"The world has finally become a global village, not just in rhetoric, but in reality" (Hennessey, 2000, p.34). In today's corporate world, it will be more difficult for businesses to survive without joining an e-partnership and taking advantage of the Internet. The fast expansion of Amazon.com, travel.com, and the like through e-partnerships, online syndicates, and e-networks and their business success reinforce the importance of online strategic alliance. Corporate e-partnerships and network-based organizations will be a crucial factor and play a key role in the future development of online business activities. The future trends will be characterized by:

- More mature (rather than experimental) nature of e-commerce and e-business practices in terms of the scope, quality and credibility of online customer services and products
- More needs for devising and popularizing e-supply chains due to the needs for integrating the flow of information with the flow of goods (Kotzab, Skjoldager, & Vinum, 2003; van Hoek, 2001)
- Greater monopoly of the flow of e-commerce and e-business by bigger online syndicates like Amazon.com through building extensive online alliances with online retailers and suppliers (Werbach, 2000)
- More brick-and-mortar companies moving online to expand their business scope and capitalize on the abundance of the Internet
- Greater reliance on joint efforts across nations in online legislation to protect IP, security, and privacy of e-commerce and e-business
- Greater challenge for dot.com industries to achieve sustainability, due to a more uncertain economic environment and the increasing complexities of new technologies and the more globalized economy

CONCLUSION

Today's complex and volatile business world calls for changes and alternatives to old and conventional paradigm of organizational design and new ways of doing business with others. E-business becomes one of the most important forces shaping today's business. Virtual corporations and e-partnerships become increasingly popular in the perception of managers and in business operations. In such circumstances, it is important that e-business managers have an insightful knowledge and are well prepared to deal with the complexities of e-partnerships and virtual organizations. This article provides a better understanding of the crucial issues in cross-firm business processes and inter-organizational partnerships in the cyberspace.

Running inter-organizational partnerships implies multiplication of decision-making bodies from each participating organization and potential clash of interest and values amongst participants. As illustrated in this article, total quality partnership embodies the fundamental principles for managing collaborative partnerships including e-partnerships and can be developed and extended to help inter-organizational collaboration to achieve desired outcomes. However, managing e-partnership and virtual organization is more complex than managing intra-organizational collaboration and collaboration between brick-and-mortar companies due to the IT issues, human and cultural issues, and inter-organizational partnership issues as discussed in the article. Failure to consider the complexities of any of these issues will lead to a divorce of e-partnerships and collapse of virtual organizations.

KEY TERMS

Brick-and-Mortar Organization: An organization located or serving customers in a physical facility as opposed to a virtual organization.

E-Business (Electronic Business): A comprehensive term used to describe the way an organization interacts with its key constituencies including employees, managers, customers, suppliers and partners through electronic technologies. It has a broader connotation than e-commerce because e-commerce is limited to business exchanges or transaction over the Internet only.

E-Partnership: A partnership relying on electronic (information) technologies to communicate and interact amongst partners. It is mostly associated with e-commerce or e-business partnerships.

E-Supply Chain: The physical dimension of e-business with the role of achieving base level of operational performance in the physical sphere (for more detail see van Hoek, 2001)

Intellectual Property (IP): A product of the intellect (intangible property) that has commercial value such as patents, trademarks, copyrights, etc.

Online Syndicate: Association of firms with a common interest formed to engage in e-business. Syndication has become an important e-business strategy of many companies.

Real Time: In the context of e-commerce, a real-time commission reporting system refers to a system in which a commission request is processed within milliseconds so that a commission report is available virtually immediately to an online salesperson.

Virtual Organization: A network form of organization that operates across space, time and organizational boundaries through an intricate Web of information technology.

Business Strategies for Outsourcing Information Technology Work

Subrata Chakrabarty
Texas A&M University, USA

INTRODUCTION

Firms pursue various strategies to exploit resources and capabilities and gain a competitive advantage (Porter, 1996). Interfirm relationships are collaborative agreements between organizations (Chakrabarty, 2006a; Whetten, 1981), and firms need to be careful in adopting suitable strategies to deal with interfirm relationships (Chakrabarty, 2007b). Interfirm relationships represent a sort of trade-off that organizations must make, whereby, in order to gain resources of other organizations, an organization must relinquish some its independence because the relationship also brings certain obligations with it (Whetten, 1981). Top management strategists might find their commitments to other firms as a sort of liability, and therefore, a serious evaluation of whether the benefits from the interfirm relationship outweigh the inevitable costs is needed before entering into interfirm relationships (Whetten, 1981).

Outsourcing is an Interfirm Relationship Between a Customer Firm and Supplier Firm

Work is outsourced to suppliers by a customer firm. A customer firm is therefore a firm that is in need of services, and a supplier firm is a firm that provides those services. The common synonyms for "customer" firm are either "client" firm or "buyer" firm. The common synonyms for "supplier" firm are either "vendor" firm, "consultant" firm, "third-party", or external service provider. This chapter will provide a useful summary of some strategies that customer firms can use for outsourcing information technology work to a supplier firm (Chakrabarty, 2006b, 2006c). For further information, readers are encouraged to refer to Chakrabarty (2006c) for real life case studies, and refer to Chakrabarty (2006b, 2007a, 2007b) for a deeper understanding of the advantages and disadvantages of various outsourcing strategies.

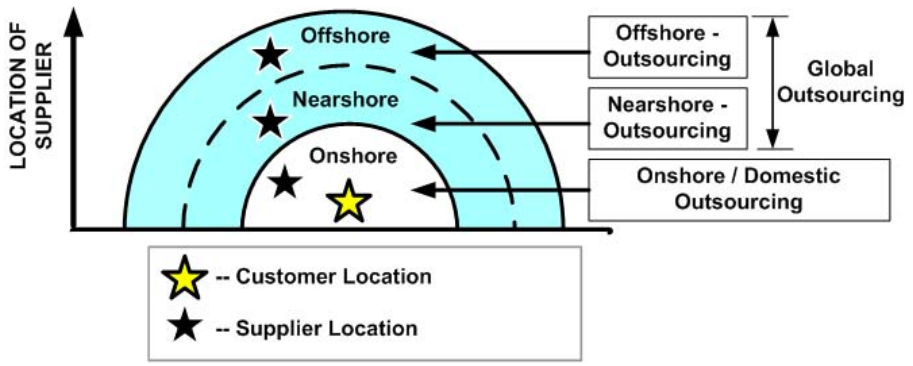
BACKGROUND

This section will provide some basic background information on outsourcing. Lacity and Hirschheim (1995) categorized the primary strategies of sourcing work into a continuum that ranges from total outsourcing at one extreme to total insourcing at the other extreme, and had selective sourcing as an intermediate strategy. *Total outsourcing strategy* is the strategy of a customer firm to outsource at least 80% of its information technology (IT) budget to suppliers. *Total insourcing strategy* (the opposite of outsourcing) is the strategy where a customer firm formally evaluates outsourcing but selects its own internal IT departments' bid over external supplier bids, and thereby allocates over 80% the IT budget to its internal IT department. *Selective outsourcing strategy* is the strategy whereby the customer firm opts to use suppliers for certain IT functions (representing around 20 to 60% of the overall IT budget, typically around 40%), and retains the remaining work for its internal IT department (Lacity & Hirschheim, 1995).

Further, Gallivan and Oh (1999), categorized the strategies for outsourcing on the basis of number of customers and suppliers into dyadic, multisupplier, cosourcing and complex outsourcing as follows. In a *dyadic outsourcing strategy*, there is just one customer and one supplier, that is, a customer firm uses only one supplier for a given activity, and the supplier in turn performs the given activity only for that customer firm. In a *multisupplier outsourcing strategy*, there is only one customer but many suppliers, that is, a customer firm uses many suppliers for a given activity. In a *cosourcing strategy*, there are many customers and only one supplier, that is, many customer firms jointly sign an outsourcing contract with a single supplier firm. In a *complex outsourcing strategy*, there are many customers and many suppliers; that is, it involves combining multiple customer firms and multiple supplier firms into a single contract (Gallivan & Oh, 1999).

Chakrabarty (2006b, 2006c) described how the location of the supplier to which work is outsourced can vary (see Figure 1). When a *domestic-outsourcing strategy* is adopted, both the customer and the supplier are located in the same country (this is also termed as *onshore-outsourcing*). In contrast, a customer and supplier can be located in different countries, and this known as a *global outsourcing strategy.* Though the term global outsourcing is widely referred to as offshore outsourcing, it can also be further classified into nearshore-outsourcing versus offshore-outsourcing. When a *nearshore-outsourcing strategy* is adopted, the chosen

Figure 1. Location of supplier in outsourcing



supplier located in a country that is geographically close to (but not the same as) the customer's country. When an *offshore-outsourcing strategy* is adopted, the chosen supplier is located in a country that is geographically far away from the customer's country. Time zones may also need to be factored during the formulation of strategy, because with improvements in communication technology and the need for 24x7 coordination of work, the time zones may be a bigger concern than geographical distance. We will now move on to more refined business strategies that can be used for outsourcing information technology work.

BUSINESS STRATEGIES FOR OUTSOURCING INFORMATION TECHNOLOGY WORK

Strategy of outsourcing selectively in a modular or flexible manner. A strategy often recommended to customer firms is that a selective set of information technology (IT) tasks need to be retained in-house based on the firm's own strengths and capabilities, and any remaining IT work that can be better performed by suppliers should be outsourced to the suppliers. *Selective outsourcing* is the strategy of outsourcing select IT tasks to suppliers, while retaining other IT tasks in-house (Lacity, Willcocks & Feeny, 1996). In selective sourcing, customer firms outsource between 20 to 60% of the IT budget to suppliers while still retaining a substantial amount of work for the internal IT department (Lacity & Hirschheim, 1995; see also Dibbern, Goles, Hirschheim & Jayatilaka, 2004, p. 10), and accordingly capitalizes on the strengths of both the internal IT department and the external suppliers. This is a flexible and modular form of outsourcing where work is broken down into multiple modules, of which, some are outsourced and some are retained in-house. This strategy of selective outsourcing has been given various other names such as *smart-sourcing, right-sourcing, flexible outsourcing*, and *modular outsourcing*.

Strategy of hiring multiple suppliers for an activity. Klotz and Chatterjee (1995) suggested that when a customer sources from two suppliers, it prevents the customer firm from being held by hostage by a monopolistic supplier, and it helps the customer firm to derive cost advantages due to competition among the suppliers. Currie and Willocks (1998) suggested the following three advantages of a *multiple-supplier outsourcing strategy*: (a) the customer firm is protected from being dependent on a single supplier, (b) the customer firm can use short-term contracts that may not be renewed with the same supplier (or combination of suppliers) and this encourages competition among the suppliers, and (c) the customer firm can focus on its core business while the suppliers manage and provide IT services. Such a strategy of multi-supplier outsourcing involves one-to-many relationships, indicating that one customer uses multiple suppliers with whom the division of labor is negotiated (Gallivan & Oh, 1999; see also Dibbern et al., 2004). Based upon the agreed division of labor, the various IT tasks are then jointly performed by the multiple suppliers, and this requires a cooperative environment among the suppliers, even though the suppliers are actually competing with each other for future business from the same customer (for case studies, see Chakrabarty, 2006c).

Strategy of contractually linking payments to realization of benefits - customer's performance determines supplier's revenue. A strategy where both the customer and supplier make upfront investments into a relationship and thereafter share both the risks and benefits is termed as a strategy of forming *benefit-based relationships* (Sparrow, 2003). Here, the customer firm makes its payments to the supplier depending on the specific benefits received. For example, if a customer can obtain potential business benefits by using the information technology services provides by a supplier, then the customer can establish a payment methodology

that links the payments to the supplier with the extent to which the customer benefits from the services. Hence, the supplier's earnings from the customer firm to which it is providing services is linked to the performance of the customer (Willcocks & Lacity, 1998).

This strategy is also termed as *business benefit contracting*, because it involves contracts that define the payments the customer will make whenever the customer earns excess revenues by using the supplier's services, and this arrangement essentially allows the sharing of both risks and rewards (Millar, 1994, as cited in Lacity & Hirschheim, 1995, pp. 4-5). The supplier provides services to the customer firm in manner that would ideally improve the customer firm's performance (Chakrabarty, Whitten & Green, 2007), and the customer evaluates the extent to which any improvement in its own performance is due to the supplier's contribution, and pays the supplier proportionately. Though such business benefit contracting has its advantages, it is often hard to adopt due to the challenges associated with negotiating and measuring the contractual criteria for sharing risks/costs and rewards/revenues (Lacity & Hirschheim, 1995).

Strategies of sharing risk and rewards using ownership and control structures. Novel ownership and control structures can be used to institutionalize the sharing of risk and rewards in two ways: (a) creating a new *joint venture* company where both the customer and supplier firms have ownership stakes, or (b) the customer firm can purchase share/equity for partial ownership of a supplier firm, and the supplier can similarly purchase share/equity for partial ownership of the customer firm (Currie & Willcocks, 1998; Sparrow, 2003; Willcocks & Lacity, 1998). These options are also known as *strategic alliances*.

The first strategy involves the customer and supplier firms creating and sharing ownership in a new *joint-venture* firm that has its own management team and IT employees, and the customer firm can outsource technology work to the joint venture company. Such joint venture companies enable the customer to gain access to new technical skills and resources, reorganize IT functions and processes and investigate new sources of revenue (Sparrow, 2003). Since the ownership of the new joint venture company is shared, the risks and rewards are also shared by the customer and supplier firms.

The second strategy involves *equity holding* deals, where the customer purchases enough shares of a supplier firm to partially own the supplier firm, and the supplier may also purchase enough shares of the customer firm to partially own the customer firm (Willcocks & Lacity, 1998). This automatically aligns the interests of both the customer and supplier firms, because each will benefit when the other performs well, and this arrangement motivates both the firms to share the risks and rewards.

Strategies for short-term requirements. A strategy for filling short-term labor demands is *body shop outsourcing*, whereby the customer goes shopping for "bodies" or human resources from suppliers. In other words, contract staff (such as programmers) are provided by a supplier, and these contract staff work at the customer firm's office and report directly to the customer firm's management executives (Lacity & Hirschheim, 1993). The contracted staff are therefore the supplier's paid employees who work under the supervision of the customer at the customer site.

Another strategy for getting temporary access to human resources for a short period of time is called *tactical outsourcing* (also known as *contracting-out* or *out-tasking*) (Sparrow, 2003). This strategy involves signing short-term outsourcing contracts with competent supplier firms who have the necessary technical skills to provide rapid solutions whenever the customer firm finds itself short of in-house employees to complete tasks in quick time.

Strategy of hiring a supplier for maintenance of technology assets. Most firms own a large amount of technology assets and infrastructure within their own facility (for example, hardware that needs maintenance or software that needs regular upgrades). A suitable strategy might be to hire a supplier who can offer the expertise and personnel to maintain the customer's technology assets and also lower the costs of maintaining these technology assets. That is, the customer owns the technology assets in the given facility, but hires a supplier to take over the operational control of these assets. This strategy is often termed as *facilities-management outsourcing* (Dibbern et al., 2004; Sparrow, 2003).

Strategy of outsourcing the process of setting up new offices/facilities abroad. Firms often need to expand their presence to new locations abroad, and this a challenge because the firm may not be knowledgeable about the processes of setting up an office/facility in the new location (Chakrabarty, 2007a). A suitable strategy to deal with this challenge is known as *managed offshore facilities' strategy*, whereby the customer firm outsources the process of creating its foreign subsidiary office to a supplier. Once the facility is up and running at the new location, the customer can take over the full ownership and control of the facility. At times, the customer firm retains the supplier for the long-term maintenance of the facility. A variant of the managed-offshore-facilities strategy is the *build-operate-transfer strategy*, whereby the supplier manages the process of creating the facility in the foreign location, and the customer firm has the option of taking full ownership by a specified date (i-Vantage, n.d.; Kobyashi-Hillary, M., 2004, p. 153). Hence, this outsourcing strategy has the potential to reduce many hassles for a firm that decides to set up its own subsidiary at a foreign location (for more details on the process of setting up a subsidiary abroad, see Chakrabarty, 2007a).

Strategies to strengthen the internal IT department. Though growth in the outsourcing of technology work is often assumed to be at the expense of the customer firm's internal IT department, a contrasting fact is that outsourcing

can also be used to strengthen the internal IT department (Green, Chakrabarty & Whitten, 2007). Firms sometimes undergo major transitions or technology overhauls in order to make use of newer technologies and bring in more efficiency. Suppliers can be used during this growth or maturation process of the customer's own IT department. For example, during a major changeover or transition, such as migration from a old technological platform to a modern technology platform, the customer firm can handover the management of the older systems to a supplier while the customer's IT department focuses on the transition to new technology. This is known as *transitional outsourcing* (Millar, 1994, as cited in Lacity & Hirschheim, 1995). A similar scenario whereby a certain work is outsourced to a supplier while the internal IT department transitions itself to a new set of skills is called a *transition-assistance* strategy (Wibbelsman & Maiero, 1994, as cited in Dibbern et al., 2004).

FUTURE TRENDS

Two distinct strategies that have gained prominence in recent times and are likely to be future trends are as follows. The use of a supplier that can provide teams at multiple locations, that is, a supplier team is at the customer site for coordination, while other skilled teams from the same supplier work at locations across the world at a lower cost. The renting of information technology services on a subscription basis.

Strategy of using suppliers with global capabilities. *Distributed consulting* implies that a supplier chosen by a customer has the ability to provide teams both at the customer's location and at the supplier's own location (Chakrabarty, 2006c). A *global delivery model* implies that the supplier can take advantage of the global talent pool and provide maximum value to the customer in terms of both quality and cost, by dividing the outsourced work into modules and distributing the modules to appropriate global locations (Infosys, n.d.).

Customer firms are increasingly adopting the strategy of offshore-outsourcing, that is, the chosen supplier is located in a country that is geographically far away from the customer's country (Chakrabarty, 2006c). This can be carried out more effectively by adopting a strategy of choosing a supplier that can provide supplier teams both at the customer's on-site location and at the supplier's offshore location. The supplier team at the customer site coordinates face-to-face with customer (Chakrabarty, 2006a), and the bulk of the outsourced work is carried out by the offshore supplier team (for case studies, see Chakrabarty, 2006c). Large IT service providers from India, such as TCS (http://www.tcs.com), Infosys (http://www.infosys.com), and Wipro (http://www.wipro.com), have incorporated such distributed consulting practices into their global delivery model (for case studies, see Chakrabarty, 2006c).

Strategy of accessing remotely hosted IT applications. One strategy that a customer firm can adopt for outsourcing information technology work is to rent the required service on a subscription basis (Chakrabarty, 2006b). Similar to the manner in which employees of a customer firm can access software applications installed on a LAN or data center within the customer firm, the customer firm's employees can also access a software application that is installed on a remote server under the control of the supplier. That is, the remote server resides at the supplier's data center and is accessed by the customer firm through a dedicated line, Internet, or extranet (Dewire, 2000). Hence, the suppliers develop, customize, install, and manage the software applications at the remote locations and host them for their customers over a suitable network or the Internet. Such suppliers are called *application service providers (ASP)* (Bennett & Timbrell, 2000; Susarla, Barua & Whinston, 2003), and this type of outsourcing strategy has been given various names such as *net-sourcing* (Kern, Lacity & Willcocks, 2002), *on-demand service, application utilities, real-time delivery* and *software-as-a-service* (Pring & Ambrose, 2004), all of which allow access to externally managed software applications.

CONCLUSION

Outsourcing is an interfirm relationship between a customer firm and supplier firm, where the customer firm is in need of services and the supplier firm provides those services. Since such interfirm relationships are essential for most businesses, and this chapter suggested that firms need to be careful in adopting suitable strategies. An array of strategies that can be used for both domestic and global outsourcing of information technology work were described, so that business managers can choose an appropriate strategy in order to get the best deal for their information technology needs.

KEY TERMS

Application Service Providing / Net-sourcing / On-Demand: Accessing remotely hosted information technology (IT) applications

Benefit Based Relationships / Business Benefit Contracting: Linking payments to realization of benefits; customer's performance determines supplier's revenue.

Body Shop Outsourcing: Using contract personnel.

Cosourcing: Many customers and only one supplier: Many customer firms jointly sign an outsourcing contract with a single supplier firm.

Distributed Consulting: Supplier has teams both at onshore and offshore.

Global Delivery: Large supplier delivering services from various global locations to customers at various global locations.

Managed Offshore Facilities: Outsourcing the process of setting up a subsidiary abroad.

Multisupplier Outsourcing / Dual Sourcing: A customer firm uses many suppliers for a given activity.

Nearshore-Outsourcing: Chosen supplier is located in a country that is geographically close to (but not the same as) the customer's country.

Offshore-Outsourcing (A Form of Global Outsourcing): Chosen supplier is located in a country that is geographically far away from the customer's country.

Onshore-Outsourcing / Domestic Outsourcing: Both customer and the supplier are located in the same country.

Outsourcing: Interfirm relationship between a customer firm and supplier firm, where the customer firm is in need of services and the supplier firm provides those services.

Selective / Smart / Right / Flexible / Modular Sourcing: Outsourcing and insourcing optimally and selectively; A customer firm uses suppliers for certain IT functions which represents between 20 and 60% of the IT budget (typically around 40%) and therefore retains substantial work for its internal IT department.

Tactical Outsourcing / Contracting-Out / Out-Tasking: Outsourcing for short term access to skilled professionals.

Transitional Outsourcing: Outsourcing during a major changeover; Helping the customer's IT department mature.

Business-to-Consumer Electronic Commerce in Developing Countries

Janet Toland
Victoria University of Wellington, New Zealand

Robert Klepper
Victoria University of Wellington, New Zealand

INTRODUCTION

Electronic commerce describes the process of buying, selling, transferring, or exchanging products, services, or information via computer networks including the Internet. In **business-to-consumer electronic commerce**, the sellers are organisations, and the buyers are individuals (Turban, Leidner, McLean, & Wetherbe, 2005). Business-to-consumer electronic commerce provides opportunities for less-developed countries to reduce transaction costs and bypass some of the intermediary linkages to connect to global supply chains (Molla & Licker, 2005). Though predictions vary, statistics seem to point to significant growth of the use of the Internet among businesses and consumers in **developing countries** in the next 10 years (Hawk, 2004). The focus here is to explore the potential for business-to-consumer electronic commerce in less-developed countries. The approach taken is to review the current worldwide usage of the Internet; to identify the factors necessary for **e-readiness**; to explore the barriers to business-to-consumer electronic commerce; and to identify strategies that can be adopted by both the public and private sectors to overcome these barriers.

By the end of 2003, developing countries accounted for more than one third of new Internet users worldwide. Though Internet access is rapidly increasing, most residents of developing countries still have no access to the Internet. For example, Internet access in Africa is less than 2% in a population of over 900 million, the lowest rate of access in the world (Dunphy, 2000; UNCTAD, 2004). Business-to-consumer electronic commerce in less-developed countries will grow in the future, but progress will be slowed by technological, cultural, economic, political, and legal problems (Davis, 1999; Enns & Huff, 1999). Differences in e-readiness and related **barriers to electronic commerce** will sustain substantial differences between regions of the world, between countries within regions, between urban and rural areas within countries, and between the genders and age groups. Despite the difficulties, when the basic communications infrastructure is available, options do exist to undertake business-to-consumer electronic commerce in less-developed countries.

BACKGROUND

Table 1 shows the number of Internet users in the major regions of the world reflecting vast differences in **e-readiness**. Less than 10% of the population in the developing regions of Africa, Latin America and the Caribbean, and Asia were using the Internet in 2004 as compared to regions such as North America, Europe, and Australasia where 30% or more used the Internet.

Africa

The **digital divide** is largest in Africa, with less than 2% of people having access to the Internet as compared to 50% in most advanced countries. There are some **business-to-consumer electronic commerce** success stories, mostly in the traditional handicrafts area, where the Internet offers the

Table 1. Internet users per 10,000 people, by region, 2005 (Adapted from http://www.internetworldstats.com/stats.htm)

REGION	USERS PER 10,000	% IN REGION (approx)
Africa	144	1.4%
Latin America & Caribbean	1,011	10.1%
North America	6,501	66.5%
Asia	738	7.4%
Europe	3,159	31.6%
Australia & New Zealand	4,735	47.4%
World	**1,385**	**12.7%**

opportunity for a niche player to access the global market of African Diaspora. All African capital cities now have local Internet connection available.

Latin America

Internet use in the region is dominated by Argentina, Brazil, Chile, and Mexico, who among them account for two thirds of Internet users in the region. **Business-to-consumer electronic commerce** is growing, with online car sales, consumer auctions, travel, computer hardware and software, and banking responsible for the highest revenue.

Asia

Among **developing countries**, Asia stands out as the leading user of **electronic commerce**. This is partly due to high population, but also because organizations tend to be more integrated into global trade flows than in other developing countries. Manufacturing enterprises in particular face pressure from their customers in developed countries to adopt electronic commerce. China offers the greatest potential electronic commerce market, and is now considered one of the top five nations in the world in terms of Internet use. While many Chinese are going online for the first time, less than 20% have done any shopping online (Hsu, 2003).

North America/Europe/Australasia

In the developed world, the **business-to-business electronic commerce** continues to grow faster than business-to-consumer, with Forrester Research (Johnson, Delhagen, & Yuen, 2003) forecasting that 26% of business-to-business sales in the United States will be traded online by 2006. **Business-to-consumer electronic commerce** has progressed significantly in some sectors particularly those offering digital products, such as software, music, and travel services.

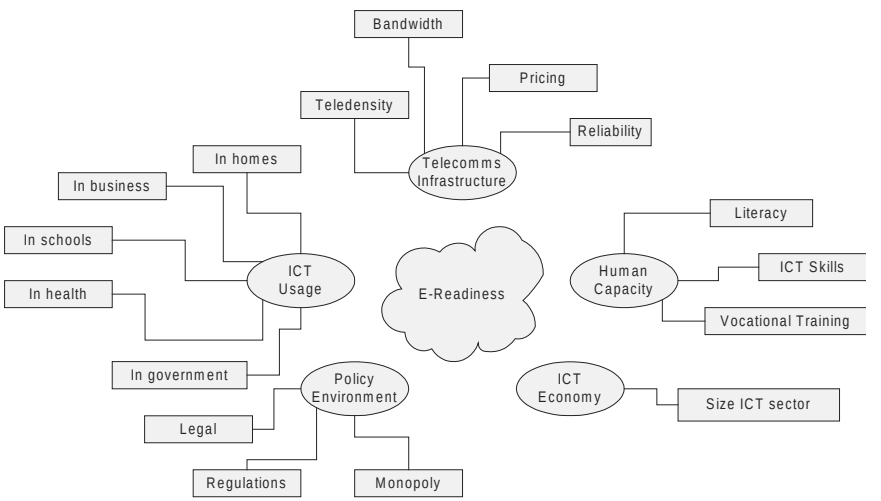
E-READINESS

An **e-readiness** assessment is an attempt to gauge how prepared a country is to benefit from information technology and electronic commerce. It is used to measure a country's ability to take advantage of the Internet as an engine of economic growth and human development (GIPI, 2001). An e-readiness assessment looks at infrastructure, the accessibility of information and communication technology (ICT) to the population at large, and the effect of the legal and regulatory framework on ICT use.

Over 15 different e-readiness assessment tools are currently available, and the assessments use a range of questionnaires, statistical methods, reports of best practice, and historical analysis (Bridges.org, 2002). Some tools look specifically at the e-economy and how ICT's can be used to improve the economy, whereas others are concerned with the broader picture, trying to measure the emergence of an e-society and assess how ICT's are improving social equality.

The assessment methods tend to include a common core of questions covering the areas of telecommunications infrastructure, levels of ICT usage throughout society, human

Figure 1. Factors commonly used to assess e-readiness



capacity in terms of educational level, the legal and regulatory environment, and the size of the ICT sector (InfoDev, 2001). Typical factors for consideration are shown in Figure 1.

The purpose of carrying out these assessments is to gather information that can assist with developing a strategy for ICT development.

BARRIERS TO ELECTRONIC COMMERCE IN LESS-DEVELOPED COUNTRIES

Business-to-consumer electronic commerce operates at three levels:

1. Information gathering and exchange (for example, a tourist may want to browse information about hotel accommodation);
2. Online transactions (for example, booking a hotel room);
3. Online payment, or paying for a hotel room online.

Most Internet use in **developing countries** is for e-mail; there is relatively little transactive use. Lack of e-readiness, or what might be called **barriers to electronic commerce**, such as low credit card use and poor logistics and fulfilment, inhibit fully developed electronic commerce (UNCTAD, 2002). Table 2 lists the main inhibitors of **electronic commerce** in developing countries. These have been grouped according to the five categories identified as important when considering e-readiness. An extra category has been introduced for general infrastructural issues, such as a poor transport network, that negatively impact the adoption of **business-to-consumer electronic commerce**.

As a result of the barriers, most electronic commerce in developing countries takes place between organizations. **Business-to-business electronic commerce** accounts for 95% of all electronic commerce in less-developed countries. Much of this is driven by large multi-national organizations operating in developing countries. Indigenous **electronic commerce** is usually small by comparison. Even within the realm of indigenous business-to-consumer electronic commerce, sales are often to offshore customers in the developed world, as is the case for the tourism, art, and handicrafts markets.

OPTIONS IN BUSINESS-TO-CONSUMER ELECTRONIC COMMERCE

Despite the barriers, **business-to-consumer electronic commerce** will grow in less-developed countries, albeit more slowly that in developed countries. Our focus is on options

Table 2. Barriers to electronic commerce in developing countries

TELECOMMUNICATIONS INFRASTRUCTURE	- Poor telecommunications service - Limited penetration of Internet - High cost of Internet connections
POLICY ENVIRONMENT	- Lack of competition in international telephone traffic - Lack of suitable regulatory environment
HUMAN CAPACITY	- Illiteracy - Low incomes - Poor customer service - Shortage of technical skills
ICT USAGE	- No tradition of mail order type shopping - Many small and medium size enterprises that lack capital for the development of electronic commerce - Lack of critical mass
ICT ECONOMY	Small ICT sector
GENERAL INFRASTRUCTURE	- Unstable power supplies - Inadequate payment systems and low credit card usage - Fulfilment problems occasioned by poor physical infrastructure (road, rail, air)

available to individuals and private sector enterprises for undertaking business-to-consumer electronic commerce.

Telecommunications Infrastructure

New technologies have the potential to bypass inadequate landline telecommunications infrastructure. **Developing countries** have the opportunity to leapfrog traditional copper and fibre-based landlines and move directly to leading-edge wireless technologies. Wireless technologies have taken off even in relatively low-income areas of the world, where prepaid cards allow access without having to pass a creditworthiness check. As of 2004, major wireless network projects have been completed in Shanghai and Fujian in China, and in Peru, Indonesia, and Ethiopia (Lancaster, 2003; Simon, 2004).

Policy Environment

The actions of government in government policy, the legal environment, the management of government owned and/or controlled telecommunications infrastructure, while important to electronic commerce success, are not our concerns here.

ICT Usage and ICT Economy

ICT usage is the aggregate of usage by individuals, businesses, and non-profit organisations. More businesses and more customers will be online if they know they can do transactions efficiently by electronic commerce. In addition, more businesses in less-developed countries will be online if they know they can reach customers across the globe efficiently. With sufficient demand from businesses and customers, the level of infrastructure represented by Internet service providers and facilities for Web site development and hosting and processing if electronic payments will also become available. These developments are interrelated and self-reinforcing.

In many less-developed countries, the evolution of ICT use for commerce will take place from the bottom up. Within the constraints mentioned earlier, the size of the ICT economy will grow with the individuals and businesses doing transactions on the Internet. In what follows, we briefly survey options for online store-type businesses:

- Hardware has become a commodity, and free, open source software tools are available for online store development and Web hosting (Klepper & Carrington, 2002). Even in countries with high tariffs on hardware, these costs are not the barrier they once were.
- Development of an online store is becoming easier for less-skilled developers as standard templates are now available on the Internet. Of course, customised stores require skilled labour, which is an issue we address next. Online store templates are widely available on the Internet and are increasingly available from Internet service providers in less-developed countries (Klepper & Carrington, 2002). Even greater availability can be expected in the future.
- Web site hosting is usually beyond the capabilities of a typical individual online store business, but hosting services are increasingly available from Internet service providers in less-developed countries. Online store businesses, particularly those aiming at a wider world market, can readily obtain hosting in developed countries; a 2003 survey of business Web sites in the nine least developed countries found that about half were hosted locally, and half offshore (Wresch, 2003).
- Most payments for online purchases are still accomplished by credit card in the developed world, an option that exists for a much smaller percentage of customers in **developing countries**. However, in cities and the portions of less-developed countries with sufficient population density, a variety of payment options are offered (Hawk, 2004). Cash payment can be made at the time of delivery, which occurs in a significant portion of such purchases in China and India, or an option of paying by a series of monthly cheques can be offered as in Latin America.
- Limitations on human capacity can be overcome. Specialized companies and consultants who build Web sites, provide Internet services, and host Web sites are already available in many developing countries (Wresch, 2003), and their numbers will grow as the demand for online transactions grow. The employment opportunities available in developed countries during the IT and dot com boom of the late 1990s have abated, and the skilled citizens of less-developed countries now have less incentive to migrate and those in developed countries are more likely to return to their native countries. Some research shows that small online businesses in **developing countries** often rely on skilled family members and friends for help on technical issues, and this is likely to continue (Utomo, 2001).

On the demand or customer side, access is growing through shared facilities like Internet cafes and through growing individual and family computer ownership.

Although the options outlined previously are still only available to higher income individuals living in cities in the developing world, the number of customers and the number of online businesses is expanding rapidly.

FUTURE TRENDS

Growth in the number of mobile telephone users worldwide has expanded from 50 million in 1998 to more than one and a half billion as of 2004 (Evans, 2004). At the end of 2003, Africa had more than 50 million mobile device users, and the majority of African nations had more mobile than fixed subscribers (Economist, 2005; UNCTAD, 2002). Similar trends have been observed in Latin America and Asia, where handheld devices enable users to overcome the difficulties caused by low fixed line penetrations. This explosive growth in **mobile telephony** in the developing world, particularly in Africa, offers an opportunity to overcome the problem of an inadequate telecommunications infrastructure. Mobile phones can provide an "Internet in your pocket".

Access to mobile phones is even more widespread than ownership numbers suggest. A telephone may be owned by one person in a village who runs a small business taking and receiving calls for neighbours. The World Bank estimates that 77% of the world's population now has the opportunity to link up to a mobile network (Atkins, 2005). The availability of prepaid cards means that no credit checks are necessary, removing a major barrier to participation. Mobile phones can be used to make payments for items as diverse as petrol, laundry, and soft drinks. This is a significant advantage because many less-developed countries' lack of a reliable credit card system is a real inhibitor of business-to-consumer electronic commerce.

Entrepreneurs in developing countries can learn by observing trends in the developed world, where it has been shown that companies using business-to-consumer electronic commerce to sell digital products, such as online travel, software, and financial services, are generating significant profits, while those selling tangible goods are not doing so well. In particular, tourism services such as hotels and travel agencies seem to transfer most successfully to electronic sales, and this has been observed across a number of countries (Wresch, 2003). The tangible products that sell least well electronically, are those that consumers want to "see and feel" such as clothing and furniture. Models for new business-to-consumer ventures should be developed with this information in mind.

CONCLUSION

The worldwide use of business-to-consumer electronic commerce is likely to remain uneven for some time. E-mail will continue to be the first priority of new users. Searching for information will also be important in the future. Growth in entertainment and online purchases will lag. **Business-to-consumer electronic commerce** growth will be largely an urban phenomenon, and rural areas will participate at much lower rates. The gaps between young and old and males and females, which have narrowed in the developed world, will persist much longer for people in less-developed countries.

The barriers to the development of business-to-consumer electronic commerce all have a common source in the conditions that create and sustain differences between the developed and developing world. These issues are beyond the scope of this brief comment on electronic commerce, but until these conditions change, less-developed countries will continually lag the developed world in electronic commerce, as they do in many, more important indicators of well-being such as health and education.

KEY TERMS

Business-to-Business Electronic Commerce (B2B): A business selling goods and/or services online to another business.

Business-to-Customer Electronic Commerce (B2C): A business selling goods and/or services online to private consumers.

Diaspora: Nationals of a country who have migrated and are scattered worldwide.

Digital Products: Goods or services that can be delivered directly over the Internet. Examples would be software, online travel, and financial services.

Less-Developed Countries (LDCs): Less-developed countries, commonly having a low standard of living, poor health, and inadequate education. Markets are less fully developed, and there is often a greater dependence on the primary sector of the economy.

Tangible Goods: Goods and services that have a physical form and cannot be delivered directly over the Internet.

Text Messaging (SMS): Short message service. The sending and receiving of short typed messages using mobile telephones.

Wireless Technologies: Technologies that communicate without landlines, that is, satellite, microwave, cellular radio, infrared. Common uses are pagers, cellular telephones, personal digital assistants, mobile data communications, and personal communications services.

CAD Software and Interoperability

INTRODUCTION

Decisions taken during the conception phases in huge architectural projects influence a lot the cost and the schedule of the building construction. To ease this decision-making, many mock-ups have been used as a project prototype. This prototyping is useful to test and to improve the conception of projects. Nowadays, collaborative sites that appear on the Web greatly improve the flexibility of the framework's actors of a distant project [Aliakseyeu, Martens, Subramanian, Vrouble, & Wesselink, 2001; Balaguer & DeGennaro, 1996; Klinker, Dutoit, Bauer, Bayes, Novak, & Matzke, 2002). Digital mock-ups are used to represent future 3D elements of the final product. Digital mock-ups are known to be often employed in the architectural field. Indeed, the visualization of the future buildings in 3D by architects and engineers is a way to facilitate the testing of the choices, the scheduling of costs and processes, and the completion dates. In the architectural field, all types of activities have developed tools for special prototyping: structural analysis, thermal and fluidic networks, and so forth. Unfortunately, this development is completely chaotic. Sometimes existing tools in the same type of activity cannot exchange information. Moreover, information stored by tools is in most cases bound by a set of files that contain only geometrical descriptions of the building. Not every actor of a project has necessarily the same knowledge as the other actors to understand and to interpret information. Thus, the collaboration between the actors as well as the data interoperability seems to be difficult to evolve without a new kind of tool. The following section presents two examples of platforms using digital mock-ups to handle conception data. The section "Collaborative Web Platform" focuses on our solution through the presentation of the Active3D collaborative platform. The section "Interoperability Demonstration" presents the Active3D platform as a central point of collaboration with the help of use-cases examples. The last section concludes on the work being undertaken.

BACKGROUND

The collaborative work between distant actors on the same project improves the conception of a prototype by reducing the time between each update. A lot of CAD software packages were modified to allow virtual prototyping, but this was done independently of specific project requirements. Unfortunately, most of these solutions do not join together the essential capabilities of interaction and collaboration for the completion of an engineer project. To avoid this problem many projects were suggested. The project Cavalcade (Cavalcade, n.d.) is based on a distributed architecture, allowing several distant teams to collaborate on a conception, to test, to validate, and to exchange documents. Cavalcade provides a visual system of 3D visualization. Contrary to classical ideas on simulation tools, the virtual representation of a prototype concerns only the visual aspect of attributes of which the objects of the building are composed. These attributes are functions like "is a part of a subsystem" and documents like technical files or Web links. The 3D model becomes then a visual interface of information requests. Cavalcade aims to manage conception data. To exchange the models created with the help of CAD software, the developers of this software use specific format files for their requirements. The set of files that forms the conception of the project constitutes the digital mock-up. The 3D model of the conception object is generally integrated in this mock-up and a set of information allows management of the project by itself.

In addition, the organization of the engineering and design department must be reconsidered. To facilitate the pooling of data, a digital mock-up should be installed. The conception work is then immediately possible from the mock-up. Access to the last updated data avoids expensive errors related to the use of data not up to date. The sharing of conception data is obviously a requirement in order to accelerate the conception cycle. Several problems must be taken into account in the conception of a 3D collaborative platform.

The first problem concerns the choice of an information storage structure. There are two kinds of information storing: files and databases. In the field of 3D, the file formats are very numerous. Although the principal information of

these files is the geometrical representation in 3D of the objects, each kind of file has its own levels of abstraction. The higher the abstraction level of information is, the more semantics contains the file. This semantics is an additional knowledge on geometrical information, making it possible to re-use in a better way the geometrical file and its definitions. Databases ensure the storage of large quantities of information by structuring and indexing information. In general, the databases carry the subjacent semantics of information which they store. Indeed, the structures which receive information model information that they must contain, therefore these structures form metadata on information. The databases are, thus, of primary importance to organize information so that it becomes possible to search for relevant data in a vast set of information such as a file.

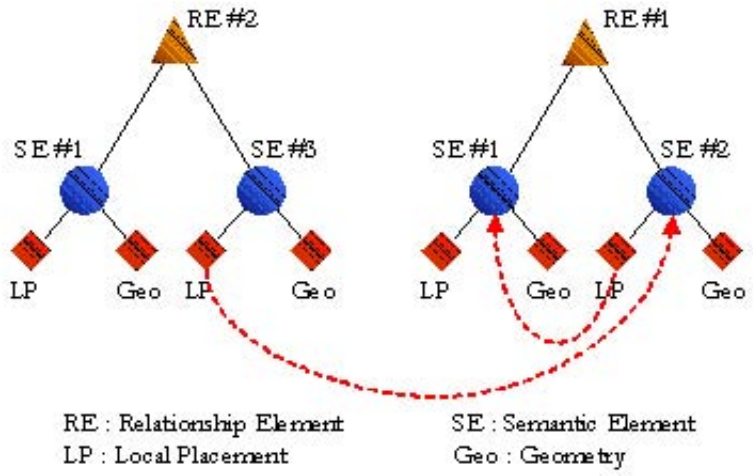
The second problem concerns the definition of an optimized 3D interface that allows a flexible and fast handling of stored information. Certain applications require at the same time a lot of memory and a minimum speed of execution. For instance, the computer-aided design often produces complex 3D geometrical models that have a very large size. Thus, the recurring problem in graphical application is the data visualization. Indeed, with the advent of design techniques, the growth of the volume to be computed is largely higher than the increase of the capacity of the graphic material. Consequently, a phase of optimization is necessary. It is located at the data model and at the data themselves. Many techniques of optimization and acceleration for interactive navigation were developed. These include calculations of visibility (Pearce, Partial, & Day, 2004), geometrical simplification (Hoppe, 1996; Pailot, Merienne, Frachet, & Nevfeu (2003), and the image-based representation (Christopoulos, Gaitatzes, & Papaioannou, 2003; Gortler, He, & Cohen, 1997; Levoy, & Hanrahan, 1996; Mark, McMillan, & Bishop, 1997). All these techniques were combined successfully to render architectural models (Funkhouser, Teller, Sequin, & Khorramabadi, 1996) and urban models (Wonka, Wimmer, & Sillion, 2001). The GigaWalk project is a rendering system that makes it possible to render CAD projects of more than 10 millions of polygons. The most striking example is the design project "DoubleEagle tanker" made up of more than four gigabytes of data, that is to say 82 million triangles and 127 thousand objects. The rate of calculation is 11 to 50 images per second which permits to navigate in real time through the digital mock-up after a time of approximately 40 hours pre-calculation (Baxter, Sud, Govindaraju, & Manocha, 2002). However, there is no perfect system. Each technique has advantages and disadvantages but certain combinations with precise conditions are very effective. These techniques described previously proved their reliability within a static framework, that is, the optimized scene is calculated once for several visualizations. In fact, the pre-computing time before the accessibility of the scene can sometimes take several days. The pre-computing of the optimized scenes is the major problem of all these techniques because if the 3D models evolve during this time then the management of the data synchronization must be taken into account. These synchronizations are not always possible because the complete structure of the scene can sometimes change. Other ways must be explored to allow for the visualization of a 3D scene to evolve during this time. Optimizations are always carried out in comparison to the geometry or the topology of the scene. On the one hand, the nature of the geometrical objects was not taken into account for computing optimization. The nature of the objects, thus, proves to be an undeniable way for research. This nature depends on the scene structuring but if it is limited to geometrical information then only geometrical optimizations are applicable. On the other hand, if information on the nature of the objects is indicated then this information provides a new way of research on the handling of geometrical information and their storage.

COLLABORATIVE WEB PLATFORM

Nowadays, the fundamental needs of all the actors in architectural engineering projects relate to a simple tool which allows a coordinated management of the actions carried out in a project. This tool must allow management of data generated during the lifecycle of the project through a 3D visualization of a digital mock-up and must also allow its access to all project actors through a collaborative Web platform. This section presents the ACTIVe3D-Build platform which makes it possible for the actors of a project, geographically dispersed - from the architect to the plumber - to exchange documents directly in a virtual environment during the lifecycle of a civil engineering project. A 3D visualization makes it possible for the actors to move around the building that is being designed and to obtain information on the objects. This section is divided into three parts. The first part presents the format used to describe the data. The second part deals with the data structuring. The third part presents the division method and exchange of data.

