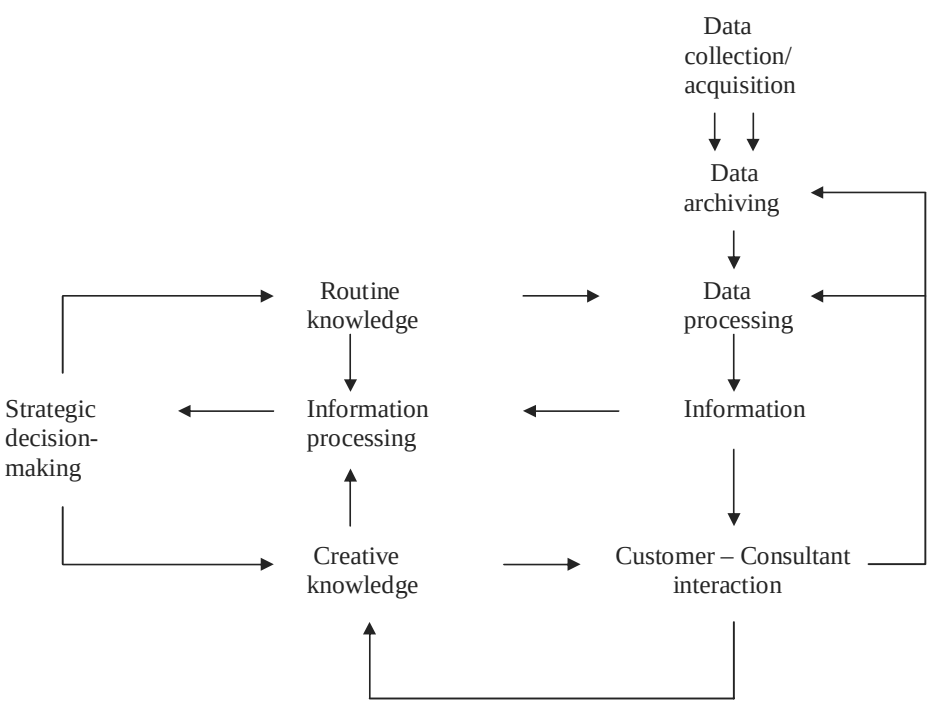


Figure 3. The inter-relations among data system, information system, and knowledge system in company Y

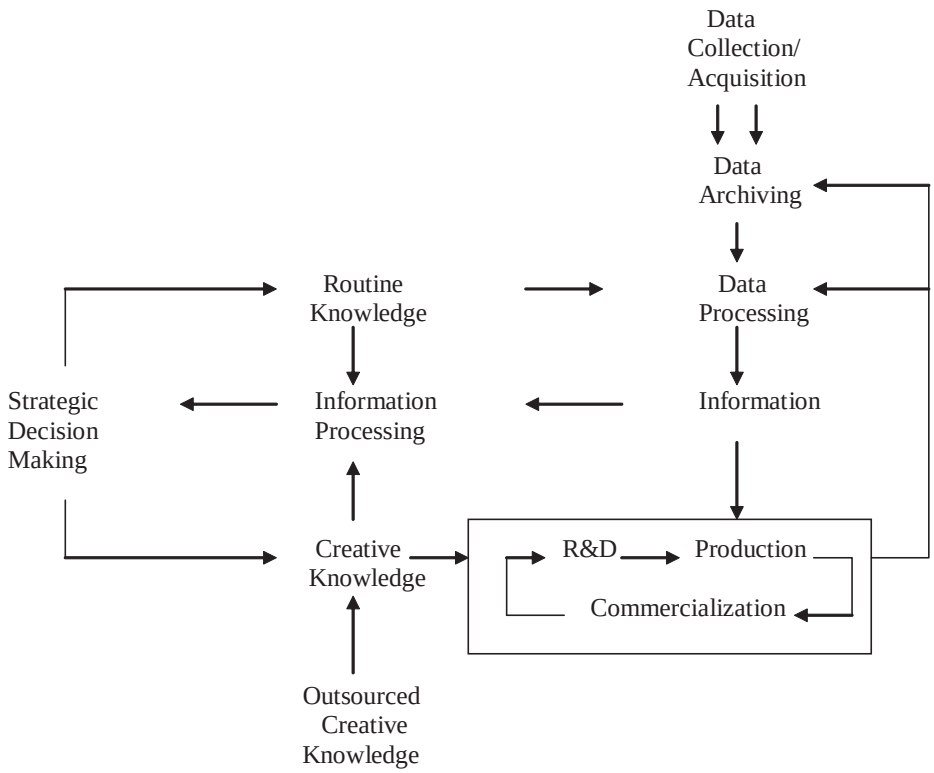

edge; and with strategic decision making, which influences the strategic orientation and the operational tactics of each department.