Data format: CAD software used in civil engineering projects models each building element by a set of vectors. In this formalism there is no semantic information on the objects that compose the building. Thus, there is no way to select automatically objects by their nature. To solve these problems the International Alliance for Interoperability (IAI) proposed a standard called IFC (Industrial Foundation Classes – http://www.iai-international.org/) which describes the representation of the objects that can be found in an architectural project. The IFC file format is a model which associates trade semantics with 2D/3D geometry for each element constituting the building. The addition of trade semantics makes it possible to limit the redundancies of information because it identifies instantaneously each element that the building is composed of for a faster

Figure 1. Example of direct and indirect links between several semantic elements



qualification of the building elements. The basic classes of the IFC include the description of the objects and provide a structure permitting the data interoperability between trade applications. For example, an IFC door is not simply a collection of lines and geometrical primitives identified as a door, but it is recognized such as "door" by the machine and has attributes corresponding to its nature. The adoption of this format by all the leaders of software CAD solves the problem of the interoperability of information between the various civil engineering professions.

Data structuring: The choice of the IFC format for the data structuring has many advantages but comprises also certain disadvantages. The study of the IFC shows the complexity of the links between the instances of relational classes and the instances of object classes. On this level there are two types of links between the objects. We call them direct and indirect links. The indirect links are defined by instances of relations, "Relationship Element" (RE: triangles - Figure 1). The direct links are defined by discontinuous red links between the instances of class resources (rhombuses - Figure 1) and an instance of "Semantic Element" classes (SE: circles - Figure 1). These indirect links are relationship elements. The instances of objects in our architecture are semantic elements. The instance resources are the attribute elements like the geometry (Geo) or the local placement (LP) and are structured as hierarchical trees.

These resources are of very diverse nature like the type of materials for a wall or the structural characteristics for a beam. Those are defined in the model IFC but we can also add other types of resource like Word® documents, requests on Web Services (elements of catalogue's suppliers), and so forth. These types of resources are added to the IFC via our structuring model of the IFC for the management of electronic documents. The IFC model defines only one type of direct link between two semantic elements. This link is the placement link used for the definition of the local placement between the graphic elements of scene 2D/3D. In the IFC model this link is called "IfcLocalPlacement". The whole local placement link forms a tree which is the graphic tree scene. Thanks to the definition of their semantics, the nature of the elements makes it possible to choose which elements are relevant for the actors of the project. Consequently, the elements are extracted from the platform only according to the needs.

Figure 2 shows a representation of the trade plumbing view of an IFC file. Figure 3 shows a representation of the architectural trade view. These trade views are textual information from which specific documents can be generated or associated (reports, information of management, etc). In the 3D scene all the geometrical forms defined in IFC trees are converted in the triangular model of surface (Ronfard & Rossignac, 1996). During this conversion, the 3D objects are associated to a GID. This GID is the general identifier used to identify each trade object of an IFC file. The GID is used to combine 3D visualization with the information stored in the database. Thanks to this database and the GID, all types of information can be combined to a trade object of a 3D scene.

Sharing and data exchange: The ACTIVe3D method: The mechanisms of management and handling of IFC files,

Figure 2. A 3D plumbing context view

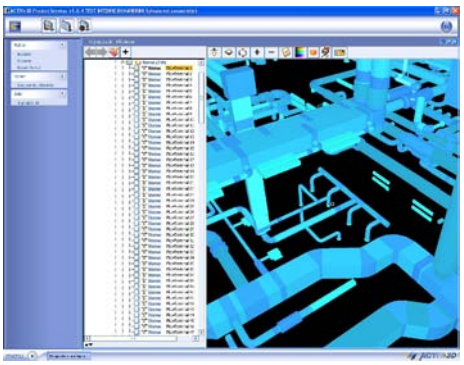


Figure 3. A 3D architectural context view

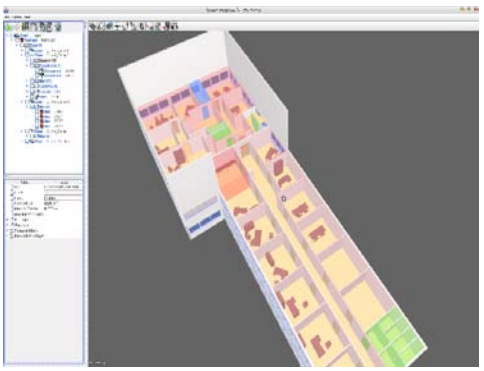
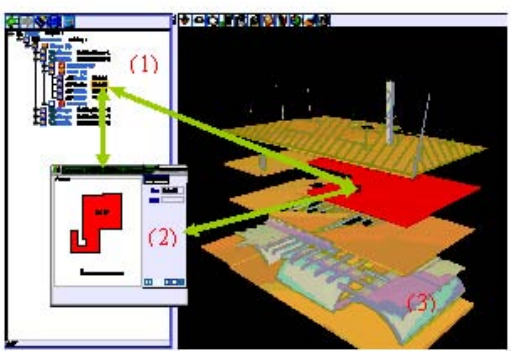


like the fusion of two files in one, the partial extraction of data from one file, visualization or storing, must take into account the multiple semantic values of the objects, which depend on the context of use. To achieve this goal, we defined a hierarchical structure of context called contextual view. The solution consists in reducing the complexity of a cyclic multiple-context graph in an acyclic mono-context graph.

Figure 4 presents the 3D scene management system which builds a specific user interface made up of a tree of composure (1), a 3D scene (2) and a technical chart (3) on a semantic element of the scene. The navigation between the elements is carried out using hypermedia links which associate a set of semantic elements to a trade object. In this case the trade object is a semantic element "Slab" (Slab - Figure 4). Certain contextual trees are generated dynamically by the system starting from IFC files. Others can be created specifically by the actors to structure their data according to their own format (starting from an IFC file or starting from existing trees).

Figure 4. Snapshot of the 3D scene management system



The principal tree is the geometrical contextual tree which contains the topological relations of the various objects. The resulting 3D scene corresponds to a particular trade view (Kim, Hwang, & Kim, 2002). This view corresponds to the actor trade association. This one is customized by the actor according to his needs, its rights, and the size of the data to be transmitted on the network. Starting from this interface, the actor can update the model while adding, modifying or removing part of the principal tree. The selection can be also carried out through the 3D scene by selecting the 3D objects. The following section shows the services available to the speakers of the project, underlining the collaborative aspect of the processes of the platform.

INTEROPERABILITY DEMONSTRATION

This section shows the use of the ACTIVe3D-Build platform as well as IFC files within the framework of civil engineering projects. In the first part of this section we will see the design phase of a building through actions made by several actors working on different CAD software. The second part of this section presents the technical study phase of the building for the structural and thermal validation of the building being designed.

Phase 1: Conception

The design of a building is divided into four phases. The first phase consists of bringing a ground statement of an old building to the platform. The second phase consists of defining an extension to this building. The third phase carries out the extension and the last phase defines the building's floors raised in the first intervention.

Viz'all: A solution for building statement via a pocket PC: Viz'all® is an automated solution of building statements, associating the use of a laser meter, a pocket PC, and software on a pocket PC. The principle consists in tracing by hand the sketch of the room on the touch screen of a pocket PC. After the connection and the deposit of the statement on the ground, the model of the building is updated and is available for all the other actors of the building restoration project. The other actors of the project can now visualize the building starting from the 3D interface of the ACTIVe3D-Build platform.

ADT, Mock-up enrichment: After the deposit of the ground statement, other actors of the project connect themselves to the platform to retrieve this statement and to enrich the mock-up. For this, the architect defines new spaces by using ADT (Autodesk Architectural Desktop). Once the architect has finished his updates on the model concerning the future building extension, he adds these new data to the platform.

ARCHICAD, Mock-up enrichment: Following the architect's updating of new spaces in the extension of the building, the engineers of the civil engineering connect themselves to the platform to collect the last information. These engineers work on ArchiCAD® from Graphisoft. When they have completed their work of building design, these new data are added to the digital building mock-up that is designed on the ACTIVe3D-Build platform.

ALLPLAN, Importation of file and finalization of the building: The second part of the project on this building is the rehabilitation of the existing building. For that, a team of engineers manages the design of this part. As the other teams do, this one is connected to the platform to extract information concerning the principal building. This team works with the software AllPlan® from Nemetschek Systems Inc. Once the updates have been carried out, the engineers put this new information on the platform.

Assessment: Thanks to the platform, a set of actors can exchange information about the building being designed and this between various types of CAD software. The IFC 2.x standard is used to format the data sent to each actor. All the data flows forward through the ACTIVe3D-Build platform because it allows each actor to have all data up-to-date, once they were placed on the server. The effectiveness of this exchange process and the centralization of information saves important time. Indeed, the data exchanges take place on a daily basis in design projects. Thus, the waiting for data updates can block the work of another team; therefore, the access to the up-to-date digital mock-up on the platform makes it possible to resolve emergencies more quickly.

Phase 2: Technical Studies

We saw in the previous section that it is possible to add information to the semantic elements of the digital mock-up of the building. This semantic information will be re-used thereafter in the creation processes of new data on the building using calculation software.

RobotBAT, Structural calculation: During the design of a building, the structures, like the beams and the columns, must be validated. Indeed, if the structures are too weak and they do not respect the standards, then the plans must be modified accordingly. RoboBAT is a structure calculation software. This software optimizes and validates the structures according to the national and the European standards about reinforced concrete, wood, steel, aluminium, and so forth. This software is able to import IFC data. Consequently, the structural engineering and design departments can validate information of the digital mock-up being designed on the ACTIVe3D-Build platform. To realize this study, the engineers must connect themselves to the platform and select all the elements concerning the structure. These elements are the walls, the slabs, the beams, etc. For that, they use the definition of the contextual tree "structural analysis".

BBS Slama, Thermal calculation: There are standards for the validation of heat exchanges between building spaces. The thermal module of the software CLIMA-WIN® made by the company "BBS Slama" makes it possible to carry out the calculation of heat loss "Th-D 1991" as well as the lawful coefficients of the buildings according to "ThBât/ThU rules" 2001. This software imports and exports IFC data. This allows to update and to validate the digital mock-up concerning the heat exchange.

Windesc, Calculation of Bill of Quantities: Windesc® is a tool of bill of quantities from the company ATTIC+ which imports IFC files. This software provides reports/ratios and estimates in connection with surfaces of walls, grounds, and so forth. This tool is essential to establish the cost revaluation of the building construction. The reports/ratios and the estimates carried out on the digital mock-up are then added to information concerning the building and the phase of design.

FUTURE TRENDS

CAD Software interoperability is a main issue that was resolved partially by the information system presented. But there still remains a second main issue, which is the semantic coherency between geometries and them semantic definition. Indeed, when users add information in the platform, this can be false. For instance, "a window is in a wall" is correct information but the different geometries can be located in a wrong place. Consequently, the window is not really in the wall. Future trends consist in defining a process to check the semantic coherency.

CONCLUSION

We have presented the importance of interoperability for civil engineering projects and how to manage it. Thus, we have presented the Active3D Web platform which makes it possible to associate semantics, 3D and documents. This method was adapted to the IFC to allow the semantic handling of the building components. Currently, we are developing a module of 3D acquisition connected to the platform to convert a cloud of points into a set of IFC semantic elements. For this, the knowledge contained in the IFC model is used to search 3D objects in a cloud of points.

KEY TERMS

Building Lifecycle: The lifecycle of a building is articulated in two parts. The first part is about the construction into a civil engineering project. The second part concerns the "use of the building" which deals with facilities management. Currently, these two parts are dissociated in the building management processes. The Teams which are concerned with the processes facilities management are rarely those who have participated in the construction of the building. The facilities management step often begins with a physical analysis of the building to obtain a numerical representation of this building in CAD software. To avoid information loss acquired during the construction of the building, it is necessary to develop a building information system at the beginning of its lifecycle.

CAD: (Computer Aided Design) The use of computer programs and systems to design detailed two- or three-dimensional models of physical objects, such as mechanical parts, buildings, and molecules.

Civil Engineering: Includes the planning, the designing, the construction, and the maintenance of structures and altering geography to suit human needs. Some of the numerous subdivisions are transportation; for instance railroad facilities and highways, hydraulics; like river control, irrigation, swamp

draining, water supply, and sewage disposal' and structures by example buildings, bridges, and tunnels.

IAI: The International Alliance for Interoperability founded in 1995 is an organization representing widely diverse constituencies from architects to software companies and building product manufacturers. The members promote effective means of exchanging information among all software platforms and applications serving the AEC+FM community by adopting a single Building Information Model (BIM).

Interoperability: It is the ability of several systems, identical or completely different, to communicate without any ambiguity and to operate together.

ISO: "International Organization for Standardization" is a network of the national standards institutes of 148 countries, on the basis of one member per country, with a Central Secretariat in Geneva, Switzerland, that coordinates the system. ISO is a non-governmental organization. *http://www.iso.org*

Mock-Up: A mock-up is usually a full-sized scale model of a structure which is used for demonstration, study or testing. A digital mockup is a 3D graphical model.

Challenges in Data Mining on Medical Databases

INTRODUCTION

Modern electronic health records are designed to capture and render vast quantities of clinical data during the health care process. Technological advancements in the form of computer-based patient records software and personal computer hardware are making the collection of and access to health care data more manageable. However, few tools exist to evaluate and analyze this clinical data after it has been captured and stored. Evaluation of stored clinical data may lead to discovery of trends and patterns hidden within the data that could significantly enhance our understanding of disease progression and management. A common goal of the medical data mining is the detection of some kind of correlation, for example, between genetic features and phenotypes or between medical treatment and reaction of patients (Abidi & Goh, 1998; Li et al., 2005). The characteristics of clinical data, including issues of data availability and complex representation models, can make data mining applications challenging.

BACKGROUND

Knowledge discovery in databases (KDD) is defined as the nontrivial extraction of implicit, previously unknown, and potentially useful information from data (Adriaans & Zantinge, 1996; Han & Kamber, 2001). Data mining is one step in the KDD where a discovery-driven data analysis technique is used for identifying patterns and relationships in datasets. Recent advances in medical science have led to revolutionary changes in medical research and technology and the accumulation of a large volume of medical data that demands in-depth analysis. The question becomes how to bridge the two fields, data mining and medical science, for an efficient and successful mining of medical data.

While data analysis and data mining methods have been extensively applied for industrial and business applications, their utilization in medicine and health care is sparse (Abadi & Goh, 1998; Babic, 1999; Brossette, Sprague, Hardin, Jones, & Moser, 1998). In Ohsaki, Yoshinori, Shinya, Hideto, and Takahira (2003), the authors discuss the methods of obtaining medically valuable rules and knowledge on pre- and post-processing and the interaction between system and human expert using the data of medical tests results on chronic hepatitis. They developed the system based on the combination of pattern extraction with clustering and classification with decision tree and generated graph-based rules to predict prognosis. In Tsumoto (2000), the author focuses on the characteristics of medical data and discusses how data miner deals with medical data. In (Ohsaki et. al., 2007), authors discuss the usefulness of the interestingness measures for medical data mining through experiments using clinical datasets on meningitis. Based on the outcomes of these experiments, they discuss how to utilize these measures in postprocessing.

The data mining techniques such as Neural Network, Naïve Bayes, and Association rules are at present not well explored on medical databases. We are in the process of experimenting with a data mining project using gastritis data from Howard University Hospital in Washington, DC to identify factors that contribute to this disease. This project implements a wide spectrum of data mining techniques. The eventual goal of this data mining effort is to identify factors that will improve the quality and cost effectiveness of patient care.

In this article, we discuss the challenges facing the medical data mining. We present and analyze our experimental results on gastritis database by employing different data mining techniques such as Neural Network, Naive Bayes, and Association rules and using the data mining tool XLMiner (Shmueli, Patel, & Bruce, 2007; XLMiner, 2007).

MEDICAL DATA MINING: CHALLENGES

The application of data mining, knowledge discovery and machine learning techniques to medical and health data is challenging and intriguing (Abidi & Goh, 1998; Brossette et al., 1998; Cios & Moore, 2002). The datasets usually are very large, complex, heterogeneous, and hierarchical and vary in quality. Data preprocessing and transformation are required even before mining and discovery can be applied. Sometimes the characteristics of the data may not be optimal for mining or analytic processing. The challenge here is to convert the data into appropriate form before any leaning or mining can begin.

There are a number of issues that must be addressed before any data mining can occur. In the following, we overview some of the challenges that face the data mining process on medical databases (Tsumoto, 2000).

High Volume of Data

Due to the high volume of the medical databases, current data mining tools may require extraction of a sample from the database (Cios & Moore, 2002; Han & Kamber, 2001). Another scheme is to select some attributes from the database. In both approaches, domain knowledge can be used to eliminate irrelevant records or attributes in reducing the size of the database (Owrang, 2007).

Update

Medical databases are updated constantly by adding new results for lab tests and new ECG signals for patients. Subsequently, any data mining technique should be able to incrementally update the discovered knowledge.

Inconsistent Data Representation

Inconsistencies due to data entry errors are common problems. Inconsistencies due to data representation can exist if more than one model for expressing a specific meaning exits (e.g., the location of disease for Colitis, one application may enter (sigmoid, or rectum, etc.) and another may enter (measurements such as 20 cm, 30 cm, etc.)). Additionally, the data type does not always reflect the true data type. For example, a column with numerical data type can represent a nominal or ordinal variable encoded with numbers instead of a continuous variable. This plays an important role during statistical analysis (mean and variance).

Poor Integration

Health data is fragmented and distributed between hospitals, insurance companies and government departments. This poses a substantial challenge for data integration and data mining in terms of the confidence that can be placed in the result and the semantics of a derived rule. One can use common data dictionary and standards to integrate data from heterogeneous systems. The emergence of XML as a data standard is gaining wider acceptance and hence making integration fairly easy in the near future (Cios & Moore, 2002).

Number of Variables

The computational complexity is not linear for certain data mining techniques. In such cases, the time required may become infeasible as the number of variables grow. Techniques such as principle component analysis, available in the XLMiner data mining tool, can be used to reduce the dimensionality (number of variables) of the dataset but retain most of the original variability in the data (XLMiner, 2007). In addition, domain knowledge can be used to eliminate the irrelevant attributes from data mining consideration (Owrang, 2007).

Missing/Incomplete Data

Clinical database systems do not often collect all the data required for analysis or discovery. Some data elements are not collected due to omission, irrelevance, excess risk or inapplicability in a specific clinical context. For some learning methods such as logistic regression (XLMiner, 2007), a complete set of data elements may be required. Even when the methods accept missing values, the data that was not collected may have independent information value and should not be ignored. One possible approach for handling the missing data is to substitute missing values with most likely values (Han & Kamber, 2001; Tsumoto, 2000; XLMiner, 2007).

Noise

Medical databases include some noises. Therefore, data mining techniques should be less sensitive to noises (Han & Kamber, 2001).

Amount of Results

The quantity of output from many data mining methods is unmanageable. Association rule mining has been used in hospital infection control and public surveillance data (Brossette et al., 1998) and in Seplic Shock patient data (Li, Fu, He, & Chen, 2005). Too many rules have been found in both projects. Other problems include trivial and similar patterns observed in drug reaction data and in chronic hepatitis data (Ohsaki, Kitaguchi, Okamoto, Yokoi, & Yamaguchi, 2004).

Pattern Tuning

Many fast heuristic data mining methods need a lot of tuning and they are not easy for users to use (Li et al., 2005). For example, K-means clustering method can generate some very good results, but adjustment of parameters and initial setting are tedious for many users. Similar problems exist in the setting of support and confidence threshold for association rule mining (Han & Kamber, 2001).

Interestingness

Risk patterns are not in line with most data mining objectives. Most data mining algorithms aim to uncover the more frequent pattern. In medical applications, the risk patterns usually exist in a small population. For example, a very small percentage of people are HIV positive or develop cancer. In medical datasets, a pattern in the abnormal group would hardly be frequent because the abnormal cases are rare. Hence, this requires a special measurement of interestingness (Ohsaki et al., 2004).

Interpretation of Mining Result Set

One of the biggest challenges in mining medical data is interpreting the results from discovery vs. noise (Li et al., 2005). In general, it is difficult to interpret results from neural networks. Decision tree can be extended to rules, and their results are more straightforward to interpret. Some techniques do not work well on the skewed cases in medical data where the normal population greatly outnumbers the population of disease (Ohsaki et al., 2004).

DATA MINING TOOL: XLMiner

XLMiner (Shmueli et al., 2007; XLMiner, 2007) is the data mining tool that we used for our experiments. XLMiner is a comprehensive data mining add-in for Excel. It has extensive coverage of statistical and machine learning techniques for classification, prediction, affinity analysis and data exploration and reduction. For our experiments, we considered Naïve Bayes (for classification), Neural Networks (for Prediction) and the Association rules (for Affinity) data mining algorithms.

DATA PREPARATION

The medical dataset is from Howard University Hospital in Washington, DC. The GastroIntestinal (GI) Pathology data contains the records of patients from the years 2002 to 2006. The data set is represented in MS Exel work sheet and contains 5,700 records. The dataset consists of the following attributes: File number, Specimen Number, Specimen Date, HP-test, ELISA, Silver stain, cag-A+, Age, Sex, Race, Nationality, Type of Surgery, Diagnosis, Location of disease, Death, Date of death, Comments, Previous History, and Present Illness.

The data preparation stage involved two stages: data cleaning and transformation. The data cleaning step eliminated inconsistent data, for example, data type inconsistencies (some numeric fields contain alphanumeric character). The transformation aims at converting all the data fields to numeric fields as required by the Neural Network data mining algorithm. It is also required to extract a subset of the fields and records that do not contain missing values.

The typical errors include the following:

1) Data field HP-test had mixed case values (positive, pos., POSITIVE, pos, negative, neg, NEGATIVE, neg.)
2) Data field Sex had values (M,F, f, male, female)

We used the SQL Update operation of the MS-Access database software to handle the records with exception. For column HP-test, all combinations were updated to represent Positive/Negative values and the Sex field values updated to M and F.

Using the Naïve Bayes mining technique (Shmueli et al., 2007; XLMiner, 2007), columns that did not contain any data were rejected by XLMiner. For example, in our gastritis data, we had a lot of empty values for the HP-test attribute. Other attributes that had empty values include Race (had 4,185 values blank), Nationality (had 4,681 values blank), and Location of disease (had 534 values blank). We used the "Missing Data Utility" of the XLMiner to substitute "n/a" for columns that had missing values.

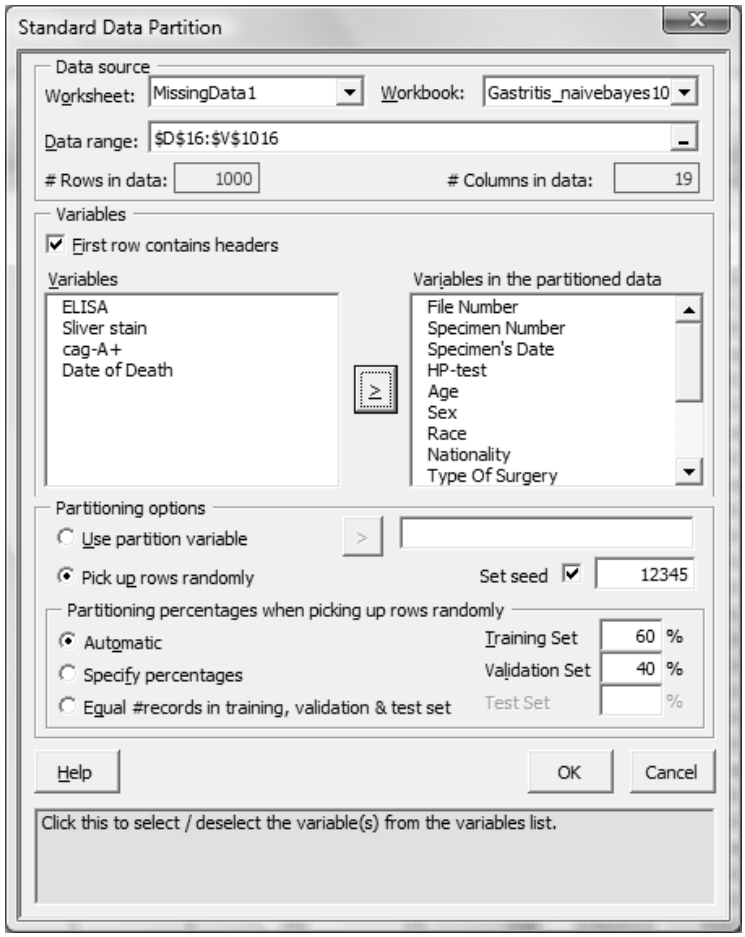
Once all NULL values were taken care of, we used the random partitioning of the XLMiner and created two mutually exclusive datasets, a training dataset comprising 60% of the total dataset, and a validation dataset of 40%, as shown in Table 1. These are the defaults for partitioning. The training dataset is used to train or build a model. For example, in a Neural Network model, the training dataset is used to obtain the network weights. Once a model is built on training data, you need to find out the accuracy of the model on unseen data, the validation dataset.

Upon selecting Naïve Bayes algorithm, we ran into distinctiveness issue as follows:

"Note: The Naive Bayes classification routine supports a maximum of 30 classes or distinct values for an Output variable."

In our original dataset, the attribute (or variable) Diagnosis contained 781 distinct values, and the attributes Type of

Table 1. Standard data partition in XLMiner



surgery contained 591 distinct values. For the experiments, we selected 1,000 records randomly. Still, we had 286 distinct values for the variable Diagnosis and 198 distinct values for the variable Type of Surgery. For Diagnosis, the values recorded had several ways to represent the same value or were spelling mistakes including the values "Mild chronic gastritis," "mild chronic gastritis." After looking at the data, we used similar grouping of values to narrow down the Diagnosis to:

1) acute and chronic gastritis
2) chronic active gastritis
3) mild chronic gastritis
4) moderate chronic gastritis
5) Chronic nonspecific gastritis
6) gastric ulcer

Type of Surgery attribute had similar issues with distinctiveness. The following are some of the possible values for Type of Surgery. Some of these values were the same due to the lack of standards in entering the data values.

1) EGD.bx (EGD.bx (EGD stands for Esophagus Gastro Dudenum and bx stands for biopsy)
2) EGD w biopsy (same as #1)
3) EGD,Gastrotomy
4) EGD.bx; colonoscopy
5) EGD.bx; polypectomy
6) Endoscopy
7) upper endoscopy,bx (same as #1)

MS-Access/SQL was used to fix issues with distinctiveness. There are some possible ways to avoid the aforementioned data issues by developing software/Web application to perform the following tasks, instead of manually entering the data:

1) Automatically filling is used that serves as counters for example Patient id, Specimen number, date and so forth.
2) Use drop down columns to select range data like Sex, Race, binary(positive or negative).

MEDICAL DATA MINING: EXPERIMENTS

There are many data mining techniques available for data classification, prediction, association analysis, and data exploration. In our experiments, we used Naïve Bayes and Association rules mining techniques. Using the gastritis dataset, Neural Networks classification rejected the majority of the input fields (17 of 19), as it does not support alphanumeric values.

In the following, we provide some of the detailed results of the experimental runs followed by a summary analysis, which includes some generated sample rules.

Gastritis Mining Using Naïve Bayes

RUN 1: Output Variable is Diagnosis. Input variables include: File Number, Specimen Number, Specimen's Date, HP-test, Age, Sex, Race, Nationality, Type of Surgery, location of disease, Death, Comments, Previous History, and Present Illness. Based on training data, the known probabilities for some of the diagnosis are shown in Table 2. Table 3 shows the diagnosis column with the highest probability for the top 2 records, upon using validation dataset.

XLMiner's Naïve Bayes data mining technique calculates the overall probability as shown above as well as conditional probabilities for other variables/attributes. In other words, Naïve Bayes classifiers assume that the effect of a variable value on a given class is independent of the values of other variables. In our case, the output variable was Diagnosis. The target attribute Diagnosis was defined through each of the input variables. Only some of those rows with the highest probability are shown in Table 4.

We have done a similar run when output variable was the Type of Surgery. The intent of choosing a second output variable was to evaluate, if using the same data, we could observe a similar or different set of conditions. In the following, we provide the summary analysis of the runs and provide our views of the results.

Gastritis Data Mining Analysis Summary

In general, the interpretation of the results of mining over medical datasets requires significant domain expertise. In many cases, the discovered rules have been generally known, at least to the medical domain expert. Only in a few cases, the mining techniques have produced genuinely new knowledge. The hope for these experiments and analyses is to find the right data mining tool, the right mining technique, for the right dataset as well as to learn to properly set the data mining parameters (e.g., defining confidence threshold, data partitioning, etc.). Table 5 shows some of the rules generated

Table 2. Prior class probabilities for diagnosis

Class	**Prob.**
Mild chronic gastritis	0.001666667
acute and chronic gastritis	0.326666667
Chronic active gastritis 0	.445
chronic nonspecific gastritis	0.003333333
chronic nonspecific gastritis and duodenitis 0	.003333333
gastric ulcer	0.001666667
Mild chronic gastritis 0	.198333333
Moderate chronic gastritis 0	.008333333
nonspecific chronic gastritis	0.006666667

Table 3. Sample output for diagnosis column with the highest probability upon validation of the dataset

Predicted Class	Actual Class	Prob. for class acute and chronic gastritis	File Number
acute and chronic gastritis	acute and chronic gastritis	1	227530
acute and chronic gastritis	acute and chronic gastritis	1	763530

Table 4. Conditional probabilities for the output variables diagnosis, defined through other variables

	Classes-->	
Input Variables	chronic nonspecific gastritis	
	Value	Prob
HP-Test	Negative 1	

a. Diagnosis is defined through the variable HP-test

	Classes-->	
Input Variables	chronic nonspecific gastritis	
	Value	Prob
Sex	M	1

b. Diagnosis is defined through the variable sex

	Classes-->	
Input Variables	Moderate chronic gastritis	
	Value	Prob
Race	AA 1	

c. Diagnosis is defined through the variable race

	Classes-->	
Input Variables	Moderate chronic gastritis	
	Value	Prob
Type of Surgery	EGD.bx 0	.8

d. Diagnosis is defined through the variable type of surgery

by XLMiner using the Naïve Bayes and Association rules data mining techniques.

SUMMARY OF OBSERVATIONS

The Bayesian routine produced 35 rows from the validation output identifying records that were a match based on the training data. When the actual value from the training set matched the predicted value, the record was identified and expressed as a confidence percentage. Apart from the overall match for records that satisfy the criteria of the target output variable 1) Diagnosis or 2) Type of Surgery, conditional probability of each input variable vs. the target output variable was also recorded. Some of the observation shows that if HP-test is negative there is a likely chance of some form of gastritis. Of the available Race data (missing for many rows) it points to the fact that if Race =AA (AA stands for African American) there is a likely chance of gastritis. Also, the generated rules indicate that more female patients had some form of chronic gastritis.

In the gastritis dataset, redundant rules were generated due to redundant data (e.g., nonspecific chronic gastritis and chronic nonspecific gastritis are the same). Furthermore, with

Table 5. Sample rules generated by XLMiner using Gastritis data

XLMiner Technique	**Findings**
Naïve Bayes	**Using Diagnosis as the target Output variable**: 1. Chronic nonspecific gastritis: if HP-test is negative. Gastric ulcer: if HP-test is negative 2. Mild chronic active gastritis: if Age is 70 Gastric ulcer: if Age is 56 3. Chronic nonspecific gastritis: if Sex =M gastric ulcer: if Sex=F 4. Mild chronic active gastritis : if Race is AA **Using Type of Surgery as target Output variable:** 1. IF Diagnosis = acute and chronic gastritis THEN HP-Test = positive has a confidence of 64% 4. IF Race=AA and Type of Surgery=EGD.bx THEN Sex= F has a confidence of 63% 5. IF Sex=F and HP-Test=positive THEN Type of Surgery=EGD.bx has a confidence of 60%

Type of Surgery as target output, several irrelevant and trivial rules were generated, which indicates a relationship between Type of Surgery and HP-test. According to domain expert, the result of HP-test does not have any relationship with the Type of Surgery. Likewise, the Type of Surgery does not imply a particular value for the HP-test. The surgery (e.g., biopsy) needs to be done so that testing can be done. This problem indicates that we need the expertise of the medical experts in order to guide the discovery process in order to avoid generating irrelevant rules.

From the Association rules data mining technique, a total of 246 rules were generated using XLMiner. There were rules that were trivial, redundant, consistent with domain expert's views, as well as some that simply represented some facts about the data, for example, more female African Americans had gastritis.

Some of the findings from both approaches match while others differ as in the case of the fields Race or HP-test. In the Bayesian routine, if HP-test is negative there is a likely chance of some form of gastritis. This observation was

missing from the Association rules, contrary to the Race observations that were similar.

In our experiments, Naïve Bayes discovered more and better findings than Association rules. Some of the factors that contributed to this suggestion are summarized as follows:

1. The quality of the gastritis data set can be best described as below average or poor. Many columns had missing data, which is not conducive for Association rules. Association rules find interesting associations and relationships among large set of data items based on value conditions that occur frequently. The confidence factors from Association rules barely touched 70%. We had to lower the thresholds to identify interesting correlations.
2. A guided learning approach was used in Naïve Bayes technique. The prediction of the overall probability as well as conditional probability was performed using output variable and its correlation with each variable independent of other variables. In contrast, Association rules technique was minimally guided. The only option was to specify an output variable, and rule sets were presented.

FUTURE TRENDS

The following are other issues that need to be addressed before we could have a comprehensive and viable medical data mining environment (Cios & Moore, 2002; Li et al., 2005).

Poor Mathematical Characterization of Data

Business, financial, and scientific data can be easily modeled, transformed and applied formulas in contrast to medical data, whose underlying structure is poorly classified in mathematical terms. Medical data consists of images and free hand data with few constraints on vocabulary or image. In comparison, business and financial data have formal structures into which we can classify and organize data that may be modeled by Linear Regression, Neural Networks, and Naïve Bayes vs. medical attributes such as bloating, inflammation and swelling.

Health Professionals Interpretation

The doctors interpretation of tests conducted, imaging and other clinical data is generally written in free text that is very difficult to comprehend and difficult to standardize. This poses a great challenge for miners. Many times, professionals from the same field cannot agree upon interpreting a patient's condition but also use different names to describe the same disease.

Imaging and Complexity of Medical Data

With advances in medicine and imaging technology, the complexity of data has increased. Increasingly, clinical procedures are employing imaging as a tool of choice for diagnosis. There needs to exist efficient mining in databases of images which are much more difficult than mining purely numerical data. X-ray, cat scans and so forth become more prevalent and necessary diagnostic techniques, and the challenges to interpret and comprehend them in data mining will grow exponentially.

Ethical, Legal, and Privacy Issues

Clinical and medical data is primarily focused on humans and thereby becomes a primary target for abuse and misuse. Effective legal and ethical frameworks need to be in place to prevent their misuse.

CONCLUSION

This article focused on the characteristics of medical data and provided some experimental results on a gastritis medical database using the data mining tool XLMiner and data mining techniques of Naïve Bayes, Neural Network, and Association rule. It should be pointed out that the experimental results indicate that the discovered rules appear to be consistent with the domain experts' views. However, several meaningless rules were generated due to the wrong data entry. Although different data mining techniques of Naïve Bayes and Association rules produced some similar rules, there were rules generated in one technique and not in the other. Neural Network data mining technique could not be used, as most of the attributes were non-numeric.

The next step in this experiment is to use a bigger gastritis dataset along with more data cleaning. In addition, data mining techniques including K-means clustering and classification trees could be used (Shmueli et al., 2006). Most of the non-numeric values of the gastritis attributes need to be transformed to numeric values in order to be able to use the Neural Network mining technique of the XLMiner. Also, it might be worthwhile to group certain categories (e.g., the field Age) which may improve our chances of discovering less and meaningful rules. In the current scheme, each age entry was evaluated independently to find out the Diagnosis or Type of Surgery. However, one could group the age as 1-10 child,11-20 youth, 21-30 young adult, 30-50 adults, 50-65 old and 66 and above very old.

It would be beneficial to use other mining tools including Insightful Miner (Insightful Miner, 2007) in order to improve/verify the correctness and completeness of the discovered knowledge. Finally, domain knowledge (Owrang, 2007) can be used to reduce the computational complexity of data mining algorithms as well as to improve the quality of the discovered knowledge.

KEY TERMS

Affinity: Association rules

Association Rules: Association rule mining finds interesting associations or correlation relationships among large set of data items. Association rules show attributes value conditions that occur frequently together in a given dataset. Association rules provide information of this type in the form of "if-then" statements.

Classification: Discriminant Analysis, Naïve Bayes, Neural Network, Classification Tree, Logistic Regression, K-Nearest Neighbor

Data Mining: Data mining is one step in the knowledge Discovery in Databases (KDD) where a discovery-driven data analysis technique, such as Naïve Bayes or Neural Networks or Association rules, is used for identifying patterns and relationships in data sets.

Data Mining Techniques: The general categories of the data mining techniques include:

Data Preparation: The data preparation stage involved two stages: data cleaning and transformation. The data cleaning step eliminated inconsistent data. The transformation aims at converting the data fields to numeric fields or vice versa.

Knowledge Discovery: Knowledge discovery in databases (KDD) is defined as the nontrivial extraction of implicit, previously unknown, and potentially useful information from data.

Naïve Bayes Classification: Bayesian classifiers operate by saying "If you see a fruit that is red and round, which type

of fruit is it most likely to be, based on the training data set? In future, classify red and round fruit as that type of fruit."

Neural Networks Classification: Artificial neural networks process records one at a time, and "learn" by comparing their prediction of the record (which, at the outset, is largely arbitrary) with the known actual record. The errors from the initial prediction of the first record is fed back into the network, and used to modify the networks algorithm the second time around, and so on for many iterations.

Prediction: Multiple Linear Regressions, K-Nearest Neighbor, Regression Tree, Neural Networks

XLMiner: XLMiner is a comprehensive data mining add-in for Excel. It offers a variety of methods to analyze data. It has extensive coverage of statistical and machine learning techniques for classification, prediction, affinity analysis and data exploration and reduction.

Challenges of Interoperability in an Ecosystem

Barbara Flügge
Otto-Von-Guericke Universität Magdeburg, Germany

Alexander Schmidt
University of St. Gallen, Switzerland

INTRODUCTION

True e-enabled collaboration has been assessed for many years. With the growing reach of companies' business and cross-border trade, the entire ecosystem enterprises are embedded in is playing a crucial role to succeed. As ICT is a key driver for deploying true interoperability and integration among the participants of the ecosystem, actors with a lack of ICT knowledge, equipment, and implementation represent the vulnerable parts within the ecosystem. This article aims at providing an overview of challenges limiting business partners in an ecosystem to truly e-collaborate. Furthermore, it describes the key elements of e-enabled collaboration and interoperability ranging from the technical and business oriented to cross-organizational and cultural aspects.

BACKGROUND

There are two main directions that have been the basis for extensive research over the last decades to touch the ground for successful electronic collaboration (e-enabled collaboration). One direction led researchers to the field of organizational development. The other direction led to the field of ICT support and solutions initiating and facilitating collaboration models. An example of the initiation of collaboration models is the commencement of the e-commerce hype in the 1990s.

The magnifying glass that allows the focus on e-enabled collaboration is the set of key characteristics in these fields that are relevant to facilitate, change, or extend the level of e-enabled collaboration. The following paragraphs are focusing on what we explore by applying the magnifying glass.

Collaborative Environments

The point of origin that leads to the foundation of any ecosystem varies. We are assuming that the ecosystem is formed because of a common interest in conducting business successfully, competitively, and innovatively. Business transactions are executed to request, support, deliver, and exchange goods, services, and data. Each of the participants in the ecosystem contributes actively to the business purpose. They are ordering, delivering, supporting, producing, assembling, and selling goods, services, and data based on their roles and capabilities. Thus, the foundation of an ecosystem is related neither to a specific sector or region nor to the means that are required to run an ecosystem.

The ecological ecosystem is providing extensive research opportunities to analyze interactions, relationship building, and the evolution of organisms. The history of ecosystem research started with Sir Arthur Tansley (1935) when he introduced the term *ecosystem* based on Phillips' studies on complex organisms and the common term of *biotic communities* valuing similarities and boundaries of communities. He is comparing these terms to his own view of describing the changing vegetation, participants, and relationships.

Ritter, Wilkinson, and Johnston (2004) are focusing on the managerial value-related competences of organizations to steer, interact, and cooperate in a business-related network. Referring to Håkansson and Snehota's (1993) role of relationship building, any enterprise needs to broaden its business role by interacting and actively building relationships with its environment (Ritter et al.). In the work of Ritter et al., the environment of an enterprise is comprised of customers, "complementors," competitors and suppliers. Besides the given terms customer, competitor, and supplier, complementors are defined as "types of firms whose outputs or functions increase the value of their own outputs" (Ritter et al., p. 3). On the value side, Brandenburger and Nalebuff (1996) introduced the value net as a term to symbolize the dedicated purpose of realizing value in any given or created relationship among business partners.

Network-related research led to comparing studies. An extensive study conducted by Changizi, McDannald, and Widders (2002) examines the relevance of network size and the capability to grow in different networks such as ecological, technical, human-being, and urban networks. The number of participants joining the network is one of the positive effects that networks participants experience according to Farrell and Saloner (1985) and Reimers and Li (2005). We cautiously draft the analogy of ecological and business-oriented networks to ecosystems due to the fact that the capability to power play and act in a competi-

tive environment is determining the capability to grow and extend the given network from within. Networks that are not business-purpose driven like the Lego network in the case of Changizi et al. are excluded from that assumption.

Collaborating Participants

Further down the exploration of the ecosystem, the decomposition of the ecosystem requires a greater analysis of its relationships and participants. First, we are amplifying in the following the most relevant details of the participants of the ecosystem, representing enterprises, business partners, governmental institutions, and any other involved entity.

The success of any participant in an ecosystem is founded in the capability of the participants themselves in relation to the underlying purpose of establishing the ecosystem. Capability is determined by the level of activity of any participant, its interaction intensity within the ecosystem with one or various intentionally or unintentionally selected participants, the role and responsibility any participant is administering compared to the other participants, and the capabilities participants are offering to the ecosystem. Eisenhardt and Santos (2005) elaborate the key elements of organizational types that are relevant to conceptualize the boundaries of an organization. They distinguish four conceptions of boundaries: efficiency, power, competence, and capability. All four conceptions are main determinants relevant to an ecosystem.

Enlarging the view of the concept of boundaries, it is also relevant to the interaction capability of an organization with its participants in the ecosystem and with other ecosystems. However, efficiency and competence are the most important assets organizations need to enrich and increase the collaboration capability. According to Eisenhardt and Santos (2005), efficiency is required to minimize governance costs, including costs of conducting exchange with other ecosystem participants and those within the individual organization. Competence allows the organization to align its resources, skills, products, and services to outperform external opportunities and market expectations (Eisenhardt & Santos). Thus, five main characteristics of the ecosystem have been elaborated: (a) the ability to individually assign the purpose of an ecosystem to its components (participants), (b) the interactions (among and between participants), (c) the development process within an ecosystem (influencing the ongoing evolution), (d) the maturity and stability of an ecosystem and its components, and (e) the effects an ecosystem is causing in terms of results, measurements, changes in size, and composition.

Coming back to the initial details that are relevant to assess the entire reach of an ecosystem, in the second part of this article we focus on the relationships within an ecosystem. These are comprised of the flow of goods, services, and data. Matutinovíc (2002) applies the concept of flow networks, elaborating on ecological ecosystems and common patterns that address the flows and needs of organizational ecosystems. According to Matutinovíc, the purpose of any existing or planned relationship is based on the following parameters: competition, cooperation, and selection, creating feedback to the participants and positively forcing each to optimize its relationships. Given the fact that resources as outlined by Eisenhardt and Santos (2005) are one of the key parameters, organizations are constrained to keep their competency level high. Any resource optimization, including ICT and process optimization, is a key determinant of successful collaboration. The choreography of ICT solutions and processes will be outlined in the next section.

Role of ICT in E-Enabled Collaboration

The second direction researchers are concentrating on is the field of ICT support and solutions initiating and facilitating collaboration models. Various e-business and e-government initiatives have been formed to get a closer view on e-enabling. Those encompass nearly any business process and collaboration scenario in nearly any industry sector, optimizing any kind of organizational types such as multinational companies as well as small and medium-sized enterprises.

As outlined above, the ecosystem research in many cases does not take governmental institutions into account explicitly, excluding Eisenhardt and Santos' (2005) conception of power, whereas ICT-related research has been including the need of governmental support and e-enabling collaboration with governmental institutions. The dimension of ICT focuses on the technical understanding of collaboration, the applicability of applications, and the key concepts of interoperability according to Theling, Zwicker, Loos, and Vanderhaeghen (2005). There is a number of studies, such as *The European E-Business Report* (European Commission, 2005) and the UN report on e-government and e-inclusion (United Nations, 2005), that point out the need and urge of focusing on the core roles of ICT. ICT should strengthen the collaborative environments with more than Web site publishing or providing electronic media to enhance paper-based documents and business processes. One example supporting the need of ICT in the form of interorganizational systems and business integration is reflected in the case of Denmark (Bjørn-Andersen & Andersen, 2004). Another example is given in the U.S. residential mortgage industry where Markus, Minton, Steinfield, and Wigand (2006) call for the development and adoption of standardized business semantics and business processes to further enhance collaboration and accomplish further benefits.

APPROACHING E-ENABLED COLLABORATION BY DETERMINING THE INTEROPERABILITY FACTOR FOR ANY GIVEN ECOSYSTEM

The traditional and posttraditional context that has been discussed in the section above still leaves a growing community of business and governmental partners who seek for constant and reliable effects of collaboration beyond traditional one-to-one solutions. In the area of electronic customs, for example, business and governmental partners are confronted with an increasing demand for secure trade, and compliant and accessible data at any time for any business partner participating in trade processes.

Given the outlined example of global trade and facilitating the collaboration within ecosystems that are acting in the context of international trade, the limitations in literature and research have been mainly set by three factors. First, governmental institutions have not been considered as ecosystem participants and business partners. Second, collaboration models did not develop top-down cross-organizational business models but rather focused on individual views and perspectives. Third, many published interoperability-related concepts and standards reveal deficits in understanding and applying the interoperability factor: semantically unambiguous business process collaboration.

Modern business-oriented research should be urged to address the need for providing financial or any other measurable evidence to get an open ear in the commercial and governmental community. The need is to prove that a conception works in real-life environments. Added value will be provided by including governmental business cases as well as research on applying the interoperability factor across the ecosystem. The expected outcome hereby is the definition and the concept of an enterprise architecture framework transforming the dimensions of collaboration, namely, the ecosystem, the participants, cross-organizational relationships, and processes, into feasible interoperable solutions.

INTEROPERABILITY AS A MULTIFACET CONCEPT

If we consider interoperability as being the fundament for e-enabled collaboration, first of all it is necessary to specify the meaning as well as relevant aspects of the notion. While research in the past regarded interoperability solely from a technical perspective,[1] nowadays there is a wide consensus that this view needs to be extended. In literature, the most common distinction is made between technical, semantic, and organizational interoperability, even though their naming might slightly defer (cf. European Commission, 2004; Ministry of Economic Affairs and Communications, 2005). We will stick to this differentiation in this section.

Technical Interoperability

On the technical layer, interoperability is mainly concerned with technical issues of linking information systems and services, particularly the interoperability of hardware (infrastructure) and software. On this level, we are mainly concerned with the integration and exchange of data (via common protocols) between software used in different organizations, the definition of interfaces, and interconnection services. From a simply syntactical perspective, the challenge of technical interoperability is solved to a large extent nowadays. However, the semantic dimension remains an unsolved problem and, consequently, constitutes one of the pivotal areas of research in the near future.

Semantic Interoperability

Semantic interoperability denotes the ability of different applications and business partners to understand exchanged data in a similar way, implying a precise and unambiguous meaning of the exchanged information. On this level, standards (for data as well as messages) are the crucial factor for achieving interoperability. However, the problem faced by most organizations today lies with the multitude of standards complicating the decision regarding which standard to take within an ecosystem while different standards are used by different business partners. The heterogeneity of information systems and data models between companies limits the capability of integration and has led to isolated business models using proprietary standards and services (Legner & Wende, 2006). The main insufficiencies for realizing e-enabled collaboration on the semantic layer can be summarized as follows.

First, concerning the exchange and integration of data, there is still no common approach for structuring and naming data types that are the basis for assembling messages. Furthermore, the enrichment of business data with semantics, necessary to guarantee a common understanding of business information, is not satisfactorily solved. Semantics are essential for specifying the context in which data are used (so-called context drivers such as a specific industry, country, etc.) and, hence, for true interoperability. Such an approach has to be built up on a common grammar and library. The introduction of XML (extensible markup language) in the late 1990s raised hopes of seamlessly integrating heterogeneous IT landscapes becoming a de facto standard for the technical representation of business data and led to a bunch of XML-based data standards with the goal of increasing interoper-

ability. However, the industry-specific XML representations do not ensure that the expressed business information will be understood equally between all systems as XML does not detail how this information is modeled or named. A very promising approach attacking the problem of business data interoperability is the CCTS (core component technical specification) methodology for semantic data modeling on an syntax-independent level from UN/CEFACT (United Nations Centre for Trade Facilitation and Electronic Business) and ISO (International Organization for Standardization; Stuhec, 2005). Embedded in the UN/CEFACT e-business stack, the CCTS methodology enhances interoperability of the business data exchange with the help of two further components. First, reusable collaborative business processes in which the business information is commonly used and correctly interpreted are defined by the UN/CEFACT modeling methodology (UMM; cf. UN/CEFACT, 2006a). Second, the XML naming and design rules specification (cf. UN/CEFACT, 2006b) recommended by the UN/CEFACT allows the systematic transfer of the syntax-independent core components to XML schema and instances.

Second, on the message level, the semantic business data building blocks can be assembled to unambiguously interpretable business messages. Such messages can overcome the traditional problem of varying document structures, sizes, amounts, content in contained data fields, and so forth, which result from country-specific legal frameworks or different industry standards.

The result of applying such a syntax-neutral integrated approach is both an increased reusability and adaptivity to varying requirements, enabling interoperability and e-enabled collaboration and cooperation between business partners.

Organizational Interoperability

However, as already mentioned, interoperability needs to consider far more than just the technical dimension. Particularly, business-oriented problems, such as the coordination of business models and collaborative processes, constitute fundamental challenges on the road to truly e-enabled collaborations. We refer to this dimension as organizational interoperability. It is associated with the activities and processes of organizations and the (strategic) agreements between them.

The organizational dimension of interoperability comprises the alignment of business goals between business partners as well as their business processes in order to realize the collaboration of companies with differing internal structures and processes. The concept of public processes (cf. Legner & Wende, 2007) represents an approach that aims at facilitating the cross-organizational design of business processes, including the allocation of responsibilities, the decoupling of internal and external processes (in order to reduce the visibility of internal activities containing confidential information), the formal specification of interfaces, and the support of the alignment with multiple partners.

Together with the concepts for semantic interoperability, the public-process approach enables the realization of semantically unambiguous business process collaborations as the ultimate goal of nontechnical interoperability.

Interoperability Road Map

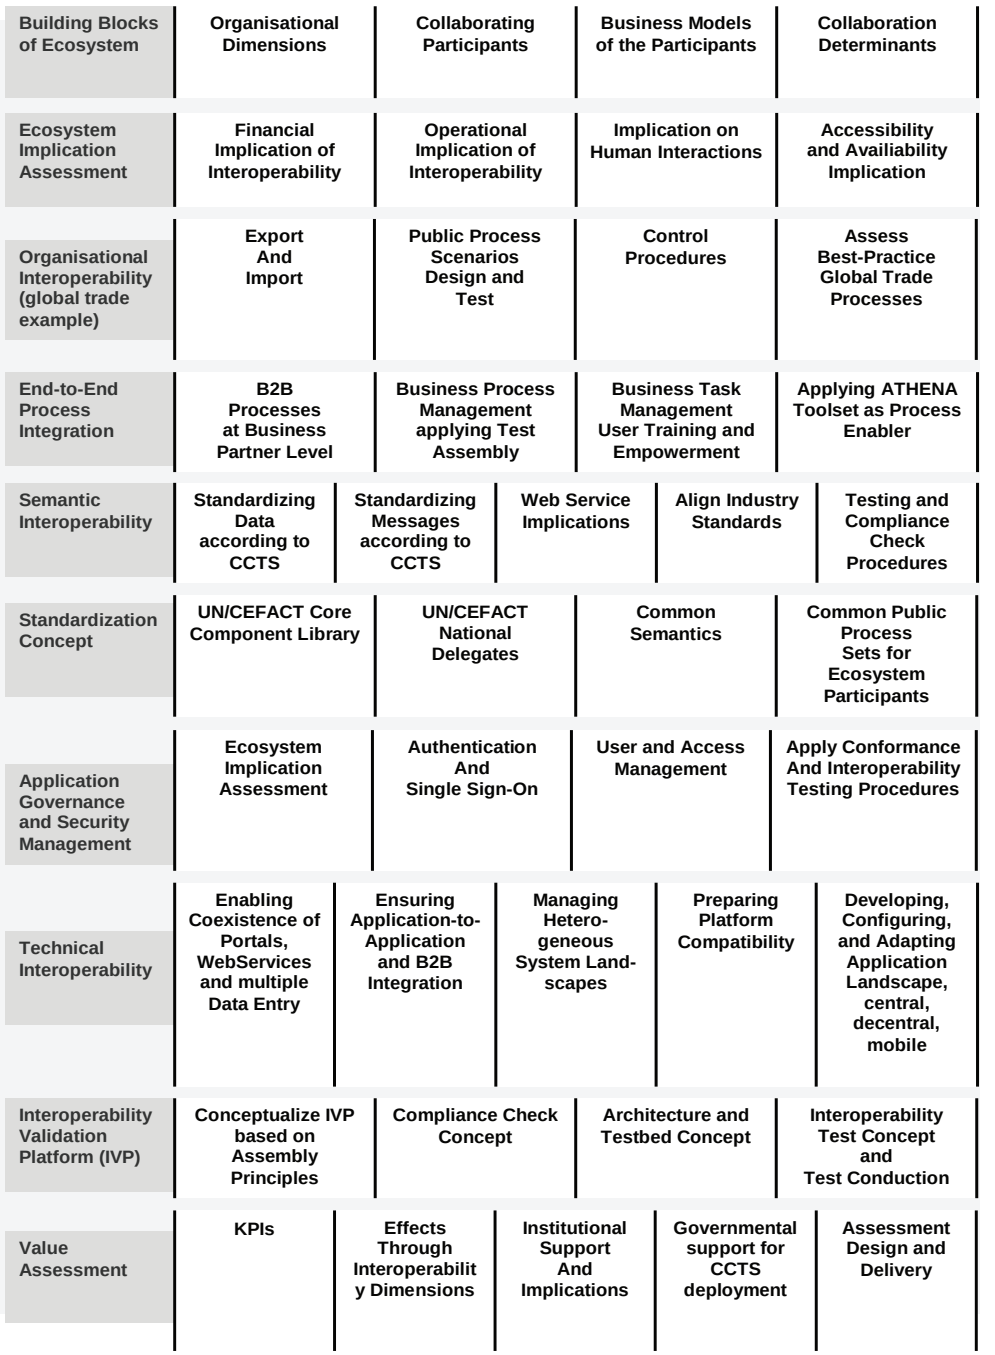
Reflecting the interoperability factor in the context of global trade, the following paragraph contains an example of how the road map to e-enabled collaboration may look like (Figure 1; Flügge, 2006). It also drafts the key components of that road map in the ecosystem. In the example of global trade, an ecosystem in the dairy-food industry is built by more than 20 participants, ranging from manufacturers such as farmers, logistics service providers, banks and insurance companies, governmental institutions such as customs and tax administration, and veterinarian authorities to service providers such as controlling companies, distributors, customs brokers, and port facilities.

The interoperability road map is comprised of a set of cornerstones seen and experienced as relevant to approach e-enabled collaboration. Each of the cornerstones covers an area that individually contributes to collaboration. They are the following: (a) organizational interoperability, (b) ecosystem implication assessment, (c) end-to-end process integration, (d) semantic interoperability, (e) the standardization concept, (f) application governance and security management, (g) technical interoperability, (h) interoperability validation platform, and (i) value assessment. Each of the cornerstones is built on a set of tasks that are highlighted in the road map and arranged next to the cornerstone they refer to.

FUTURE TRENDS

Research and development tasks in the interoperability and e-enabled collaboration areas will continue to be one of the main topics. Their success is a prerequisite for tomorrow's software engineering and development. There is a need in academic research to reflect on real business environments and their complexity on the one hand, and to transform that complexity into a research approach that allows academic partners to draw upon business needs and feedback, transferring those back into their research fields, on the other hand. Successful execution of ecosystems and collaboration is highly dependent on the standardization efforts. Research institutes and academic partners approaching collaboration and ecosystems from various perspectives and directions need to collaborate to truly assess all implications of collaboration.

Figure 1. Interoperability road map version 1.3 (Flügge, 2006)



To enable business partners to respond to innovative, commercial, and competitive objectives, researchers and practitioners should discuss the impact of value for each of the participants and the ecosystem itself. Key performance indicators to measure successful collaboration will be required to prove against the models as well as interoperability tools such as the outlined road map.

CONCLUSION

True e-enabled collaboration reaches beyond technical capabilities of software and middleware solutions. Any interaction in today's and tomorrow's business activities requires a common understanding of what needs to be shared, delivered, and exchanged and to what extent to fulfill a (common) busi-

ness purpose. The complexity in ecosystems requires a solid interoperability-grounded methodology. The methodology should provide guidelines to add collaboration as an out-of-the-box and built-in characteristic of any software solution that is offered in the market. In addition, the methodology should provide a framework with procedures suitable for any company regardless of its size, its industry focus, its technical competence, and its cultural context. Companies should not worry anymore about how they can technically content- and document-wise invite a new business partner to join the ecosystem.

KEY TERMS

Core Component Technical Specification (CCTS): CCTS represents a methodology for a semantically unambiguous definition of business information based on syntax-neutral and technology-independent building blocks that can be used for (semantic) data modeling. Therefore, it facilitates the reuse of existing data entities, increases semantic interoperability, and allows for an integration of vertical industry standards.

Cross-Organizational Processes: These are so-called public processes that are relevant to any business and governmental partner in a given ecosystem. Public processes reflect the common process elements that need to be visible, achievable, and executable by the participants of the ecosystem.

Ecosystem: The ecosystem is the real-life environment business and governmental partners form to interact, share, and execute goods, products, and services relevant to a common business purpose.

Interoperability: Interoperability is the capability to exchange and reuse information, messages, and documents between applications and business partners. As a multifaceted concept, it possesses three different dimensions: technical, semantic, and organizational interoperability.

Interoperability Factor: It is the maximum grade of applying the interoperable layers; refer to the term *interoperability*.

Interoperability Road Map: The interoperability road map is a tool set enabling companies and ecosystems to define a common denominator for interoperable solutions.

Semantic Interoperability: Semantic interoperability denotes the ability of different applications and business partners to understand exchanged data in a similar way, implying a precise and unambiguous meaning of the exchanged information.

United Nations Centre for Trade Facilitation and Electronic Business (UN/CEFACT): The UN/CEFACT, as part of the United Nations Economic Commission for Europe (UNECE), aims at facilitating international transactions by simplifying and harmonizing the electronic exchange of information. The UN/CEFACT has long-lasting experience in developing e-business standards, amongst others ebXML and UN/EDIFACT.

ENDNOTE

[1] According to the Institute for Electrical and Electronics Engineers (IEEE, 1990), interoperability can be defined as "the ability of two or more systems or components to exchange information and to use the information that has been exchanged."

Characteristics and Technologies of Advanced CNC Systems

INTRODUCTION

Computer Numerical Control (CNC) systems are the "backbones" of modern manufacturing industry for over the last 50 years and the machine tools have evolved from simple machines with controllers that had no memory and were driven by punched tape, to today's highly sophisticated, multiprocess workstations. These CNC systems are still being worked and improved on. The key issues center on autonomous planning, decision making, process monitoring and control systems that can adjust automatically to the changeable requirements.

Introduction of CNC systems has made it possible to produce goods with consistent qualities, apart from enabling the industry to enhance productivity with a high degree of flexibility in a manufacturing system. CNC systems sit at the end of the process starting from product design using Computer Aided Design (CAD) tools to the generation of machining instructions that instruct a CNC machine to produce the final product. This process chain also includes Computer Aided Process Planning (CAPP) and Computer Aided Manufacturing (CAM).

BACKGROUND

The development of an intelligent CNC controller architecture has been one of the main goals for both CNC manufacturers and end users. This new trend comes with a suite of new technologies and concepts. In today's manufacturing world, understanding the true meaning and implication of these technologies and characteristics is the top priority. Extensibility is the ease with which a third party is able to add capabilities to software or hardware. Interoperability is the ability of two or more systems or devices to exchange information and make use of it transparently. Portability is the ease with which application software can be transferred from one environment to another. Scalability is the ease with which an existing system's performance can be increased or decreased to suit different applications of different magnitude. The recent CNC controller development includes a digital signal processor (DSP) (Chang, 2007), virtual CNC (Erkormaz & Wong, 2007) and CNC system based on STEP-NC and Function Blocks (Wang, Xu, & Tedford, 2007).

STEP-NC (ISO 14649, 2003) is viewed to be an effective means of documenting task-level information in the CAD/CAPP/CAM/CNC manufacturing chain. The new standard of Function Block (IEC 61499, 1999) has the advantages of generating method-level data for the control unit. The kernel software proposed by Park, Kim, and Cho (2006) organized and managed various control software modules dynamically by using process and resource models. It enabled the CNC controller to be easily reconfigurable because the software modules can be plugged-and-played and be built modularly so that new features or number of control axes could be added easily. Bi, Yu, and Li (2006) introduced a new type of CNC, which is based on Sinumerik 840D and STEP-NC. This is a kernel of Intelligent Integrated Manufacturing System (I^2MS).

Open CNCs

Open CNC architecture can be understood as having standard hardware and software which permit system scalability, and ensure future performance enhancement. The development of an open CNC architecture entails the establishment of a type of software architecture that fits in with a "general" computer which is independent of a control vendor, plus a communication standard among computer hardware, an operation system and application software (Ambra, Oldknow Migliorini, & Yellowley, 2002; Pritschow et al., 2001).

Most of the advanced CNC controllers and supporting hardware have closed architecture designs which make it difficult, if not impossible, to incorporate advanced control schemes within the CNC itself as well as integrate with other manufacturing resources. Open architecture controllers are designed to remove this type of obstacles by creating a flexible control system that can be attached to a wide variety of machine tool systems in such a way that the original axis and spindle drive motors and supporting electronic interfaces can remain intact.

Work concerning open CNC architecture has been one of the main topic areas in CNC research activities since the mid-1980s, but it was not until the early 1990s that a few

Table 1. Some open-architecture controllers

Vendor and location	Product	Computer(s)	Operating systems(s)	Bus and net
Advanced Technology & Research Corp Burtonsville, Md.	RCS	Dual PCs	• Windows NT for GUI • Real-time kernel for control	• Ethernet • Sercos motion bus • Profibus distributed I/O

commercial products were investigated and prototyped by some leading companies in the CNC industry. Table 1 summarizes some of the developed or prototyped open-architecture controllers (OSACA, 2007).

World-wide, three industrial consortiums have been active since the early 1990s. They are the Open System Environment for controllers (OSE) of Japan (Zhang, Wang, & Wang, 2003), OSACA of Europe, and OMAC consortium of the USA. Although different approaches are used, they all share a similar vision of using open-architecture controllers in replacement of the current closed CNC systems.

Adaptive/Adaptable CNCs

"Adaptive" or "adaptable" describes a high level of robustness in dealing with changes in a manufacturing environment such as machining process in a timely fashion. Both terms have been used to refer to similar situations. However, differences between "adaptive" and "adaptable" have been observed in that adaptable is often used to describe the science of a system, whereas adaptive is usually used to describe the enabling technologies for such a system. In other words, adaptable is at the system level, whereas adaptive is at the component level.

CNC machine tools require experienced and qualified programmers to operate. More often than not, they select and set operating parameters off-line based on their experience and knowledge, hence the tendency in using extremely proprietary machining parameters. This situation requires CNC machine tools to be adaptable to any changes that may occur and make the initial settings invalid. This is deemed necessary so as to protect the cutters, workpiece and machine tools from being damaged as well as achieve a desired productivity (Qin & Park, 2005; Soliman & Ismail, 2001). Adaptability is also an indispensable feature in an unmanned machining system.

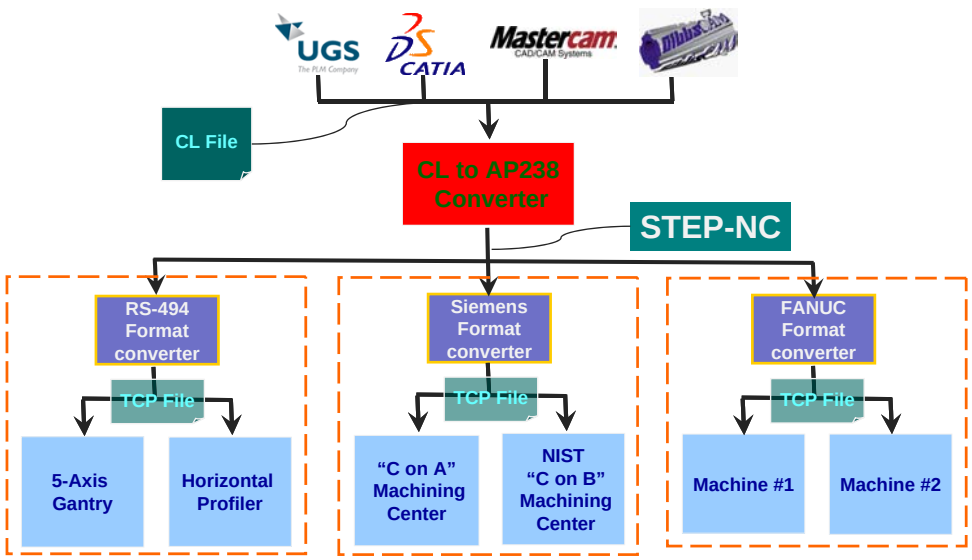
Various adaptive control technologies have been developed in the past 30 years. These include different feed-forward and feedback control mechanisms that enable automatic monitoring and adjustment of machining conditions (e.g., cutting speed, depth of cut and feed rate) in response to variations in operation performance. Various sensor-related technologies have been investigated (Liu, Zhang, & Tang, 2004; Morales-Menendez, Sheyla Aguilar, Rodriguez, Elizalde, & Garza Castanon, 2005). The adaptive control systems can be classified into two types, Adaptive Control with Constraints (ACC) and Adaptive Control with Optimization (ACO) (Cheng, Zhang, Hu, Wu, & Yang, 2001). ACC systems control and regulate one or more output parameters, typically cutting force or cutting power, to a set of limiting values by updating the machining parameters online and in real-time (Huh & Pac, 2003; Zuperl, Cus, & Milfelner, 2005). In the case of ACO, optimal goal(s) are set to be achieved by adjusting a number of controllable parameters.

More and more research effort has been spent on the development of adaptable kernel CNC software that can be easily taken up by system developers. The research work by Park et al. (2006) proposed several adaptable control architectures to enable the incorporation of new technologies into existing CNC controllers. Both kernel software and CNC control have adaptable functions. Kernel software-based controller consists of four distributed components, that is, intelligent control software modules, motion control software modules, kernel software, and a motion control card. The components can be easily replaced or adaptable to respond to any changes of the machining parameter.

Interoperable CNCs

Interoperability is often seen as an enabling technology in contemporary computer systems and their peripherals. Interoperability, in accordance with the definition proposed by the SEMI organization (Semiconductor Equipment and Material International), can be described by (i) interoperability for communication; (ii) interoperability for application services; and (iii) interoperability for interchangeability

Figure 1. Making CNC data interoperable



toward adaptability (Iung, Neunreuther, & Morel, 2001). Interoperability is now regarded as a key characteristic of the modern manufacturing system in its drive for a seamless product information flow and collaborative product development capability.

There are effectively two major issues that need to be addressed, namely product data interoperability and CNC machine tool compatibility. CNC machine tools' compatibility has been severely restricted by the way the machine control data is structured and generated. The ISO 6983 standard (i.e., G-codes) is being perceived as the contributor to the problem. This is due to the fact that the standard focuses on programming the path of the cutter centre location (CL) with respect to the machine axes. A specific post-processor has to be used for almost any individual machine tools, and of course the end result is that almost every single machine tool has to have its own specific machine control data. The consequences are the machine tools are not compatible and the entire CAD/CAPP/CAM/CNC process chain is broken.

There have been some efforts in making machine control data interchangeable, hence machine tools are made interoperable. Use of STEP-NC data model is one example. At the STEP-NC Forum in Orlando in 2005, four CAD/CAM systems (i.e., Unigraphics, Catia, GibbsCAM and MasterCAM) were used to generate CL part programs (Xu, Wang, & Rong, 2006). These CL data represent angular cutter motions in a CNC configuration-independent *I, J, K* way, with the assumption that the underlying machine tool controller will translate the *I, J, K* into machine specific five-axes angular configuration. Different CL-STEP-NC (AP-238) converters were developed to translate the CL file into a STEP-NC file (Figure 1). These converters, once embedded in the controllers, will make the STEP-NC file portable across the CNC machine tools, that is, in this particular case, the STEP-NC file has become neutral to all five-axis machines, be it a five-axis gantry CNC, "*C* on *A*" machining centre or "*C* on *B*" machining centre.

STEP-NC enabled interoperable CNC machining systems can be characterized as being capable of (i) seamless information flow; (ii) feature-based machining; (iii) autonomous CNC; (iv) fault tolerable; (v) networked (vi); scalable and (vii) portable.

Function blocks (IEC-61499) (Xu et al., 2006) are another emerging standard that can support interoperable manufacturing systems. Function block standard is being developed for distributed industrial process measurement and control systems. Because a function block can be viewed as a fundamental functional and executable unit, it is suitable to model machining information and can be designed to match individual machining features. CNC controllers can be built with function blocks as part of their device firmware or with function block libraries from which function blocks can be selected and downloaded. This renders a useful tool for developing interoperable CNC controllers and the control strategies.

Distributable CNCs

A distributable CNC system consists of several components distributed over a network of computers. These distributed components synchronize and coordinate their activities, via the communication network, to achieve a specified goal.

Figure 2. Distributed process planning

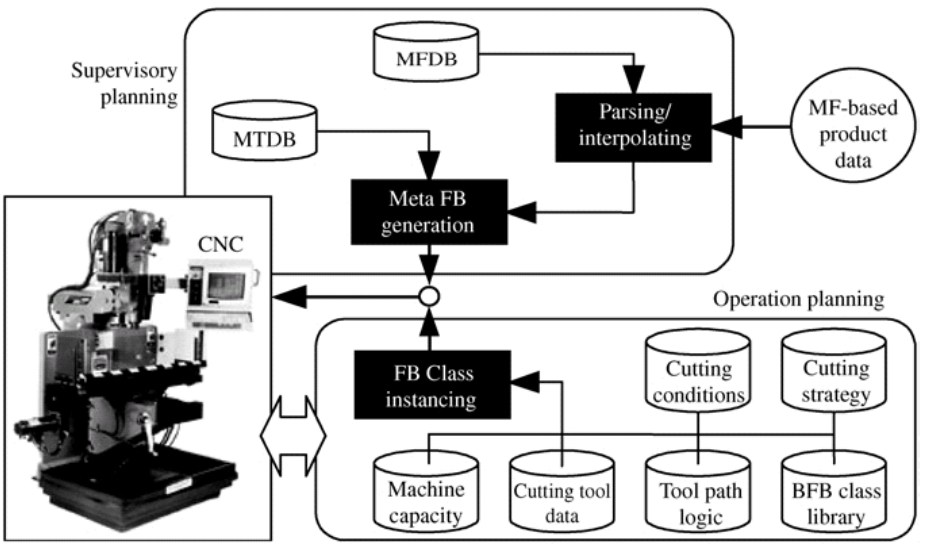


Figure 3. Distributed, STEP compliant NC machining

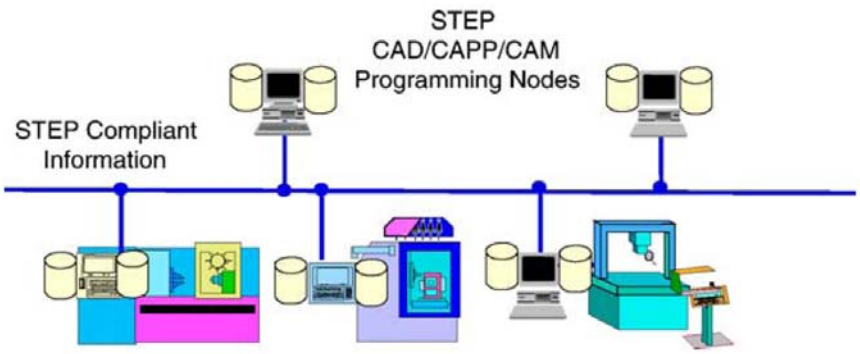

Such a system must be able to support an arbitrary number of processes, the distribution of which should be transparent to the user; provide an efficient communication facility; and be incorporated into a single virtual computer.

The key to a distributed CNC system is believed to be the ability of maintaining a constant availability of the functional components of the distributed operating system, for example system services and, more importantly, to improve the manageability of the distributed environment or network. The distributable functional components aim to help make the behaviour of the distributed system more predictable. Therefore, the infrastructure, that is, the set of control system services of the distributed operating system, is to be designed to include extra functionality to facilitate this task. To improve the quality of distributed software, the functional requirement of a distributed system infrastructure is needed and the problems inherent in a distributed operating system environment need to be identified.

Wang et al. (2006) proposed an architecture for Distributed Process Planning (DPP), using multi-agent negotiation and cooperation (Figure 2). It adopted technologies such as machining feature-based planning and function block-based control. Different from traditional methods, the proposed approach uses two-level decision-making, supervisory planning and operation planning. The former focuses on product data analysis, machine selection, and machining sequence planning, while the latter considers the detailed working steps of the machining operations inside each process plan and is accomplished by intelligent NC controllers. Through the nature of decentralization, the DPP shows promise of improving system performance within the continually changing shop floor environment.

Xu and Newman (2006) proposed a system model to support a scenario of "design anywhere/build anywhere" (Figure 3) (Liu, Yu, & Wang, 2005). It supports distributed manufacturing scenario through, for example, Ethernet connections to accomplish data collection, diagnostics and maintenance, monitoring and production scheduling on the same platform. This distributed feature is made possible by employing STEP as the universal data model across the CAD/CAPP/CAM/CNC process chain. Distributed CNC systems are often characterized as reconfigurable and modularized.

Reconfigurable CNCs

In general, any substantial changes that influence the production process in a manufacturing company will initiate reconfiguration of the manufacturing company's organisation. The principal causes may be a change of product demand, producing a new product on an existing system, or integrating new process technology into the existing system. In response to these changes, flexible manufacturing cell (FMC) and flexible manufacturing system (FMS) were developed and widely used.

More recently, the concept of reconfigurable manufacturing systems has been suggested and developed. Unlike FMCs and FMSs, they are capable of rapid changes in structure as well as hardware and software components in order to quickly adjust machining capacity and functionality in response to sudden changes in market or in regulatory requirements. The changing components may be machines and conveyors for entire production systems, mechanisms for individual machines, new sensors, and new controller algorithms.

A reconfigurable CNC system can be created by incorporating basic process components, hardware and software, which can be rearranged or replaced quickly and reliably to allow adding, removing, or modifying specific process capabilities, controls, software, or machine structure (Landers, Min, & Koren, 2001). This type of system will provide customized flexibility for a particular part family, and will be open-ended, so that it can be improved, upgraded, and reconfigured, rather than replaced.

The key characteristics of a reconfigurable CNC system can be summarized as follows,

- Integrability: Design systems and components for both ready integration and future introduction of new technologies. This requires a combination of hardware and software which can be rearranged in a rapid and reliable way.
- Convertibility: Allow quick changeover between existing products and quick system adaptability for future products.
- Diagnosability: Identify quickly the sources of quality and reliability problems that occur in large systems.
- Customization: Design the system capability and flexibility (hardware and controls) to match the application (product family).
- Modularity: Design all system components, both software and hardware, to be modular.

Modular CNCs

Modularity can be defined as the degree to which a product is composed of independent modules whose internal functionality is intact without any necessary interactions between them. A modular CNC system may consist of off-the-shelf units and it is nowadays considered a key attribute of any CNC systems to meet the need for mass customization. From the system point of view, modularized structure can improve its robustness, software maintenance, portability and reusability.

Although some of the modern CNC systems and the controllers are multiprocessor-based, they do not offer the flexibility to include sensing, monitoring and control modules. The type of the machine-specific components that can be modularized include, machine actuator mapping, servo control, and input/output interface. These components need to be designed independently so that they can be easily added to the controller, removed from the controller, or replaced by other components during system reconstruction. In a normal situation the integral designs result in complex parts that require more complicated and costly resources. Therefore, the modular CNC system is vital to be regarded as a strategy for effectively organizing complex products and processes. Having a modular feature allows a designer to control the degree to which changes in processes or requirements affect the product and, by promoting interchangeability, modularity gives designers more flexibility to meet these changing processes. It also allows for flexibility in function and flexibility in meeting end-user needs. In fact, modularity is a fundamental requirement for system interchangeability, openness, flexibility, scalability, portability and distributability. Different types of technologies have been deployed to achieve modularized CNC systems. Function Block is one of them. It is based on an explicit event-driven model and provides for data flow and finite-state automata-based control.

FUTURE TRENDS

Tomorrow's manufacturing world is believed to take a more distributed, decentralized and collaborated shape, the traces of which are already abundantly clear in many parts of the world. In fact, many factors help shape the future trends of advanced CNC systems due to the rapid development of manufacturing systems. The legacy of CNC control systems, or rather their development, has had a prolonged influence on today's CNC machine tools. Each CNC control system will not have its own software and hardware structure that is different from others, or else much of it will remain as a "black box" to the outside users.

Being proprietary in nature, these conventional CNC systems are limited in flexibility and robustness when there are needs to interface them with other systems. To unlock the unfulfilled potential, CNC machine tools will become more open, adaptable, interoperable, distributable, reconfigurable and modularized. The next generation of CNC systems can increase their capabilities and lower the cost by closing the loop of CAD/CAPP/CAM/CNC process chain.

CONCLUSION

Open CNCs have been extensively researched. Thank to the advances in modern control theories, adaptive control functions of these machine tools have been significantly improved. Interoperability is defined as the ability of two or more CNC systems to exchange information with no barriers. This is best described as having plug-and-play features (Wang et al., 2006). A key enabler for such a plug-and-play feature is portability, which is the ease with which machine control data can be transferred from one environment to another, or simply reused on a different machine. Distributability is needed to meet collaborative product development environment where machine control data have to be made transferable across the Internet or Intranet. Reconfigurability and modularity go hand in hand to give CNC machine tools additional features such extensibility and scalability, where extensibility is defined as the ease with which a third party is able to add capabilities to software or hardware, and scalability is the ease with which an existing system's performance can be adjusted to suit production demand.

STEP-NC and function blocks are two emerging standards that seem to hold the key for developing a generation of CNC system that is open, distributable, reconfigurable and modularized in structure, and adaptable and interoperable in functions. To a varying degree, both standards though unrelated, seem to complement each other. STEP-NC completes the entire product development chain by offering a STEP-compliant link between CAPP and CNC. It can therefore supply CNCs with a complete product model. STEP-NC is good at

supporting bi-directional information flow in CAD/CAM, data sharing over Internet, use of feature-based machining concept, modularity and reusability, and portability among resources. Function blocks, on the other hand, provide a useful tool for developing interoperable and modular CNC controllers and the control strategies. This is because a function block can be viewed as a fundamental functional and executable unit. Function blocks can be designed to match individual machining features and have needed algorithms and data embedded to decide the best cutting conditions and tool path once a machine and tool are selected. This makes function blocks best suited for CNC controls. In short, STEP-NC can be viewed as a "job-setter" (providing all the necessary information), whereas function blocks can be viewed as a "job-doer" (executing the machining commands) for a new generation of CNC systems.

KEY TERMS

Adaptable: Describes a high level of robustness in dealing with control system or machine's components changes in a manufacturing environment especially during machining process for future unmanned machining system.

Distributable: Consists of several components distributed over a network of computers involving Computer Aided Design (CAD), Computer Aided Process Planning (CAPP), Computer Aided Manufacturing (CAM) and Computer Numerical Control (CNC) try to synchronize and coordinate machining activities.

Extensibility: The facility by which a third party is able to add capabilities to software or hardware.

Interoperable: The ability of two or more computer systems to exchange information and make use of it transparently.

Interoperability: The ability of two or more computer systems to exchange information with no barriers and make use of it transparently.

Modular: The degree to which a product of CNC system components is composed of independent modules whose internal functionality is intact without any necessary interactions between them.

Open: Having standard hardware and software which permit system scalability, and ensure future performance enhancement; a vendor-neutrality and component-integrability; tool-neutral, and controller-neutral architecture.

Portability: The facility which applications software can be transferred to one environment from another, while maintaining its capabilities.

Reconfigurable: Is composed of multiple software and hardware, and incorporates basic process components which can be replaced, permitting disassembly, reassembly, rearrangement, or replaced quickly to the main system to allow adding, removing, or modifying specific process capabilities, controls, software, or machine structure.

Scalability: The facility which an existing system's performance can be increased or decreased in the application demand.

INTRODUCTION

Knowledge management (KM) refers to a range of practices used by organizations to identify, create, represent, and distribute knowledge for reuse, awareness, and learning across the organization. KM typically takes the form of programs that are tied to organizational objectives and are intended to lead to the achievement of specific outcomes such as shared intelligence, improved performance, competitive advantage, or higher levels of innovation.

Knowledge management focuses on developing and maintaining intellectual capital across the organization. It attempts to bring under one set of practices various strands of thought and practice relating to:

- Harnessing the effective use of data, information, and know-how in a knowledge-based organization and economy
- The idea of the learning organization
- Various enabling organizational practices such as communities of practice and corporate yellow page directories for accessing key personnel and expertise
- Various enabling technologies such as knowledge bases and expert systems, help desks, corporate intranets and extranets, and content management systems (Wikipedia, 2007).

Beginning in the 1990s, the person responsible for directing and coordinating these activities for organizations was oftentimes designated the chief knowledge office (CKO).

BACKGROUND

The role of a CKO was created and promoted by consultants in the late 1990s to develop a firm's knowledge infrastructure, to promote knowledge capture, storage, and distribution, and to act as a symbol that employees look to for guidance in a knowledge management culture. Bontis (2002) states that the CKO position was intended to help a firm to leverage its intellectual capital by:

- Promoting stability in a turbulent business environment
- Enabling the speedy delivery of products and services
- Creating high efficiency in the knowledge value chain by sharing of resources and realization of synergies
- Enabling the separation of work so that specialization is feasible

The CKO job description frequently encompassed a number of different responsibilities. For example, the CKO might be responsible for leading executive management to develop an enterprise knowledge strategy, validating this strategy across the enterprise, and then ensuring that its evolution complements and integrates with business strategy. The CKO might also be charged with setting priorities and securing funding for knowledge management programs as well as defining policies for security, usage, and maintenance of intellectual capital. Depending on the organizational culture, the CKO could also act as the chief advocate for KM as a discipline—walking and talking the program throughout the enterprise and assisting executives and senior management in building and communicating personal commitment and advocacy for KM (Davenport & Prusak, 1998).

Rarely did the CKO come from an information systems or human resource organization. In fact, CKO backgrounds were quite varied, though most had substantial experience with their firm and knowledge of the firm's industry. Whatever their background, CKOs were supposed to straddle business and information technology (IT) with a mandate to convince workers that it is good to share information and to work with IT to build applications to support such sharing (Earl & Scott, 1999).

In 2001, 25% of Fortune 500 companies had a CKO and 80% of Fortune 500 companies had a knowledge management staff. Forty-two percent of Fortune 500 companies anticipated appointing a CKO within the next three years (Flash, 2001).

While many organizations were enthusiastic about knowledge management programs, there were also firms that believed that a CKO function was not needed. Sometimes senior management felt that having a CKO was the wrong way to harness corporate know-how. Instead, they preferred a more grassroots approach, in which a team of knowledge management experts worked closely with--or were even as part of--the business units. The underlying rationale for this approach lay in the belief that by putting more control of knowledge management in the hands of end users, knowledge management would be an easier sell because knowledge sharing would be actively inculcated within business units.

Accordingly, these firms believed that centralizing knowledge management under a CKO would send out the wrong message (Cole-Gomolski, 1999).

In firms where CKOs did exist, Pringle (2003) notes that many of these survived by judiciously distancing themselves from the original "craze" while still exploiting knowledge management concepts. This oftentimes meant that CKOs didn't talk about knowledge management per se. Instead, the CKO pursued activities that encouraged employees to talk to one another or that allowed workers to reuse already existing materials or information. Pringle indicates that these CKOs typically imbedded knowledge management activities within performance management systems that gave staff members the incentive to learn and to share their expertise. That is, assessments of employee sharing of information efforts as well as demonstrable learning activities became an integral part of employee annual performance reviews.

CURRENT TRENDS

Quite a number of books and articles about knowledge management and CKOs were published in the late 1990s and the early 2000s. However, in 2007, while knowledge management is a concept still practiced and written about, new articles about the CKO entity are rare. The reason for this may be that either the desire for such a position with this title has diminished or that the knowledge management environment has evolved such that the need for a figurehead or program leader has been reduced.

Boothby (2007) believes that the CKO position itself still exists, but he also believes that the responsibilities of the position have changed. He states, that while the old definition of a CKO's job was to guide knowledge management, the new definition of the CKO's job is to empower knowledge workers. He argues that empowering workers means giving knowledge workers tools that make them more productive, which is operationalized as helping knowledge workers to communicate more effectively.

Boothby asserts that CKOs used to hire people who categorized everything and wrote complex taxonomies to organize knowledge. Moreover, this "traditional" CKO employed large, complex systems to create, capture, store, and distribute knowledge. That is, they looked for a standard approach that would satisfy the needs of their whole company.

The problem for the CKO today, according to Boothby, is that such an approach is not viable anymore. Needing to find one universal solution is a false constraint he asserts. He argues that an open Internet works just fine with multiple blogging systems, wiki systems, and open source programs and operating systems. In the current technology environment, large companies do not need one universal enterprise solution. Instead, Boothby states, large organizations probably need many different tools for different types of users and different types of problems.

In the past, knowledge management technology was oftentimes expensive, centralized, and coordinated. Today, knowledge management technology can be inexpensive, decentralized, and perfuse. Boothby notes that knowledge management technology can cost less than a tenth of the price of old systems. Moreover, with many systems today, users can generate their own software content (e.g., via Linux, blogs, wikis, etc). Boothby concludes that CKOs should stop focusing on what is ideal and allow any system, so long as it complies with some basic open Internet standards.

Boothby's arguments do assume that CKOs only seek technology solutions to knowledge management efforts. This is only partially true. In many organizations, CKOs are responsible for the sharing of both explicit and tacit knowledge and technology typically only addresses the former well.

However, Boothby's assertion that knowledge management technology is evolving appears affirmed by an Executive Report of the 2006 CKO Summit held at the Bath Priory in the United Kingdom (TFPL, 2007). Here, social computing, identified as blogs and wikis, was seen as the backbone of current knowledge sharing efforts. These technologies, combined with the use of search engines and document management systems, were seen by Summit participants as facilitating and diffusing knowledge transfer capabilities and better enabling knowledge harvesting. Moreover, social computing technologies were viewed as providing common and standardized information architectures for knowledge management programs, resulting in more active knowledge sharing activity.

The 2006 CKO Summit report also suggests that previously prescribed knowledge management leadership responsibilities have remained somewhat constant over time. The report indicates that the current issue for managers of knowledge management programs is to articulate the common framework for knowledge and information management for their organization. Articulated components of this framework include:

- Mission, vision, and objectives for shared services
- Governance (an agreed strategy for inter-organizational KM)
- KM vision and mission
- Operating model
- Information architecture
- Metrics/performance measures
- Delivery and benefits

What the Summit's report additionally makes apparent is the changing nature of knowledge sharing itself. In the earlier days of knowledge management, emphasis was placed on the need to manage "pull" technology. That is, organization's

had to promote sharing of information on existing platforms by encouraging employees to pull down information from repositories of data and information. Now, emphasis is being place on "push" technologies that allow employees and partners the opportunity to easily and readily publish information to platforms that are comparable to those used in the public domain. Hence, since sharing of explicit information is easy to do, management must now shift to helping to ensure that content generated is both valid and reliable.

Tacit knowledge, on the other hand, still appears to remain somewhat elusive in knowledge management circles. Current thinking argues that knowledge management programs should employ narratives and story telling to elicit this form of intellectual capital (e.g., Brown, Denning, Groh, & Prusak, 2005).