The complexity of this model is further enhanced by the fact that each department has connections with the other two departments in terms of exchange of data, information, and knowledge, as well as with the general structure and functioning of the organization. As in the previous case, the closed loops indicate an organizational learning process, functioning at a specific level within the company.

FUTURE TRENDS

The 'knowledge management' science and the connection of organizational knowledge with enterprise data and information systems represent very recent areas of research and analysis. The increased awareness that knowledge is the main asset of the company has forced management to transform the classical organizational paradigm of information systems/information technology in a complex model centered on various types of knowledge.

However, despite the increased professional and academic interest in this area, much progress is still to be done. The business modeling approach used in this study provides a clear representation of the inter-relationship among various organizational systems, but needs to be complemented by a clear identification of the main sources of routine and creative knowledge, and with an analysis of various roles and competencies that must be fulfilled by a company's personnel in the functional architecture of the company. On the other hand, researchers should explore the possibility of developing quantitative models of the relationship between data, information, and knowledge within the organizational system.

The connection between data, information, and knowledge flows should also be analyzed, in order to identify the possible blockages in the system, by applying simulation and

modeling procedures. The efficient transformation of data in information and then in knowledge, as well the effective application of knowledge in all organizational departments and processes, can significantly enhance the organizational learning process, which can provide an invaluable competitive advantage in a dynamic market environment (Cader, 2007; Reich, 2007).

CONCLUSION

Starting from a general discussion about the importance of data, information, and knowledge systems for the modern business organization, this study has developed and presented a basic graphical representation of data, information, and knowledge flows within two real companies that provided empirical data for this project.

The modeling approach that has been used has a number of advantages, permitting a clear representation of various organizational processes, and in the case of inter-organizational analysis, an easy comparison of various company structures. However, it also has a number of important limitations, offering only a general representation of the company's functional architecture.

The analysis of two different enterprises indicates that although the general representation of data, information, and knowledge flows is relatively similar, the level of complexity might vary from one enterprise to another. On the other hand, previous studies have indicated that the structure and the functioning of the organizational knowledge system might also be influenced by the specific corporate culture: adhocracy, clan, hierarchy, and market (Gray & Desten, 2005; Jorna, 2002; Lemken et al., 2000; Stoica, Liao, & Welsch, 2004). Future projects can identify additional characteristics that might determine the shape and functioning of the internal knowledge system, such as the company' stage of development, its size, or the level of technology/innovativeness that is integrated in its products and services.

The findings of this study can represent the basis for future research projects. The analysis of various data, information, and knowledge flows must be complemented by an investigation of the human resource management and technology used by the organization. For each specific process identified in the model, the enterprise should identify the main personnel capacities and the technological platform required to ensure an effective functioning of the system. Ultimately, these requirements should be compared with the real situation of the enterprise in order to map the main organizational gaps between the necessary and the existing level of resources.

KEY TERMS

Adhocracy Culture: An organizational culture in which various groups of individuals reach consensus by responding in an ad hoc fashion to frequently changing priorities.

Clan Culture: An organizational culture that emphasizes the internal maintenance organizational structures and processes, using flexibility, concern for people, and sensitivity toward customers.

Explicit Knowledge: Knowledge that is coded and cataloged in order to facilitate its use by people.

Hierarchy Culture: An organizational culture that focuses on the development and maintenance of stable organizational rules, structures, and processes, by implementing a hierarchical system of power and management.

Implicit Knowledge: Knowledge that is contained in people's 'modes', and based on their personal experience and insight.

Knowledge Management: A central function of an organization that contains a number of rules and processes applied so to comprehensively collect, organize, share, analyze, and distribute knowledge in order to maximize the organizational performance.

Market Culture: An organizational culture that attempts to achieve market performance using internal processes that emphasize stability and control.

Information Project Assessment by the ANDA Method

Alexandru Tugui
"Alexandru Ioan Cuza" University, Romania

INTRODUCTION

It is well known that the decision to invest is preceded by (pre-)feasibility analysis and studies, which should show that the investment is necessary, opportune, and efficient. As concerns the information field, we consider this feasibility study practice as partially adequate, as there is no full financial assessment of the *necessity* and *opportunity* of the information project by taking into account its advantages/disadvantages, the studies presenting only a list of these advantages/disadvantages. Moreover, given the impossibility of determining the contribution of each information function to the economic efficiency indicators of the organization (turnover, profit, etc.), the final result is also a partial assessment of the efficiency of the *information project*, which may lead to bad influences on the managerial team when making the decision of investing or not in that project. This is why we proposed in this study *a new method of financial assessment of the necessity and opportunity of the information project*, namely the annual net discounted advantages method or, more simply, the **ANDA method**). This chapter also includes, besides theoretical aspects, a case study with a concrete application of the ANDA method to an information project.