Remarkably, of the 28 participants at the 2006 CKO Summit (TFPL, 2007), not one held the title of CKO. In fact, only nine of the participants even had the words "knowledge management" in their job titles.

However, CKO positions do still exist. In England, for example, the CKO of the National Health Service is seen as a role and not a job, a role that has to make sure that the knowledge flows easily between all parts of the organization, thus helping it achieve it objectives more productively. Specifically, the responsibilities of the NHS CKO are:

- To coordinate the outputs of all those national bodies charged with the production of knowledge for patients and professionals
- To ensure that the knowledge derived from research is integrated with knowledge derived from the analysis of data and the knowledge derived from experience
- To ensure that all the Directorates of the Department of Health have their work supported by a National Knowledge Service
- To ensure that there is a national system for knowledge management in the mainstream of the NHS (National Knowledge Service, 2007).

Of note here is that the CKO's responsibilities make no reference to technology specifics. Instead it emphasizes knowledge coordination, sharing and integration.

Six Sigma recently hired a new CKO and their announcement also made no reference to technology issues. The responsibility of their CKO is to accelerate ongoing efforts to develop new, more efficient ways of delivering client value by pushing the envelope of business performance (Six Sigma, 2006).

FUTURE TRENDS

Is the CKO title diminishing in popularity? I suspect so. For example, at one Web site, the title of "CKO" is not even listed under knowledge management careers. However, this is not a sign that knowledge management efforts and programs are in any way declining. It is more likely that the concepts enabled by new technologies and encouraged by the more pervasive understanding and appreciation of what intellectual capital is, are now more widely understood and practiced throughout organizations. In fact, while the need for a specific recognizable symbol called the "CKO" probably has diminished, general emphasis on the importance of knowledge management tenets appears to have increased.

One indicator of this is that the number of academic programs in knowledge management is increasing. For example:

- Hong Kong Polytechnic University now offers a Master of Science and Postgraduate Diploma in Knowledge Management.
- Nanyang Technological University's School of Communication and Information in Singapore offers students a Master of Science in Knowledge Management degree.
- Kent State University in the United States promotes their certificate program in knowledge management and a Master of Science degree in Information Architecture and Knowledge Management.
- Saint Joseph's University in Philadelphia has developed three business intelligence programs, a field that is a subset of knowledge management (Herschel & Jones, 2005). These programs include a Masters in Decision & Systems Sciences, a Business Intelligence Certificate, and a Business Intelligence Minor.
- George Mason University's School of Public Policy lists a Master of Science in New Professional Studies in Knowledge Management.
- Walden University offers online Masters and Ph.D. programs that concentrate in knowledge management.

And organizations are also sponsoring in-house workshops to enhance employee understanding of knowledge principles so as to enhance organizational decision-making (e.g., Bank of England, 2006).

While none of the current educational activities emphasize or even mention the role of chief knowledge officers per se, their emergence indicates an increased public awareness of and sensitivity to the need to become more educated in knowledge management concepts, skills, and technologies.

Finally, there has been one recent study reaffirming the potential importance of CKO leadership. Chua and Lam (2005) conducted research designed to determine the effectiveness of a having a CKO. The findings confirmed that use of a CKO was a viable and effective instructional tool for imparting knowledge to study participants. Chua's and Lam's results indicate that having a CKO has a moderating

effect on study participants' attitude towards the experiment's subject matter. However, it can also be argued that it is not the existence of a CKO per se that is important, but rather having someone acting in the capacity of knowledge facilitator is key.

CONCLUSION

Today, the popularization and ease of use of e-mail, cell phones, wikis, and blogs have served to make the sharing of information a globalized phenomenon that is commonplace. And it is not just with text and voice-based systems that have become pervasive communication commodities. The creation and sharing of videos on a global platform are also becoming routine. The popularity of internet-based video platforms such as those provided at YouTube, AOL, and Yahoo have the potential to revolutionize the volume of tacit knowledge that is captured and distributed, especially since these technologies can be readily adapted to internal organizational applications. Of all the technologies used in knowledge management, video holds the most promise for enabling the efficient transformation of tacit knowledge to explicit knowledge via externalization (Herschel, Nemati, & Steiger, 2001, 2003).

In one of the first studies conducted on the CKO function, Earl et al. (1999) found that having a CKO was unlikely to be absolutely necessary for organizations to realize an effective knowledge management program: nor was it likely to be universally necessary. They conceded that some organizations would invest in aspects of knowledge management without appointing a CKO. They believed that knowledge management, like total quality management, would become embedded in organizations and that knowledge would become an obvious imperative source of value creation and competitiveness. In this scenario, they predicted that all members of the organization would own and drive knowledge management and, hence, the importance of and need for a CKO would decline. It seems that this prediction may be coming true.

However, while knowledge management technology, education, and concept awareness have generally increased, the need for organizational leadership remains important and constant. Appointing a CKO may no longer be seen as a prerequisite for galvanizing, directing, and coordinating knowledge management programs, but the need for knowledge management coordination probably remains viable and even essential. Intellectual capital, like any other form of capital, should be effectively managed.

KEY TERMS

Business Intelligence (BI): A business management term, which refers to applications and technologies which are used to gather, provide access to, and analyze data and information about their company operations.

Chief Knowledge Officer (CKO): A senior level executive responsible for managing a firm's knowledge management initiative.

Explicit Knowledge: Knowledge that can be expressed formally using a system of symbols, and can therefore be easily communicated or diffused. It is either object based or rule based.

Intellectual Capital: Can be divided into three categories:

- **Human Capital:** That in the minds of individuals: knowledge, competences, experience, know-how etc.
- **Structural Capital:** "That which is left after employees go home for the night": processes, information systems, databases etc.
- **Customer Capital:** Customer relationships, brands, trademarks, etc.

Knowledge Management: A program for managing a firm's intellectual capital by systematically capturing, storing, sharing, and disseminating the firm's explicit and tacit knowledge.

Knowledge Management Architecture: The technology and procedural platforms employed by a firm to enable knowledge capture, sharing, retention, and distribution.

Tacit Knowledge: Knowledge that is uncodified and difficult to diffuse. It is hard to verbalize because it is expressed through action-based skills and cannot be reduced to rules and recipes. Tacit knowledge is the same as implicit knowledge.

INTRODUCTION

After this article introduction, we review the prevailing theory of organizations, and what it means to organizational science and the new discipline of Quantum Interaction to have an uncertainty principle (ir.dcs.gla.ac.uk/qi2008; the corresponding author is one of the organizers). Further into the background, we review control theory for organizations and its importance to machine and human agents; we review the hypothesis for the uncertainty principle; and we review the status of the field and laboratory evidence so far collected to establish the uncertainty principle for organizations. Then we review future trends and provide the conclusion.

BACKGROUND

At the first Quantum Interaction conference, held at Stanford University in the spring of 2007, a panel addressed whether QI was relegated to being a metaphor or whether it could function as a working model that could be applied in an agent-based model to solve social problems like organizational decision making. Of the 24 papers presented at this inaugural conference, few put forth a working model with sufficient details to be falsified. We accept the challenge by proposing in this review a path forward to a working model.

Rieffel (2007) suggested that few advantages accrue from claiming that the quantum model is applicable to the social interaction when it is not, and few disadvantages from applying an uncertainty principle to demonstrate classical tradeoffs, as in the case of signal detection theory, or to demonstrate nonseparability when the tensor calculus fails to hold. In response, the model should lay the groundwork to demonstrate classical effects of the uncertainty principle for organizations.

As an example from common experience, movie entrepreneurs manipulate individuals en masse with entertainment exchanged for payment, as in the joint viewing of a Clint Eastwood movie where individual brains have been found to "tick collectively" (Hasson, Nir, Levy, Fuhrmann, & Malach, 2004). For organizational tradeoffs, the uncertainty principle means that under interdependence, the probability of applying sufficient attention to a plan or to execute it shifts uncertainty in an opposing direction, and vice versa, *iff* the state of interdependence continues (Note: the symbol *iff* means "if and only if").

The interdependent tradeoffs to control a system requires channels that enhance the ability of management to diminish the destructive interference from inside or outside of an organization. It means that tradeoffs form cross-sections that reflect defensive and offensive maneuvers to expand or limit the size of an organization. Tradeoffs mean that as perspectives shift, what is observed to change in an organization also shifts (Weick & Quinn, 1999); that illusions are fundamental to organizational hierarchies (Pfeffer & Fong, 2005) by driving or dampening feedback oscillations (Lawless, Whitton, & Poppeliers, 2008); and that tradeoffs explain why criteria for organizational performance has been intractable (Kohli & Hoadley, 2006).

We define illusions not as false realities, but as bistable interpretations of the same reality that can only be held simultaneously by neutrals while "true believers" drive neutrals to weigh one and then its opposing reality, for example, an ideology of nuclear waste cleanup or the concrete steps needed for cleanup. Single ideological views are usually

driven by strong-minded agents who we represent as forcing functions, *f(t)*, where the valence of each marginal element of fact they present to neutrals is represented by one bit of additional information. Illusions entangle only neutral agents not wedded to either competing view, where the valence of both views is represented by two bits of entangled information. Courting neutrals to decide outcomes moderates the heated debates between opposing drivers; when neutrals abandon the decision process, it becomes volatile and unstable (Kirk, 2003). Tradeoffs can reduce the effect of illusions by decreasing the volatility in organizational performance that produces "gridlock" (Lawless et al., 2008).

We define social influence as a form of social entanglement, which means that entangled elements can be manipulated together (von Bayer, 2004). Per Rieffel, a state $|\psi>$ is entangled when it cannot be written as the tensor product of single qubit states (p. 139). Here, we define interdependence from social influence as operating across neutral individuals as a superposition of waveforms composed of two or more simultaneous values that linearly combine under constructive interference such as rationalizing similar views into a single world view, or under destructive interference to disambiguate dissimilar views into the best concrete plan. Both interdependence and entanglement are fragile, do not always produce uniform effects, and experience rapid decay; the greater the clarity of an interdependent social situation (observation), the greater the uncertainty in the effect of social influence (action).

Establishing the uncertainty principle for organizational tradeoffs is not only important to move beyond the "quantum" as metaphor, but also because organizational theory has not progressed much beyond Lewin. Lewin himself has been blamed for putting too much attention on individual differences rather than an understanding of groups (Moreland, 2006), which remains elusive (Levine & Moreland, 1998). Instead of blaming Lewin, we attribute the problem to the recondite nature of tradeoffs; the greater the clarity of an interdependent social situation (observation), the greater the uncertainty in the effects from social influence (action).

MAIN FOCUS OF THE CHAPTER

Tradeoffs are inherent in the interdependence that exists in knowledge *iff* interdependence is nonseparable either at the level of information sources (e.g., the interdependence between static and dynamic visual perception; in Gibson, 1986), interdependent uncertainties, or interdependent contexts for decision-making (e.g., hierarchical framing effects). Organizations exist in states of interdependence (Romanelli & Tushman, 1994), characterized as a whole being different from the sum of its parts (Lewin, 1951).

Two of the goals for organizational science are to increase knowledge and to reflect associated uncertainties. A current goal of social science is to simulate human cognition. A unique contribution to these goals is to extend human cognitive simulation with a mathematical model of an organization(s) set within a system operating on knowledge interdependent with uncertainty. The ultimate goal is to design the control of a system of future human and artificial agents (in the military, warfighters and mobile machines advanced beyond present sensors, platforms like Predator-Global Hawk, and robots), or mixtures of both, but *iff* they are interdependent deciders operating under uncertainty. The system model can be used to study human organizations making decisions in marginal situations like mergers to address complex tasks under uncertainty. The primary characteristic of this interdependence is reflected in tradeoffs between coordinating social objects communicating to solve problems in states of uncertainty (Lawless & Grayson, 2004).

Mergers seem unlikely as a model because the explanations for mergers are controversial (Andrade & Stafford, 1999). Most researchers believe that mergers are a bad choice for a firm to consider because they often fail (e.g., Daimler merged with Chrysler in 1998 for $36 billion, only to sell it in 2007 for $7 billion). But mergers have been found to increase efficiency and market power in response to unexpected market shocks (Andrade, Mitchell, & Stafford, 2001). To protect against shocks, we have found that successful mergers, like SBC's with AT&T and Bellsouth increase stability (see below).

Mergers exemplify tradeoffs in nonseparable interdependent knowledge. However, mergers form forced cooperative systems that reduce internal and external information, a censorship that stabilizes systems, compared to the disambiguation and volatility under competition so easily observed by outsiders (Lawless & Grayson, 2004).

As an extreme tradeoff, organizations under central, command-driven or authoritarian leadership easily exploit consensus-seeking rules for decision making (Kruglanski, Pierro, Mannetti, & De Grada, 2006). Censorship under dictatorships reduces socio-political volatility in exchange for rigid control (May, 1973). Recent examples of censorship are found in news accounts of Myanmar's denials of village purges (Bhattacharjee, 2007); China's imprisonment of journalists; and Russian censorship of TV commentators. Censorship occurs in organizations within democracies, too; but when censored information is released, its volatility often forces attention to address the consequences (e.g., Sen, 2000, concluded that no modern democracy has ever suffered from famine).

Whether cooperation or competition increases social or individual welfare during decision making is the canonical tradeoff. Enforced consensus-seeking actions are predicated on a consensus world view, making knowledge more easily acquired *iff* the courses of action conform to a chosen world view, making them impractical for all actions except simple ones. In contrast, focusing on practical applications

under competition and uncertainty disambiguates complex actions for robots (Bongard, Zykov, & Lipson, 2006) and humans (Lawless et al., 2008); however, because it is driven by a polarization of at least two opposing viewpoints (bi-stable illusion), disambiguation less readily transforms into knowledge. These results have implications for the limits of knowledge.

As examples of *separable*, noninterdependent information, a meta-analysis of 30 years of research on self-esteem and academic or work performance, one of the most studied topics in social psychology, Baumeister, Campbell, Krueger, and Vohs (2005) found only a minimal association. They countered the prevailing belief by concluding that surveys of humans produced surprisingly limited information. Similarly, in a study with multiple regressions of USAF air-combat maneuvering (ACM) attempting to affirm the proposition that ACM educational courses improved air combat outcomes in machine space, we found no association (Lawless, Castelao, & Ballas, 2000). In the ACM study, we concluded that current machine "god's-eye-views" were limited to separable information. A god's-eye-view describes the situation where perfect information exists regarding the interactions occurring in machine space among artificial agents, humans or both (e.g., a computer's perfect access to the information produced by Swarm).

One well-used approach is to use game theory to model interdependence, its strength. But the weakness of game theory, including the quantum version by Eisert, Wilkens, and Lewenstein (1999), is the arbitrary value it assigns to cooperation and competition, exacerbated when the number of players is greater than two in complex and uncertain contexts (social vs. individual welfare). Kelley (1992) spent his career admittedly failing to link the expectations of subjects to the choices they later made while playing Prisoner Dilemma Games, only to conclude that individual subjects rarely acted as he or they expected once in a group. Game theory can be improved upon with an interdependent model of uncertainty determined by outcomes. For example, we have found that competition improves social welfare with practical decisions that feedback readily accelerates (Lawless, Bergman, & Feltovich, 2005). In contrast, we have found that gridlock is more likely under cooperative decision making because it is less able to challenge illusions (Lawless et al., 2008).

In the search for a classical organizational uncertainty principle, we have found in the field and confirmed in the laboratory a planning cognitive-execution tradeoff between consensus-seeking and majority rule decision making as citizen groups made decisions over complex issues like nuclear waste management (Lawless et al., 2005). In the field study, we looked at the decisions of all nine of the Department of Energy's Citizen Advisory Boards as they responded to DOE's formal request to support DOE's plans to speed the shipments of transuranic wastes to its repository in New Mexico (i.e., the WIPP facility; see www.wipp.energy.gov) as part of its mission to accelerate the cleanup of DOE facilities across the U.S. These nine boards were located at the DOE sites where the transuranic wastes were being removed and shipped to WIPP. DOE's plans were entailed in 13 concrete recommendations and explained to the various boards by DOE engineers (e.g., "DOE, in consultation with stakeholders and regulators, reexamine the categorization of TRU [transuranic] waste using a risk-based approach"). Consequently, 4/5 of DOE's majority-rule boards endorsed these recommendations, while ¾ of its consensus-ruled boards rejected them. In addition, the time spent in deciding for majority-ruled boards was about 1/4th the amount of time taken by the consensus-ruled boards. In a follow-on field study of consensus decisions by the Hanford Board and majority rule decisions at the Savannah River Site Board, we also found that consensus rule decisions produced a volatility that resulted in "gridlock" when the single world view of the board conflicted with DOE's vision (Lawless et al., 2008).

The results of these two field studies have many implications for advanced human-robot systems. Tradeoffs occur between cooperative and competitive approaches to decision making, suggesting an organizational uncertainty principle. Consensus-seeking is more likely to build on prior world views (e.g., situational awareness) at the expense of action; majority rule is more likely to produce practical decisions that will be enacted but under conflict, meaning that a shared world view is less likely to be retrieved. And consensus-seeking is more rational, but ill-suited to govern illusions, the very rule used by the DOE Boards to seek consensus precluded the rejection of any view no matter how bizarre (Bradbury, Branch, & Malone, 2003); majority-rule disambiguates illusions well, but is less suited to produce or unify rational perspectives (Lawless et al., 2008). But, and unexpectedly, cooperative decisions produced more anger between the DOE sponsor and DOE's Hanford Board. The probable cause was a conflict in the world views of these two organizations, with few neutrals available to resolve the conflict.

It may be that the cooperation under consensus-seeking is more volatile over the long run than the conflict generated in the short run from truth-seeking under majority rule. Stability arises from majority rule as decision drivers attempt to "entangle" neutrals into their view of reality by courting them on the rightness of their view, a confrontational approach between two drivers that dampens conflict by harnessing it to entangle neutrals into solving complex problems. The result is a tradeoff between decision processes that partly demonstrates the classical uncertainty principle for organizations.

To test whether this approach is on the right track, using multiple regressions, we have found tradeoffs among stock market sectors. In the tradeoffs among stock market sectors,

Table 1. Volatility and market leadership. In addition to the data shown, two columns representing two factors not shown but tested in the multiple regressions were "market value/revenue" and "market value/EBITDA."

	Beta	gross profit	EBITDA	ROE	mktcap/indcap

multiple regressions were computed for a broad cross-section of stock market firms. Selecting data about the leader and laggard in a market where data were available (see Table 1 below), the results were significant only for volatility (Beta) and market capitalization/industry capitalization (i.e., Beta = -4.34 * mktcap/indcap + 2.88, $p < .05$). We interpret this result to have two meanings: First, it indicated that one of the reasons organizations attempt to grow, organically or via mergers and acquisitions, is that it increases organizational stability, a finding that offers a novel explanation for mergers. Second, it supported the notion that the organizational uncertainty principle exists as a tradeoff between firm size and volatility (Frieden, 2004).

FUTURE TRENDS

In the future, we expect that the study of Fourier transform pairs and measures market power should continue to advance. We also believe that Monte Carlo simulations of the cognitive tradeoffs made by managers and their control of large, complex organizations will become increasingly important. If the Monte Carlo simulations with Gaussian-Fourier pairs prove to be as successful as we believe they will become, models can be constructed by using machine language (e.g., genetic algorithms) and Agent-based Models (e.g., with agents running in NetLogo or Repast).

CONCLUSION

The result of the multiple regressions is presented as the first evidence of the possible existence of an uncertainty principle for organizations. We laid the groundwork for this principle by reviewing the importance of moving beyond metaphor in applying the quantum model to the social interaction, especially to interdependence in the organization. In the future, we plan to explore the ramifications of this principle.

KEY TERMS

Entanglement (quantum): Occurs when one quantum object enters into a (quantum) superposition with another, characterized by having a mutual influence on each other that requires a description of both with reference to the other whether or not spatially separated.

Fourier Pairs: The Fourier transform and its inverse form Fourier pairs; e.g., $f(t) \Leftrightarrow F(\omega)$.

Fourier Transforms: A representation of a signal received over time can be transformed into harmonic frequencies in the frequency domain. A uniform sine wave is transformed into a single frequency. The Fourier transform and its inverse are also known as harmonic analysis.

Interdependence: Occurs when two or more objects influence each other. Also, mutual sensitivity, mutual connectedness, or where an action on one object affects the other(s).

Social Influence: Occurs when an action on one or more individual(s) affects the other individuals in a group of two or more agents.

Tradeoffs: Occurs when one aspect of a phenomenon, such as its resolution, is improved while another aspect is lost or degraded.

Uncertainty Principle: Applies when a system with a pair of observables, such as the factors of action and observation, that are not independent, but rather interdependent, precluding a precise knowledge of both observables simultaneously.

A Classification of Approaches to Web-Enhanced Learning

University of Western Australia, Australia

INTRODUCTION

The World Wide Web has become a mature platform for the support of learning at universities. Several patterns have emerged, both in the nature of use, and in understanding the conditions associated with successful adoption and application of web-enhanced learning (WEL). This article summarizes, in the form of nine scenarios, the ways in which the Internet is being used to enhance learning in traditional universities. It also discusses the changes needed if universities are to benefit more widely from WEL.

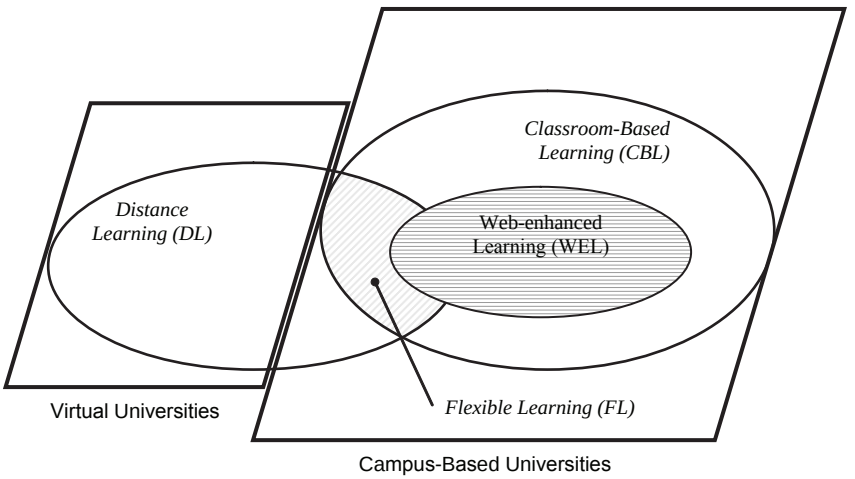
BACKGROUND

The Web is used by universities to make courses available to students who are distant from campus (*distance learning*, DL) and to enhance learning by students who attend courses on-campus (*web-enhanced learning*, WEL). Universities may be classified on the basis of the modes of learning that they offer. *Virtual universities* offer access to courses by DL only. Traditional, or *campus-based universities*, offer courses that are based on formal lessons held in classrooms or laboratories (*classroom-based learning*, CBL), but may also offer courses by DL, or *flexible learning* (FL), a combination of DL and CBL.

WEL is the use of the Web to enhance CBL in traditional universities. WEL provides students studying in the classroom with access to electronic resources and learning activities that would not be available to them in traditional classroom-based study. The simplest forms of WEL provide access to the Web from within the classroom, using the Web as a platform for real-time demonstration or as a digital library. More sophisticated forms of WEL blend activities in the classroom with Web-enabled learning activities that promote collaborative learning among students, even when they are distant from the classroom.

Figure 1 illustrates the relationship between the modes of learning offered by universities. WEL is represented as that portion of CBL that uses the Web to enhance learning.

Figure 1. The relationship between Web-enhanced learning (WEL) and other modes



When it is used to blend in-classroom and out-of-classroom activities, WEL shares the characteristics of DL and FL.

WEL differs from flexible learning in that the focus of the lesson remains the traditional classroom. With FL, classroom-based learning is mixed with learning at a distance. In the most common form of FL, *distributed learning* (also known as *blended learning* or *mixed mode learning*), students participate in formal lessons both in the classroom and at a distance, according to a schedule prepared by the instructor. Some flexible learning may be enhanced by use of the Web, for example, to provide discussion forums in which students studying at a distance and in the classroom may participate together, but use of the Web is not necessary for flexible learning.

This article is concerned with integration of online learning and classroom-based learning to achieve effective and manageable WEL for campus-based students. The focus is on change across a university system rather than in an individual classroom. We argue that WEL adds the most value when it is used to enable new forms of learning, and in particular, online collaborative learning by students working at a distance from the classroom as well as within it (Rudestam & Schoenholtz-Read, 2002). This value can only be obtained through attention at the institutional level to the organizational transformation required to implement, support, and sustain WEL (Bates, 2000).

WEL SCENARIOS

Nine distinct scenarios for use of WEL can be identified (Table 1, based on Klobas & Renzi, 2003). They can be divided into four groups: *information provision* scenarios, in which the Web is used to provide information to students and others outside the classroom; *classroom resource* scenarios, in which the Web is used to extend the classroom, either by providing access to resources in the classroom or by enabling lessons to be broadcast outside the classroom; *interactive learning* scenarios, which range from interactive virtual classrooms to the use of the Web to support collaborative learning among students working at a distance; and an *experimental* scenario, in which the Web is used to experiment with technology and pedagogy in ways not envisaged by the preceding scenarios. Any or all of the scenarios may be used alone or in combination, in a single course or by a single university.

Table 1. A hierarchy of WEL use scenarios

Scenario	Label	Use
INFORMATION PROVISION SCENARIOS		
1	Catalog	Provision of static, and primarily logistic, information about the course
2	Notice Board	Distribution of course materials in electronic form
3	Class Resource	Provision of additional materials and references in response to student and teacher experience in the course as it progresses
CLASSROOM RESOURCE SCENARIOS		
4	Classroom Resource	Use of the Web for demonstration or as a digital library during classroom sessions
5	Streaming Video	Broadcast of classroom sessions
INTERACTIVE LEARNING SCENARIOS		
6	Virtual Classroom	Synchronous interactive classroom sessions that include video and voice communication among instructors and students
7	Interactive Web	An interactive environment outside the classroom
8	CSCL	Computer Supported Collaborative Learning
EXPERIMENTAL SCENARIO		
9	Experimental	An experimental environment for innovative use of the Web

Information Provision

The first group of scenarios (1 to 3) represent incremental changes to traditional classroom-based learning: In these scenarios, the Web is used as an information delivery mechanism that provides students with some flexibility in the time and place with which they access some of the information required for the course. The scenarios range from simple publication of course catalog information to use of streaming video to permit students to 'attend' classes outside the classroom. The information and communications technology (ICT) infrastructure, training, and skills required for successful use of each scenario ranges from simple in the case of the *catalog* scenario to more complex in the case of the *streaming video* scenario.

The simplest, and most common, of WEL scenarios consists of provision of basic *catalog* information about a course: course description, list of textbooks, name of teacher(s), class schedule, allocated classroom(s), and examination procedures. Most university Web sites contain at least a subset of this information. This is a simple scenario to manage. The university needs a web server and the staff to maintain it. The information posted in such catalogs is often pooled or available from a single source. Because it is static, and seldom needs to be updated more than once a semester, the effort involved in maintaining currency is quite low.

In Scenario 2, *notice board*, teachers use the Web to distribute course materials in electronic form. Such material might include: educational material used by teachers in the classroom (slides, case studies, newspaper articles, site URLs related to the course content), past exam scripts and solutions, and official University communication. The content may be made available all at once before the course begins in the online equivalent of a coursebook, or from time to time during the life of the course (for example, lesson slides may be put online after each lesson).

Use of the Web in Scenario 3, *class resource*, is more dynamic than in Scenario 2. The teacher selects new material to add to the course Web site during the course, in response to questions asked, interest expressed, and other experiences of how the students are responding to the course as it is delivered. In courses with multiple classes (sections), each class may share the material available on the common course notice board, but may have quite different additional resources.

Effective adoption of Scenario 2 and Scenario 3 requires more extensive ICT infrastructure than Scenario 1 to permit students to access the course web sites on a regular basis. At Scenario 2, some universities make staff available to load materials to the site on behalf of the teacher, but at Scenario 3, the teachers need the IT and the training to be able to load their own materials. This level therefore marks a significant shift in the resources required to support WEL. At the same time, it marks a significant shift in the value added by WEL; at this level, WEL provides the opportunity to quickly and easily provide students with access to current material of direct relevance to their learning and experience in the course as it unfolds.

The Web as a Classroom Resource

In Scenario 4, *classroom resource*, the teacher may use the Web to access reference materials, presentations and demonstrations from sources outside the classroom. In this scenario, the Web provides convenient access to resources that might previously have been drawn from other sources or accessed in other ways by the teacher. While relatively simple for the teacher, this scenario requires provision of secure access to appropriate IT and Internet infrastructure from within the classroom.

Scenario 5, *streaming video*, requires more substantial investment in technology, including quality recording equipment in classrooms and the staff to operate and maintain it, high end servers, and high speed networks to all locations where the video may be watched. There are many systems available on the market. The University of Toronto has developed a system called ePresence which allows students to navigate inside the lesson and assists with management of an archive of lessons (Baecker, Moore & Zijdemans, 2003). Lectopia, developed by the University of Western Australia, offers a high level of automation in recording and publishing, making it unintrusive for teaching staff (Fardon, 2003). For effective use, teachers need to learn how to structure and present visual aids that will be suitable both in the classroom and for presentation by video. The primary uses of streaming video, to allow students the option of 'attending classes' from outside the classroom and to review the teacher's presentation of different material (Creighton & Buchanan, 2001), represent only an incremental change in the nature of education.

Learning Through Interaction

Use of the Web is more dynamic in the Interactive Learning scenarios, which involve interaction between the teacher and students, and among the students themselves.

In the WEL *virtual classroom* scenario (Scenario 6), the Web is used to transmit complete classroom lessons using synchronous video, voice, whiteboard, and other utilities. Teachers and students from different locations may share lesson components, ask questions, respond and interact with one another in a variety of ways. For campus-based students, a virtual classroom provides the opportunity to share classroom experiences with teachers and students in classrooms located on other campuses (Hiltz & Wellman, 1997). Universities

considering this option for WEL should weigh the considerable costs of investment in ICT infrastructure, training and course redesign against the return to students.

At Scenario 7, *interactive web*, the interactions are somewhat passive, based mainly on the use of course forums, resource contributions, self evaluation tests, delivery of assignments, and secure online exams. This is the most common application of online learning platforms. Teachers require considerable training and support to adopt this scenario effectively. Students also require preparation, both in use of the functions of the technology, and in how to use the provided functions to improve the quality of their course experience and learning.

A more complex interactive scenario is *CSCL* (Computer Supported Collaborative Learning, Scenario 8), an environment where at least the online component of teaching and learning is based primarily on interactions among students working in groups. This scenario includes collaborative group learning activities that go beyond those possible with simple course forums. Such activities may include group projects which involve sharing materials or preparation of joint documents. This scenario offers greater potential for improving the quality of learning at universities than any of the preceding scenarios.

Indeed, the power of WEL to change the quality of education is based on its potential to make collaborative learning possible. WEL makes a difference when it is used to enable students to learn collaboratively (Friedlander, 2002; Klobas & Renzi, 2003; Lammintakanen & Rissanen, 2003; Rudestam & Schoenholtz-Read, 2002). Students, themselves, describe the value of participation in learning communities of peers (Hamilton & Zimmerman, 2002), while educators claim that participation in collaborative learning not only results in better quality learning of course subject matter, but also in changes in the world view of the students and their capacity for lifelong learning and contribution to society (Klobas, Renzi, Francescato, & Renzi, 2002; Rudestam & Schoenholtz-Read, 2002). Furthermore, collaborative learning that makes a difference does not need expensive technologies. CSCL does not require the investment in ICT infrastructure of Scenario 6, and can be implemented with simple asynchronous conferencing software (Hazemi & Hailes, 2002; Hiltz & Turoff, 2002).

Experimental Scenario

The final scenario, *experimental* (Scenario 9), provides an environment for teachers to experiment with new applications of the Web in the classroom, new Web-based technologies, new educational strategies, and the interaction between these innovations. While current thinking focuses on CSCL as the most advanced form of WEL, the existence of an experimental scenario reminds us to be open to further changes in learning theory and technology. For example, the debate about how to assess both social interaction and learning in CSCL is still open and practical examples of assessment (Chan & van Aalst, 2004; Roberts, 2006) can still be considered as experimental. It also reminds us of the need to evaluate new approaches to learning associated with WEL.

FUTURE TRENDS

Universities across the globe, in developed and developing countries, have been quick to adopt technologies to support WEL, including the infrastructure to support widespread use of the Web as an information resource, and university-wide platforms to support online learning. But this rapid adoption of technology has had relatively little impact on the education of campus-based students (Middlehurst, 2003, as cited in Collis & Van der Wende, 2002; Observatory of Borderless Education, 2002). Those changes that have occurred have been incremental rather than transformational. The Web is most frequently used in a "distributive" mode to provide access to resources—as a substitute for, or complement to, notice boards, distribution of handouts, and use of the library—rather than to provide access to new forms of learning. Thus, the Web is being used to automate rather than to transform university education. Few attempts to go beyond this simple automation have been successful (Pollock & Cornford, 2000). Those universities that are making greater use of the Web are not distinguished from the others by virtue of their information technology infrastructure, but in terms of their focus on students, markets, and policy. Those looking to 'stretch the mould' of the future university emphasize flexibility in the location of learning, and have policies in place for quality, future markets, and costs and efficiency (Collis & Van der Wende, 2002) along with systems for training and supporting teachers (Trentin, 2006).

Radical changes in our approach to university education are therefore needed if universities are to benefit from WEL. Bates (2000) claims that "If universities and colleges are successfully to adopt the use of technologies for teaching and learning, much more than minor adjustments in current practice will be required. Indeed, the effective use of technology requires a revolution in thinking about teaching and learning." (p. v). That revolution, according to Rudestam & Schoenholtz-Read (2002), "demands a reexamination of our core beliefs about pedagogy and how students learn" (p. 4) based on theories of constructivism and collaborative learning (Leidner & Jarvenpaa, 1995). Change on this scale requires vision and leadership, as well as appropriate resources.

While much of the literature points to CSCL as a necessary part of the radical change, issues associated with implementing CSCL illustrate how difficult such a change might be. There is, for example, still no agreement on how CSCL can

be assessed in a way that is feasible for the teacher and the university. There continue to be calls for assessment practices to support the shift toward social constructivist educational theories (Chan & van Aalst, 2004).

Bates (2000) calls for "fundamental change in the way our higher education institutions are organized and managed" (p. 5) because "history dictates that the introduction of new technology is usually accompanied by major changes in the organization of work" (p. 1). This requires leadership, vision, policies, planning and evaluation that emphasize the educational goals of WEL rather than just its technological characteristics (Bates, 2000; Collis and Van der Wende, 2002; Friedlander, 2002; Klobas & Renzi, 2003; Pollock & Cornford, 2000; Surry, 2002). To this end, a group of Australian and British universities have developed a model for benchmarking the use of ICT in teaching and learning (Ellis & Moore, 2006).

While they have put the necessary ICT infrastructure in place, universities have paid relatively little attention to development of the human resources needed for successful adoption of WEL (Collis & Van der Wende, 2002). Financial investment in training and skill development for teachers, students, and technical staff is required. It is not surprising, given arguments for attention to pedagogy rather than technology, that successful adoption of WEL is associated with training to develop teachers' ability to design courses that use WEL to improve pedagogy rather than training that emphasizes the features of specific software (Klobas & Renzi, 2003).

Human resource issues associated with optimization and management of the ICT infrastructure also need to be addressed. This requires attention to engagement with the university's partners in the supply and maintenance of the ICT infrastructure for WEL (Pollock & Cornford, 2000). The ICT infrastructure for WEL involves several layers of technology (internal and external networks, servers, and applications), and successful WEL requires skillful coordination of suppliers (Klobas & Renzi, 2003).

Changes in the reward systems for university staff are necessary to support the changes in work demanded by WEL (Bates, 2000; Collis & Van der Wende, 2002; Klobas & Renzi, 2000, 2003; Surry, 2002). Such changes in reward systems require short term financial investment, but in the longer term are associated with changes in the nature and structure of work in the university.

CONCLUSION

WEL provides traditional universities with opportunities to enhance the quality of the education they provide to students on campus. While most current approaches to WEL involve incremental changes to classroom teaching, greater value is obtained through application of WEL to improve opportunities for collaborative learning among students. Success therefore requires attention–at the most senior levels–to educational values, financial and human resources, and transformation of educational processes and organizational structure, as well as to technology. WEL will become a natural part of the educational model of those universities with the management commitment and skill to implement and sustain the transformation required, while other universities may find it difficult to survive.

KEY TERMS

Blended Learning: *See mixed mode learning.*

Collaborative Learning: Learning that occurs through the exchange of knowledge among learners. Collaborative learning is a form of social learning.

Computer-Supported Collaborative Learning (CSCL): Collaborative learning that occurs via the medium of computer-based communication networks such as the Internet.

CSCL: *See computer-supported collaborative learning.*

Distributed Learning: *See mixed mode learning.*

Flexible Learning: Systems in which students may choose to complete some of their learning on-campus and some of their learning off-campus.

Mixed Mode Learning: Study that combines traditional face-to-face learning with learning at a distance in a structured program. The Web may be used to enhance learning during study by one or both of these modes. Mixed Mode is also known as Blended Learning and Distributed Learning.

Online learning Activities: Learning activities in which students interact with resources, or other students, or both, using the capabilities of the Internet or other computer-based communication networks.

Social Learning: Learning through social interaction with other people.

Web-Enhanced Learning (WEL): Use of the World Wide Web (Web) to provide students studying in the classroom with access to electronic resources and learning activities that would not be available to them in traditional classroom-based study. The simplest forms of WEL provide information about a course on the Web and access to the Web from within the classroom. More sophisticated forms of WEL blend activities in the classroom with Web-enabled online learning activities which promote collaborative learning among students even when they are distant from the classroom.

Classification of Semantic Web Technologies

Rui G. Pereira
University of Beira Interior, Portugal

Mário M. Freire
University of Beira Interior, Portugal

INTRODUCTION

Semantic Web is the name of the next generation World Wide Web, that has been recently proposed by Tim Berners-Lee and the World Wide Web Consortium (W3C)[1]. In this new Web architecture, information and Web services will be easily understandable and usable by both humans and computers. The objective is not to make computers understand the human language, but to define a universal model for the expression of the information and a set of inference rules that machines can easily use in order to process and relate the information as if they really understood it (Berners-Lee, 1998). Though, as the current Web provided sharing of documents among previously incompatible computers, the Semantic Web intends to go beyond, allowing stovepipe systems, hardwired computers, and other devices to share contents embedded in different documents. The most known architecture for Semantic Web is based on a stack of related technologies, each one being a whole research area by itself (Berners-Lee, Hendler, & Lassila. 2001; Pereira & Freire, 2005).

Accomplishment of the Semantic Web is considered a great challenge, not only due to the complexity of implementation but also because of the vast applicability in several areas. In spite of this, Semantic Web is still one of the most promising research areas among those which aim to define a new architecture for the Web.

Semantic Web goes far beyond previous information retrieval and knowledge representation projects, presenting a non-centralized way to represent and contextualize real-world concepts, unambiguously, for several areas of knowledge. Semantic Web-enabled machines will handle information at our communication level. It is clear that the ability to interpret reality is still very primitive, however, Semantic Web points a way towards machine interaction and learning (Pereira et al., 2005). Semantic Web will integrate, interact with, and bring benefits to most human activities. Its full potential will go beyond the Web to real-world machines, providing increased interaction between machines and with humans—smarter phones, radios, and other electronic devices. Semantic Web will bring a different kind of approach in the understanding of reality by the machines and will constitute a mark in the evolution of human knowledge (Pereira et al., 2005).

BACKGROUND

The arrival of many new Semantic Web technologies over the last few years reveals the acceptance and credibility of the Semantic Web architecture. Nevertheless, the fast appearance of these new technologies and the wide diversity of areas and forms where they can apply demand a high effort of knowledge updating about actual features used in Semantic Web technologies to all future developers. Due to the urgent need of eliminating a huge lack of information about recent Semantic Web technologies, we provide a classification in categories for 80 of more than 100 recent Semantic Web technologies that are accessible from the Web. Their main features are also presented.

This work is mainly based on information presented in Bizer (2005) and SemWebCentral (2005). We have classified the 80 Semantic Web technologies in 11 categories: Visualization, validation, conversion, annotation, brower, query, editor, integration, repository, API (Application Programming Interface), and reasoner. Next section provides a detailed description by category of the main existing Semantic Web technologies.

SEMANTIC WEB TECHNOLOGIES BY CATEGORY

In this section we present eleven tables with technologies grouped by each category and up to ten of their main characteristics:

- **Developer:** Developer name;
- **Release:** Latest release number and publication date;
- **License:** License under which the technology is distributed;
- **Language:** Language development used to develop the technology;
- **API-Paradigm:** API-Paradigm for the manipulation of RDF data;
- **Query-Languages:** Query-Languages used by technology;

Table 1. Main features of annotation technologies

	Developer	Release	License	Language	Input	Output	O.S.
AeroSWARM[2]	UBOT Team	-	-	-	HTML	OWL	Independent
OntoMat--Annotizer[3]	Handschuh, S., Braunv, M., Buerkle, C., Kühn, K., Meyer, L. and Krekeler, T.	0.8.2 Feb-05	LGPL	Java	N3 OWL RDF	N3 OWL RDF	Independent
PhotoStuff[4]	Mindswap	2.11 Mar-05	Mozilla	-	-	-	Independent
RIC[5]	Michael Grove (Mindswap)	3.0 Alpha	(Grove, 2002)	Java	-	-	Independent
SemanticWord[6]	Teknowledge Corporation	Alfa 1.0 Aug-04	-	Visual Basic	OWL	OWL	Windows NT/2000
Swangler[7]	STET	1.0.1 Apr-05	GPL	Java	OWL RDF	OWL	Independent

Table 2. Main features of API technologies

	Developer	Release	License	Language	API-Paradigm	Storage Model	Input	Output	O.S.
CARA[8]	Stefan Kokkelink	Pre0.001 Mar-01	GPL	Perl	Resource-centric	Memory	RDF/XML N-Triples	RDF/XML N-Triples	-
CODIP[9]	DARPA	0.9.0 Dec-04	BSD	Java	-	-	OWL UML XMI	OWL UML XMI	Independent
HAWK[10]	SWAT Lab, Lehigh University	1.1 Beta Dec-04	GPL	Java PL/SQL	-	-	OWL RDF	OWL RDF	Independent
Kazuki[11]	Self, T., Lerner, J., and Rager D.	1.2 Jun-04	BSD	Java	-	-	OWL	-	Independent
NG4J[12]	Chris Bizer Richard Cyganiak Rowland Watkins	0.4 Fev-05	BSD	Java	Statement-centric	Memory MySQL	RDF/XML N-Triples N3 TriX TriG	RDF/XML N-Triples N3 TriX TriG	Independent
OWL API[13]	Bechhofer, S., Volz, R., Kalyanpur, A., Crowther, P., Horan, B., Turi, D., and Lord, P.	1.4.2 Mar-05	LGPL	Java	-	-	OWL	OWL	Independent
OWL-S API[14]	Paolucci, M., Srinivasan, N. Softagents Group	0.1 beta Dec-04	LGPL	Java	-	-	OWL	OWL	Independent
OWL Semantic Search Services[15]	Bhanu Vasireddy John Li	0.1 beta Dec-04	-	Java Java-Script Prolog	-	-	-	-	Linux
Pyrple[16]	Sean B. Palmer	Jun-04	-	Python	Statement-centric	Memory	RDF/XML N3 N-Triples	RDF/XML N3 N-Triples	-
SOFA[17]	Alishevskikh, A. Mihalik, I. and Ganesh, S.	0.3 Mar-05	LGPL	Java	Resource-centric Ontology-centric	Memory JDBC compliant DB	OWL RDF	OWL RDF	Independent
Sparta[18]	Mark Nottingham	0.6	-	Python	Resource-centric	-	RDF/XML N3 N-Triples	RDF/XML N3 N-Triples	-

- **Model Storage:** Model storage for information;
- **Input:** Input formats that technology can use;
- **Output:** Output formats that technology can export;
- **O.S.:** Operation System that supports the technology.

Technologies had been grouped in accordance with its main characteristics. Despite this, some technologies could have been associated with more than one category.

Annotation Category

Annotation category is defined as the group of Semantic Web technologies that has as goal the manipulation of extra information associated with a particular point in a document. Main features of these technologies can be seen in Table 1.

API Category

API category is defined as the group of Semantic Web technologies that provides a set of commonly-used functions that can be use by others technologies. Main features of these technologies can be seen in Table 2.

Browser Category

Browser category is defined as the group of Semantic Web technologies that enables a user to display and interact with documents hosted by Web servers. Main features of these technologies can be seen in Table 3.

Conversion Category

Conversion category is defined as the group of Semantic Web technologies that has as a goal the changing of an entity of

Table 3. Main features of browser technologies

	Developer	Release	License	Language	Input	Output	O.S.
DumpOnt[19]	Moore, D., Kolas, D. Lerner, J., Dean, M. Blace, R., and Self, T.	1.2 Feb-04	BSD	Java	OWL RDF	HTML	Independent
FlinkCommands[20]	Barreau, G., Rocha, R. Machado, M., Gama, C. Abdalla, D., Gagnon, M. Oliveira, K., Anquetil, N.	-	GPL	Java	OWL	OWL	Linux
HyperDAML[21]	Lerner, J. Dean, M., and Self, T.	Jan-04	BSD	Java	OWL RDF	HTML	Independent
Object Viewer[22]	Jeremy Lerner Troy Self	Jul-04	BSD	Java	OWL RDF	-	Independent
OWL-P[23]	Mallya, A., and Desai, N.	1 Nov-04	-	Java	OWL	OWL	Independent
OWL-S IDE[24]	Naveen Srinivasan Softagents Group	0.1 beta Nov-04	-	Java	OWL XML	OWL	Linux Windows

one datatype into another. Main features of these technologies can be seen in Table 4.

Editor Category

Editor category is defined as the group of Semantic Web technologies that can be used to make changes to documents of a particular type. Main features of these technologies can be seen in Table 5.

Integration Category

Integration category is defined as the group of Semantic Web technologies that has as a goal the combination of several components that are very useful when used together. Main features of these technologies can be seen in Table 6.

Query Category

Query category is defined as the group of Semantic Web technologies that allows interrogating and filtering described information in RDF/XML, N3, and OWL formats. Main features of these technologies can be seen in Table 7.

Reasoner Category

Reasoner category is defined as the group of Semantic Web technologies that has as a goal the manipulation of data in a way that can find new facts from existing data. Main features of these technologies can be seen in Table 8.

Repository Category

Repository category is defined as the group of Semantic Web technologies that has as a goal the storage and retrieval of Semantic Web metadata. Main features of these technologies can be seen in Table 9.

Validation Category

Validation category is defined as the group of Semantic Web technologies that can be used to check the consistency of semantic web documents. Main features of these technologies can be seen in Table 10.

Visualization Category

Visualization category is defined as the group of Semantic Web technologies that can be used to create graphical representations of RDF models and OWL ontologies. Main features of these technologies can be seen in Table 11.

CONCLUSION

This study presented a classification and assessment of the majority of existing Semantic Web technologies. It helps to establish a link between Semantic Web developers/researches and the actual Web users, in order to draw the attention of current Web users to available Semantic Web technologies. This interest is vital to the viability of the Semantic Web

itself because it is known that even a very promising technology will not become a reality without the acceptance of its end-users. Finally, this study calls attention to the fact that the need for information exchange between different kinds of Semantic Web technologies is increasing every day and will prevail in the future. Most of current Semantic Web tools present different user interfaces and need constantly to map information resulting from each one. Therefore, it is crucial to create technologies that can be easily integrated among themselves.

KEY TERMS

Ontology: The word *ontology* comes from the Greek *ontos* (being) and *logia* (written or spoken discourse). It is in use since Empedocles described the four elements – air, earth, fire, and water. In artificial intelligence, *ontology* is defined as a working model of concepts and interactions from a particular domain of knowledge, like medicine, mathematics, automobile repair, and so forth, which is used to easily describe the meaning of different contents that can be exchanged in information systems. Any *ontology* can be easily extended, refined, and reused by other *ontologies*, providing expressive representation for a wide diversity of real-world concepts.

OWL: The concept of Web Ontology Language, the most expressive of ontology languages currently defined for the Semantic Web. It has been developed by the W3C's Web Ontology Working Group and intended to be the successor of the DAML+May 5, 2005 OIL language. It is an extension of RDF Schema and a W3C Recommendation since 2004.

RDF: It is the concept of Resource Description Framework, a W3C Recommendation since 1999. It is a XML-based language that uses a triple-based assertion model and syntax to describe resources. RDF model is called "triple" because it can be described in terms of subject, predicate, and object, like grammatical parts of a sentence.

RDF API-Paradigm: There are four types of API-Paradigm for RDF:

- **Model-centric API:** Only allows loading, saving, and deleting whole RDF models.
- **Statement-Centric API:** RDF data is manipulated as a set of RDF triples each consisting of a subject, predicate, and object.
- **Resource-centric API:** Presents an RDF model as resources having properties.
- **Ontology-Centric API:** Adding direct support for the kinds of objects expected to be in an ontology: classes (in a class hierarchy), properties (in a property hierarchy), and individuals.

RDF Schema: Expresses a hierarchy class data model used for the classification and description of standard RDF resources. The role of RDF Schema is to facilitate the definition of metadata by providing a data model, much like many object-oriented programming languages, to allow the creation of data classes. It is a simple language that enables people to create their own RDF vocabularies in RDF/XML syntax.

Stovepipe Systems: A system where all the components are hardwired to only work with each other.

W3C Recommendation: A Recommendation W3C is interpreted by the industry and by the Web community, as being one synonym of normalization for the Web. Each Recommendation W3C is not more of the one than a steady specification developed by a Work group W3C (W3C Working Group) and reviewed by the members of the W3C. This type of recommendation promotes the interoperability of Web technologies from consensus gotten between the industry and the academy.

XML: The concept of Extensible Markup Language, a small set of rules in human-readable plaintext used to describe and share common structured platform-independent information. Its structure main components are elements and attributes of elements that are nested to create a hierarchical tree that can be easily validated. XML is *extensible* because, unlike HTML, anyone can define new tags and attribute names to parameterize or semantically qualify contents. It is a formal recommendation from W3C since 1998 playing an increasingly important role in the exchange of a wide variety of data on the Web.

Client Expectations in Virtual Construction Concepts

O.K.B Barima
University of Hong Kong, Hong Kong

INTRODUCTION

Meeting the expectations of clients through better service delivery has been a key concern of the construction industry over the years (Hui, 2005; Shen & Liu, 2004). One recommendation often suggested in recent studies to support the delivery of construction works to the construction client is the use of information and communication technology (ICT) (Weippert, Kajewski, & Tilley, 2003). In recent times the virtual construction concept has emerged where construction actors may rely on modern ICT tools to operate irrespective of time and space, to attain common value delivery goals in construction projects. For example, highly skilled construction parties may be in different physical geographic locations in the world, but they may use modern ICT tools to collaborate to achieve common project goals. The virtual construction concept has the potential to provide cost and time savings to the construction client, and it is also likely to play an important role in the delivery of construction works (Barima, 2003). A key party to the construction delivery process is the construction client, and it may be important to know the client's expectations in the use of the virtual construction concept. This knowledge may provide understanding on the potential expectations of construction clients and also assist construction service providers to improve on their value delivery systems to their clients. This chapter explores the potential expectations of construction clients in the virtual construction project environment. First, the background to this study is provided via review of previous literature, then the research methodology and key findings of this exploratory study are presented, before recommendations for future studies and the conclusions are given.

BACKGROUND

In recent years the customer (or client) has received attention in literature in various disciplines (Ellegaard, Johansen, & Drejer, 2003; Huang & Lin, 2002). Most of the studies have argued for paying attention to customers and their requirements, with the aim to either fulfill or exceed them, so as to create customer satisfaction (Huang & Lin, 2002; Winters, 2003). Recent perspectives on the customer appear to differ from traditional management perceptions, where there may be the orientation to focus on the internal transformation processes of the supplier.

In the construction industry the important role or needs of the construction client has also been directly or indirectly studied by scholars over the years (Briscoe, Dainty, Millett, & Neale, 2004; Hui, 2005; Kaya, 2004; Pries, Doree, Van Der Veen, & Vrijhoef, 2004; Shen & Liu, 2004; Winters, 2003). For example, Pries et al. (2004) have argued for client orientation in the construction industry. Briscoe et al. (2004) also suggested that construction clients are the influential drivers for innovation and performance improvement in the industry. According to a study by Pries et al. (2004) in spite of the arguments by scholars for client and market orientation in the construction industry, major industry leaders are still technology or project oriented.

Recent developments in the ICT sector in addition to changing perceptions have led to paradigm changes in the way businesses are executed (Barima, 2003). Varied management concepts have emerged, and one of these is the virtual concept in the construction industry, where actors may rely on modern ICT to operate independent of time and space to support the delivery of common goals (Barima, 2003). This model differs from traditional construction works delivery, which use physical delivery systems like face-to-face interactions, traditional mail delivery, and so forth.

The virtual concept is likely to play an important role in the construction industry in the future. However, research on the virtual concept (with a few exceptions see, e.g., Andresen, Christensen, & Howard, 2003; Rivard et al., 2004) have focused on the evolution of tools, software, pedagogic issues, and so on (Clayton, Warden, & Parker, 2002; Goh, 2005; Tse & Wong, 2004). As a relatively young research area little research has been done to explore the potential value delivery expectations of clients in the use of the virtual concept to support construction works delivery. Such exploration may improve understanding in this young area of research and also assist construction service providers to provide better service to the client. This chapter reports on an exploratory study on the potential client value delivery expectations in virtual construction projects. The next section provides the research methodology and findings of the study.

RESEARCH METHODOLOGY AND FINDINGS

Research Methodology

General

Although this report will emphasize the quantitative aspects of the study, it is worthy to note that a triangulated approach involving both qualitative and quantitative studies was used for this research (see, e.g., Mangan, Lalwani, & Gardner, 2004). This research approach was adopted to answer the research question on: what may construction clients potentially expect from service providers (or agents) in projects supported by the virtual concept. The mixed method approach provides (among others) the advantage of supporting the weaknesses of each of the mainstream research methods with the strengths of the other (Mangan et al., 2004).

After initial literature review, semi-structured in-depth interviews (1-2.5 hours long) were conducted with construction experts (in Hong Kong). The respondents were selected on purpose and deemed to have adequate knowledge on the subject. The interviews provided the opportunity to collate perspectives on what construction clients were likely to expect from their agents in the use of the virtual concept to support construction value delivery. The cross validated results of the qualitative studies were then used as key input for the subsequent exploratory quantitative studies.

The Sample

Stratified random sampling was used in the quantitative studies. The addresses of the potential respondents were obtained from the available professional addresses of the various construction-related associations (contractors; property developers; civil, architectural, mechanical/electrical engineering associations; and quantity surveyors in Hong Kong). The data collection method was via postal mail, and at the end of the data collection period 31 valid responses were received. This represents a response rate of about 8%. The respondents consisted of people deemed to have adequate knowledge of this study's subject, via built-in feedback questions in the scale (on their perceived knowledge of the subject).

The median experience of the respondents was about 16 years in construction. The modal single group (22.6% of the respondents) worked for property development companies. About 45% of the respondents worked for various consultancy companies (engineering, architectural, quantity surveying, facilities management, or multi-disciplinary), while 32.3% of the respondents worked for construction contracting or subcontracting companies.

Scale

The scale applied was a 5-point interval scale with potential scores which ranged from 1 (not important) to 5 (extremely important). Respondents were asked to provide scores on the perceived importance of the set of proposed items. The items were mainly generated from the qualitative studies. The items included in the scale may be broadly classified under: communications delivery and feedback systems; trust; tasks delivery skills and behavior for results delivery; and other management issues. The reliability (Cronbach alpha) of the 13-item scale used in the research was 0.9. This alpha value is greater than the minimum acceptable limit of 0.7, and hence the various subitems of the scale were accepted for further analysis (Herrmann, Tomczak, & Befurt, 2006).

Results of the study

General

The Statistical Package for the Social Sciences (SPSS) was used in the analysis of the data in this study. Unless otherwise stated all statistical tests were done at the 95% confidence level. Data analysis in this exploratory study also includes descriptive analysis, which uses the mean and standard deviations (SD). It must be noted that although the mean is a commonly used statistic, which could be understood easily, there is the tendency for mean scores to be affected by extreme values (Urdan, 2005).

Key Findings

The unit of analysis is the construction professional employed by various construction and client companies in Hong Kong. Table 1 shows a summary of the relative rankings of the proposed items (on the potential client demands in virtual construction project delivery) and their perceived mean scores and SDs. The prime perceived item is "enhanced communication delivery and skills in the virtual environment" with a mean of 4.1 and a SD of 0.71. The second ranked item is the display of "proven competence and dependability in delivering similar tasks in the virtual environment with minimum physical supervision" (mean = 3.93, SD=1.02). The third ranked item concerns the "proven assurance in protecting the shared information of other parties in the project" (mean=3.80, SD=0.81). Surprisingly placed at the fourth position is "enhanced productivity and effectiveness in results delivery" (mean=3.73, SD= 0.81).

The first and second ranked items are statistically not different from each other (t=-1.; df=29; p= 0.326, 2tail). The first and the third ranked items are marginally not significantly different (t=-1.964; df=29; p=0.06, 2tail). The second and third ranked items are also not significantly different from

Table 1. Summary of potential client expectations

Item	Description	Mean	SD*	Rank
a	Enhanced communication delivery and skills in the virtual environment.	4.10	0.71	1
b	Proven competence and dependability in delivering similar tasks/works in the virtual environment with minimum physical supervision.	3.93	1.02	2
c	Proven assurance in protecting the shared information of other parties in the project.	3.80	0.81	3
d	Enhanced productivity and effectiveness in product delivery.	3.73	1.05	4
e	Availing in real time accurate, timely, user-friendly project progress; cost; and other relevant project information.	3.63	0.81	5
f	Digital environment risk management capabilities and security consciousness.	3.57	0.73	6
g	Orientation to reasonably share information with other partners.	3.57	0.86	6
h	Enhanced communications and visualization of designed products.	3.57	0.77	6
j	Increased demands to leverage skills and best practices around the world coupled with cross-cultural delivery skills.	3.57	0.94	6
k	Proven corporate belief and commitment to digital tasks delivery and sustained capacity development.	3.50	0.82	10
l	Proven process efficiency and commitment to internal customer-focused quality orientation.	3.43	0.86	11
m	Costs and time reductions or savings.	3.40	1.07	12
n	Digital content quality delivery and customer-focused digital service delivery.	3.34	1.56	13

* SD (standard deviation)

each other (t=0.941; df=29, p=0.354, 2tail). There is, however, a statistically significant difference between the fourth and first ranked items (t=2.36; df =29; p=0.025, 2tail).

While the first ranked item is about communication delivery and skill in the virtual project environment, the second and third ranked items relate to issues which deal with trust. The fourth ranked item, however, concerns actual task delivery. Thus in other words softer items which could potentially enhance the delivery of actual construction tasks are perceived to be more important. It may however be better to perceive the items as intercorrelated. For example, the first ranked item "enhanced communication delivery and skills in the virtual environment" has a fairly strong and significant positive correlation with the fourth ranked item (enhanced productivity and effectiveness in product delivery) (r=0.591 at the 99% confidence level, 2tail). The first ranked item is also positively related to:

- The second ranked item (proven assurance in protecting the shared information of other parties in the project) (r= 0.397 at the 95% confidence level, 2tail).
- The third ranked item (proven competence and dependability in delivering similar tasks in the virtual environment with minimum supervision) (r=0.487 at the 99% confidence level, 2tail).

The correlations among the items may not necessarily imply causation, but they seem to suggest reasonable and meaningful relationships of association.

One important item (ranked fifth) is "availing in real time accurate and timely user-friendly project progress, cost, and other relevant information" (mean=3.63, SD=0.81). This fifth ranked item is seen as relatively more important than another item (h) which also concerns communication but is focused on enhanced product visualization. It may be noted that an "enhanced visualization and communication of designed products" (item h) could provide construction clients the opportunity to clearly see the nature of any proposed final construction products (in three or four dimensions). This visualization may enable clients to both appreciate and make effective contributions to the design of the product via clear descriptions of what they actually need.

Other issues like item j which deals with the use of international skills, best practice, and cross-cultural capabilities is in a joint sixth position with item f (digital environment risk management capabilities and security consciousness). The two items (j and f) are both seen as more important (in terms of the mean scores) than item k (proven corporate belief and commitment to digital tasks delivery and sustained capacity development).

The highest positive significant correlation among any two items in the 13-item scale was between the 10th ranked item k (proven corporate belief and commitment to digital tasks delivery and sustained capacity development) and the sixth ranked item g (orientation to reasonably share information with other partners) (r= .76 at the 99% confidence level). Thus, a very strong association exists between the expectations on the commitment by construction agents to digital task delivery, and the orientation of agents to reasonably share information with other partners.

Although two items (m and n) which concern "costs and time reduction or savings" and digital quality content and service delivery are in the respective positions of 12th and 13th, both of them have above average mean scores.

Implications of the Studies

Scholars have stressed the importance of trust and communication delivery in the general literature on the virtual concept (Hossain & Wigand, 2004). This exploratory study seems to suggest that apart from enhanced communication delivery and skills, other issues which concern trust (i.e., competence and dependability; ability to protect shared information of other parties) may also require comparable attention by service providers. Training all virtual construction participants/staff in effective virtual communication delivery and skills, as well as giving attention to other softer issues (on business efficacy) that concern trust, may be very useful. The study also appears to suggest that the expectation of construction clients on "cost and time savings," which may be potentially gained from the use of the virtual construction concept (Barima, 2003), is not seen as relatively more important than issues on enhanced communication and trust. The results of the study also seem to emphasize on the softer items which could potentially enhance the delivery of actual construction tasks. However, since all the proposed items in the study are perceived to be above average importance, a more useful approach may be via a robust focus (in which the items are seen as interrelated).

Limitations of the Studies

This study must be seen as exploratory in nature. Limitations like the size of the sample (and also nonresponse issues) used in the study do not make any statistical generalization useful, although statistically the sample size may be seen as large (Urdan, 2005). This exploratory study however provides important awareness on issues concerning trends and perceptions in this young area of research and practice.

FUTURE TRENDS

Future studies could focus on the evolution of robust virtual construction task delivery metrics to support construction service delivery improvement. Case studies may then be used across varying sizes/scales of construction project types to enhance understanding in this young area of research.

CONCLUSION

This article examined the potential expectations of construction clients for likely construction services in the virtual construction project environment. Although all the items in the study were seen as being above average importance, the study suggests that service providers may have to enhance communication delivery and skills, as well as display relevant behavior on soft issues which relate to trust. A better and useful position may be via adopting a robust systemic focus on the items (where the items are seen as interlinked). It is hoped that further studies could advance knowledge of the potential value delivery expectations in the use of the virtual concept to support construction works delivery.

KEY TERMS

Client Orientation: Client orientation relates to the mental positioning matched by behavioral evidence of actors to deliver value to the client.

Client Value Expectations: Client value expectations refer to the potential characteristics of value which are expected to be delivered to the construction client.

Construction Paradigms Shift: Construction paradigms shift refers to the change in the traditional methods of thinking and execution of construction works.

Corporate Value Delivery Metrics: Corporate value delivery metrics are the collectively evolved measurable targets which may be used by the various parties of the construction value delivery process. They may be used to improve the construction delivery process.

Parties in a Construction Process: Various stakeholders who may have an interest in either the construction process or its product. Usually they may include construction contractors, consulting professionals (architects, engineers, quantity surveyors, etc.), the construction client, governments (if not the client), public or society, and so forth.

Virtual Construction Project: This is a construction project which is supported by the virtual concept.

Virtual Concept: Virtual concept refers to the reliance by actors on ICT tools to mimic the real world and operate independent of time and space to attain common goals.

Cluster Analysis Using Rough Clustering and k–Means Clustering

Kevin E. Voges
University of Canterbury, New Zealand

INTRODUCTION

Cluster analysis is a fundamental data reduction technique used in the physical and social sciences. It is of potential interest to managers in Information Science, as it can be used to identify user needs though segmenting users such as Web site visitors. In addition, the theory of Rough sets is the subject of intense interest in computational intelligence research. The extension of this theory into rough clustering provides an important and potentially useful addition to the range of cluster analysis techniques available to the manager.

Cluster analysis is defined as the grouping of "individuals or objects into clusters so that objects in the same cluster are more similar to one another than they are to objects in other clusters" (Hair, Black, Babin, Anderson, & Tatham, 2006). There are a number of comprehensive introductions to cluster analysis (Abonyi & Feil, 2007; Arabie, Hubert, & De Soete, 1994; Cramer, 2003; Everitt, Landau, & Leese, 2001; Gan, Ma, & Wu, 2007; Härdle & Hlávka, 2007). Techniques are often classified as hierarchical or nonhierarchical (Hair et al., 2006), and the most commonly used nonhierarchical technique is the *k*-means approach developed by MacQueen (1967). Recently, techniques based on developments in computational intelligence have also been used as clustering algorithms. For example, the theory of fuzzy sets developed by Zadeh (1965), which introduced the concept of partial set membership, has been applied to clustering (Abonyi & Feil, 2007; Dumitrescu, Lazzerini, & Jain, 2000). Another technique receiving considerable attention is the theory of rough sets (Pawlak, 1982), which has led to clustering algorithms referred to as rough clustering (do Prado, Engel, & Filho, 2002; Kumar, Krishna, Bapi, & De, 2007; Parmar, Wu, & Blackhurst, 2007; Voges, Pope, & Brown, 2002).

This article provides brief introductions to *k*-means cluster analysis, rough sets theory, and rough clustering, and compares *k*-means clustering and rough clustering. It shows that rough clustering provides a more flexible solution to the clustering problem, and can be conceptualized as extracting *concepts* from the data, rather than strictly delineated subgroupings (Pawlak, 1991). Traditional clustering methods generate *extensional* descriptions of groups (i.e., which objects are members of each cluster), whereas clustering techniques based on rough sets theory generate *intentional* descriptions (i.e., what are the main characteristics of each cluster) (do Prado et al., 2002). These different goals suggest that both *k*-means clustering and rough clustering have their place in the data analyst's and the information manager's toolbox.

BACKGROUND

k-Means Cluster Analysis

In the *k*-means approach, the number of clusters (*k*) in each partition of the data set is decided *prior to* the analysis, and data points are randomly selected as the initial estimates of the cluster centers (referred to as centroids). The remaining data points are assigned to the closest centroid on the basis of the distance between them, usually using a Euclidean distance measure. The aim is to obtain maximal homogeneity within clusters (i.e., members of the same cluster are most similar to each other) and maximal heterogeneity between clusters (i.e., members of different clusters are most dissimilar to each other).

K-means cluster analysis has been shown to be quite robust (Punj & Stewart, 1983). Despite this, the approach suffers from many of the problems associated with all traditional multivariate statistical analysis methods. These methods were developed for use with variables that are normally distributed and have an equal variance-covariance matrix in all groups. In most realistic data sets, neither of these conditions necessarily holds.

Rough Sets

The concept of rough sets (also known as approximation sets) was introduced by Pawlak (1982, 1991) and is based on the assumption that with every record in the information system (the data matrix in traditional data analysis terms), there is associated a certain amount of information. This information is expressed by means of attributes (variables in traditional data analysis terms) used as descriptions of the objects. For example, objects could be individual users in a study of user needs, and attributes could be characteristics of the users such as gender, level of experience, age, or other characteristics considered relevant. See Pawlak (1991) or Munakata (1998) for comprehensive introductions.

In rough set theory, the data matrix is represented as a table, the information system. The complete information system expresses all the knowledge available about the objects being studied. More formally, the information system is a pair, $S = (U, A)$, where U is a non-empty finite set of objects called the universe and $A = \{ a1, \ldots, aj \}$ is a non-empty finite set of attributes describing the objects in U. With every attribute $a \in A$, we associate a set Va such that $a : U \rightarrow Va$. The set Va is called the domain or value set of a. In traditional data analysis terms, these are the values that each variable can take (e.g., gender can be male or female, users can have varying levels of experience).

A core concept of rough sets is that of indiscernibility. Two objects in the information system about which we have the same knowledge are indiscernible. Let $S = (U, A)$ be an information system, then with any subset of attributes B, ($B \subseteq A$), there is associated an equivalence relation, INDA (B), called the B-indiscernibility relation. It is defined as:

$$\text{IND}A\ (B) = \{(x, x') \in U^2 \mid a \in B\ a(x) = a(x')\}$$

In other words, for any two objects (x and x') being considered from the complete data set, if any attribute a from the subset of attributes B is the same for both objects, they are indiscernible on that attribute. If $(x, x') \in$ INDA (B), then the objects x and x' are indiscernible from each other when considering the subset B of attributes.

Equivalence relations lead to the universe being divided into partitions, which can then be used to build new subsets of the universe. Two of these subsets of particular use in rough sets theory are the lower approximation and the upper approximation. Let $S = (U, A)$ be an information system, and let $B \subseteq A$ and $X \subseteq U$. We can describe the set X using only the information contained in the attribute values from B by constructing the B-lower and B-upper approximations of X, denoted $B_*(X)$ and $B^*(X)$ respectively, where:

$$B_*(X) = \{x \mid [x]B \subseteq X\} \text{ and } B^*(X) = \{x \mid [x]B \cap X \neq \varnothing\}$$

The set BN$B(X)$ is referred to as the boundary region of X, and is defined as the difference between the upper approximation and the lower approximation. That is:

$$\text{BN}B(\text{X}) = B^*(X) - B_*(X)$$

If the boundary region of X is the empty set, then X is a crisp (exact) set with respect to B. If the boundary region is not empty, X is referred to as a rough (inexact) set with respect to B. The important insight of Pawlak's work is his definition of a set in terms of these two sets, the lower approximation and the upper approximation. This extends the standard definition of a set in a fundamentally important way.

Rough Clustering

Rough clusters are a simple extension of the notion of rough sets. The value set (Va) is ordered, which allows a measure of the distance between each object to be defined, and clusters of objects are then formed on the basis of their distance from each other. An object can belong to more than one cluster. Clusters can then be defined by a lower approximation (objects exclusive to that cluster) and an upper approximation (all objects in the cluster which are also members of other clusters), in a manner similar to rough sets.

Let $S = (U, A)$ be an information system, where U is a non-empty finite set of M objects ($1 \leq i \leq M$), and A is a non-empty finite set of N attributes ($1 \leq j \leq N$) on U. The j^{th} attribute of the i^{th} object has value $R (i, j)$ drawn from the ordered value set Va.

For any pair of objects, p and q, the distance between the objects is defined as:

$$D(p,q) = \sum_{j=1}^{N} |R(p,j) - R(q,j)$$

That is, the absolute differences between the values for each object pair's attributes are summed. The distance measure ranges from 0 (indicating indiscernible objects) to a maximum determined by the number of attributes and the size of the value set for each attribute.

EXTENSIONS

The theory of rough sets continues to generate numerous edited books and conferences extending Pawlak's original insight into new areas of application and theory (e.g., An et al., 2007; Lin & Cercone, 1997; Polkowski & Skowron, 1998; Polkowski, Tsumoto, & Lin, 2000; Wang, Liu, Yao, & Skowron, 2003; Zhong, Skowron, & Ohsuga, 1999).

Rough *k*-Means Clustering

Lingras and West (2004) present a generalization of rough sets theory based on a relaxation of the basic equivalence relation (in fact most of the extensions of rough sets-based theory are based on this relaxation). They present a new technique combining k-means and rough set approaches by introducing a concept of upper and lower bounds to the k-means centroid. They applied this technique to a study of Web user behaviors in a first-year computer science class, and clearly identified three clusters of users—studious (continuous users), crammers (intermittent users, particularly before tests), and workers (users who mainly used access to

complete assignments). Lingras and West also found some overlaps between the clusters, a useful characteristic of all rough set-based clustering approaches.

Peters (2005, 2006) extended Lingras and West's technique to make it more compatible with the classical *k*-means algorithm when the upper and lower bounds converge, and to deal with outliers. He applied this improved technique to forest cover data and to cancer data. However, both the original technique and improved version have not solved the problem of the selection of initial parameters.

Rough Clustering Using an Evolutionary Algorithm

Voges and Pope (2004) developed a new technique for generating rough cluster descriptions using an evolutionary algorithm, with templates (Polkowski et al., 2000) as the building block of the data structure. The technique was applied to an analysis of a data set of perceptions of city destination image attributes (Voges, 2007) and was found to scale-up well to relatively large data sets (>6,000).

Clustering Different Data Types

Recently, rough clustering techniques have been applied to sequential data (Kumar et al., 2007) and categorical data (Parmar et al., 2007).

FUTURE TRENDS

Since Pawlak's original formulation of rough sets theory, theoreticians and practitioners have continued to explore and extend this rich field. Developments will continue in the underlying theory, the algorithms used for analysis, and the areas of application.

Developments in the underlying theory of rough sets include specifying an algebra of rough sets, formalizing rough reasoning, and extending rough topology. The underlying concepts will continue to be explored, including extending the definition of roughness through variable precision techniques. There will be a widespread utilization of fuzzy and rough sets as granulation sources within the field of Granular Computing, which provides a method of modeling that is far closer to the way human beings perceive their environment (Bello, 2008).

Analysis algorithms continue to be developed for rule extraction and the identification of reducts and cores. There will be an increasing use of hybrid applications, such as rough approximations of fuzzy sets and the use of rough set techniques in neural networks. New areas of applications continue to be explored, including language processing, video de-interlacing, image retrieval, face recognition, Web-based support systems, anomaly detection, text mining, and bioinformatics.

CONCLUSION

In rough clustering an object can belong to more than one cluster and therefore necessarily produce different solutions to *k*-means clustering, where an object can belong to only one cluster. This section briefly outlines a comparison between rough clustering and *k*-means clustering. A more detailed comparison can be found in Voges et al. (2002). See also Lingras and Huang (2005) for a comprehensive comparison of a number of clustering techniques.

In business, one of the most common applications of cluster analysis is the segmentation of a market by identifying homogeneous groups of buyers (Punj & Stewart, 1983; Wedel & Kamakura, 2000). Segmentation can also be applied to groups of users to assist in identifying user needs. In a market segmentation study that compared *k*-means and rough clustering analyses of shopping orientations of Internet shoppers, Voges et al. (2002) found that the two clustering techniques resulted in some clusters that were identified by both techniques, and some clusters that were unique to the particular technique used. The rough clustering technique also found clusters that were "refined" sub-clusters of those found by *k*-means clustering, and which identified a more specific sub-segment of the market.

Rough clustering produces more clusters than *k*-means clustering (Voges et al., 2002), with the number of clusters required to describe the data dependent on the interobject distance (D). It was found that the lower approximation of each cluster was dependent on the number of clusters selected for the solution. More clusters means an object has a higher chance of being in more than one cluster, which moves the object from the lower approximation to the boundary region and reduces the size of the lower approximation. This suggested that a number of factors needed to be considered when determining the best maximum value for D and the best number of clusters to include in the solution. A solution with too few clusters does not provide a useful interpretation of the partitioning of the data. On the other hand, too many clusters make interpretation difficult. In addition, the degree of overlap between the clusters needs to be minimized to ensure that each cluster provided information to aid in interpretation. Determining a good rough cluster solution requires a trade-off between these factors.

KEY TERMS

Approximation Set: An alternative (and more technically correct) name for a rough set, which is defined by two sets, the lower approximation and the upper approximation.

Boundary Region: Those object that may or may not be in the approximation set. It is the difference between the upper approximation and the lower approximation. If the boundary region is empty, the set is said to be crisp. If the boundary region is not empty, the set is rough.

Cluster Analysis: A data analysis technique involving the grouping of objects into sub-groups or clusters so that objects in the same cluster are more similar to one another than they are to objects in other clusters.

***K*-Means Clustering:** A cluster analysis technique in which clusters are formed by randomly selecting *k* data points as initial seeds or centroids, and the remaining data points are assigned to the closest cluster on the basis of the distance between the data point and the cluster centroid.

Lower Approximation: In rough sets theory, one of the two sets used to define a rough, or approximate set. The lower approximation contains objects that are definitely in the approximation set.

Market Segmentation: A central concept in marketing theory and practice; involves identifying homogeneous sub-groups of buyers within a heterogeneous market. It is most commonly conducted using cluster analysis of the measured demographic or psychographic characteristics of consumers. Forming groups that are homogenous with respect to these measured characteristics segments the market.

Rough Classification: Finds mappings from the partitions induced by the equivalence relations in the condition attributes to the partitions induced by the equivalence relations in the decision attribute(s). These mappings are usually expressed in terms of decision rules. It performs the same type of classification function as discriminant analysis or logistic regression, where there is a known sub-grouping in the data set, which is identified by the decision attribute.

Rough Clustering: A simple extension of rough sets theory, analogous to traditional cluster analysis. The information table has no pre-existing subgroups, and clusters of objects are formed based on a distance measure. Clusters are defined by a lower approximation (objects exclusive to that cluster) and an upper approximation (all objects in the cluster that are also members of other clusters), in a manner similar to rough sets. An object can belong to more than one cluster.

Rough Set: The concept of rough, or approximation, sets was introduced by Pawlak and is based on the single assumption that information is associated with every object in an information system. This information is expressed through attributes that describe the objects; objects that cannot be distinguished on the basis of a selected attribute are referred to as indiscernible. A rough set is defined by two sets, the lower approximation and the upper approximation.

Upper Approximation: In rough sets theory, one of the two sets used to define a rough, or approximate set. The upper approximation contains objects that may or may not be in the approximation set. It can be formally defined as the union of the lower approximation and the boundary region. It is the complement of the set of objects definitely not in the set.

Clustering Algorithms for Data Streams

Christos Makris
University of Patras, Greece

Nikos Tsirakis
University of Patras, Greece

INTRODUCTION

The World Wide Web has rapidly become the dominant Internet tool which has overwhelmed us with a combination of rich hypertext information, multimedia data and various resources of dynamic information. This evolution in conjunction with the immense amount of available information imposes the need of new computational methods and techniques in order to provide, in a systematical way, useful information among billions of Web pages. In other words, this situation poses great challenges for providing knowledge from Web-based information. The area of data mining has arisen over the last decade to address this type of issues. There are many methods, techniques and algorithms that accomplish different tasks in this area. All these efforts examine the data and try to find a model that fits to their characteristics in order to examine them. Data can be either typical information from files, databases and so forth, or with the form of a stream. Streams constitute a data model where information is an undifferentiated, byte-by-byte flow that passes over the time. The area of algorithms for processing data streams and associated applications has become an emerging area of interest, especially when all this is done over the Web. Generally, there are many data mining functions (Tan, Steinbach, & Kumar, 2006) that can be applied in data streams. Among them one can discriminate clustering, which belongs to the descriptive data mining models. Clustering is a useful and ubiquitous tool in data analysis.

BACKGROUND

Data Mining and Knowledge Discovery

Classic algorithms handle small amounts of data and face up performance problems when data are huge in capacity. For example, a sorting algorithm runs efficiently with some megabytes of data but could have difficulties in running for some gigabytes of data. Many methods such as clustering and classification have been widely studied in the data mining community. However, a majority of such methods may not be working effectively on data streams. This happens because data streams provide huge volumes of data and at the same time require online mining, in which we wish to mine the data in a continuous fashion. Generally, there are many specific problems with traditional algorithms. Data mining is a technology that blends traditional data analysis methods with sophisticated algorithms for processing large volumes of data. In addition, it gives new opportunities for exploring and analyzing new types of data and for analyzing old types of data with new ways. Data mining is an integral part of knowledge discovery in databases (KDD). These two terms are often used interchangeably (Dunham, 2003). Over the last few years, KDD has been used to refer to a process consisting of many phases, while data mining is only one of these phases. Below are some definitions of knowledge discovery in databases and data mining (Fayyad, Piatetsky-Shapiro, &Smyth, 1996a, 1996b).

- **Knowledge discovery in databases (KDD):** Is the process for finding useful information and patterns in data.

Knowledge discovery in databases is a process that involves five different phases which are listed bellow (Dunham, 2003):

1. Data selection
2. Data preprocessing
3. Data transformation
4. Data mining
5. Data interpretation/evaluation

Data mining attempts to autonomously extract useful information or knowledge from large data stores or sets. It involves many different algorithms to accomplish different tasks. All these algorithms attempt to fit a model to the data. The algorithms examine the data and determine a model that is closest to the characteristics of the data being examined. These algorithms consist of three parts:

- **Model:** The purpose of the algorithm is to fit to the data.
- **Preference:** Some criteria must be used to fit one model over another.

- **Search:** All algorithms require some technique to search the data.

There are many different methods used to perform data mining tasks. These techniques not only require specific types of data structures, but also imply certain types of algorithmic approaches. Data mining tasks are generally divided into two different categories.

- **Predictive tasks:** These tasks predict the value of a particular attribute based on the values of other attributes. Predictive tasks include classification, regression, time series analysis and prediction.
- **Descriptive tasks:** Here, the objective is to derive patterns or relationships in data. Descriptive tasks include clustering, summarization, association rules and sequence discovery.

CLUSTERING

Clustering and other mining techniques have grasped the interest of the data mining community. It is alternatively referred to as unsupervised learning or segmentation. In broad strokes, clustering is the problem of finding a partition of a data set so that, under some definition of "similarity," similar items are in the same part of partition and different items are in different parts. These parts are called clusters. Items can be any type of data in any form. The most "common used" form of items in clustering are vectors. These vectors consist of *d*-dimensions in the Euclidian or generally metric space, so we talk about clustering in many dimensions. Some techniques meet some limitations in the value of *d* and most of the times *d* is the metric which differentiates algorithms.

Sometimes it is useful to use a threshold in order to specify that all objects in a cluster must be sufficiently close to one another. A more enlightening definition could be (Dunham, 2003):

- We have a set of alike elements. Elements from different clusters are not alike.
- The distance between points in a cluster is less than the distance between a point in the cluster and any point outside it.

A proportional process in data bases is segmentation where alike records are grouped together. Clustering is one of the most useful processes of data mining for cluster recognition and to define patterns and trends over data. It is similar to classification except that the groups are not predefined, but rather extracted by the specific distribution of the data.

Classification of Clustering Algorithms

There are various classes of clustering algorithms depending, each time, on the method for the clusters definition. The most common division of them is as *hierarchical* or *partitional*. In the first class of algorithms, we have a nested set of clusters. In addition, each level of hierarchy has a separate set of clusters. At the lowest level, each item is in its own unique cluster and at the highest level all items belong to the same cluster. Hierarchical clustering does not have as input the desired number of clusters. In the second class of algorithms, we meet only one set of clusters. Apart from these two classes of clustering algorithms, there are some recent studies that look at *categorical* data and are targeted to *large databases*. Algorithms targeted to large databases may adopt memory constraints by either *sampling* the database or using data structures which can be *compressed* or pruned to fit into memory regardless of the size of the database. Another approach of clustering algorithms is to further classify them based on the implementation technique used.

Data Streams

Traditional data bases store static data without the sense of time apart from the case the time is a part of the data. As time elapses the data explode and there is a need of online processing and analysis of data from many applications. This need made current methods deficient and processed data took another form and name. Data streams are data which change continuously over the time in a fast rate. There are many types of applications like network monitoring, telecommunications data managements, clickstream monitoring, manufacturing, sensor networks and many others, where data have the form of streams and not finite sum of data. In these applications users make continuous queries in contrast with the classic queries (one-time queries).

Models

We consider an input stream with x_i items that arrives sequentially and describes a signal X, a one-dimensional function X: $[1....N] \rightarrow R^2$. Models differ on how x_i's describe X and can be divided into three categories (Muthukrishnan, 2003):

- **Time series model:** This model is suitable for time series data such as observing the traffic at an IP link for a predefined time horizon (e.g., every 5 minutes).
- **Cash register model:** This is the most popular data stream model. It is suitable for applications such as monitoring IP addresses that access a Web server and source IP addresses that send packages to a link.
- **Turnstile model:** This is the most general model and it is appropriate in order to study fully dynamic situations where there are inserts as well as deletes, but it is often hard to get interesting bounds in this model.

The above models can be sorted according to their generality in decreasing order as follows: Turnstile, Cash Register and Time Series. More information about these models can be found in Gilbert, Kotidis, Muthukrishnan and Strauss (2001a). Finally, if we want to compute various functions on the signal at different times during the stream there are some different performance measures:

- The processing time per item x_i in the data stream.
- The space used to store the data structure on X_t at time t.
- The time needed to compute functions on X.

Applications

There are many applications that handle data streams. *Sensor networks* are used in many control applications that make complicated processes of filtering. These applications require aggregation and merging of multiple data streams in order to provide analysis from different sources of data. These applications usually collaborate with DSMSs (Data Stream Management Systems) in order to be controlled by a central mechanism, and the most common technique there is special purpose Query Languages. *Network monitoring* is a category of applications where systems do analysis as far as concerning the network traffic in a real time manner and are used to compute statistical methods in order to identify strange situations (Cranor et al., 2002; Gilbert, Kotidis, & Muthukrishan, 2001b; Sullivan & Heybey, 1998). There are DSMSs that provide long-running continuous queries which are required here. *Financial tickets* are another type of application where we meet online analysis of financial data like association discovery, trend recognition and prediction of future values. Finally, transaction analysis systems are systems that monitor all transactions that take place through Internet, telecommunications and banks. The aim of these systems, that handle data streams, is to find patterns of user behavior that are interesting and to recognize special and insecure user movements.

Some notable data stream managements systems (DSMS) are *Aurora* (Abadi et al., 2003) and *QuickSand* (Gilbert et al., 2001b). *Aurora* is a system for monitoring applications developed in consultation with defense, financial, and natural science communities. The core of the Aurora system consists of a large network of triggers. It deals with large numbers of data streams and users can build queries out of a small set of operators (called boxes) via a friendly user interface. Aurora consists of three components. A GUI environment where tuple structures and Aurora flow networks are defined, and also a server that executes an Aurora network. The inputs and outputs of the Aurora server are streams of tuples, delivered over TCP/IP sockets. Finally, Aurora has another GUI performance monitor that shows the quality of service being provided by the server at a given moment. The second system, *QuickSand,* gives solutions for monitoring and analyzing track data generated from large ISP networks. More precisely, it builds compact summaries of the track data called sketches at distributed network elements and centers. These sketches are able to respond well to queries that seek features that stand out of the data. Sketches use small space, they can be computed as data streams, and can be combined across distributed sites.

Clustering Data Steams

Clustering as mentioned above can be defined as the process of grouping a collection of N patterns into distinct segments or clusters based on a suitable notion of closeness or similarity among these patterns. As a procedure, it can be applied in many fields and in many daily problems. Some outstanding examples are clustering for understanding and clustering for usability. Good clusters show high similarity within a group and low similarity between patterns belonging to two different groups. The data stream model has been defined for new classes of application involving massive data being generated at a fast pace. Both data streams and online or incremental models are similar in that they require decisions to be made before all the data are available. For this purpose cluster analysis on data streams becomes more difficult, because the data objects in a data stream must be accessed in order and can be read only once or a few times with limited resources. There are some notable works in this area with algorithms that have been developed for data streams analysis. Many methods are based on traditional data mining techniques and provide ways to analyze this type of contemporary data. Clustering techniques are the most common techniques in this analysis phase as they can provide better and useful results to the analysts.

In the bibliography there is much research in streaming algorithms. Problems that can be solved in a small space when the data is a stream include (Guha et al., 2003): frequency estimation, norm estimation, order statistics, synopsis structures, time indexed data, and signal reconstructions.

One of the most interesting approaches to the clustering problem for data stream applications is (Aggarwal et al., 2003) where a framework is proposed for clustering evolving data streams. They divide the procedure of clustering into two phases, an online phase where periodically summary statistics are stored and an off-line phase which uses this summary statistics. The off-line phase is utilized by the analyst who can use a variety of inputs in order to provide a quick understanding of the broad clusters in the data stream. This two-phased approach provides the user with the flexibility to explore the nature of the evolution of the clusters over different time periods. One of the most important issues that this research is studding is the fact that a data stream cannot be revised over the time. Hence, the clustering algorithm must have a basic attribute, to be one pass algorithm. This means that this algorithm maintains a substantial amount of

information so that important details are not lost. K-means is the most common clustering algorithm for this purpose (MacQueen, 1967) and there is rich literature about this algorithm and its variants.

Clustering Click Stream Data

A special and interesting kind of data streams is click stream data. This kind of streams is centralized to user behavior. A visitor in a Web site is characterized by a set of one or more sessions. Each session is comprised by the sequence of pages visited, the time spent on each page, the information typed in and so forth. This information is huge when we are referring to popular Web sites, and at the same time this information is rapid and has the form of a stream. Consequently, clustering visitors based on such clickstream information can help a Web site to provide customized content for the users, suggest additional content from other user's preferences and generally separate users according to some similarity measures.