We mention that the ANDA method may be applied to the assessment of the efficiency and of the opportunity of any investment project of modernization in any business area.

BACKGROUND

Modern management lays increasing emphasis on the organization on *projects* of investment activities and their funding, by means of the *budget technique*.

Briefly, a project is the first decomposition of a program, with a beginning and an ending, including a series of logically chained and efficiently planned actions/activities, which are supposed to be carried out in a certain period of time, for which a financial support is associated/assigned by budget, aimed at achieving one or a set of objectives (Belanger, 1995; Devaraj & Kohli, 2002; Hayes, 1989; Lewis, 2000; Lientz & Rea, 1999; Mantel, Meredith, Shafer, & Sutton, 2001; Oprea, 2001; Project Management Institute [PMI], 1996; Sages Group [SG], 1997; Țugui & Fătu, 2004).

The previous definition leads to the idea that a project should include:

1. A (logic) schemata for running the established activities depending on the objectives undertaken;
2. An adequate financial support, that would enable the mobilization of the resources necessary for objective achievement;
3. A project administration team with a project manager that should coordinate the necessary procedures like a traditional manager.

The three items required for objective/objectives achievement within a project, support the project management concept, which has been thoroughly developed and widely used lately.

Basically, project management is defined as being the application of the knowledge and techniques specific to the project-oriented activities, so that the stakeholders' expectations and requirements should be attained or even overcome (Beise, Neiderman, & Mattord, 2006; Kern, Galup & Nemiro, 2000; Laudon & Laudon, 2000; PMI, 1996; Sisco, 2001; Walker, 2001).

Information project is a particular case of the project concept. As to the information-related activities in an organization, we can state that the project which reassembles them is an information project within a program run by such organization.

For a project to succeed, it is necessary to perform all the tasks assigned to the project management team resulting from the objective set, so the project management work becomes of primary importance.

Irrespective of the type of project considered for financial efficiency and opportunity analysis, the following information is necessary (Țugui & Fătu, 2004, p. 139):

- The initial investment value;
- The future cash flows;
- The analysis period; and
- The advantages and disadvantages as to the scenario "without project".

Please note that decisions related to information projects rely on feasibility studies stating their necessity, opportunity, and efficiency.

ANDA METHOD: THE METHOD OF ANNUAL NET DISCOUNTED ADVANTAGES

Motivation of ANDA Method

The assessment of the *necessity*, *opportunity*, and *efficiency* of an investment project is a stage of the utmost importance in any economic entity.

Usually, the *necessity* and *opportunity* of an investment project is justified by a description, under the form of a list, of the technical-economic advantages or disadvantages, without an *integrated financial value estimation*, under the form of impact studies, market surveys, and so forth, while for economic *efficiency*, the information included in the previous studies under the form of business plans, cost-profit analysis and, finally, feasibility studies, is molded.

As for the assessment of the efficiency of investment projects, there are specific indicators, such as: internal rate of return (IRR or ROI), payback time, net present value (NPV), and so forth. All these indicators apply to future cash flows for each project. In Table 1, we present the work schemata to obtain the analysis indicators of the efficiency of an investment project.

There is also the practice of justifying the *necessity* and *opportunity* of investment projects through sensitivity analysis of *efficiency indicators* between the scenario "with project" and the scenario "without project". The disadvantage of this comparison consists of the fact that it does not provide actual indicators to estimate the necessity and opportunity of the project, but only some differences that should be interpretation and supported.

***Note*:** The scenario "*without project*" is the variant in which the analyzed investment project is not applied, while the scenario "*with project*" is meant to commission the analyzed project.

Thus, the building of a set of economic-financial assessment indicators is justified for the assessment of the necessity and opportunity of an investment project.

The Essence of ANDA Method

As seen earlier, there is no set of economic-financial assessment indicators to assess the necessity and opportunity of an investment project, should the organization management request such information.

Under such circumstances, in order to assess the *necessity* and *opportunity* of an investment project we propose the employment of the **method of annual net discounted advantages (ANDA)**.

The essence of the *ANDA method* consists in substituting the cash flows with net advantages within the method of discounted cash flows (DCF) in order to calculate the indicators

Table 1. Model of data organization for the assessment of the efficiency of an information project. Note: IRR: Internal rate of return; NPV: Net present value; Vr: Residual value; ra: Discounted rate

Explanations	**Years**					
	0	**1**	**2**	**3**	**4**	**5**
Investment value (I_1)	I_1					
Net cash flows (F)		F1	F2	F3	F4	F5+Vr
Discount factor		$(1+ra)^{-1}$	$(1+ra)^{-2}$	$(1+ra)^{-3}$	$(1+ra)^{-4}$	$(1+ra)^{-5}$
Net discounted flows		$F_1*(1+ra)^{-1}$	$F_2*(1+ra)^{-2}$	$F_3*(1+ra)^{-3}$	$F_4*(1+ra)^{-4}$	$(F_5+Vr)*(1+ra)^{-5}$
Cumulated net discounted flows		$F_1*(1+ra)^{-1}$	$F_1*(1+ra)^{-1}+F_2*(1+ra)^{-2}$	$F_1*(1+ra)^{-1}+F_2*(1+ra)^{-2}+F_3*(1+ra)^{-3}$	$F_1*(1+ra)^{-1}+F_2*(1+ra)^{-2}+F_3*(1+ra)^{-3}+F_4*(1+ra)^{-4}$	$F_1*(1+ra)^{-1}+F_2*(1+ra)^{-2}+F_3*(1+ra)^{-3}+F_4*(1+ra)^{-4}+(F_5+Vr)*(1+ra)^{-5}$
Payback period	The investment value is compared to the cumulated net discounted flow. The year that overruns the investment value is the payback period.					
NPV	$-I+\sum F_i*(1+ra)^{-i}+Vr*(1+ra)^{-i}$ i takes values from 1 to 5					
IRR	For NPV = 0, ra is determined $-I+\sum F_i*(1+ra)^{-i}+Vr*(1+ra)^{-i}=0$					

Table 2. Data organization model for an information project opportunity assessment. Note: IRR: Internal rate of return; NPV: Net present value; Vr: Residual value; ra: Discounted rate

Explanations	**Years**					
	0	**1**	**2**	**3**	**4**	**5**
New Investment Value (I_1)	I_1					
Residual value of Old Project (Vro)	Vro					
Net New Investment Value (I_{1net})	$(I_1 – Vro)$					
Residual Value of New Project (Vr)						Vr
Net advantage /disadvantage (A)		A1	A2	A3	A4	A5+Vr
Discount factor		$(1+ra)^{-1}$	$(1+ra)^{-2}$	$(1+ra)^{-3}$	$(1+ra)^{-4}$	$(1+ra)^{-5}$
Net discounted advantage/disadvantage		$A_1*(1+ra)^{-1}$	$A_2*(1+ra)^{-2}$	$A_3*(1+ra)^{-3}$	$A_4*(1+ra)^{-4}$	$(A_5+Vr)*(1+ra)^{-5}$
Cumulated net discounted advantage/disadvantage		$A_1*(1+ra)^{-1}$	$A_1*(1+ra)^{-1}+$ $A_2*(1+ra)^{-2}$	$A_1*(1+ra)^{-1}+$ $A_2*(1+ra)^{-2}+$ $A_3*(1+ra)^{-3}$	$A_1*(1+ra)^{-1}+$ $A_2*(1+ra)^{-2}+$ $A_3*(1+ra)^{-3}+$ $A_4*(1+ra)^{-4}$	$A_1*(1+ra)^{-1}+$ $A_2*(1+ra)^{-2}+$ $A_3*(1+ra)^{-3}+$ $A_4*(1+ra)^{-4}+$ $(A_5+Vr)*(1+ra)^{-5}$
Payback period	The investment value is compared with the cumulated net discounted advantage. The year that overruns the investment value is the payback period.					
NPV	$- I_{1net} + \sum A_i*(1+ ra)^{-i} + Vr*(1+ ra)^{-i}$ i assumes values from 1 to 5					
IRR	For NPV = 0, ra is determined $- I_{1net} + \sum A_i*(1+ ra)^{-i} + Vr*(1+ ra)^{-i} = 0$					

IRR, NPV, and so forth. Hence, this method requires having run the following stages:

1. **Value assessment of annual net advantages/disadvantages**, that an information resource investment brings, as they are presented in Table 1;
2. **Discounting such advantages/disadvantages** upon the completion of the investment project;
3. **Calculation of the efficiency assessment indicators** based on the annual net discounted advantages/disadvantages.

In Table 2, we present the work scheme for obtaining the analysis and opportunity assessment indicators of an information project.