In Makris and Tsirakis (2006) the authors have proposed a model for clustering clickstream data. The main purpose of the model is to provide different kinds of data mining results from user behavior and to form this idea through a fast and efficient way. The model is based on three different states of data processing. First, click streams are being collected in real time manner and useful information is stored in a compressive way. A clustering procedure works on these stored data and provides clusters of users (short-term results), and finally a metaclustering procedure analyses the changes of these clusters over the time and provides long-term clustering results. The second step of the model is being designed in a way to support simultaneous data mining techniques such as different clustering algorithms of other mining techniques. With this opportunity, there is a variety of results and data inputs for the final metaclustering procedure.

In the field of Web usage mining, where the click stream clustering belongs to, there are many research studies. Clustering users based on their Web access patterns is the main concern and remains an active area. Among them marks out (Garofalakis et al., 1999) where the most popular techniques and algorithms for discovery Web, hypertext and hyperlink structure are reviewed. In Fu, Sandhu and Shih (1999) authors study the clustering of sessions based on browsing activities or access patterns on the Web, while Cadez et al. (2000) present a methodology for visualizing navigation patterns on a Web site using model-based clustering and describe a tool based on this technology. In Phoha, Iyengar, and Kannan (2002) the authors propose a new learning algorithm for fast Web page allocation on a server using the self-organizing properties of the neural network. One interesting aspect of mining clickstream data is models that predict user behaviour. Finally, in Gunduz and Ozsu (2003) the authors study the problem of modeling the behaviour of a Web user by introducing a similarity metric to find pair-wise similarities between user sessions. By partitioning user sessions based on that similarity metric, they propose a tree construction for representing clusters. This can be applied in Web sites with different structure.

FUTURE TRENDS

Clustering is a fundamental data analysis step and has been studied widely for decades in many disciplines. Considering the fact that the amount of data is continuously increasing in real life applications, efficient mining on data streams becomes a challenge to existing data mining techniques and algorithms. A wide research activity has taken place in the data mining area, but a few have been examined in the context of stream data clustering. Some open research issues are: detection of cluster-based outliers and semantic outliers in the data stream environment, new scalable clustering techniques that preserve privacy issues and ways to provide results with usability perspectives and finally, new techniques that deal with distributed data streams.

CONCLUSION

Efficient mining on data streams becomes a challenge to existing data mining algorithms, partially because of the high cost on both storage and time of distributed computation. Clustering data streams constitutes one of the most powerful data mining methods in data mining area. Only few of the techniques developed scale to support clustering of very large data sets. Data mining applications and the associated data sets have brought new clustering challenges. This article highlighted some of these issues and also described recent advances for successfully addressing them with great interest in click stream data.

KEY TERMS

ClickStream: Series of page visits and associated clicks executed by a Web site visitor when navigating through the site. As the user clicks on a link on a Web page, the action is logged inside the Web server, as well as possibly the Web browser, routers, proxy servers, and ad servers.

Clustering: Clustering is an algorithmic concept where data points occur in bunches, rather than evenly spaced over their range. A data set which tends to bunch only in the middle is said to possess centrality. Data sets which bunch in several places do not possess centrality. What they do possess has not been very much studied, and there are no infallible methods for locating the describing more than one cluster in a data set (the problem is much worse when some of the clusters overlap).

Data Bases: A database is a collection of information stored in a computer in a systematic way, such that a computer program can consult it to answer questions. The software used to manage and query a database is known as a database management system (DBMS). The properties of database systems are studied in information science.

Data Mining: Is the process of autonomously extracting useful information or knowledge from large data stores or sets. Data mining can be performed on a variety of data stores, including the World Wide Web, relational databases, transactional databases, internal legacy systems, pdf documents, and data warehouses.

Data Streams: An undifferentiated, byte-by-byte flow of data. A data stream can be distinguished in practice from a block transfer, although the moving of blocks could itself be considered a "stream" (of coarser granularity).

Knowledge Discovery: Is the process of finding novel, interesting, and useful patterns in data.

Synopsis Data Structures: Are data structures that use very little space, can be any data structures that are substantively smaller than their base data sets. The design and analysis of effective synopsis data structures offer many algorithmic challenges.

Web Mining: Is the application of data mining techniques to discover patterns from the Web. According to analysis targets, Web mining can be divided into three different types, which are Web usage mining, Web content mining and Web structure mining.

Cognitive Research in Information Systems

Auckland University of Technology, New Zealand

M. Gordon Hunter
University of Lethbridge, Canada

INTRODUCTION

The existence and significance of cognition in organizations and its influence on patterns of behaviour in organizations and organizational outcomes are increasingly accepted in information systems (IS) research (Barley, 1986; DeSanctis & Poole, 1994; Griffith, 1999; Griffith & Northcraft, 1996; Orlikowski, 1992, 1994 #208). However, assessing the commonality and individuality in cognition and eliciting the subjective understanding of research participants either as individuals or as groups of individuals remain a challenge to IS researchers (Orlikowski & Gash, 1994). Various methods for studying cognition in organizations have been offered - for example, clinical interviewing (Schein, 1987), focus groups (Krueger, 1988), discourse-based interviewing (Odell, Goswami & Herrington, 1983). This article proposes that cognition applied to making sense of IT in organizations can also be explored using Kelly's (1955) Personal Construct Theory and its methodological extension, the Repertory Grid (RepGrid). The RepGrid can be used in IS research for uncovering the constructs research participants use to structure and interpret events relating to the development, implementation, use and management of IS in organizations.

In the context of this article, cognition is considered to be synonymous with subjective understanding: "the everyday common sense and everyday meanings with which the observed human subjects see themselves and which gives rise to the behaviour that they manifest in socially constructed settings" (Lee, 1991, p. 351). Research into cognition in organizations investigates the subjective understanding of individual members within the organization and the similarities and differences in the understandings among groups of individuals (Jelinek & Litterer, 1994; Porac & Thomas, 1989). In IS research, it is the personal constructs managers, users and IS professionals use to interpret and make sense of information technology (IT) and its role in organizations. The discussion here outlines the myriad of ways the RepGrid can be employed to address specific research objectives relating to subjective understanding and cognition in organizations. It illustrates, from a variety of published studies in IS (see Table 1), the flexibility of the RepGrid to support both qualitative and/or quantitative analyses of the subjective understandings of research participants.

BACKGROUND

We propose to use a framework to facilitate this discussion (see Figure 1) that presents a two-dimensional view of the types of research using the repertory grid. The examples in Table 1 are mapped along these two dimensions.

Theory-Focused vs. Method-Focused

On one dimension, we distinguish research that applies Kelly's (1955) personal construct theory (theory-focused)

Figure 1. Distinguishing research using the repertory grid

Theory-Focused	Hunter (1997)[R]	Latta and Swigger (1992)[=]
Method-focused	Moynihan (1996)[R]	Phythian and King (1992)[=]

[R] Idiographic (i.e. individual interpretations – unique grids)
[=] Nomothetic (i.e. group interpretations – common grids)

from those applying the repertory grid method, without delving into the conceptual underpinnings of the theory (method-focused). When introduced some 45 years ago, the repertory grid technique served as the methodological extension of the personal construct theory. It operationalizes key aspects of Kelly's fundamental postulate and corollaries. IS researchers interested in the subjective understandings of individuals will find the repertory grid a powerful tool that permits the study of the individual's construct system and provides richer cognitive insights into research findings. For example, Latta and Swigger (1992) validated the use of the repertory grid for representing commonality of construing among participants regarding the design of intelligent user interfaces. The study lent strong support to the commonality corollary in grids, which can be confidently used to represent a consensus of knowledge around a problem domain. Hunter (1997) used the laddering technique to elicit what Kelly termed as super-ordinate constructs – constructs that are core to the individual's system of interpretation.

In contrast, there is research that has accepted Kelly's theory and employed the repertory grid solely as a data gathering technique. These works have employed the utility of the technique purely for its methodological strengths. Stewart and Stewart (1981) suggest, "At its simplest, Grids provide a way of doing research into problems – any problems – in a more precise, less biased way than any other research method" (pp. vii). These authors further contend that the repertory grid "….enables one to interview someone in detail, extracting a good deal of information … and to do this in such a way that the input from the observer is reduced to zero" (p. 5). Two of the examples in Table 1 have taken the method-focused approach to the use of the repertory grid technique. For instance, Moynihan (1996) was purely interested in using the repertory grid technique to collect data and to compare the results with the extant literature. Moynihan argued that the free-ranging responses resulting from the non-prohibitive nature of the technique permitted the participants to apply the "theories-of-action" (theories individuals use to guide their actions) they employ daily – resulting in the identification of themes and issues over and above the extant literature. In the studies by Phythian and King (1992), the repertory grid was used to explore the similarity and differences in the views between individual managers. No direct references were made to Kelly's personal construct theory, as the focus was to identify key factors influencing tender decisions and the relationships among these factors by interviewing two managers closely involved in such tender activities.

Qualitative vs. Quantitative

On the second dimension, we distinguish research that is either qualitative or quantitative. The identification of emerging themes from elicited constructs is common in a qualitative approach using the repertory grid. For example, Hunter (1997), when investigating how certain groups of individuals interpreted the qualities of "excellent" systems analysts, employed content analysis of the data gathered from individual interviews conducted using the repertory grid technique. The numeric component of the grid was only employed to conduct visual focusing at the end of each interview as a means of quickly assessing what had transpired during the interview and whether the research participant agreed with this initial assessment. Similarly, Moynihan (1996) employed the repertory grid technique as a method to elicit interpretations from research participants of what aspects were considered important when deciding upon an approach to adopt for projects to be conducted for external clients. Unique grids were developed for each research participant. Then the data were analyzed from a qualitative perspective via content analysis at the construct level, where emerging themes were identified and categorized. In these examples, the researchers took an open view toward gathering data and allowed themes or categories to emerge from the data as the investigation proceeded.

In contrast, the quantitative approach utilizes mathematical and/or statistical analyses of grid data (Daniels, Markoczy & de Chernatony, 1994). These techniques are commonly used to explore the structure and content of an individual's construct systems or make comparisons between groups of individuals (Ginsberg, 1989). This approach was adopted by two of the examples in Table 1. For instance, in Phythian and King (1992), statistical analyses (specifically, cluster analysis and correlation analysis) were conducted on individual and combined grids. These data were used to support the development of an expert support system. Similarly, Latta and Swigger (1992) applied cluster analysis and Spearman's rank order correlation to analyze the grids. The study revealed an overall correlation between the students' and the instructor's grids, promoting the utility of the repertory grid technique in modeling knowledge relating to the design of information systems.

Idiographic vs. Nomothetic

Within both the qualitative and quantitative perspectives, research using the repertory grid technique is either idiographic or nomothetic in nature. The idiographic approach focuses on the subjective experiences of the individual and presents results in expressions and terms used by the individual. The resulting grid is considered unique in that there are no common elements or constructs employed in the elicitation process. For example, in the study of systems analysts, each participant was asked to name up to six systems analysts with whom s/he had interacted. In this project, Hunter (1997) provided a role description (i.e., system analysts interacted with) and asked each participant to specify examples that fit this category. The analysts named were not common

Table 1. Examples of IS research using the RepGrid

Table 1. Examples of IS Research Using the RepGrid

	Hunter (1997)	Moynihan (1996)	Phythian and King (1992)	Latta and Swigger (1992)
Research Objectives	Explore the qualities of "excellent" systems analysts	Identify the situational factors considered in the planning/running of new systems development projects	Develop rules for an expert system to support customer tender evaluations	Validate the RepGrid in modeling communal knowledge regarding design of system interfaces
Research Perspective	Qualitative	Qualitative	Quantitative	Quantitative
Nature of RepGrid	Idiographic	Idiographic	Nomothetic	Nomothetic
Key Findings	Several themes considered as qualities of "excellent" systems analysts	Identified themes over and above literature. Differences in project managers' construction of project contexts	Identified key factors and rules influencing tender decisions. Expert system improved consistency	Commonality of constructions support the use of the RepGrid to model group knowledge
Research Design:				
Element Selection	Systems analysts with whom participant has interacted	Systems development projects on which participant has worked	Previous customer tender enquiries	Components of online bibliographic retrieval systems
	Elicited	Elicited	Supplied	Supplied
Construct Elicitation	Qualities of "excellent" systems analysts	Situational factors influencing risks in new systems projects	Key factors and rules influencing tender decisions	Attributes of system interface design
	Minimum context form (triadic sort) and laddering	Minimum context form (triadic sort)	Minimum context form (triadic sort) and laddering	Minimum context form (triadic sort) and supplied constructs
Linking	Rating	None	Rating (Grid) Ranking (Elements)	Rating
RepGrid Analysis	Content analysis Visual focusing COPE and VISA	Content analysis	Cluster analysis (FOCUS), correlation, mathematical modeling	Cluster analysis, correlation
Sample and Size	53 (users and IT professionals) from two insurance companies	14 systems development project managers	Two manager-experts involved in assessing tender enquiries	Instructor and students who completed an "information search and retrieval" course

among participants and as such the resulting grids were not common in terms of the elements used. Similarly, Moynihan (1988) asked each participating project manager to make a list of systems development projects s/he had worked on as a project manager. If the project manager named more than nine projects, s/he was then asked to choose the three that were most successful, the three that were the least successful, and three in between. Moynihan's research objective was to identify the situational factors project managers regard as important when planning new development projects and not to compare the subjective understandings of different project managers. As such, he did not supply a common set of systems development projects that would have permitted a comparative analysis of individual grids.

In contrast, research comparing the grids of individuals or groups of individuals requires different decisions to be made concerning the elements and constructs in the repertory grid process. This nomothetic approach necessitates the use of a common set of elements and/or constructs to permit comparisons to be made between grids (Easterby-Smith, 1980). Such research also tends to be quantitative in nature. For example, research to identify the similarities and differences in two managers' views on tender enquiry evaluations imposed a common set of tender enquiries as elements in the repertory grid process (Phythian & King, 1992). This permitted the comparison of the construct systems of the two managers based on their personal experiences of similar events. In another example, a set of constructs was elicited from an instructor and then supplied as common constructs for a group of students to evaluate against a prescribed set of elements representing the features of online bibliographic retrieval systems (Latta & Swigger, 1992). This permitted the commonality of construing among students and between students and the instructor to be tested. In these examples, the reason for the use of common components in the repertory grid process was to compare grids.

Finally, none of the examples discussed in this section approached their studies using both qualitative and quantitative approaches. This does not imply that the repertory grid cannot lend itself to both qualitative and quantitative analysis of the collected data.

CONCLUSION

This article has demonstrated the flexibility of the repertory grid technique to support both qualitative and/or quantitative approaches to investigating the subjective understanding of human subjects in complex and socially dynamic organizations. With this technique, both qualitative and quantitative approaches need not be mutually exclusive. For instance, Hunter (1997) approached his study of systems analysts from a grounded theory perspective. The data collected using the repertory grid were analysed to identify themes or qualities of "excellent" systems analysts. In an extension of this investigation, the characteristics of excellent systems analysts were statistically tested to highlight the similarities and differences in the subjective understandings of Canadian and Singaporean research participants (Hunter & Beck, 1996).

We would like to conclude by reiterating two important points. The first is a word of caution. The repertory grid should not be considered a panacea to investigating the subjective understanding of individuals in an organizational setting. It can be used in conjunction with other methods – as a means of validating other techniques or as a preliminary phase to further interpretive or positivist investigations. The second is that the personal construct theory is one of several theories in cognitive science (Berkowitz, 1978). The repertory grid is one of several cognitive mapping methods available to the IS researcher (Huff, 1990). This article was written in an attempt to stimulate interest in the IS research community of the need for more cognitive emphasis in our field. Hopefully, IS researchers will be encouraged to further reflect on the virtues of applied theories and methods that can deliver utilizable and consumable outcomes to research and practice in IS.

KEY TERMS

Cognition: Cognition is considered to be synonymous with subjective understanding, "the everyday common sense and everyday meanings with which the observed human subjects see themselves and which gives rise to the behaviour that they manifest in socially constructed settings" (Lee, 1991, p. 351).

Construct: Constructs represent the research participant's interpretations of the elements. Further understanding of these interpretations may be gained by eliciting contrasts resulting in bi-polar labels. Using the same example, research participants may come up with bi-polar constructs such as "high user involvement – low user involvement" to differentiate the elements (i.e., IS projects). The labels represent the CSFs of IS projects.

Elements: Elements are the objects of attention within the domain of investigation. They define the entities upon which the administration of the RepGrid is based. For example, to explore the critical success factors (CSFs) of IS projects, IS researchers can use IS projects as elements in the RepGrid.

Idiographic: The idiographic approach focuses on the subjective experiences of the individual and presents results in expressions and terms used by the individual. The resulting RepGrid is considered unique in that there are no common elements or constructs employed in the elicitation process across the sample.

Links: Links are ways of relating the elements and constructs. The links show how the research participants interpret each element relative to each construct. Further, the links reveal the research participant's interpretations of the similarities and differences between the elements and constructs.

Nomothetic: The nomothetic approach permits the comparison of RepGrids of individuals or groups of individuals. It necessitates the use of a common set of elements and/or constructs to permit comparisons to be made between RepGrids.

Repertory Grid (RepGrid): The RepGrid is a cognitive mapping technique that can be used to describe how people think about a phenomenon in their world. The RepGrid technique, for IS, entails a set of procedures for uncovering the personal constructs individuals use to structure and interpret events relating to the development, implementation, use, and management of IT in organizations. The RepGrid contains three components – elements, constructs and links.

A Cognitively-Based Framework for Evaluating Multimedia Systems

Eshaa M. Alkhalifa
University of Bahrain, Bahrain

INTRODUCTION

Multimedia systems waltzed into the lives of students and educators without allowing anyone the time required for the development of suitable evaluation techniques. Although everyone in the field is aware that judging this type of teaching software can only come through evaluations, the work done in this regard is scarce and ill-organized. Unfortunately, in many of the cases the evaluation forms were just filled in by instructors who pretended to be students when they went through the tutorial systems (Reiser & Kegelmann, 1994). Nowadays, however, awareness of the impact of evaluation results on the credibility of the claims made is rising.

BACKGROUND

Ever since the early days, researchers recognized the existence of two main dimensions of multimedia evaluations. Formative evaluation is concerned with the program's functional abilities and efficiency, while summative evaluations are concerned with the effectiveness of the system in achieving its goals (Bloom, Hastings, & Madaus, 1971; Scriven, 1967).

Heller and Martin (1999) inform us that the evaluation question depends on the core subject from which it emerges, and they present a list of four subjects, namely, computer science, computer graphics, education, and human-computer interaction. They explain that if the core subject is computer science, then the research question concerns the technical requirements of the multimedia systems, including data compression, storage requirements, bandwidth, and data transmission. If the question is from computer graphics, then the focus is on speed of image rendering, representation of light, and creation of animation. If the question is from education, then media is evaluated in terms of its impact on teaching and learning along with attributes such as motivation, feedback, and information delivery. If the question is from human-computer interaction, then it is concerned with the use of multimedia in interface design focusing on issues that impact the interaction itself, such as screen design, the use of metaphor, and navigational strategies.

In retrospect, when examining their classification, we find that the main two dimensions are well covered. Formative evaluation is the focus of computer science and computer graphics as a whole, while summative evaluation is the main, but not only, focus of education and human-computer interaction. With education, we find that "motivation" does not conform to any of the two dimensions, while human-computer interaction requires both formative evaluation in addition to summative evaluation.

Researchers tested their systems through a summative evaluation frequently using a pretest and posttest where the first is taken prior to using the system and the second following the use of the system. Unfortunately, this type of testing has been plagued with no significant[1] differences in student grades when multimedia is compared to classroom lectures or to carefully organized, well-illustrated textbooks (Pane, Corbett, & John, 1996). Others widened the scope of their evaluation procedure by adding learning style questionnaires that targeted student-learning preferences and a subjective questionnaire that investigated motivation issues (Kinshuk, Patel, & Russell, 2000).

Disappointment in the results of pretests and posttests caused researchers to alter the main summation evaluation question. They wondered if the test is for the educational effects of interactivity versus lack of interactivity, or should one compare animation with textual media (McKenna, 1995). If Pane et al. (1996) were aware of the work done by Freyd (1987) who studied the cognitive effects of exposing subjects to a series of still images to find that they are equivalent in the reactions they elicit to being exposed to a moving picture, then perhaps they would not have asked whether animation is equivalent to a textbook with carefully set images of all stages.

The problem that emerged in the summation dimension is therefore the question itself. Tam, Wedd, and McKerchar (1997) proposed a three-part evaluation procedure that includes peer review, student evaluation, and pre- and post-testing. They were not able to get rid of the pretest and posttest evaluation, as it is the primary test for how much learning was achieved, and they still saw no significant differences in their results. In other words, they collected more subjective feedback from users, and this is not classified under summation evaluation.

At this stage, researchers recognized that evaluations did not target the appropriate level of detail that would enable them to detect differences that may exist in their results. Song, Cho, and Han (2000, 2001) presented empirical support that animation helps reduce the cognitive load on the

learner. They also showed that multimedia is more effective in teaching processes than in teaching conceptual definitions, while textual presentations are better at the latter. However, all this was done in very limited test domains that lacked the realistic world of an educational system. Al Balooshi and Alkhalifa (2002) presented such an educational system evaluation by showing that the student cognitive styles do affect how they learn and that only the correct research question is capable of detecting these differences.

The evaluation framework therefore has to be expanded to include the motivation measure that is tested by designers but does not conform to any predefined dimension and to include these more detailed research questions at the appropriate level of abstraction to detect the differences between the multimedia systems subject to evaluation.

A THREE-DIMENSIONAL FRAMEWORK FOR EVALUATION

All evaluations start with an evaluation question that compares the one thing to another. If the words used to classify the question are not distinctive enough, then research will not benefit from the findings or misclassify them. Motivating students, for example, does not necessarily imply that the educational impact will be influenced. Asking a question that is at a high level of abstraction, like if one media teaches as well as another without specifying the details of the design, difference, and materials, may also generalize to the degree that true benefits are shadowed or lost in the generalization. Consequently, a complete framework of evaluation is required to take into account all issues concerning the software and the learning process. Evaluation questions can be channeled into three main dimensions of evaluation that could then be subdivided into the various methods that form possible criteria that guides the evaluation process.[2]

The framework is composed of three main steps that will be explained through a case study of a Data Structure Tutorial System (DAST) that was developed and evaluated at the University of Bahrain (Alkhalifa & Al Balooshi, 2003).

The first dimension was first reviewed by distributing three instructor surveys based on a series of questions proposed by Caffarella (1987), to allow them to illuminate the various anomalies that may be present in the multimedia system design. A similar evaluation was distributed among students to allow them to evaluate the system subjectively.

The second dimension required a slightly more complicated process, which started with a pre-evaluation test of all students to ensure they were divided into groups of equivalent mean grades. Then the pretests and posttests were written to ensure that one set of questions mapped onto the next by altering their order while ensuring they included declarative questions that required verbalization

Table 1. A three-dimensional framework for evaluation

First Dimension: System Architecture

This dimension is concerned with the system's main modules, their programming complexity, and their interactions. Evaluation within this dimension should be performed in any or all of the following methods:

- Operation of the system as a whole is described and evaluated to show optimization techniques used, and so forth.
- Expert survey of the system filled by experts in the field or educators.
- User evaluations of the way the system works, to indicate if they ran into any errors or problems that have not been predicted by designers.
- Architectural design of the system is presented and evaluated against prior work and evaluations of similar systems to ensure that it benefits from the lessons learned.
- All business related issues such as cost analysis and portability, time frame required for mass production of similar systems, and so forth.

Second Dimension: Cognitive Impact

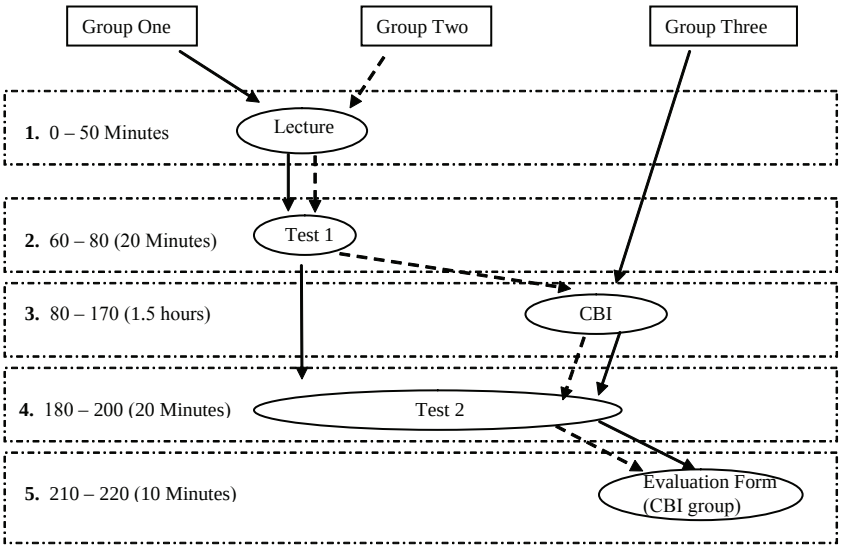
This dimension is concerned with assessing the benefits that could be gained by students when they use the system. Classically all the following methods must be measured using pretests and posttests of educational impact prior to and following use of the system. Here we find four areas of focus: two types of knowledge, cognitive traits, and the classification of the materials presented.

- Tests of declarative knowledge that required verbalization of what users understood or learned following the use of the system.
- Tests of procedural knowledge that tested if students understood how the concepts could be applied in novel situations.
- Tests of cognitive styles that impacted how well students learned from one approach to presenting information vs. an alternative approach.
- Tests of the alignment of the materials taught with the teaching style selected for that material. For example, is teaching mathematics more effective if it is interactive with live computation or if it is through textual presentation.

Third Dimension: Affective Measures

This dimension is mainly concerned with student opinions on the user friendliness of the system and allows them to express any shortcomings in the system. This could best be done through surveys where students are allowed to add any comments they wish freely and without restraints.

Figure 1. The evaluation procedure



of how students understood concepts as well as procedural questions that tested if students understood how the concepts could be applied. The evaluation procedure for students is shown in Figure 1.

ANALYSIS OF RESULTS

Results of the first dimension survey distributed to three peer experts showed the system earned an average rating of 5.33 on a scale of 0 to 6. Students of groups two and three generally gave ratings of around 4 to 5 on a scale from 0 to 6 with the highest for "The use of graphics, sound, and color contributes to the student's achievement of the objectives" and "The user can control the sequence of topics within the CBI program." The lowest score was 3.559 for "The level of difficult is appropriate for you." Therefore, it seems that the students in general enjoyed learning through the system, although they found the level of difficulty of the concepts presented challenging.

For the second dimension, student grades were first analyzed using the Analysis of Variance (ANOVA) test. This test allows the evaluation of the difference between the means by placing all the data into one number, which is F, and returning as a result one p for the null hypothesis. It also compares the variability that is observed between conditions to the variability observed within each condition. The statistic F is obtained as a ratio of two estimates of students' variances. If the ratio is sufficiently larger than 1, then the observed differences among the obtained means are described as being statistically significant. The term "null hypothesis" represents an investigation done between samples of the groups with the assumption that additional learning will not occur as a result of the treatment. In order to conduct a significance test, it is necessary to know the sampling distribution of F given the significance level needed to investigate the null hypothesis. It must be also mentioned that the range of variation of averages is given by the standard deviation of the estimated means.

The ANOVA test did show that there is a significant improvement in group two between the first test, which was taken after the lecture, and the second test, which was taken after using the system, which indicates that learning did occur during that phase for group two students. In order to be able to properly assess the amount of learning made by the CBI alone, one must compare student results to that of the classroom alone, to avoid the issue of confounding by assessing students who were exposed to the same material twice. To assess this, one may examine the scores by using the total average, which is approximately 10.5, calling this a borderline figure. Then a count of how many students scored above this borderline is given for each group as follows: group one has six students above this line, while group two has 11 students, and group three has 10, with all groups composed of the same total number of students (15). This shows that the third group, which took the CBI package alone, and the second group, which had both the classroom lecture and the CBI package exposure, are close. It also underlines how much the second group improved their test results after taking the CBI and in the same time showing that the first group had not improved much only with the lecture learning.

However, this was not sufficient to be able to pinpoint the strengths of the system. Therefore, a more detailed analysis was done of student performance in the individual questions

of test one and test two. Questions were placed carefully to test the various types of knowledge students may acquire. The largest differences were observed in the effects of the CBI on procedural knowledge with the question "*Using an example, explain the stack concept and its possible use*." In group two there was a significant improvement made from the pretest to posttest with F=58 and $\underline{p}$<.000. When comparing group one to group two students on the same questions, results turned out to be in favor of the classroom only group with an F=5.02 and $\underline{p}$ <.03. This result indicates that using the system following a classroom lecture reinforces student comprehension of how the concept relates to the real world, while teaching them through the CBI alone produces a worse effect than that in the classroom perhaps because it "limits" their imagination to the graphical representations shown in the system (Al Balooshi & Alkhalifa, 2002). Classroom lectures introduce students to the concepts allowing them all the freedom to select all types of applications, which is in some ways overwhelming. The use of the system, on the other hand, produces a safe haven to test their ideas and strongly pursue the examples they can imagine, which helps them arrive at a solid procedural understanding of the concepts.

For the third dimension, the same survey distributed to students reflected their enthusiasm to incorporate the use of this educational system into the course curriculum as is shown by achieving a rate of 5.085 on a scale of 6. They also voiced some comments requesting more examples that go more in depth into the theory to solve more complex questions that they face during the course. Other affective measures were included asking students what they feel about the course materials, level of difficulty and necessary prerequisites, and how much they learned from it.

FINE-GRAINED EVALUATION

The evaluation framework proposed here classifies the evaluation question as to focus on one or more of three specific dimensions. The first dimension focuses on the design issues to ensure avoiding asking the wrong question as was done in studies (Byrne, Catrambone, & Stasko, 1999; Lawrence, Badre, & Stasko, 1994) that did not take into account that a sequence of images are translated as animation (Freyd, 1987).

The second dimension evaluates multimedia educational software at a finer level of detail than what was previously followed. This was done carefully by asking clear questions of how groups differ from each other, causes of differences, and how to assess the level of learning attained using students' total average grade. More detailed results identified differences in procedural knowledge and not in declarative knowledge.

Last but not least, the same evaluation survey utilized for the first dimension contained measures for the motivational issues and how students rate the usefulness of the system from a subjective point of view.

FUTURE TRENDS

A number of researchers, including Magenheim and Scheel (2004), found this evaluation procedure credible enough to base future work upon it. On the other hand, we have renewed interest in the system architecture dimension as evident in the work done by Jones and Cockton (2004).

This is clear evidence that the ideas presented here are gradually finding their way to attract researcher attention to determine and clarify their research questions clearly and formulate them according to the context of the presented system and educational material without neglecting any of the factors that may influence results.

CONCLUSION

A three-dimensional framework is presented as a means to evaluating multimedia educational software in order to resolve the shortcomings of the current evaluation techniques. It differs from the other in that it adds a dimension that was previously tested but never given a title in addition to seeking a clearer more fine-grained analysis of the comparisons made and statistical analysis carried out. In other words, this framework offers a step-by-step guide of a credible evaluation technique of multimedia systems that is currently accepted by peer researchers.

KEY TERMS

Cognition: The psychological result of perception, learning, and reasoning.

Cognitive Load: The degree of cognitive processes required to accomplish a specific task.

Cognitive Science: The field of science concerned with cognition and includes parts of cognitive psychology, linguistics, computer science cognitive neuroscience, and philosophy of mind.

Cognitive Tool: A tool that reduces the cognitive load required by a specific task.

Declarative vs. Procedural Knowledge: The verbalized form of knowledge versus the implemented form of knowledge.

Learning Style: The manner in which an individual acquires information.

Multimedia System: Any computer delivered electronic system that presents information through different media that may include text, sound, video computer graphics, and animation.

ENDNOTES

1 This term is defined in the Analysis of Results section.

2 This framework is an enhanced version of a previously published framework (Alkhalifa, 2005) with most changes resulting from further work by either the author or other researchers who referenced the author's work.

Collaborative Virtual Environments

Thrasyvoulos Tsiatsos
Aristotle University of Thessaloniki, Greece

Andreas Konstantinidis
Aristotle University of Thessaloniki, Greece

INTRODUCTION

Computer supported collaboration is one of the most promising innovations to improve teaching, learning, and collaborating with the help of modern information and communication technology (Lehtinen & Hakkarainen, 2001). Continuous enhancements in computer technology and the current widespread computer literacy among the public have resulted in a new generation of users (less so in developing countries) that expect increasingly more from their e-learning experiences. To keep up with such expectations, e-learning systems have gone through a radical change from the initial text-based environments to more stimulating multimedia systems (Monahan, McArdle & Bertolotto, in press).

Generally a collaborative virtual environment (CVE) can be defined as a computer-based, distributed, virtual space or set of places. In such places, people can meet and interact with others, with agents (artificial intelligence), or with virtual objects. CVEs might vary in their representational richness from 3D graphical spaces, 2.5D and 2D environments, to text-based environments. Access to CVEs is by no means limited to desktop devices, but might well include mobile or wearable devices, public kiosks, and so forth (Churchill, Snowdon & Munro, 2001). CVEs are a subset of Virtual Environments (VEs) in that only VEs which support collaborative operations can be considered CVEs. The two primary uses of CVEs are for collaborative learning and/or collaborative work in either educational and/or professional environments.

Computer supported collaborative learning (CSCL) is an umbrella term for a variety of approaches in education that involve the joint intellectual effort by students or students and teachers and that require the use of computer and communication technology. Researchers (e.g., Ahern, Peck & Laycock, 1992; Bruckman & Hudson, 2001; Singhal & Zyda, 1990) have proven the effectiveness of collaborative learning compared to other educational practices (e.g., competitive or personalized learning), praising this method's way of aiding the acquisition of higher level cognitive abilities, problem solving abilities, ease in scientific expression and the development of communication, social and higher order thinking skills.

The most important advantages of using CSCL are discussed in Bruckman et al. (2002). It is mentioned that through CSCL teacher/student interactions become more balanced and that there is also some evidence to suggest that gender differences are reduced in online environments. In addition, students exhibit higher levels of attention and appear more honest and candid toward those in a position of authority. Learning becomes more student-oriented, thus increasing the likelihood that students will absorb and remember what they learn.

On the other hand, computer supported collaborative work (CSCW) is a generic term, which combines the understanding of the way people work in groups with the enabling technologies of computer networking, and associated hardware, software, services and techniques (Wilson, 1991). Although some authors consider CSCW and groupware as synonyms, others argue that that while groupware refers to real computer-based systems, CSCW focuses on the study of tools and techniques of groupware as well as their psychological, social, and organizational effects. For example, researchers Hiltz and Turoff (1993) conclude that the social connectivity of users who adopt a computer-mediated communication system increases notably. They also found a strong tendency toward more equal participation, and that more opinions tended to be asked for and offered.

The purpose of this chapter is to present a concise yet complete overview of collaborative virtual environments. In the following sections we will discuss the technological evolution of CVEs, their basic characteristics and architectures, and the tools and services integrated within them. Finally, there will be a brief mention of the design challenges facing CVE designers and of future trends with which CVE functionality will be extended.

BACKGROUND

The first virtual worlds were text based, in that their environments and the events occurring within them were described using words rather than images. Their primary use was for entertainment and specifically as fantasy role-playing games. Virtual worlds are often called MUDs (Multi User Dungeons) because MUD was the name of the first one to prosper. Its author was Roy Trubshaw. In 1989, TinyMUD was one of the first virtual worlds to focus on the social aspects of these environments. Users could create new locations and objects,

spending most of their time creating and talking about their creations. In 1990 MOO (MUD, Object Oriented), introduced a fully functional scripting language and allowed users of social-oriented virtual worlds to add not only objects, but also powerful functionality to the environment as it ran. MOO's descendents have found a niche in the educational world, as they are easy to use and can demonstrate the principles of programming to new users. Also in 1990, TinyMUSH, among other things, introduced event triggering and software automatons (known as puppets then and as agents today). In 1993, before the advent of the World Wide Web, MUDs constituted some 10% of the Internet (Bartle, 2004).

Text based collaboration started around 1990 with a system called "Reality Built for Two"; there is one system in 1987 by Sim et al. which can be classified as a Collaborative Virtual Environment, but was built using dedicated hardware for military training purposes (Joslin, Di Giacomo & Magnenat-Thalmann, 2004). It is interesting to note that CVE systems have been around long before the World Wide Web was invented, but have not been used as extensively by the general public for personal or commercial activities. This is possibly because of their complexity and base requirements being much more demanding, or possibly the content being much harder to create. Reality Built for Two (RB2) was a development platform for designing and implementing real-time virtual realities (Blanchard & Burgess, 1990). Development was rapid and interactive in RB2. Behavior constraints and interactions could be edited in real time with the system running. Changes made to interactions in the world were seen immediately in Virtual Reality (VR). The primary user input devices in use in RB2 were the DataGlove which allowed gestural and direct manipulation of the environment, and the Polhemus tracker for head tracking.

After 1990, the popularity of CVEs remained almost stable with the appearance of three to four new systems each year. A more substantial increase in popularity was observed in 1995 with the release of systems such as RING, Virtual Society, MASSIVE and SmallView. CVE popularity peaked in 1997 with new developments generally falling off ever since (Joslin et al., 2004). It seems 1997 can be seen as the point of maturity for CVEs. The decline of the scientific community's interest in the theoretical basis of CVEs has seen a rise in commercial CVE products today. Contemporary systems include Active Worlds (released in 1997), There (released in 2003, http://www.there.com/), I-maginer (http://www.i-maginer.fr), Workspace3D (http://www.tixeo.com), Second Life and Croquet.

The most successful CVE today seems to be Second Life with over four million total sign-ups. Released in 2003, the I nternet-based virtual world Second Life (SL, http://secondlife.com/) came to international attention via mainstream news media in late 2006 and early 2007. Users in SL can explore, meet other users, socialize, participate in individual and group activities and create and trade items

Table 1. The CSCW matrix

	Same Time (synchronous)	**Different Time (asynchronous)**
Same Place (collocated)	**Face-to-face interactions** – decision rooms, single display groupware, shared table, wall displays, room ware …	**Continuous task** – shift work groupware, project management, and so forth
Different Place (remote)	**Remote interaction** – video conferencing, instance messaging, chats/ MUDs/ virtual worlds, shared screens, multi-user editors, and so forth	**Communication and coordination** – email, bulletin boards, blogs, asynchronous conferencing, group calendars, workflow, version control, wikis, and so forth

or services from one another. Although signing up is free in SL, several activities such as the building of items and use of land are not.

On the other hand, Croquet (http://www.croquetconsortium.org/) is an open source cross platform 3D environment designed for rich interaction and simulation, with a combination of powerful graphics and multiuser collaborations (McCahill, 2004). Although Croquet started officially in 2001, it attracted most attention in 2006 with the release of the Croquet SDK Beta as open source.

ISSUES CONCERNING THE CHARACTERISTICS AND DESIGN OF CVES

Basic Characteristics

Computer supported collaboration systems can be categorized based on the spatial and temporal coexistence of the participants and their interactions, as shown in the CSCW matrix (Table 1) introduced in 1988 by Johansen (Baecker, 1995). Different forms of groupware, communication tools and collaboration activities can be organized in this way. In this matrix CVEs are located in the bottom left quadrant since they facilitate a remote yet synchronous form of collaboration.

VEs provide: (a) a shared sense of space, creating the illusion to the users that they are located in the same place, (b) a shared sense of presence, in relation to the virtual representation of the users that is commonly realized through anthropomorphic personas called avatars. Furthermore, VEs provide communication methods, such as gestures, text, and audio-visual cues. Finally, VEs support a sharing functionality, allowing participants to distribute workload between them (Singhal & Zyda, 1999) and, for example, cobrowse the Web and/or coauthor a document.

According to Bouras and Tsiatsos (2006), a CVE is an environment in which the users participating have different roles and privileges. The educational interactions (interactions which are intellectually beneficial) in the environment transform the simple virtual space into a communication space, meaning that multiple communication channels are available to the users, allowing them to interact in multiple ways with each other inside the virtual environment. Information in a CVE is represented in multiple ways that can vary from simple text to 3D graphics which usually visualize recognizable elements from the real world. On the pedagogical side, students are not passive users but can interact with each other and with the virtual environment which also supports the possibility of implementing multiple learning scenarios. On the technical side, the system that supports the CVE incorporates multiple technologies such as network architectures and 3D graphics engines.

Architectures

The network architectures that support CVEs can be categorized into: (a) client-server architectures, where the clients communicate their changes to one or more servers and these servers, in turn, are responsible for the redistribution of the received information to all connected clients and (b) peer-to-peer architectures, where the clients transmit their modifications and updates of the virtual world directly to all other connected clients (McGregor, Kapolka, Zyda & Brutzman, 2003). The client-server model is the simpler of the two, yet it cannot support high scalability as there is a central point of failure: the server. On the other hand, the peer-to-peer architecture's scalability is restricted by the network properties. It should be noted that hybrid solutions can be adopted, so as to cater for the specific needs and the type of the application that each system aims to support. There are hybrid architectures, which adopt the simple client-server model with peer-to-peer communication among groups of servers or with server hierarchies, where certain servers act as clients to others. Also, the client-server and peer-to-peer structures can be integrated into peer-server architectures, where some data packets are transmitted through certain nodes using peer-to-peer while others through a server.

When client server architecture is utilised to provide for the virtual environment of the CVE, it usually consists of layers. For example Bartle (2004) mentions that the most basic and fundamental layer handles things like memory management, parsing, data structures, input/output queuing, packet handling, and so forth. This layer makes available two foundation concepts: entities that make up the world and the association of input/output with some of those entities. The second layer up defines the physics of the virtual world, such as mass, movement, communication, and so forth. The next layer up adds world-specific concepts and functionality consequent of the physics defined in the previous layer. In the final layer actual data items define the individual world, differentiating it from all the worlds that could possibly be defined.

Collaborative Virtual Environments Tools and Services

In order to support the collaborative process, CVEs must be equipped with a multitude of tools and services catering for communication, file sharing, coauthoring of documents and cobrowsing of the Internet. Current collaborative learning environments offer many helpful tools which constitute and augment their pedagogical value. Typical tools and services

of CVEs include desktop conferencing, videoconferencing, electronic mail, blogs, forums, chat, meeting support systems, voice applications, workflow systems, group calendars and intelligent agents (Goebbels, Lalioti & Göbel, 2003). Based on the features and advantages of CVEs in general, these can be separated into five categories: tools for communication, management and coordination, teacher and student support, shared applications and avatar functions. These categories will be analyzed in the following paragraphs.

Email technology is the most broadly used method for text based asynchronous communication today (Ballesteros, 2006). In most contemporary CVEs access to email is usually available through an external application, or through an embedded Web browser. The same goes for discussion forums. An e-mail-based learning environment can be used as a very open system for spontaneous collaboration or it can be more organized, controlled, and tutored (Ahern et al, 1992). Other tools for communication include chat, videoconference, avatar gestures and VoIP. Many users deem the VoIP service necessary, since the ability to send sound messages strengthens the psychological sense of presence in the virtual world (Monahan et al., 2007), without increasing costs and bandwidth requirements.

Applications which can be shared between users include, but are not limited to, word processors, internet browsers, whiteboards, Computer Aided Design (CAD) and brainstorming tools. Also, many CVEs host links to multiple external sources of information, such as the Internet and third party applications.

Another group of tools concern the collaboration and interaction of teachers with students within virtual environments. The tools in this group are relevant with class management tasks and the evaluation of both the students and the teaching procedure in general. Other tools include voting and argumentation tools, RSS feeds and wikis.

For the efficient coordination of a collaborative process or a collaborative learning session, the way the users gain access to the common workspace is very important. Several methods have been employed including action key, attention focus and automatic agents. In the action key method, the user possessing the action key is the only one with access to the common workspace. The rest of the users can ask to obtain the key from the current owner. Attention focus is the ability to focus the attention of the students by the teacher. Here, the user who has access to the medium can lock the first person perspectives of all the other users to a certain object. Finally automatic agents are intelligent entities that can monitor students' progress and manage the system more efficiently. They can also be used to personalize the learning experience for each user tailoring the interface or the delivery of learning content to their individual preferences.

Inside a CVE users interact with the virtual world and its inhabitants through an avatar. Some of the basic operations that avatars can perform are interacting with objects and other users, navigating the virtual environment by walking, flying or teleporting, and communicating through gestures and facial expressions. Many CVEs allow the user to directly manipulate their avatar's appearance and thus enhance the feeling of trust and security between the members of a team.

Design Challenges

The design challenges faced by CVE developers vary. Some concern the technical requirements of the virtual environment, such as system responsiveness and network bandwidth, while others have to do with the users themselves or the type of interfaces that are realized.