As shown in Tables 1 and 2, the difference between the DCF method and the ANDA method are:

1. the replacement of cash flows (Fi) by annual net advantages (Ai);
2. the replacement of investment value (I_1) by net investment value (I_{1net}), obtained by deducting from (I_1) the residual value of the old project (Vro), if it exists.

Figure 1 shows clearly that from the old project to the new one there are financial advantages/disadvantages, which we presented separately. It is obvious that these financial advantages/disadvantages are present in all the years of our analysis. Please note that most of the times, in the first year there may be greater advantages as compared to the old project, after which these advantages may diminish and/or become uniform in the following years.

Figure 2 shows the financial advantages/disadvantages between the two projects for a period of five years. Depending on the nature of the field we analyze, on the type of project funding, one may choose a shorter or longer period of analysis. However, in case of information projects, we advise that this period should not exceed five years, given the high obsolescence of information technologies.

Figure 3 presents the graph of the ANDA method, as described in Table 3.

The main strengths of the ANDA method for any type of project, including information projects, are:

1. The necessity and opportunity of a new project are also supported by figures;
2. There is a direct connection between the “old project” and the “new project”, or between the scenario “with project” and the one “without project”;

Figure 1. Comparison between the financial advantages/disadvantages of the new project and of the old project

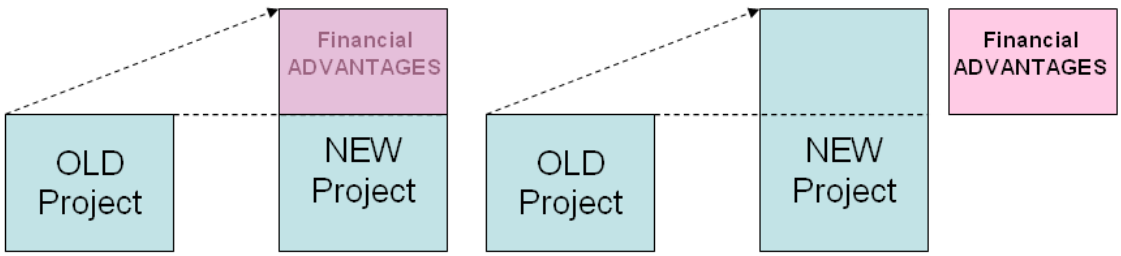

Figure 2. Five-year presentation of advantages/disadvantages Note: A1: 1st year's Financial Advantages

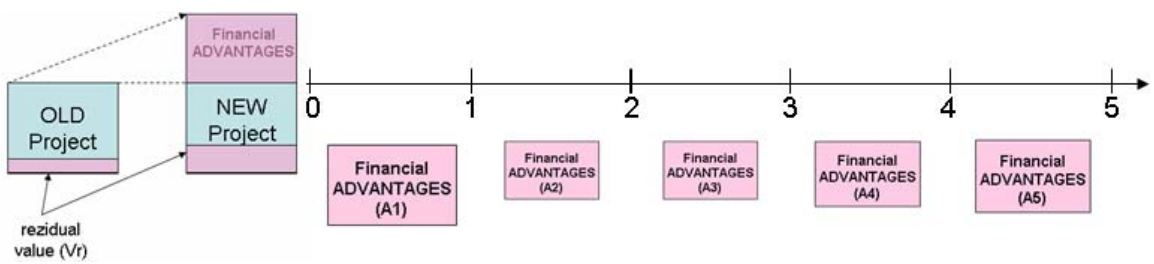

Figure 3. Graphic presentation of the ANDA method

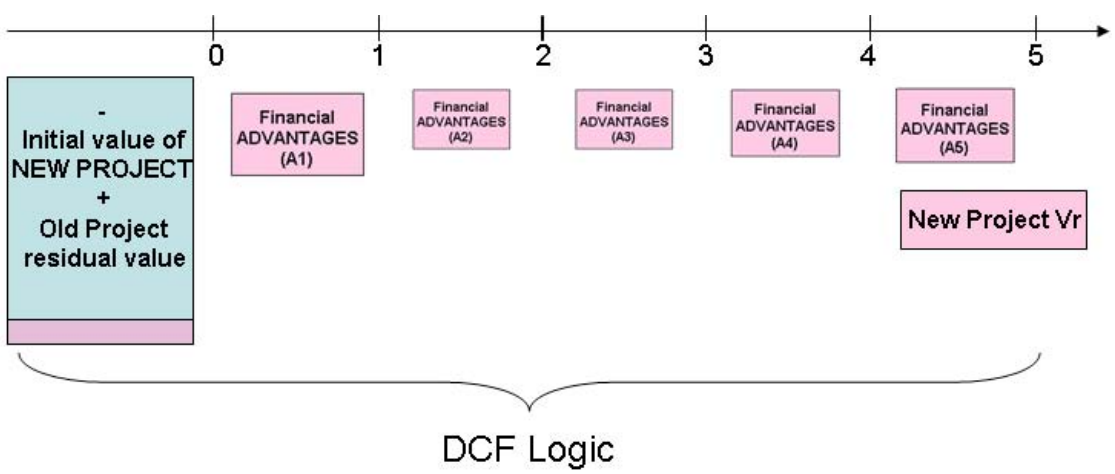

Table 3. Recommendations for investment project assessment

Indicators		Efficiency	
		Favorable	**Unfavorable**
Necessity Opportunity	**Favorable**	Investment project accepted.	The investment project may be accepted, but we advise the use of a more efficient technology.
	Unfavorable	The investment project should be rejected. We advise its later resuming.	Investment project rejected.

3. The same set of indicators as the ones used for assessing the financial efficiency of a project are employed;
4. It is an efficient tool for those who want to convince the organization management, including the financial and accounting department, of the necessity and opportunity of an investment project.

Here are some of the weaknesses of the ANDA method:

1. The indicators calculated by means of the ANDA method may have unfavorable values. If so, we advise its later resuming, maybe even finding new variants for the project, if the project efficiency indicators are favorable;
2. The difficulty of determining and quantifying advantages for all the years of analysis;
3. The residual value of the replaced project may be null or even negative;
4. The values of the indicators are lower if an old project is modernized.

Thus, the forecast economic data for the two variants, scenario "with project" and scenario "without project" are combined, which provides the grounds in figures to decision-makers. Moreover, we can see that the ANDA method achieves a hybrid between efficiency and opportunity in supporting the *financial opportunity*.

Table 3 contains a few recommendations depending on the favorable or unfavorable values pertaining to the efficiency assessment indicators and to the indicators used to assess the necessity and opportunity of an investment project.

A few aspects that we should consider in assessing a project opportunity are presented in the following:

1. If calculated efficiency indicators are positive, then the opportunity of the scenario "with project" may be supported, otherwise it is not appropriate, as the scenario "without project" has more advantages.
2. In case we have several new projects, the net advantages of each of them compared to the scenario "without project" will be assessed for the envisaged analysis periods, concomitantly to their discounting and the calculation of these indicators. Having compared the results, the project with the best indicators will be chosen, that is the project with the greater internal rate of return, with the shortest payback period and the greatest net present value.
3. If the indicators calculated on the basis of the new advantages presents lower values than those calculated on the basis of the cash flows afferent to the scenario "with project". This is the very fact that justifies the opportunity of resorting to the scenario "with project".
4. It is difficult to assess the values of certain qualitative advantages and disadvantages. In this case, we shall tackle categories of projects and types of decisions, the sources of advantages and disadvantages between the scenario "with project" and the one "without project". For information projects, we present in Table 2 a centralizing example regarding the main decisions on categories of resources.

INFORMATION-RELATED DECISION-MAKING

An *information project* may be regarded from the perspective of the time it is carried out as plain investment, but also from the perspective of the time it is carried out as continuous activity going on after the investment.

In all cases the information project may regard the automation of a function inside an organization or the re-engineering of an older computer investment, as well as all the activities that are meant to reorganize information-related processes.

As for information-related decisions, we are presenting an analysis starting from the information resources which are subject to these decisions. So we present in Table 5 the main decisions on categories of information resources.

In other words, an information project may be an investment (marked with +) or an disinvestment (market with -),

Table 4. Main information decisions on categories of information resources and their advantages/disadvantages

Explanations	Information resources			
	Human Resources	**Equipment**	**Software**	**Documentations/ Information**
Investment (+)	Training Continuous training Employment Motivation	Integral purchases Leasing Modernization Extension Maintenance	Purchase Own production Production in END USER logic Update Subscriptions	Purchase Internal development Update
Advantages/ Disadvantages	Training expenses Quality enhancement Continuous training expenses	Efficiency enhancement Information expense lowering Initial investment Operation indicators improvement Maintenance expenses	Initial investment Information expense cut Efficiency enhancement Update or subscription expense	Initial investment Time saving in documentation Update expenses
Disinvestments (-)	Externalizing Discharge Transfer	Externalizing Replacement Annulment Sale	Externalizing Replacement Sale	Replacement Sale
Advantages/ Disadvantages	Expense reduction Income reception Compensatory payments	Expense reduction Income from sale and annulment assignment	Expense reduction Income from license sale	Income from sale Expense reduction

under the conditions in which one may employ one, two or several types of information resources. For instance, the procurement of an information product also assumes the involvement of the human resources of the information department or of other departments, as the training and the licensing to use and maintain the information product is required.