Concerning technical issues, high system responsiveness is perceived as having a very positive impact on collaboration. Even downsizing the application in order to decrease the CPU load is recommendable. Good system responsiveness is guaranteed if all inputs and outputs are processed and rendered within less than 50 milliseconds (Goebbels et al., 2003). A typical issue is that of the virtual world slowing or stopping when new scene components are loaded. Given the user's expectation of free movement at all times, this suggests to the user that an error has occurred, or that the operation failed.

An inherent failure of multi-user applications (and therefore of CVEs also) is that they never provide precisely the same benefit to every group member (Grudin, 1991). For instance the fact that low achievers progressively become passive when collaborating with high achievers must be taken into account when organizing groups (Dillenbourg, Baker, Blaye & O'Malley, 1996). Another consideration is that a group of three is less effective because it tends to be competitive, whilst pairs tend to be more cooperative.

Application issues are generally concerned with the affordances of objects and the lack of help with the virtual environment itself. They are broad in nature, from problems with objects whose operation is not obvious, to wider topics such as how best to represent group services to group members.

Interaction and interface issues challenging designers have to do with some tasks being less "shareable" than others and that although users might find 3D interfaces enjoyable, recognizable, and memorable because they improve spatial memory use, they can also be distracting and confusing because of increased visual complexity.

Finally, empirical testing confirms that virtual reality systems induce physical symptoms and effects that need to be compensated for. In addition, more research is needed in order to assess social discomfort levels generated in a CVE and caused by participants working concurrently with real people and their avatars.

FUTURE TRENDS

Although the commercial success of CVEs has proven their effectiveness in entertainment, for real world organisational users there is the matter of fitness for purpose, and consequently, confidence in such novel technology. CVEs must show they can deliver safety-critical training to senior professionals within simulated real life working environments and through this lead to a validation by a recognized training and standards body as being of a suitable standard. Finally, CVEs must be accepted by the trainers, trainees and employers who will have to use them (Turner & Turner, 2002).

In order to meet the criteria listed previously, CVEs must enhance the sense of realism through advanced graphics capabilities and the incorporation of pioneering technologies such as haptic technology and brain computer interfaces. Strong utility of pure 3D interfaces for medical, architectural, product design, and scientific visualization means that interface design for pure 3D remains an important challenge.

Furthermore, server and network technology needs to be augmented in order to efficiently support large-scale applications. The term "large-scale" refers both to the data size (in terms of virtual space and graphics) as well as to the concurrent number of users. In conclusion, the same way the Internet is driven by standards, there should also be work towards the standardization of protocols for designing, developing and evaluating CVEs (Ballesteros, 2006).

CONCLUSION

In this chapter we presented some basic information concerning collaborative virtual environments. The areas presented were the evolution of CVEs in the last three decades, their characteristics and the fundamental architectures available for their development, as well as some significant issues that should be taken into account when designing a CVE. It seems that although many challenges remain to be overcome, the future social and educational use of CVEs will aid in engaging students in more meaningful ways than are typically seen in the classroom and in revolutionizing the pedagogical process.

KEY TERMS

Brain Computer Interface: A novel technology which allows the construction of a communication pathway between an organisms brain and a computer

Collaborative Virtual Environment (CVE): An extension of a networked virtual environment which aims at a collaborative task. CVEs aim to provide an integrated, explicit and persistent context for cooperation that combines both the participants and their information into a common display space. These objectives create the potential to support a broad range of cooperative applications such as training.

Computer Supported Collaborative Learning (CSCL): A variety of approaches in education that involve the joint intellectual effort by students or students and teachers and require the use of computer and communication technology.

Computer-Supported Cooperative work (CSCW): Is a computer-assisted coordinated activity carried out by groups of collaborating individuals.

Groupware: Is software that accentuates the multiple user environments, coordinating and orchestrating things so that users can "see" each other and yet not conflict with each other.

Haptic Technology: Refers to technology which enables users to interact with virtual environments through hand motions and receive feedback through the sense of touch

MUD Object Oriented (MOO): Refers to any MUD that uses object oriented techniques to organize its database of objects and allow players to create objects and alter their functionality.

Multiple User Dungeon (MUD): Was the name of the first VE to prosper and has been used ever since to refer to a multi-player computer game that combines elements of role-playing games, hack and slash style computer games and social chat rooms.

Virtual Environment (VE): A computer-generated simulation which is to some degree shared and persistent, allowing its users to interact with it and with each other in real time.

Virtual Reality (VR): A technology which allows a user to interact with a computer-simulated environment.

Combination of Forecasts in Data Mining

Chi Kin Chan
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

The traditional approach to forecasting involves choosing the forecasting method judged most appropriate of the available methods and applying it to some specific situations. The choice of a method depends upon the characteristics of the series and the type of application. The rationale behind such an approach is the notion that a "best" method exists and can be identified. Further that the "best" method for the past will continue to be the best for the future. An alternative to the traditional approach is to aggregate information from different forecasting methods by aggregating forecasts. This eliminates the problem of having to select a single method and rely exclusively on its forecasts.

Considerable literature has accumulated over the years regarding the combination of forecasts. The primary conclusion of this line of research is that combining multiple forecasts leads to increased forecast accuracy. This has been the result whether the forecasts are judgmental or statistical, econometric or extrapolation. Furthermore, in many cases one can make dramatic performance improvements by simply averaging the forecasts.

BACKGROUND OF COMBINATION OF FORECASTS

The concept of combining forecasts started with the seminal work 37 years ago of Bates and Granger (1969). Given two individual forecasts of a time series, Bates and Granger (1969) demonstrated that a suitable linear combination of the two forecasts may result in a better forecast than the two original ones, in the sense of a smaller error variance. Table 1 shows an example in which two individual forecasts (1 and 2) and their arithmetic mean (combined forecast) were used to forecast 12 monthly data of a certain time series (actual data).

The forecast errors (i.e., actual value – forecast value) and the variances of errors are shown in Table 2.

From Table 2, it can be seen that the error variance of Individual Forecast 1, Individual Forecast 2, and the Combined Forecast are 196, 188, and 150, respectively. This shows that the error variance of the combined forecast is smaller than any one of the individual forecasts and hence demonstrates an example how combined forecast may work better than its constituent forecasts.

Table 1. Individual and combined forecasts

Actual data (monthly data)	Individual Forecast 1	Individual Forecast 2	Combined Forecast (Simple Average of Forecast 1 and Forecast 2)
196	195	199	197
196	190	206	198
236	218	212	215
235	217	213	215
229	226	238	232
243	260	265	262.5
264	288	254	271
272	288	270	279
237	249	248	248.5
211	220	221	220.5
180	192	192	192
201	214	208	211

Note: The individual forecasts are rounded to the nearest integers as the actual data are in integers.

Table 2. Forecast errors and variances of errors

Errors of Individual Forecast 1	Errors of Individual Forecast 2	Errors of Combined Forecast
1	-3	-1
6	-10	-2
18	24	21
18	22	20
3	-9	-3
-17	-22	-19.5
-24	10	-7
-16	2	-7
-12	-11	-11.5
-9	-10	-9.5
-12	-12	-12
-13	-7	-10
Variance of errors = 196	**Variance of errors = 188**	**Variance of errors = 150**

Bates and Granger (1969) also illustrated the theoretical base of combination of forecasts. Let X_{1t} and X_{2t} be two individual forecasts of Y_t at time t with errors

$$e_{jt} = Y_t - X_{jt}, \quad j = 1,2$$

such that

$$E[e_t] = 0, \quad E[e_{jt}^2] = \sigma_j^2 \quad j = 1,2$$

and

$$E[e_{1t}e_{2t}] = \rho\,\sigma_1\sigma_2$$

where σ_j^2 is the error variance of the j^{th} individual forecast and ρ is the correlation coefficient between the errors in the first set of forecasts and those in the second set.

Consider now a combined forecast, taken to be a weighted average of the two individual forecasts,

$$X_{ct} = kX_{1t} + (1-k)X_{2t}.$$

The forecast error is

$$e_{ct} = Y_t - X_{ct} = ke_{1t} + (1-k)e_{2t}.$$

Hence the error variance is

$$\sigma_c^2 = k^2\sigma^2 + (1-k)^2\sigma_2^2 + 2k(1-k)\rho\,\sigma_1\sigma_2. \qquad (1)$$

This expression is minimized for the value of k given by

$$k_0 = \frac{\sigma_2^2 - \rho\,\sigma_1\sigma_2}{\sigma_1^2 + \sigma_2^2 - 2\rho\,\sigma_1\sigma_2},$$

and substitution into equation (1) yields the minimum achievable error variance as

$$\sigma_{c0}^2 = \frac{\sigma_1^2\sigma_2^2(1-\rho^2)}{\sigma_1^2 + \sigma_2^2 - 2\rho\,\sigma_1\sigma_2}.$$

Note that $\sigma_{c0}^2 < \min(\sigma_1^2, \sigma_2^2)$ unless either ρ is exactly equal to σ_1 / σ_2 or σ_2 / σ_1. If either equality holds, then the variance of the combined forecast is equal to the smaller of the two error variances. Thus, a priori, it is reasonable to expect in most practical situations that the best available combined forecast will outperform the better individual forecast—it cannot, in any case, do worse.

Makridakis et al. (1982), Makridakis and Hibon (2000), Makridakis and Winkler (1983), Newbold and Granger (1974), Terui and Van Dijk (2002), and Winkler and Makridakis (1983) have also reported empirical results that show that combinations of forecasts outperformed individual methods. However, Koning, Franses, Hibon, and Stekler

(2005) commented that one of the conclusions of the M3-competition (Makridakis & Hibon, 2000) that a combination of methods is better than that of the methods being combined was not proven.

Since Bates and Granger (1969), there have been numerous methods proposed in the literature for combining forecasts. However, the performance of different methods of combining forecasts varies from case to case. There is still neither a definitive nor a generally accepted conclusion that sophisticated methods work better than simple ones, including simple averages. As Clemen (1989, p. 566) commented, "In many studies, the average of the individual forecasts has performed the best or almost best." Others would agree with the comment of Bunn (1985, p. 152) that the Newbold and Granger (1974) study and that of Winkler and Makridakis (1983) "demonstrated that an overall *policy* of combining forecasts was an efficient one and that if an *automatic* forecasting system were required, [for example], for inventory planning, then a linear combination using a 'moving-window' estimator would appear to be the best overall."

DATA MINING AND COMBINATION OF FORECASTS IN INVENTORY MANAGEMENT

Data mining is the process of selection, exploration, and modeling of large quantities of data to discover regularities or relations that are at first unknown with the aim of obtaining clear and useful results for the owner of the database.

The data mining process is deemed necessary in a forecasting system, and it is particularly important in combining forecasts for inventory demands. Errors in forecasting demand can have a significant impact on the costs of operating and the customer service provided by an inventory management system. It is therefore important to make the errors as small as possible. The usual practice in deciding which system to use is to evaluate alternative forecasting methods over past data and select the best. However, there may have been changes in the process, generating the demand for an item over the past period used in the evaluation analysis. The methods evaluated may differ in their relative performance over subperiods of the method that was best only part of the time, or in fact never the best method and perhaps only generally second best. Each method evaluated may be modeling a different aspect of the underlying process generating demands. The methods discarded in the selection process may contain some useful independent information. A combined forecast from two or more methods might improve upon the best individual forecasts. Furthermore, the inventory manager typically has to order and stock hundreds or thousands of different items. Given the practical difficulty of finding the best method for every individual item, the general approach is to find the best single compromise method over a sample of items, unless there are obvious simple ways of classifying the items, by item value or average demand per year, and so forth. Even if this is possible, there will still be many items in each distinct category for which the same forecasting method will be used. All of the points made on dealing an individual data series, as earlier, apply with even more force when dealing with a group of items. If no one individual forecasting method is best for all items, then some system of combining two or more forecasts would seem *a priori* an obvious approach, if the inventory manager is going to use the same forecasting system for all items.

The need for data mining in combining forecasts for inventory demands comes from selection of sample items on which forecasting strategy can be made for all items, selection of constituent forecasts to be combined, and selection of weighting method for the combination.

The selection of the sample items is a process of exploratory data analysis. In this process, summary statistics such as mean and coefficient of variation can be investigated so that the sample selected could represent the total set of data series on inventory demands.

The selection of constituent forecasts to be combined is the first stage of model building. The forecasting methods might be selected from popular time series procedures such as Exponential Smoothing, Box-Jenkins, and Regression over Time. One could include only one method from each procedure in the linear combination, as the three groups of methods were different classes of forecasting model and thus might contribute something distinct, whilst there was likely to be much less extra contribution from different methods within the same class. It might also be useful to attempt to tailor the choice of methods to particular situations. For example, Lewandowski's FORSYS system, in the M-competition (Makridakis et al., 1982), appears to be particularly valuable for long forecast horizons. Thus it might be a prime candidate for inclusion in situations with long horizons but not necessarily in situations with short horizons. It is also important to note that combining forecasts is not confined to combination utilizing time series methods, as was the case in this research. The desire to consider any and all available information means that forecasts from different types of sources should be considered. For example, one could combine forecasts from time series methods with forecasts from econometric models and with subjective forecasts from experts.

The second stage of model building is to select the weighting method for the combination of forecasts. The weighting method could be simple average or "optimal" weighting estimated by a certain approach, for instance, the constrained OLS method (Chan, Kingsman, & Wong, 1999b). Furthermore, the "optimal" weights obtained could either be fixed for a number of periods (Fixed Weighting) or re-estimated every period (Rolling Window Weighting)

(Chan, Kingsman, & Wong, 1999a, 2004). The selection process can then be done by comparing the different weighting methods with an appropriate performance measure. In the case of inventory management, the carrying of safety stocks is to guard against the uncertainties and variations in demand and the forecasting of demand. These safety stocks are directly related, or made directly proportional, to the standard errors of forecasts. If, as is usually the case, a stock controller is dealing with many items, it is the performance across the group of items that matters. Hence, the sum of the standard errors of the forecasts, measured by the sum of the root mean squared errors over all the items, can be used to compare the results between the different weighting methods. The ultimate aim is to find the one best overall method for the weighting process to use for all the items.

FUTURE TRENDS

The usual approach in practical inventory management is to evaluate alternative forecasting methods over a sample of items and then select the one that gives the lowest errors for a majority of the items in the sample to use for all items being stocked. The methods discarded in the selection process may contain some useful independent information. A combined forecast from two or more methods might improve upon the best individual forecasts. Studying how to select between methods and their combinations is an important direction of research. For example, the variance of the individual methods may be useful for how to select among methods and their combination. This gives us some insights into the process of data mining. There are a number of well-known methods in data mining such as clustering, classification, decision trees, neural networks, and so forth. Finding a good individual method from our tool kit to handle the data is clearly an important initial step in data mining. Then we should always bear in mind the power in combining the individual methods.

CONCLUSION

There are two kinds of direction to do the combination. The first one is basically a direct combination of the individual methods, such as simple average or "optimal" weighting. The other one is to classify our data first, and then select the weighting method. Classification is always an important aspect of data mining, and combination of forecasts sheds some new light on this. Another important message is that if we are dealing with large data sets, then it is not very worthwhile to find the "best" individual method. Obviously there may not be any best individual at all. A viable alternative is to find several sensible individual methods and then combine them as the final method. This approach will usually relieve much of our effort in finding the best individual method, as justified by the law of diminishing return. More recently, Hibon and Evgeniou (2005) conducted experiments on combining forecasts using 14 individual methods and all 3003 time series from the M3-competition (Makridakis & Hibon, 2000). Their empirical results indicate that,

…when we do not know which individual forecasting method is the best, selecting among combinations in practice leads to a choice that has, on average, significantly better performance than that of a selected individual method. Therefore the advantage of combinations is ... that selecting among combinations is less risky than selecting among individual forecasts. (p. 16)

KEY TERMS

Combination of Forecasts: Combine two or more individual forecasts to form a composite one.

Constrained OLS Method: A method to estimate the "optimal" weights for combination of forecasts by minimizing the sum of squared errors as in a regression framework, and the weights are constrained to sum to one.

Data Mining: The process of selection, exploration, and modeling of large quantities of data to discover regularities or relations that are at first unknown with the aim of obtaining clear and useful results for the owner of the database.

Fixed Weighting: "Optimal" weights are estimated and are used unchanged to combine forecasts for a number of periods.

Highest Weighting: Use the individual forecast procedure that is given the highest weight in the fixed weighting method. This is not a combination. This method is equivalent to choosing the forecasting technique that is the best on the weight estimation period.

Rolling Window Weighting: "Optimal" weights are estimated in each period by minimizing the errors over the preceding *m* periods, where *m* is the length in periods of the "rolling window." The weights are then used to combine forecasts for the present period.

Simple Average Weighting: A simple linear average of the forecasts, implying equal weights for combination of forecasts.

Combining Local and Global Expertise in Services

Hannu Salmela
Turku School of Economics and Business Administration, Finland

Juha Pärnistö
Fujitsu Services, Finland

INTRODUCTION

Since the 1990s, services characterized by a considerable geographical distance between the service person and the customer have become increasingly commonplace. Banks and insurance companies are introducing call centers or service centers to complement, or even replace, the old regional service organization. In the information and communication technology (ICT) sector, companies such as Fujitsu and IBM provide part of the end-user support for their clients from a few centralized call centers. Telecommunications operators have established call centers to serve their customers in conducting basic business transactions. To a large extent, the change in the 1990s can be attributed to ICT development. As call centers and local offices have equal access to all the information, many of the services that previously had to be provided locally can now come from a call center. Furthermore, this decade will bring new technologies that will further enhance capabilities to serve customers over long distances. They will, for instance, provide increasingly rich media for interaction between customers and remote service personnel.

This article investigates factors that need to be considered when moving service production from regional offices to service centers. The empirical part of the study comprises a longitudinal analysis of the ways how Fujitsu Invia, a European IS company within Fujitsu Group, has transformed its service organization. The company has moved a long way from local, site-specific service units to national service centers, and ultimately to a few global centers that provide services to thousands of computer users worldwide. In retrospect, it can be said that the decision to centralize service production turned out to be very successful. However, the reasons why Fujitsu Invia decided to return part of the end-user support closer to customer sites illustrates the complexities associated with centralizing services that were previously produced locally.

BACKGROUND

The ability to centralize services appears to provide a cure for some of the traditional problems of service organizations. Managers of distributed service organizations are painfully aware of the difficulties to maintain an equal level of knowledge among all individual service persons in all regional offices. Centralizing the services to a call center or service center seems like an easy solution for ensuring that all customers receive equal service.

The more complex the services are, the more difficult it becomes to maintain equal knowledge in all regional offices. Hence, the analysis of forces for specialization among service staff is one of the key issues when considering the potential advantages of centralizing service production. Because of the special expertise necessary to solve the specific problems they encounter, professional service providers need a high level of specialization (Koelemeijer & Vriens, 1998). Factors that increase service complexity and thus pressure for specialization include (Mäkelin & Vepsäläinen, 1989), for instance,

1. diversity in customer needs and requests,
2. variety in the services available,
3. the number of situational factors that need to be considered,
4. uncertainty related to customer needs and circumstances,
5. the ability of the customer to define the services, and
6. the complexity of contracts used for governing the transactions.

In essence, complexity makes it difficult for a generalist service person to be able to handle all possible inquiries from all customers adequately. While generalists can deal with routine cases, specialists are needed to handle the difficult and unique cases. The main problem for producing complex services in regional offices is that it is difficult to maintain highly specialized knowledge in every regional office. The most forceful argument for establishing a service center is that the customer with a unique problem can talk

with a global specialist rather than with a local generalist. In addition, the cost savings that can be achieved in regional offices (office space, service personnel) are often sufficient to make the projects acceptable in terms of financial profitability measures.

In this chapter we suggest, however, that managers should also pay considerable attention to the opposite forces as well, that is, forces for providing local service. An obvious reason for providing services locally is that the service has a physical component and thus requires presence close to the customer. There are, however, many soft issues that may also make the customers prefer a local and personal service. In face-to-face discussions, information can be communicated with multiple cues like the sound of voice, facial expressions, and body language. Thus, the richness of communication media is very high (Daft & Lengel, 1986; Huang, Watson, & Wei, 1998). In this respect, the need to rely on conversations over phone or e-mail may have a negative impact on the quality of service.

A TYPOLOGY OF SERVICE ORGANIZATIONS

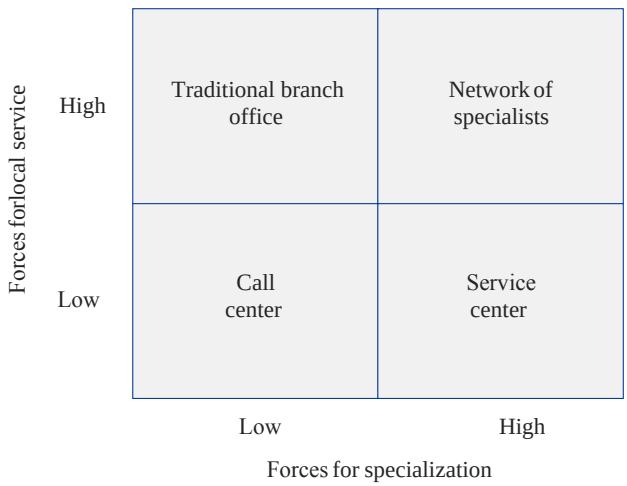
The typology that is suggested in this article is based on forces for providing local service and forces for specialization among service staff. Figure 1 provides a typology of four ideal types of service organizations, each designed to take into account the particular nature of service situations. Each organizational type has its strengths as well as its typical ways of using technology. More often than not, service organizations provide a mix of services for their customers. Some of the services provided may require local presence and some of them specialization. Thus, the objective is not to locate the whole company to a single quadrant. Rather, it is essential to identify all services that are provided to customers and to locate each of them to the right quadrant.

A *traditional branch office* is best suited to relatively simple service situations that require local presence. In simple services, the local generalist service persons are able to provide sufficient service quality. The quality and profitability of service is ensured by replicating and controlling precisely defined activity cycles, personal selling approaches, inventory control patterns, and counter display techniques (Quinn & Paquette, 1990). The possibilities for more stringent specialization are limited because a relatively small number of service personnel in one office have to deal with a full variety of customer inquiries.

In a *call center*, service personnel are centralized to one physical location. Part of the service personnel is moved from regional offices to a physical location to answer a definite set of requests from customers. The change is usually motivated by a managers' observation that some of the simple services are such that customers don't really expect to be served locally. The objectives for establishing a call center are a reduced cost of service, extended contact hours, and standardized quality. As the services provided are fairly simple, there is no need for specialization between service personnel: Any service person can solve any incoming customer inquiry.

A *service center* type of organization takes advantage of the fact that one centralized unit handling inquiries from

Figure 1. Simple typology of service organizations



a large number of customers allows greater specialization of service personnel. Each service person specializes in a particular type of customer problem, and incoming customer inquiries are routed to the best specialist in that area. The assumption is that a specialist with experience in solving similar problems with many companies can provide a more accurate service, particularly with regard to complex customer problems.

A *differentiated network* is the most challenging type of service organization as the service should be simultaneously local and specialized. Neither a local service office nor a centralized service center alone can provide the service. Finding a perfect organization in this quadrant is difficult. Often, organizations in this quadrant rely on a combination of traditional branch offices and centralized service centers (which deal with more complex cases). The potential for using sophisticated information and communication technologies is clearly highest in a differentiated network.

Even if the differentiated network may seem like a less attractive organizational solution, one should keep in mind that in service situations requiring both a local presence and specialization, there may be no alternative. In this situation, a service center may not be able to respond to local needs.

In fact, writings about multinational manufacturing enterprises often favor a differentiated network, which allows local responsiveness in different areas but possesses the control mechanisms to ensure global integration (Bartlett & Ghoshal, 1998; Nohria & Ghoshal, 1997; Prahalad & Doz, 1987). Rather than choosing a fully centralized or decentralized structure, the assets and resources of the company are widely dispersed but mutually supportive to achieve global-scale efficiency, the roles and responsibilities of organizational units are differentiated but interdependent to maximize national flexibility, and its knowledge and initiatives are linked through a worldwide learning capability that assures the efficient development and diffusion of innovations (Bartlett & Ghoshal).

With such practices, the organization provides a context for employees to create and share both tacit and explicit knowledge (Nonaka & Takeuchi, 1995; Polanyi, 1966). The relationships between individual actors are seen as a form of social capital that constitutes a valuable resource (Castells, 1996; Nahapiet & Ghoshal, 1998). In essence, it is asserted that creating and sharing knowledge in a geographically distributed organization is not only possible, but it may even be more effective than knowledge creation in one centralized point.

It seems apparent that many service organizations could benefit from similar practices. In fact, predictions of the impact of IT on service organizations have discussed the "spider's web" type of organization, where local offices are independent but are also able to use each other's knowledge resources as and when needed (Quinn & Paquette, 1990). Similarly, a recent study concluded that the competence to do global product development is both collective and distributed (Orlikowski, 2002).

DEVELOPMENT OF SERVICES IN FUJITSU INVIA

Fujitsu Invia (formerly ICL Invia) is a North-European vendor of information technology products and services. It belongs to Fujitsu Group, which operates in more than 100 countries and has almost 200,000 employees. Because the case describes developments mainly in the Fujitsu Invia, this brand name will be used below hereafter. According to a recently launched strategy, Fujitsu Invia has two main businesses: solutions and services. Solutions business refers to consulting, designing, and constructing information systems. Services business mainly involves operating customer's IT infrastructure as well as business applications. The case description focuses on service business and its evolution during the past few years.

Stage 1: All Services Produced Locally

Only a few years ago, Fujitsu Invia was mainly a hardware vendor. The main service was naturally hardware maintenance, which is typically a local service. The customers were provided with a service number to which they could call and report a hardware failure. The maintenance organization also delivered large installation projects, but not actual end-user support or administrative services (e.g., opening of a new e-mail address). These were typically delivered by the customer's own IT department. Maintenance was organized in regional business units that were quite independent. Customer-call management and the information system for managing service processes were typically shared by business units on a national level. Service coordination between countries was not really required, although certain issues such as pricing and service levels were negotiated on a corporate level.

Stage 2: Initiation of Centralized Service Production

In the second stage, customers became interested in acquiring relatively large service packages so that one vendor takes responsibility for a relatively large and logical part of the IT services. The change was initiated by customers who found managing IT and particularly the IT infrastructure increasingly difficult. These packages typically include a selection of IS services, for example (Weill & Broadbent, 1998),

- on-site support (i.e., solving end users' problems locally),

- help desk (i.e., a contact point where end users' requests are registered and escalated; also attempts to solve requests),
- hardware maintenance (i.e., fixing broken IT equipment),
- systems management (i.e., monitoring and operating systems typically from a centralized service center), and
- service management (i.e., customer reporting, maintaining contracts, improving service quality).

It was not possible to deliver these services by a maintenance organization, so in order to respond to this request, Fujitsu Invia established new business units. Centralized services (mainly help desk and systems management) are used to support the IT infrastructure. Centralization seemed like an obvious solution because of cost-effectiveness requirements and also because the technical expertise is easier to acquire and maintain in specialized teams. The aim was to minimize local service. Maintenance is the only local service. New technologies, like remote management, further improved the quality of service as end users no longer needed to describe the problems in detail. The help-desk specialist simply opened a remote connection to the end user's workstation, diagnosed the problem, and changed the parameters or trained the end user.

Stage 3: End-User Services Return to be Produced Locally

Although a centralized service center is probably the most cost-effective way to organize this type of services, there are also some problems. Customer organizations are not standardized really well even though the technological solutions are. Information systems can be installed in many ways, a situation that has implications on their operation. The quality of service perceived by end users is an even more significant issue. It seems that people prefer to be served locally. The barrier to call to a distant help desk and to an unknown specialist is rather formidable, even within a single nation. Furthermore, transferring the necessary knowledge about local environments to a help desk is not easy. Therefore, a local service organization is frequently required to manage situations like this. The end user easily feels that he or she has to call a help desk, which mainly escalates problems to a local organization. The added value of the service can be questioned.

Because of the problems described above, the help desk has been reorganized in some customer cases so that the first line is either integrated with a local service organization, or the help-desk first line is actually on the customer site. Some members of the on-site support team receive customer service requests, and other members undertake installations and problem solving. The roles within the team can be changed, which means that the on-site support team knows the local customer environment very well, and also the end users know on-site support people. This makes communication easier and the barrier to calling is lower. The solution rate has improved significantly in the pilot cases (in one case, from a level of 50% to 80%), which makes it possible to deliver the same service with fewer resources. At the same time, customer satisfaction improved (in the example case, from 6.5 to 8.4 when measured on a 1 to 10 scale). Their second-line and third-line support is still delivered from a centralized service center during the night and weekends.

Analysis of the Nature of Services

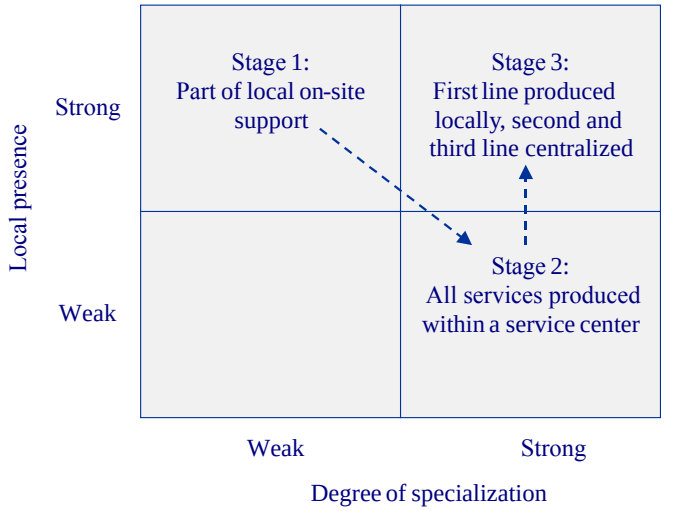
The most problematic service for Fujitsu Invia has been how help-desk services should be organized. What makes it problematic is that on the one hand, end users in customer companies prefer to contact local service persons instead of a distant call center. On the other hand, solving the problems often requires a specialized knowledge that the local service persons lack. The fact that the service should be both simultaneously local and also specialized has made the service difficult to organize, and the attempt to find the best means of organization has been a trial-and-error process (Figure 2).

In the first stage, the idea of providing help-desk services to end users was more or less informal. While end-user satisfaction for services was probably high, the customers felt that the cost of producing services locally was too high. Outsourcing these services to Fujitsu Invia and simultaneously centralizing them was considered an interesting option. The new technologies appeared to provide excellent tools for centralized production of help-desk services. When the service was centralized, however, more was learned about its nature. Service turned out to be more local than what the customers and Fujitsu Invia had expected. In the third stage, help-desk services for large-site customers are based on a combination of local and centralized services. While the experiences from this organizational form are highly positive, it is also more costly and can be applied only to customers with relatively large sites.

FUTURE TRENDS

The sociological theory of the postindustrial society was elaborated more than 3 decades ago (Bell, 1973; Touraine, 1969). In essence, the theory combined three postulates (Castells & Aoyama, 1994): (a) The source of productivity and growth lies in the generation of knowledge, (b) economic activity shifts from goods production to services delivery, and (c) the importance of occupations with a high information and knowledge content will increase.

Figure 2. Organizational arrangements for help-desk services in different stages



Existing postindustrial societies do not fully reflect all predictions made within this theory (Castells, 1996; Castells & Aoyama, 1994). Nevertheless, the significance of various types of services, for example, capital management services, services produced for industrial companies, and social and health services, is increasing. As firms in advanced economies have off-shored manufacturing jobs, the society as a whole has transformed toward a "service economy" model (Castells & Aoyama). Hence, the significance of services in general and knowledge-intensive services in particular is increasing.

The point raised in this paper is that information and communication technology will also induce a major transformation inside the service sector. Increasing telecommunications bandwidth together with its falling cost will enable new applications that are particularly useful for geographically dispersed production of services. In the future, the possibility to use wide computer screens for face-to-face interaction is likely to have a major impact on the way services are organized. Furthermore, the penetration of innovations such as integrated customer databases, e-services, global scheduling systems, call center technology, and virtual learning environments is likely to continue.

The emergence of call centers and service centers provides first visible evidence that the transformation is already taking place. However, as the Fujitsu Invia case illustrates, a call center can be too remote for providing services that require local presence. Hence, the organizational forms required in many services may be more complex than mere centralization of service production. The pressures for local responsiveness are likely to force service organizations to adopt similar complex network structures as some of the advanced manufacturing companies are already using.

This research was, however, based on only one project in one service organization. As service organizations both in the private and public sector have been slow in adopting new technologies, previous IS research has paid relatively little attention to these sectors. The need for further research about the ways in which organizational structures, processes, and information infrastructures are being transformed is evident.

CONCLUSION

This paper provides a simple typology of service situations that can be used when planning IT investments in service organizations. The use of the typology is illustrated through a longitudinal analysis of the ways in which Fujitsu Invia, a European IS service company, has transformed its service organization to better meet customer expectations and needs. Practicing managers can use the typology to analyze organizations' services, to investigate where services ought to be produced, and how ICT technology should be employed to support customer service situations. The authors hope that this article will be useful for people working in companies either providing a service business or aiming to enter a service business in an international context. For research, the typology, its dimensions, and the background theories identified provide some early steps on the way toward a more comprehensive understanding about the impact of ICT on service organizations.

KEY TERMS

Capabilities: Are repeatable patterns of action in the use of assets to create, produce, and/or offer products to a market (Sanchez et al., 1996).

Competence: An ability to sustain the coordinated deployment of assets in a way that helps a firm to achieve its goals (ability here is used in the ordinary language meaning "of a power to do something"; Sanchez, Heene, & Thomas, 1996).

Information: Refers to data that give meaning by reducing ambiguity, equivocality, or uncertainty, or data that indicate that conditions are not presupposed (Huber, 1991).

Knowledge: Refers to interpretations of information, know-how, and beliefs about cause-effect relationships (Huber, 1991).

An entity **learns:** If, through its processing of information, the range of its potential behaviors is changed. The information processing can involve acquiring, distributing, or interpreting information (Huber, 1991).

Perceived Service Quality: Refers to customers' cognitive evaluation of the service across episodes compared with some explicit or implicit comparison standard (Storbacka, Strandvik, & Grönroos, 1994).

Skill: Understood as a special form of capability, with the connotation of a rather specific capability useful in a specialized situation or related to the use of a specialized asset (Sanchez et al., 1996).

Communicability of Natural Language in Software Representations

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

In software engineering, separating problem and solution-level concerns and analyzing each of them in an abstract manner are established principles (Ghezzi, Jazayeri, & Mandrioli, 2003). A software representation, for instance, a model or a specification, is a product of such an analysis. These software representations can vary across a formality spectrum: informal (natural language), semi-formal (mathematics-based syntax), or formal (mathematics-based syntax and semantics).

As software representations become pervasive in software process environments, the issue of their communicative efficacy arises. Our interest here is in software representations that make use of natural language and their communicability to their stakeholders in doing so. In this article, we take the position that if one cannot communicate well in a natural language, then one cannot communicate via other, more formal, means.

The rest of the article is organized as follows. We first outline the background necessary for later discussion. This is followed by the proposal for a framework for communicability software representations that are created early in the software process and the role of natural language in them. We then illustrate that in software representations expressed in certain specific nonnatural languages. Next, challenges and directions for future research are outlined and, finally, concluding remarks are given.

BACKGROUND

The use of natural language in software is ubiquitous. In spite of its well-known shortcomings that are primarily related to the potential for ambiguity or limitations of automatic verifiability, surveys have shown (Berry & Kamsties, 2005) that the use of natural language (such as English) continues to play an important role in software representations. Agile software process environments such as Extreme Programming (XP) (Beck & Andres, 2005) tend to accentuate the use of "lightweight" models such as user stories (for input to software requirements and test cases) (Alexander & Maiden, 2004) that often depend exclusively on the use of natural language. In Literate Programming, natural language prose is used in documenting (explaining) the source code as if it were the work of literature to make it more readable to both humans as well as to machines.

In recent years, there has been an increasing emphasis on the quality of software representations that are created "early" from the point of view of control and prevention of problems that can propagate into later stages. The significance of expressing software requirements in natural language that minimizes ambiguity is emphasized in Berry and Kamsties (2005) whereas a model to study their quality is presented in (Fabbrini, Fusani, Gervasi, Gnesi, & Ruggieri, 1998). However, these efforts do not systematically address the issue of communicability in software representations.

USE OF NATURAL LANGUAGE IN SOFTWARE REPRESENTATIONS

Our understanding of communicability of a software representation is based on the following interrelated hypotheses:

- **Hypothesis 1.** Readability is a prerequisite to communicability, which in turn is a prelude to comprehensibility. The basis for this hypothesis is that if a user has difficulty accessing or deciphering a certain message, then that user will not be able to understand it in part or in its entirety either.
- **Hypothesis 2.** The comprehension of a given software representation in a nonnatural language takes place only when it is first internally translated into the user's natural language of choice. The basis for this hypothesis is that the mode of internalization of some knowledge is the conversion of explicit knowledge into the tacit knowledge. The natural language acts as a "proxy" in this internalization of knowledge inherent in a semiformal/formal software representation.

Using these as the basis, the discussion of software representations that follows rests on the framework given in Table 1.

Table 1 provides necessary but not sufficient conditions for communicability. We now discuss the elements of the framework in detail.

Table 1. A high-level view of communicability of a software representation making use of natural language

Entity	Natural Language Use in Software Representation	
Pragmatic goal	Communicability	Feasibility
External quality attributes	Readability, other	
Internal quality attributes	Secondary notation (labeling, typography)	

Communicability and Semiotics

Semiotics (Nöth, 1990) is concerned with the use of symbols to convey knowledge. From a semiotics' perspective, a representation can be viewed on three interrelated levels: syntactic, semantic, and pragmatic. Our concern here is the pragmatic level, which is the practical knowledge needed to use a language for communicative purposes.

Readability

For our purposes, readability (legibility or clarity) is the ease with which a stakeholder can interpret a piece of text character by character. In general, readability applies to both textual statements and nontextual constructs (say, a histogram), but we shall restrict ourselves to the former.

Secondary Notation

The *secondary notation* (Petre, 1995) is one of the cognitive dimensions and, in our context, defined as the stylistic use of the primary notation (that is, the normative syntax) for perceptual cues to clarify information or to give hints to the stakeholder. The nonmutually exclusive natural language secondary elements that affect the communicability of artifacts are labeling and typography.

- **Labeling.** Labels are comprised of names and, in general, names are not useful by themselves (Laitinen, 1996). For example, names such as `iIndex` for an integer variable reflect their type rather than their purpose or role. Use of the terminology of the application domain in text labels and metaphors (Boyd, 1999) makes it particularly easier for nontechnical stakeholders or users new to language extension to become familiar with the representation. Furthermore, these labels will be more readable and reduce possibilities of misinterpretations if they follow a *natural naming* scheme. Natural naming (Keller, 1990) is a technique initially used in source code contexts that encourages the use of names that consist of one or more full words of the natural language for program elements in preference to acronyms or abbreviations. For example, `QueueManager` is a combination of two real-world metaphors placed into a natural naming scheme.
- **Typography.** The positioning (layout, justification, space between words and lines) of text impacts readability in any document context. Of special concern in our case are the choice and the sequence of characters in the use of text that can affect readability. For example, the characters in a name like `O0lI1` are hard to distinguish and therefore difficult to read. The choice of fonts used for labeling depends on a variety of factors (serif/sans serif, kerning, font size, and so forth) that are important for legibility. Color can be used as an emphasis indicator and for discriminability in text. For example, by associating different colors with text, a stakeholder can be informed of the semantic similarity and differences between operations and attributes in two object classes.

Feasibility

By acknowledging that there are time, effort, and budgetary constraints on producing a software representation, we include the notion of feasibility as an all-encompassing factor to make the framework practical. There are well-known techniques such as Analytical Hierarchy Process (AHP) and Quality Function Deployment (QFD) for carrying out feasibility analysis, and further discussion of this aspect is beyond the scope of this article. Any feasibility analysis, however, also needs to be in agreement with the organizational emphasis on decision support for software engineering in general.

Use of Natural Language in UML

The Unified Modeling Language (UML) (Booch, Jacobson, & Rumbaugh, 2005) is a standard language for modeling the structure and behavior of object-oriented software. The issue of communicability of UML models has been addressed in (Kamthan, 2006).

Natural language enters UML models in several places, especially metadata in the form of annotation (using UML Note construct); class/object, operation, and attribute names; state and transition names; extensions (tags, stereotypes, constraints); and so on. Natural naming can be useful in these cases in general, but particularly when application domain-specific UML extensions are used, as even a UML-aware stakeholder may not be familiar with them. For example, it would be difficult for a reader to decide if the stereotypes `<<TP>>` and `<<TermProc>>` stand for terminal process or terminate process.

We now briefly discuss, from a UML viewpoint, two of the software representations that are typically created earliest in a software process.

Domain Models

A domain model is a vocabulary of the domain, including key concepts, their properties, and the relationships between the concepts necessary to describe the domain sufficiently enough for the purpose at hand. The UML class diagrams at a high level of abstraction (only class and attribute names) and relationships types (association, generalization, aggregation, and composition) are often used for constructing domain models (Larman, 2004), and these constructs are amenable proper use of secondary notation. To distinguish concepts, properties, and relationships different case schemes for their natural names can be adopted. For example, the concept `PaymentSystem --{isComposedOf}-->` the concept `CreditCardSystem` (with attributes/types `cardtype:String` and `valid:Boolean`).

Use Case Models

A use case reflects external observable behavior of the interaction of an actor (human, program) with the system (Kulak & Guiney, 2004). The development of a use case model and domain model go hand in hand (Larman, 2004). Actor names, use case names, and interaction (stimulus, response) message labels can all benefit from proper use of secondary notation. For example, actor names should represent roles rather than designations or positions of people, and use case names should reflect a domain concept rather than a system or interaction mode-dependent entity. Therefore, in a Course Registration System, we would have actor names like `RegisteredStudent` (rather than `JohnSmith`) and use case names like `CourseScheduler` (rather than `CourseInterfaceMenu`).

The natural language use in previous models can be generalized to other UML modeling contexts such as macro- and micro-architecture design models.

Use of Natural Language in XML

The Extensible Markup Language (XML) (Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2004) is a metamarkup mechanism that lends a suitable basis for concrete serialization syntax for expressing information within a software representation. XML is an exemplary of descriptive markup that defines the notion of a document in terms of the ordered hierarchy of content objects. The content objects (elements) of an XML document can be associated with properties (attributes). Both elements and attributes are labeled using mnemonic names, based on author discretion and usually inspired by the domain being addressed.

As an example, the following shows a fragment of a simple Requirements Markup Language (RML). The root element is `rml` (that is an acronym rather than a natural name), `id` and `lang` are attributes (that are abbreviations for identification and language, respectively), while names of other elements and attributes do follow natural naming.

```
<rml version="1.0" xml:lang="en">
 <requirement id="..." type="..." priority-level="...">
  <statement>...</statement>
  <rationale>...</rationale>
 </requirement>
</rml>
```

The descriptive markup in its source form, particularly when there are complex (usually nonlinear) structural relationships involved, is not considered very readable. This is ameliorated to a certain extent by rendering tools that highlight the encapsulated content and suppress the markup. (This, for example, is similar to user agent processing a HyperText Markup Language [HTML] document.) Specifically, XML does not have native support for presentation semantics and therefore relies on ancillary mechanisms such as the Cascading Style Sheets (CSS) for presenting XML documents on different devices and user agents.

Use of Natural Language in OWL

The declarative knowledge of a domain is often modeled using ontology. The Web Ontology Language (OWL) (Dean & Schreiber, 2004) is an ontology specification language designed for the Semantic Web.

An OWL ontology can be used as an alternate to the traditional UML-based domain models with better opportunities for expressiveness and reasoning of knowledge. A typical OWL ontology has classes and relationships between those classes. These classes and relationships can also have their own unique properties modeled in OWL by datatype and object properties, respectively. The labels of (some but not all) classes, relationships, and properties are author defined and could benefit from natural naming. Since OWL is based

Figure 1. A box structure presentation of a Z schema

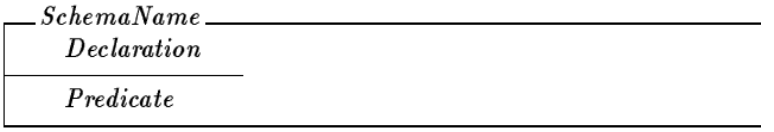

Figure 2. A fragment of the Birthday Book System in Z

$$[NAME, DATE]$$

$$\begin{array}{|l} \textit{BirthdayBook} \\ \hline known : \mathbb{P}\, NAME \\ birthday : NAME \pfun DATE \\ \hline known = \mathrm{dom}\, birthday \end{array}$$

on XML, it inherits both the advantages and limitations of the natural language use in it.