When presenting the ANDA method, the determination of the financial implications of the advantages/disadvantages supporting the necessity and opportunity of a project is an extremely complex stage. Therefore, we present in Table 4 the main decisions to make by the information function of an organization and the related financial advantages and disadvantages.

Similarly to the processing in Table 4, we may analyze any investment field by its specialists.

Based on the analysis of Table 4, we may establish the value advantages and disadvantages attached to any computer-related decision that is meant for any resource.

CASE STUDY

We are providing the example of how to calculate the estimation indicators of the financial opportunity for an information project.

At a trade company, the computer system is replaced with a new one. This replacement is the subject of an information project that will be conducted over a month. To approve the investment project, a feasibility study is requested, by which its efficiency and opportunity are to be analyzed. From the data provided, we realize that the project is efficient because these indicators are positive. As to project opportunity, the company management requests its demonstration. To this purpose, we use the ANDA method. Hence, in order to assess the advantages that result by applying this project, the following financial information is available:

- Increase of customer handling rate by 5%, under the conditions of a profitability of 12%;
- Reduction of information expenses with turnover by 1.25%;
- Before-project turnover is of $400,000;
- Investment value is $42,000;
- The residual value of the replaced project is $5,500;
- The discounted rate afferent to the period is of 8%;
- Project assessment period is of 5 years;
- The residual value of the new project is of $7,500;
- The turnover increase annual rate is of 7%.

In Tables 5 and 6 we present how data are organized in order to appreciate the investment project opportunity as a worksheet is being used.

Table 5. Work hypotheses % or $

Explanations	Values
Prior turnover	400000
Increase of customer handling rate	5%
Information expense cut rate (% of turnover)	1.25%
Rate of return/general profitability (%)	12%
Recovery from the old project	5500
New project investment	42000
Discount rate	8%
Project assessment duration (years)	5
Turnover increase rate	7%
Residual value	7500

Table 6. Efficiency indicators % or $

Explanations	Values	Years				
		1	2	3	4	5
Investment value	42000					
Recovery from the old project	5500					
Net investment value	36500					
Residual value						7500
Project advantage calculation						
Additional profit	2400	2400	2568	2748	2940	3146
Expense reduction	5250	5250	5618	6011	6431	6882
Total advantages	7650	7650	8186	8758	9372	17528
Discount rate		10%	10%	10%	10%	10%
Discount factor		91%	83%	75%	68%	62%
Net discounted advantages		6955	6765	6580	6401	10883
Cumulated net discounted advantages		6955	13719	20300	26701	37584
Investment payback period	5 years					x
Net present value	1084					
Internal rate of return (IRR)						
Net investment value	-36500					
Year 1	7650					
Year 2	8186					
Year 3	8758					
Year 4	9372					
Year 5	17528					
IRR	11,01%					

Table 6 shows the financial opportunity of this project, because positive indicators are obtained only from the advantages of commissioning it.

FUTURE TRENDS

We consider that the ANDA we proposed may be extended for the project management of any area, being necessary to list the specific advantages and disadvantages. The advantages/disadvantages assessment requires a theoretical approach similar to that of Table 4 and a practical approach like in the previous case study.

The ANDA method enables the building of new indicators for the assessment of the necessity and appropriateness of an investment project, irrespective of the business area.

CONCLUSION

The assessment of an information project efficiency is a primary issue for the future information society. The speed of information equipment renewal is increasing sensibly, fact which requires that computer system managers should resort to the scenario and option theories.

The method we propose hands to the decision-maker a valuable tool in making information-related decisions.

At the same time, we are aware that ANDA is a radical method of both opportunity and efficiency assessment because if its indicators are positive, it results that the set of indicators calculated based on the discounted cash flows are positive. Hence, the ANDA method succeeds in harmoniously blending aspects that regard the efficiency and the opportunity of an investment project of any kind.

We believe that this method stands for further improvement especially in the field of advantages/disadvantages determination and assessment. This will be the subject of our further research.

KEY TERMS

ANDA Method: This consists in substituting the cash flows with net advantages within the method of present value cash flows in order to calculate the indicators IRR, NPV, and so forth.

Financial Opportunity: In practical life, it is much simpler to convince a manager or a managing team of the opportunity of an investment project if the indicators calculated

by the ANDA method are positive because the project value can be redeemed only from the highlighted advantages.

Information Project: This is a particular case of the project concept. Information project may regard the computerizing of a function inside an organization or the modernizing of an older computer investment, as well as all the activities that are meant to reorganize information-related processes.

Opportunity/Efficiency Assessment: The opportunity and efficiency assessment of an investment project is a very important stage in any economic entity. As for the assessment of the efficiency of investment projects, there are specific indicators, such as: internal rate of return (IRR), payback time, net present value (NPV), and so forth.

Project: First decomposition of a program, with a beginning and an end, made up of a set of interlinked actions planned to be run over a certain time period, with its own budget established in order to reach a well-defined objective/objectives set.

Project Management: The application of the knowledge and techniques specific to the project-oriented activities, so that the stakeholders' expectations and requirements should be attained or surpassed.

Scenario Project: The scenario "without project" is the variant in which the analyzed investment project is not applied, while the scenario "with project" is meant to commission the analyzed project.

Information Resources Development in China

INTRODUCTION

In its several thousand years of social progress, China has put continuous effort into cultural development, which to a certain extent contributed to the exploitation and utilization of information resources. This article reviews the history and present situation of China's information resources development (IRD), with the focus on some IRD projects launched since the mid-1990s.

The specific projects that will be introduced include the China Academic Library and Information System, the China Digital Library Project, the construction of the China National Science and Technology Library, the China Online Government Project, and the construction of the National Institute for Information Resources Management. The goal of each project is described and its initial impact is discussed.

BACKGROUND

Since the founding of the People's Republic of China in 1949, the government has been attaching great importance to information resources development. In 1956, the government set "Marching Towards Science" as the directing principle for the course of information resources management, and made a conscientious plan in information resources development with emphasis on collecting, rearranging, analyzing, indexing, and reporting scientific and technical documents from home and abroad to serve the needs of professionals in various disciplines. By 1987, the scientific and technical information sector alone had already possessed 26,000 foreign periodicals, 6,000 domestic periodicals, 120 million patent manuals, and more than 32 million books. There were 236 abstracting and indexing journals published annually, covering more than 1.2 million documents and articles. Also, there were 2,038 public libraries at the county level and higher, collecting more than 200 million books. There were 745 academic libraries, collecting 250 million books. There were also more than 4,000 libraries at research institutes (Guan, 1988).

In the late 1980s and early 1990s, however, information resources development was affected by the readjusting of China's economy. Non-profitable libraries and information service institutions suffered from a severe shortage of money for collection development. As a result, information resources development was captured in a severe logjam or even retrogresses. Types of document collections in some libraries dropped by half or even two-thirds (Fu, 1996). Many abstracting and indexing journals stopped publication. But on the other hand, some new abstracting and indexing journals emerged, as did bibliographical databases that catered to market demand.

Under the promotion of the international information technology revolution, China has been experiencing an upsurge in information development since the last decade of the 20th century. Information infrastructure construction keeps a rapid pace in development. The ownership of telephones, cell phones, and computers has been increasing steadily. The overall scale of China's information infrastructure in terms of network capacity ranks first in the world (China Telecommunications, 2003; He, 2004), and the number of users ranks second in the world (CNNIC, 2006a). However, information resources development is lagging far behind. The lack of information, especially Chinese information, in networks and information systems influences the benefit of investment in information technology, which has become a major obstacle not only to China's informationalization drive, but also to the competitiveness of the Chinese economy.

Since the mid-1990s, under the promotion of the tide of information superhighway construction in many countries, information resources development in China entered a new phase. In 1997, the Chinese government constituted the "Draft on China's Informationalization," drawing the outline of China's information infrastructure (Zou, 1997), which includes six elements: information resources, national information network, information technology (IT) applica-

tion, information industry, information professional, and information policy code and standard.

Information resources was set as the primary element among the six, showing the state's emphasis on its development. This also indicated that people once again realized the importance of information resources development. Several years later, the proposal was accepted as a part of China's tenth "five-year plan," which marked that information resources development became the central task of China's informationalization drive. In China's eleventh "five-year plan," several parts mentioned the issue of information resources development and regarded it indispensable. For example, in Chapter 15, developing information resources is listed as a central task of advancing Chinese informationalization, which includes accelerating the construction of national fundamental databases; adjusting information resources structure; and strengthening the development, disposal, dissemination, and utilization of information resources. Information resources development is also mentioned in Chapter 16. In that chapter, several areas of information resources development, such as governmental and geographic domains, are emphasized.