Use of Natural Language in Z

Z is a widely used formal specification language for describing sequential software systems, especially those that are safety critical. Z has traditionally used LATEX mathematically typesetting language for its syntax and relies on first-order predicate logic and typed set theory for its semantics.

The primary construct for structuring and reusing mathematical notation in Z is the schema. A schema is divided into two parts (Figure 1): (1) a declaration part (signature) and (2) a predicate part (axioms). The declaration part of the schema contains variables representing the before and after states, input and outputs. It consists of declarations of the form *s : T*, where *s* is a state variable of type *T*. The predicate part of the schema consists of predicate logic expressions that define the relationships between the declared variables. It defines the relationship between the before and after states of an operation. The names of state variables and operations are chosen by the author of the Z specification and can benefit from proper use of secondary notation.

Figure 2 illustrates part of the well-known example of the birthday book system (Spivey, 2001) in Z. It contains the type definitions and the state of the system modeled as a state space schema. The types `NAME` and `DATE` are defined as basic types. The variable known is a set of names that records the birth dates and birthday is a partial function from `NAME` to `DATE` . The invariant condition states that the variable *known* can be derived from the value of *birthday*. We note the use of natural naming here. For instance, the name `BirthdayBook` is more intuitive than the name `BB` , even though they are both syntactically legal under Z.

Abbreviating a Z schema can have a negative impact on readability. For instance, in Figure 2, the invariant condition states that the variable *known* can be derived from the value of *birthday*. Therefore, although it is possible to specify this part of the birthday book system without any reference to the variable *known*, introducing redundancy by giving a name to the concept *known* makes the specification more readable.

Challenges to Natural Language Use in Software Representation

There are a few challenges in the use of secondary notation pertaining to the use of natural language in software representations.

It is obvious that over use of natural naming will increase the file size of a software representation. Also, once it is known that stakeholders are aware of a certain acronym or abbreviation, natural naming may not be necessary and even counter productive if used. It is straightforward to automatically check for spelling errors in names but not for pseudonyms or homonyms.

As for typography, fonts specifically designed for presentation on paper may in general be hard to read on a computer screen. Often fonts created by the manufacturer of one operating system are not portable to others. Any use of color should take into account the variations in the interpretation of primary colors by computer monitors, contrast between background and foreground, the way people with color vision deficiency read text, and the possibility that diagrams may be printed on a black and white printer.

The automated use of tools eases much of the tedium involved in the task of improving the use of natural language in software representations. Refactoring (Wake, 2004) provides transformation methods for eradicating the undesirables from

software representations while preserving their semantics; and the support for it in modeling tools is on the rise. However, getting consensus on the notion of "semantics" has proven difficult and the process of refactoring "impurities" related to names can only be partially automated.

FUTURE TRENDS

The discussion of the previous section was limited to one natural language setting, namely English. As internationalization of software increases, exploring the role of non-English languages in software representations would be of interest. This is already a challenge if one needs to preserve natural naming in descriptive markup context. For example, an element or attribute name for Québec Déjà Vu has to be written as `Qu&eacute;becD&eacute;j&agrave;Vu`, or a variant thereof, which is not in the spirit of readability support in natural naming. This could even be more challenging in languages where pictographs rather than words are used for communication.

Besides the secondary notation, it would also be of interest to examine the impact of cognitive dimensions pertaining to language characteristics (such as the number of elements in the syntax, their discriminability, frequency of their use in software representations, steepness of the learning curve, and so forth) towards readability in special cases such as UML, XML/OWL, and Z.

Finally, it would be useful to consider the issues related to secondary notation, readability, and eventually communicability of heterogeneous specifications that contain interoperable fragments from different semiformal/formal languages. In such cases, XML could be used as uniform serialization syntax, however, the issue of a common basis for semantics is still a challenge.

CONCLUSION

The computer software stakeholder "family" has broadened over the years to include nondomain experts and noncomputer scientists/software engineers. If documentation was the "castor oil" of the early years of programming (Weinberg, 1998), representations are the castor oil of software engineering today.

The natural and formal representations of software *complement* each other and should be seen as such. We simply cannot abandon our natural language knowledge and skills for the sake of novelty. If the move from informality to formality in software representations is to reduce unpredictability, then we cannot afford "ad hoc-ness" to creep in.

In conclusion, the purpose of software representations from a stakeholder viewpoint is communication and natural language (still) matters. The burden of accomplishing that largely rests on the author. An optimal and systematic means of the use of secondary notation is essential for readability of software representations. Although there is no need to abandon abbreviations or acronyms in names, it is important to realize that succinctness has its trade-offs. A labeling scheme relying on natural naming, when deployed appropriately, provides a means for communicable names in software representations. A feasible plan for typography that takes the stakeholder environment into consideration only strengthens this.

KEY TERMS

Cognitive Dimensions of Notations: A generic framework for describing the utility of information artifacts by taking the system environment and the user characteristics into consideration.

Descriptive Markup: A model of text that focuses on description of information using markup delimiters for consumption by both humans and machines.

Domain Model: A simplified abstraction from a certain viewpoint of an area of software interest.

Formal Specification: A software representation with well-defined syntax and semantics that is usually used to express software requirements or detailed software design.

Natural Naming: A technique for using full names based on the terminology of the application domain that consists of one or more words of the natural language instead of acronyms or abbreviations for elements in a software representation.

Ontology: An explicit formal specification of a conceptualization that consists of a set of terms in a domain and relations among them.

Software Representation: A representation of the system expressed at some level of abstraction, in some modality, and at certain level of formality.

Communication Integration in Virtual Construction

O.K.B. Barima
University of Hong Kong, Hong Kong

INTRODUCTION

In recent times the use of the virtual and allied concepts in the delivery of tasks in the construction industry has received attention in literature (Barima, 2003). However it appears there is the lack of integrated models to support the study and practice of communication in the physical world (the place) and the virtual realms (the space) in the construction industry. This chapter seeks to evolve frameworks which integrate communication paths in the traditional construction place with that of the construction space. This approach may provide an integrated perspective to support the study and practice of communication in the place and space in the construction industry. First, a review of traditional communication theories is done, and then integrated models of the construction place and space are presented, before an integrated matrix of potential communication paths across likely construction work scenarios is given. The suggestions for future studies and the conclusions to this chapter are preceded by a map of the potential communication conflicts (or agreements) in both realms (i.e., physical and virtual).

BACKGROUND

Communication Theories

The study and practice of communication is not a new science. It has been claimed that the formal origin of this science may be traced to an essay in the year 3000 BC (Bryant, 2004). In this essay advice was given to the son of an Egyptian king on how to communicate effectively (Bryant, 2004). Other notable historical contributors to the communication theory are Aristotle, who advanced the works of Heraclitus, and Socrates and Plato in rhetoric theory (Bryant, 2004).

Communication theory has evolved over the years since the days of Aristotle, and seven traditional communication typologies are now established in communications studies. The seven traditions are: (1) the semiotic, (2) sociopsychological, (3) cybernetic, (4) phenomenological, (5) sociocultural, (6) rhetorical, and (7) critical traditions (Craig, 1999; Griffin, 2003). There has been suggestions to add areas like ethical, economic, aesthetic, and so on to the seven communication traditions, however there seems to be a consensus that the seven traditions have the capacity to explain (to a greater extent) the research and practice of communication (Griffin, 2003). The seven traditions of communication theory may be summarized as follows (Craig, 1999; Griffin, 2003):

- Semiotic involves the study of signs. According to the semiotic tradition, meaning does not reside in words or other symbols, but it resides in people. Words, for example, are perceived to be arbitrary symbols with no latent meaning.
- In the sociopsychological tradition communication is seen from the perspective of interpersonal influence. Studies focus on the cause-and-effect factors in relationships, so as to understand which communication behavior will succeed.
- Cybernetic tradition perceives communication as the link which binds the components of a system together, and also as a means for processing information.
- The phenomenological tradition emphasizes (among others) the personal experience of communication and that of others via discourse.
- The sociocultural perspective of communication is very helpful in understanding the gaps in culture which may exist among parties. This tradition perceives communication to involve the creation and realization of social reality, and culture is created and recreated when people talk.
- The rhetorical tradition concerns (among others) the art of public speaking or practical art of discourse.
- The critical theorists are against the use of language to attain imbalances in power; the blind acceptance of scientific methods and empirical findings without criticisms. They theorize communication via discursive reflection.

In relating the summary of the seven communication traditions to the theme of this chapter, communication may be seen as the information processing glue which may connect actors in a construction project together. This process may involve emphasizing: the communication experience of construction actors; interpersonal influences; and the effective communication of meaning which resides in the actors and their effect on successful communication. Communication may also be put under the lens of critical thinking/analysis to advance any desired communication

objectives in a construction project. In a construction project the objectives may include effective results delivery across both the construction space and place. Another important communication aspect may concern ethical issues in the virtual construction project. Ethical issues may require critical attention in the communication processes in both the space and place. With the track of traditional communication studies and practice reviewed, the next section discusses recent developments in communication and the virtual construction project environment.

Communication and Virtual Construction Projects

Communication in the construction industry has been directly or indirectly studied by a number of scholars (Jaggar, Ross, Love, & Smith, 2001). Over the years most of the studies have focused on traditional communication systems which use media like face-to-face collocation (see e.g., Jaggar et al., 2001). However, recent revolutionary developments in the information and communication technology (ICT) sector have provided significant transformations in the manner in which construction project actors are able to communicate and share information. Concepts like virtual construction where construction actors may rely on ICT to function irrespective of time and space to deliver common goals have emerged (Barima, 2003). The two major means used to support communication in virtual construction environments are either via fixed or mobile ICT terminals. For example, fixed computer terminals may be used to access virtual construction project environments like project Web sites via the Internet (Andresen, Christensen, & Howard, 2003). Another access to the virtual construction environment may be via mobile ICT tools. Certain earlier studies on the virtual concept used or implied the use of fixed ICT terminals to access the virtual environment (Caneparo, 2001; Clayton, Warden, & Parker, 2002). This review will emphasize on the most recent trends in this field of communication, and this appears to be on the use of mobile computing in the construction industry. The next paragraph discusses the use of mobile computing in the construction industry.

In recent times scholars have given recognition to the important use of mobile and allied facilities to support the exchange of information in the construction industry (Johanson & Törlind, 2004; Kuladinithi, Timm-Giel, & Görg, 2004; Olofsson & Emborg, 2004; Rebolj & Menzel, 2004; Ward, Thorpe, Price, & Wren, 2004). Various proposals for the empirical use of mobile computing have been made to assist in fieldwork, partner integration, supervision, scheduling, and less formal specifications (Olofsson & Emborg, 2004; Rebolj & Menzel, 2004). Also the utility in the use of portable computing tools like mobile phones to access databases, CAD drawings, and hold video conferences among parties (either on construction sites or via remote means) without being burdened by any extra hardware have been reported (Kuladinithi et al., 2004). At the construction site level, the use of mobile devices to capture and store data for easy and timely access to the flow of information and also manage projects for cost reduction and performance improvement have also been examined (Ward et al., 2004). Despite their noted limitations like communications costs, bandwidth and coverage, and so forth (Johanson & Törlind, 2004; Kuladinithi et al., 2004), mobile computing also appears to hold promise for the future of communication in the construction industry just like the use of fixed terminals/tools.

The Need for Integration

Certain scholars have directly or indirectly noted the potential benefits of the virtual construction concept in task delivery (Barima, 2003; Savioja et al., 2003; Sulankivi, 2004). For example, the use of the virtual concept to support construction works delivery among dispersed parties may potentially provide cost and time savings (Barima, 2003). However, it is also essential to remember that the nature of construction work makes traditional communication media like rich physical face-to-face interaction very important. The two scenarios therefore necessitate the integration of communication processes in both the physical and virtual realms in the construction industry. This will remind, structure, and focus communication studies and practice within the construction industry. In reality the two may support each other, and the strengths of one may be leveraged to support the weaknesses of the other. Further, the rich lessons learned from the traditional systems (in particular) could also aid communication in the construction place and space. The next sections introduce models for the structured integration of the two worlds.

MODEL PRESENTATION

Construction Space and the Construction Place

Rayport and Sviokla (1999) have identified and classified two worlds where business communications may occur as the market place and market space. In a similar analogy construction activities (or value delivery mechanisms) may also occur within the construction place and construction space. Figure 1 demonstrates the two realms of operation. Each of the two realms (construction space and construction place) have two dimensions which may be characterized as mobile and fixed: locations or spaces (see Figure 1). The construction place may refer to the traditional physical places/sites where physical construction activities/delivery may occur, while the fixed and mobile construction space refer to the

use of ICT tools to support task deliveries. The boundaries of communication within the construction place (fixed and mobile) and the construction space (fixed and mobile) are shown in Figure 1.

As may be seen in Figure 1, diverse communication paths may be identified in the diagram. Communication in the fixed and mobile construction places are respectively shown as PF (1…n) and MP (1…w) across varied times (t1, t2, t3, etc.). In a similar manner potential communication across the mobile and fixed construction space are respectively shown as M (1…t) and F (1…z) across times t1, t2, t3 respectively. Communication may be via synchronous or asynchronous modes across varied times (t1, t2, t3, etc.) depending on any given context.

There may also be intra- or inter-boundary communication across the identified construction space and locations. For example, intra-boundary communication between parties in the fixed construction place may be limited to a particular location (e.g., site PF1); or across construction sites PF 1 and PF2 which are within walking distance of each other. Inter-boundary communication may occur between parties across each of the four boundaries. For example, this may occur from a mobile construction space M1 to: a fixed construction space F1, or a fixed construction place PF1, or a mobile construction place MP1. Other potential paths are also shown across all the identified boundaries.

Complex communication paths may also be potentially viable between communication objects at both the construction place and space. Objects may refer to humans or machines, or combinations of both. There may be transactions involving: one-to-one communication, one-to-many communication, many-to-many communication, and so forth either within or across the identified boundaries. For example, machine-to-machine, construction task interaction may occur in an electronic data interchange (EDI) transaction in the procurement of say construction materials, and so on. Human-to-human transaction may also, for example, occur between two parties within the construction space (say chat room).

There may also be differences in communication within (or across) the construction space and places, and not all communication types may suit specific types of information exchanges. Time may also become a critical dimension in the choice of any type of communication (i.e., synchronous/asynchronous) within the identified boundaries in the diagram (Figure 1) to suit any given context. Communication across the identified boundaries may also sometimes require critical thought. For example, what may be the effect of differences in culture, language, and so forth on the communication of meaning across potential diverse geographic distances? Ethical issues on potential use of information (which may be easily gathered and stored) may also be another dimension for critical consideration, especially in the space. The next section presents a matrix of potential communication paths across various scenarios and also potential conflicts (or agreements) in communication.

Matrix of Potential Communication Paths

Many types of communication may exist at different operational levels in the construction project process. Table 1 shows a matrix of potential communication paths across varying traditional levels and functional jobs within a construction project. This matrix may be combined with the concept of the construction space and place. As shown in Table 1 communication may be formal or informal, and may also occur within (or outside of) the boundaries of the construction project environment. For example, formal communication paths may be required for the execution of technical construction tasks, while informal communication may be needed for social and other purposes.

Figure 1. Communication paths in the construction space and place

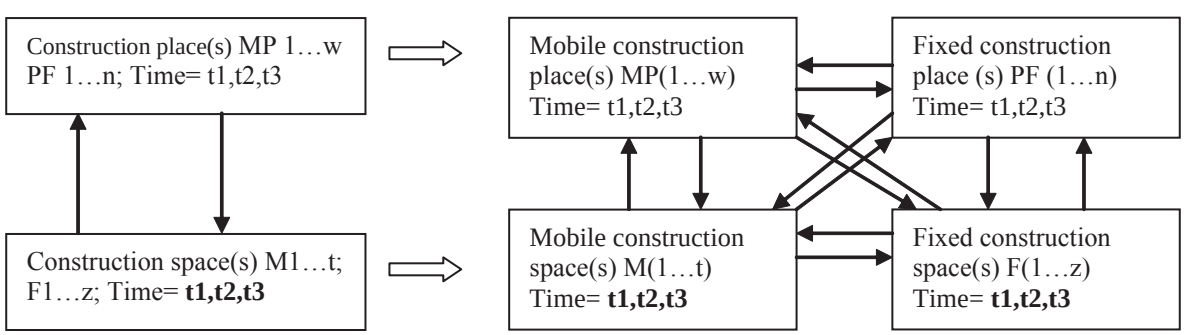

Table 1. Matrix for understanding communication paths between objects

	Project environment				Outside the project environment (ICT, business environment, etc)
	Formal (virtual/physical)		Informal operations		
Project level (1….n)	Function 1	Function (2…n)	Social, etc		
Strategic level	A	B	C	D	E
Management level	G	H	J	K	L
Operational level	M	N	O	P	Q
Other					

Figure 2. Map of potential conflicts (or agreements) in construction places and space

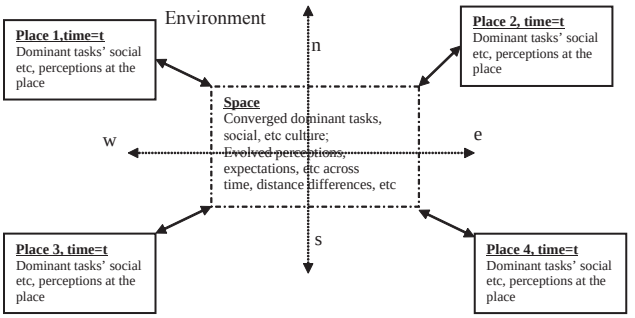

Table 1 also shows communication paths at the strategic, managerial, or operational levels for interactions within (and across) functional areas 1, 2,…n, and also the social context. Two types of paths are shown: (1) one in bold lines (to show physical communication interaction) and (2) the other in broken lines (to indicate virtual communication/interaction). For example, path AHO may refer to formal and informal communication in the construction space across the strategic, managerial, and operational levels for the different functional areas (1..2...n) and also the social context. Path distance AB may refer to say a machine-to-machine, EDI communication initiated at the strategic level across two functional groups. Path AE may refer to a communication path in the construction space between say a party from the strategic functional area 1 and another party not within the project's environment. This interaction along path AE may, for example, represent transactions for the procurement of goods using e-commerce. Path GL in a bold line may refer to physical face-to-face communication between people at the managerial level and other potential public stakeholders outside of the project's environment. Each of the square boxes in Table 1 also provide potential for tailoring information delivery to meet specific needs of users, and also grading access to certain types of information (in the space if necessary).

Potential Conflicts (or Agreements) in Communication

The diagram in Figure 2 shows the map of a typical example of potential communication conflicts (or agreements) across the construction places and space. In construction projects there are bound to be dominant local task cultures, language, legal, and perceptions/expectations. These perceptions and expectations may act as latent influence on the dispersed construction space from the local construction places 1, 2, 3, and 4. This latent influence may require effective management, training, and so forth to transform any potential chaos into a synergistic culture in the construction space for effective task delivery.

Figure 2 also shows feedback arrows between the indicated constructs to remind construction actors about the potential effect of the evolved culture (adopted/adapted) within the construction space on the indicated construction places. For example, a relatively easy access to information (and also potentially blurred communication paths) in the construction space may psychologically affect construction actors, who may operate in very rigid formal settings in the construction place. This psychological impact may continue in a dynamic iterative fashion throughout the project until dynamic equilibrium is attained. Another example may concern the sharing of technical information. Communication of task information via 3-D or 4-D graphics/modeling in the construction space may be used to support construction operations across the varying construction places. The use of 3-D or 4-D graphics/modeling in the construction space may potentially impact on operations at the construction places which may have the rooted culture of working with 2-D drawings, and so forth. There may be the need for effective change management to mitigate the effects of potential resistance (and even sabotage) in the use of 3-D or 4-D model applications in the affected construction places which may prefer working with 2-D drawings.

Other potential conflicts to consider may be technical units of measurement; operational laws; time zones; and economic, political, and ethical issues which may indirectly affect the construction space from the construction places 1, 2, 3, and 4. In summary the potential interaction between the environ-

ments of the physical distributed construction places and the evolved construction space may require critical attention and management to avoid most of the identified threats.

FUTURE TRENDS

The models in this article provide varied research opportunities. For example, future studies may be based on the models to consider how dominant local construction cultures in distributed geographic construction places could shape communication flow in the construction space. Focused case studies may also be used to explore the dynamics of why and how specific communication cultures may evolve in the construction space and place for task delivery in varied scales of construction projects. Lessons from such case studies could form good basis for the evolution of metrics to improve the integrated communication processes in the construction place and space for effective task delivery.

CONCLUSION

This article discussed the communication paths within the space and place in virtual construction projects and argued for the need to integrate both realms to aid structure and remind and focus communication theory and practice. Although communications in the construction space may usefully support construction task delivery, the nature of construction work makes traditional communication processes in the construction place also very important. Various models were proposed in the article to illuminate the concepts of integrated communication in the construction place and space. From an integrated perspective, the potential communication conflicts (or agreements) across the construction places and space on communication and task delivery processes were also explored. The integrated view provides a better understanding of the potential effect of latent occurrences in each world on the other. The study and practice of communication in the virtual construction project environment from an integrated (rather than discrete) perspective (of the space and place) therefore seems to be a useful route.

KEY TERMS

3-D Graphics/Modeling: 3-D graphics/modeling refers to three dimensional perspectives of communicated graphics.

Communication Paths: Communication paths refer to the tracks of potential communications which may occur between communication objects (humans or computers).

Construction Place: The physical geographic locations where the construction activities take place.

Construction Space: The "imaginary" space (via ICT terminals/tools) where construction activities are executed as imitations of the real world scenarios by means of computers.

Fixed Construction Place: Fixed construction place refers to the bounded construction locations where construction activities take place.

Intra-Boundary Communication: Intra-boundary communication refers to communication within identified systemic boundaries.

Inter-Boundary Communication: Inter-boundary communication refers to communication across identified systemic boundaries.

Mobile Construction Place: Mobile construction place relates to the dynamic construction locations within the fixed locations where construction works are done.

A Comparison of Data Modeling in UML and ORM

Terry Halpin
Neumont University, USA

INTRODUCTION

The *Unified Modeling Language* (UML) was adopted by the Object Management Group (OMG) in 1997 as a language for object-oriented (OO) analysis and design. After several minor revisions, a major overhaul resulted in UML version 2.0 (OMG, 2003), and the language is still being refined. Although suitable for object-oriented code design, UML is less suitable for information analysis, since its graphical language provides only weak support for the kinds of business rules found in data-intensive applications, and its textual Object Constraint Language (OCL) is too technical for most business people to understand. Moreover, UML's graphical language does not lend itself readily to verbalization and multiple instantiation for validating data models with domain experts.

These problems can be remedied by using a *fact-oriented* approach for information analysis, where communication takes place in simple sentences, each sentence type can easily be populated with multiple instances, and attributes are avoided in the base model. At design time, a fact-oriented model can be used to derive a UML class model or a logical database model. *Object Role Modeling* (ORM), the main exemplar of the fact-oriented approach, originated in Europe in the mid-1970s (Falkenberg, 1976), and has been extensively revised and extended since, along with commercial tool support (e.g., Halpin, Evans, Hallock, & MacLean, 2003). Recently, a major upgrade to the methodology resulted in ORM 2, a second-generation ORM (Halpin 2005). Neumont ORM Architect (NORMA), an open source tool accessible online at *http://sourceforge.net/projects/orm*, is under development to provide deep support for ORM 2 (Curland & Halpin, 2007).

This article provides a concise comparison of the data modeling features within UML and ORM. The next section provides background on both approaches. The following section summarizes the main structural differences between the two approaches, and outlines some benefits of ORM's fact-oriented approach. A simple example is then used to highlight the need to supplement UML's class modeling notation with additional constraints, especially those underpinning natural identification schemes. Future trends are then briefly outlined, and the conclusion motivates the use of both approaches in concert to provide a richer data modeling experience, and provides references for further reading.

BACKGROUND

Detailed treatments of early UML use are provided in several articles by Booch, Rumbaugh, and Jacobson (Booch et al., 1999; Jacobson et al., 1999; Rumbaugh et al., 1999). The latest specifications for UML 2 may be accessed at *www.uml.org/*. The UML notation includes hundreds of symbols, from which various diagrams may be constructed to model different perspectives of an application. Structural perspectives may be modeled with class, object, component, deployment, package, and composite structure diagrams. Behavioral perspectives may be modeled with use case, state machine, activity, sequence, collaboration, interaction overview, and timing diagrams. This article focuses on data modeling, so considers only the static structure (class and object) diagrams. UML diagrams may be supplemented by textual constraints expressed in the Object Constraint Language (OCL). For detailed coverage of OCL 2.0, see Warmer and Kleppe (2003).

ORM pictures the world simply in terms of objects (entities or values) that play roles (parts in relationships). For example, you are now playing the role of reading, and this article is playing the role of being read. Overviews of ORM may be found in Halpin (2006, 2007b) and a detailed treatment in Halpin and Morgan (2008). For advanced treatment of some specific ORM topics, see Bloesch and Halpin (1997), De Troyer and Meersman (1995), Halpin (2001, 2002, 2004a), Halpin and Bloesch (1999), and Hofstede, Proper, and van der Weide (1993).

DATA STRUCTURES

Table 1 summarizes the correspondences between the main, high-level data constructs in ORM and UML. An uncommented "—" indicates no predefined support for the corresponding concept, and "†" indicates incomplete support. This comparison indicates that ORM's built-in symbols provide greater expressive power for capturing conceptual constraints in graphical data models.

Classes and data types in UML correspond to *object types* in ORM. ORM classifies objects into *entities* (UML objects) and *values* (UML data values—constants such as character strings or numbers). A *fact type* (relationship type)

Table 1. Comparison of the main data constructs in ORM and UML

ORM	*UML*
Data structures:	**Data structures**:
object type: entity type;	object class
value type	data type
— { use fact type }	attribute
unary fact type	— { use Boolean attribute }
2^+-ary fact type	2^+-ary association
objectified association (nesting)	association class
co-reference	qualified association †
Predefined Alethic Constraints:	**Predefined Constraints**:
internal uniqueness	multiplicity of ..1 †
external uniqueness	— { use qualified association } †
simple mandatory role	multiplicity of 1^+.. †
disjunctive mandatory role	—
frequency: internal; external	multiplicity †; —
value	enumeration, and textual
subset and equality	subset †
exclusion	xor †
subtype link and definition	subclass, discriminator, etc. †
ring constraints	—
join constraints	—
object cardinality	class multiplicity
— { use uniqueness and ring } †	aggregation/composition
—	initial value, changeability
Deontic Rules	—
User-Defined Textual Constraints	**User-Defined Textual Constraints**

† = incomplete coverage of corresponding concept

in ORM is called an *association* in UML (e.g., Employee works for Company). The main structural difference between ORM and UML is that ORM avoids *attributes* in its base models. Implicitly, attributes may be associated with roles in a relationship. For example, Employee.birthdate is modeled in ORM as the second role of the fact type: Employee was born on Date.

The main advantages of attribute-free models are that all facts and rules can be naturally verbalized as sentences, all data structures can be easily populated with multiple instances, models and queries are more stable since they are immune to changes that reshape attributes as associations (e.g., if we later wish to record the historical origin of a family name, a family name attribute needs to be remodeled using a relationship), nulls are avoided, connectedness via semantic domains is clarified, and the metamodel is simplified. The price paid is that attribute-free diagrams usually consume more space. This disadvantage can be offset by deriving an attribute-based view (e.g., a UML class model or a relational database schema) when desired (tools can automate this).

ORM allows relationships of any *arity* (number of roles). A relationship may have many readings starting at any role, to naturally verbalize constraints and navigation paths in any direction. Fact type readings use *mixfix* notation to allow object terms at any position in the sentence, allowing natural verbalization in any language. Role names are also allowed. ORM includes procedures for creating, verbalizing, and transforming models. The first step in creating a data

model is to verbalize relevant information examples—these "*data use cases*" are in the spirit of UML use cases, except the focus is on the underlying data.

In an ORM diagram, object types appear as named, soft rectangles, and roles appear as boxes connected by a line to their object type. A predicate appears as an ordered set of role boxes together with a predicate reading. Since role boxes are set out in a line, fact types may be conveniently populated with tables holding multiple fact instances, one column for each role. This allows all fact types and constraints to be *validated by verbalization as well as sample populations.*

While supporting binary and longer associations, UML uses Boolean attributes instead of *unary* relationships. For example, the fact instance expressed in ORM as "Person 'Sam Spade' smokes" would typically be rendered awkwardly in UML as "SamSpade: Person.isSmoker = true." To be business friendly, UML should support unary fact types directly (e.g., Room has a window, Person smokes, etc.).

In UML, each association has at most one name, and verbalization into sentences is practical only for infix binaries. Since roles for ternaries and higher arity associations are not on the same line, directional verbalization and multiple instantiation for population checks are ruled out. UML does provide object diagrams for instantiation, but these are convenient only for populating with a few instances.

Both UML and ORM allow associations to be objectified as first-class object types, called *association classes* in UML and *objectified* (or *nested) associations* in ORM. UML requires the same name to be used for the association and the association class, impeding natural verbalization, in contrast to ORM nesting based on linguistic nominalization (a verb phrase is objectified by a noun phrase).

CONSTRAINTS AND IDENTIFICATION SCHEMES

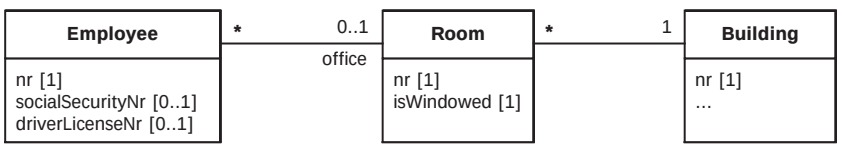
Business people communicate about things using value-based identification schemes, not memory addresses or hidden object identifiers, and hence these need to be supported in any conceptual model. This entails rich support for what ORM calls internal and external uniqueness constraints, which may be used as a basis for identification of entities. UML 2.0 includes only a restricted form of internal uniqueness (maximum multiplicity of 1) and an even weaker form of external uniqueness (via qualified associations). Moreover, UML 2.0 does not require any value-based identification scheme for a class.

For example, consider the UML class model in Figure 1. Classes are depicted as rectangles, with the class name in the top compartment, and attribute names in a lower compartment. Binary associations are depicted as lines connecting the classes involved. *Multiplicity constraints* may be applied to attributes and roles (association ends), using "1" for "exactly one," "0..1" for "at most one," and "*" for "zero or more.

Here, the attribute *multiplicity constraints* tell us that each employee has exactly one employee number and at most one social security number and at most one driver's license number, each room has exactly one room number and exactly one value for isWindowed (a Boolean attribute to indicate whether a room has a window), and each building has exactly one building number. The multiplicity constraints on the associations tell us that each employee has at most one office, each room is the office of zero or more employees, each room is in exactly one building, and each building houses zero or more rooms. What semantics are missing (allowing that appropriate association names can be added)?

To begin with, there is no declaration of how entities are identified by business people. In the business domain, employees are identified by their employee numbers, and rooms are identified by combining their local room number with the number of the building in which they are housed. The lack of the ability to declare these identification schemes prevents an understanding of these business rules, and excludes any formal way to populate the data structures with fact instances. Moreover, the uniqueness constraint that each social security number applies to at most one employee is lost, because UML cannot graphically declare the 1:1 nature of an association that is modeled as an attribute. Finally, in this business domain each employee is required to have

Figure 1. What semantics are missing?



either a social security number or a driver's license number or both, but this is not captured in the diagram.

One partial solution to this problem would be to add additional constructs in UML to apply uniqueness constraints to arbitrary combinations of attributes or binary association roles that may be considered properties of the same class. Perhaps some future version of UML might do this.

For comparison, an ORM schema for the same domain is shown in Figure 2. Entity types are depicted as named, soft rectangles. Value types appear as named, dashed, soft rectangles. Fact types are depicted as role sequences with at least one reading. Each role is depicted as a box connected to the object type whose instances play that role.

Here we have one unary fact type: Room has a window. The other fact types are binary. For example, "Employee has office in Room" and "Room is office of Employee" are forward and inverse readings of the same fact type. Role names may be added (e.g., office). Employees are identified by their employee number, and buildings by their building number. Simple identification schemes like these may be abbreviated in parentheses as shown. The bars over roles depict internal uniqueness constraints (e.g., **Each** Room is in **at most one** Building) and the solid dots are mandatory role constraints (e.g., **Each** Room is in **at least one** Building). The circled dot is an inclusive-or constraint (**Each** Employee has **some** SocialSecurityNr **or** has **some** DriverLicenseNr).

The external uniqueness constraint (circled bar) indicates that each room number and building combination applies to at most one room; the double bar indicates this provides the preferred identification scheme for rooms. If we instead introduced a simple identifier for Room, the external uniqueness constraint would be depicted as a single bar.

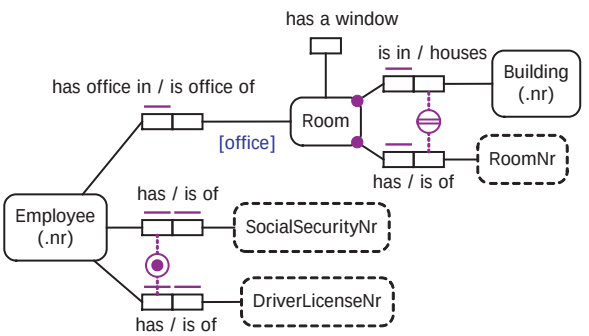
Given an *n*-ary association ($n > 2$), UML's multiplicity notation cannot express a mandatory role constraint on any association that has between 1 and $n-2$ mandatory roles. This is because multiplicity on one role is defined in terms of the other n–1 roles. This is fine for binary associations, but not for ternaries and beyond. For practical examples of such constraint patterns, see Halpin (2001).

ORM includes many other graphical constraint primitives that go far beyond those found in UML class diagrams, for example set-comparison (subset, exclusion, equality) constraints over compatible role sequences, ring constraints (asymmetric, intransitive, acyclic, etc.), and join constraints (Halpin & Morgan, 2008). In addition to these alethic constraints (which hold necessarily for each state of the business domain), ORM supports deontic rules (which ought to be obeyed but may be violated). This makes ORM far richer for capturing business rules, many of which are deontic in nature (Halpin, 2007a). Moreover, ORM's constraint primitives are far more orthogonal than those of UML.

UML and ORM both permit users to add other constraints and derivation rules in a textual language of their choice. UML suggests OCL for this purpose (Warmer & Kleppe, 2003). Although OCL is an unambiguous language, its mathematical syntax renders it unsuitable for validating rules with non-technical domain experts. For example, the inclusive-or constraint displayed earlier as a circled dot on the ORM diagram is expressed in OCL as follows in the context of the Employee class: {self.socialSecurityNr -> notEmpty() or self.driverLicenseNr -> notEmpty() }. Compare this with the automated ORM verbalization given earlier.

ORM's conceptual query language, ConQuer, is both formal and readily understandable to non-technical users, and its attribute-free nature makes it much more *semantically stable* than an attribute-based language such as OCL (Bloesch & Halpin, 1997; Halpin & Bloesch, 1999). Currently a number of Conquer-like languages are being developed to provide a single textual language for ORM that can be used for both models and queries. Recently an ORM foundation (*www.ormfoundation.org*) has been set up as a non-profit organization to promote the fact-oriented approach.

Figure 2. The ORM model captures the semantics lost in the UML model



FUTURE TRENDS

The OMG recommends its Model Driven Architecture framework as a way to facilitate the generation of software artifacts from high-level models, starting with a Computation Independent Model (CIM), and then moving down to a Platform Independent Model (PIM), and finally the Platform Specific Model (PSM) used in the actual implementation. For reasons given earlier, although useful for code design, UML currently has some shortcomings with regard to conceptual data analysis and the specification of business rules to be validated by business domain experts.

With a view to providing better support at the CIM level, the OMG recently adopted the Semantics of Business Vocabulary and Business Rules (SBVR) specification (OMG, 2007).

Like ORM, the SBVR approach is fact oriented instead of attribute based, and includes deontic as well as alethic rules. Many companies are now looking to model-driven development as a way to dramatically increase the productivity, reliability, and adaptability of software engineering approaches. It seems clear that both object-oriented and fact-oriented approaches will be increasingly utilized in the future to raise the percentage of quality code in software applications that can be generated from higher-level models.

CONCLUSION

UML class diagrams are often more compact than ORM models, and they can be adorned with implementation detail for engineering to and from object-oriented programming code. Moreover, UML includes mechanisms for modeling behavior, and its adoption by the OMG is helping it gain wide support in industry, especially for the design of object-oriented software.

ORM is based on a small set of easily mastered, orthogonal concepts, its attribute-free nature facilitates model validation by verbalization and population and conveys semantic stability, and its graphical constraint language can formally capture many business rules. UML modelers willing to learn ORM can get the best of both approaches by using ORM as a front end to their information analysis and then mapping their ORM models to UML, where ORM constraints with no UML counterpart can be captured in notes or formal textual constraints. This option will become more attractive once more software tools provide automatic transformation between ORM and UML.

KEY TERMS

Arity: The number of roles in a fact type (unary = 1, binary = 2, ternary = 3, etc.). In ORM, fact types may be of arity 1 or more. In UML fact types (associations) may be of arity 2 or more.

Business Rule: A constraint or derivation rule that applies to the business domain. An alethic/deontic static constraint restricts the possible/permitted states of the business, and a dynamic constraint restricts the possible/permitted transitions between states. A derivation rule declares how a fact may be derived from existing facts, or how an object is defined in terms of existing objects.

Conceptual Schema: Specification of the structure of a business domain using language and terms easily understood by a non-technical, domain expert. A conceptual schema typically declares the fact types and business rules that are relevant to the business domain.

Elementary Fact Type: In ORM, an elementary fact is an atomic proposition that applies a logical predicate to a sequence of one or more objects of a given type; it cannot be split into smaller facts without information loss. An elementary fact type is a kind of elementary fact. For example: Person smokes; Person was born in Country; Person introduced Person to Person. In UML, a non-unary elementary fact type is an elementary association.

Entity Type: An entity is a non-lexical object that in the real world is identified using a definite description that relates it to other things (e.g., the Country that has CountryCode 'US'). Typically, an entity may undergo changes over time. An entity type is a kind of entity, for example, Person, Country. In UML, an entity is called an object, and an entity type is called a class.

Object Type: In ORM, an object is either an entity (non-lexical thing) or a value (lexical constant, such as a character string), and an object type is a kind of object (e.g., Person, CountryCode). In UML, the term "object" is restricted to entities (instances of classes), while the term "data value" is used for instances of data types.

Object-Role Modeling (ORM): A fact-oriented approach for modeling information at a conceptual level, using language that is easily understood by non-technical, domain experts. ORM includes rich graphical and textual languages for modeling facts and business rules, and provides procedures for creating conceptual models and transforming them to lower-level models for implementation.

Role: In ORM, a role is a part played in a fact type (relationship type). In UML, this is known as an association-end. For example, in the fact type Person works for Company, Person plays the role of employee, and Company plays the role of employer.

Unified Modeling Language (UML): Language adopted by the Object Management Group as a modeling language for object-oriented analysis and design of software systems. UML includes several sublanguages and diagram notations for modeling different aspects of software systems.

Completeness Concerns in Requirements Engineering

INTRODUCTION

The difficulties that software developers must face to understand and elicit clients' and users' necessities are widely known. The more complex the context of the problem, the more difficult the elicitation of software requirements becomes. Many times, requirements engineers must become themselves problem-domain experts during the acquisition of knowledge about the context of the application. The requirements engineering (RE) objective is to systematize the process of requirements definition (Maculay, 1993; Maté & Silva, 2005; Reubenstein & Waters, 1991) along with creating a compromise among clients and users with developers since they must both participate and collaborate together. The requirements engineering process consists of three main activities: elicitation, modeling, and analysis of the application domain (Kotonya & Sommerville, 1998; Sommerville & Sawyer, 1997). Later, requirements management deals with the changes in the requirements and the irruption of new ones.

RE provides methods, techniques, and tools to help requirements engineers elicit and specify requirements, ensuring their highest quality and completeness. However, the problem of completeness is a certain menace to requirements quality and casts a serious doubt on the whole RE process. Completeness is an unreachable goal, and to estimate the degree of completeness obtained at a certain step in the project is even more difficult. The requirements engineer faces a universe of discourse (UofD) that he or she will hardly ever fully know. This situation is not unique during the whole software development process since something similar happens while testing.

The use of statistical models to predict the number of defects in a software artifact was successfully introduced some time ago (Petersson, Thelin, Runeson, & Wohlin, 2003). In this article, the use of capture and recapture information is applied in the RE field in order to make an estimation of the number of undiscovered requirements after a requirements elicitation process.

The following section analyses the validation problem in RE. Then, a section describing the use of LEL (language-extended lexicon) and scenarios in requirements engineering is included. After that, the problem of estimating closed populations is studied. Later, the use of capture and recapture in the RE domain is introduced, and finally, some future work and conclusions are presented.

BACKGROUND

The completeness problem in software engineering and requirements engineering is very similar to others in many knowledge areas. Otis, Burnham, White, and Anderson (1978) introduced a method to estimate the size of a closed population of wild animals based on the data gathered during repetitive capture of specimens. This method has been extended to the area of software inspections by several authors (Biffl, 2003; Briand, El Emam, Freimut, & Laitenberger, 2000; Thelin, 2004; Petersson, Thelin, Runeson & Wohlin, 2003; Wohlin & Runeson, 1998).

Requirements validation has become a complex task mainly due to the kind of representation models used, which requires clients and users with special skills to understand them. As it is pointed out by several authors (Cysneiros & Yu, 2003; Sommerville & Sawyer, 1997), the requirements validation seldom discovers all defects, which may reach later stages in the software development process. It has been proven that the use of natural-language representation for requirements helps validation, especially when requirements are expressed using the client user's vocabulary (Leite & Franco, 1990). To be able to provide such representation, the requirements engineer should acquire the clients' and users' vocabulary. However, ambiguity is the main drawback of the natural-language approach (Berry & Kamsties, 2004; Jackson, 1995; Sommerville & Sawyer, 1997). The construction of a glossary of clients' and users' jargon helps reduce ambiguity and build requirements specification in an understandable language. Several experiences have

shown that a glossary of the clients' and users' vocabulary is, in itself, a source of information to elicit valuable UofD information (Ben Achour, Rolland, Maiden, & Souveyet, 1999; Oberg, Probasco, & Ericsson, 1998; Regnell, 1999; Rolland & Ben Achour, 1998; Weidenhaupt, Pohl, Jarke, & Haumer, 1998).

In this entry, an RE process that begins with the construction of an LEL as its first activity (Leite, Hadad, Doorn & Kaplan, 2000) is addressed in order to analyse the impact of completeness in it. In this process, the LEL construction is followed first by the building of scenarios to understand and model the current UofD, and later by the building of another set of scenarios to figure out how the future UofD could be and to model it. Finally, this process ends with the set of requirements of the software system to be developed.

THE PROCESS

The backbone of the process is to anchor every model in the UofD vocabulary. Knowledge acquired by means of observations, document reading, interviews, and other techniques is first modeled using LEL and later by means of scenarios (Leite et al., 2000). LEL and scenarios are verified for internal consistency and validated with the collaboration of clients and users. During verification and validation (V&V), completeness is a key issue since several steps during LEL and scenario inspections (Leite, Doorn, Hadad & Kaplan, 2005) and also some guidelines for validation are designed with completeness as their main target. However, this is far from being enough.

Language Extended Lexicon

Most relevant or peculiar words or phrases (named LEL symbols) of the UofD are included in the LEL. Every symbol is identified by its name (including synonyms) and by two descriptions: notion and behavioral response. The notion contains sentences defining the symbol and the behavioral response reflects how it influences the UofD. Figure 1 depicts the model used to represent LEL symbols.

Scenarios

Scenarios are used to understand the UofD first, and later to understand the problem and its functionality. Each scenario describes a specific situation of the UofD focusing on its behavior. The scenario model (see Figure 2) contains the following components: title, goal, context, resources, actors, episodes, and exceptions.

A scenario must satisfy a goal, which is reached by performing its episodes. Episodes represent the main course of action, but they may include variations or possible alternatives. Actors carry out episodes using resources. While performing episodes, an exception may arise, signaling an obstacle to goal achievement. The context is described detailing a geographical location, a temporal location, or preconditions. Context, resources, and episodes may have constraints, which are used to record restrictions of any kind. Constraints are used to characterize nonfunctional requirements.

Figure 1. Language-extended lexicon model

LEL: LEL is the representation of the symbols in the language of the application domain.
Syntax: $\{Symbol\}_1^N$

Symbol: It is an entry of the lexicon that has a special meaning in the application domain.
Syntax: $\{Name\}_1^N + \{Notion\}_1^N + \{Behavioral\ Response\}_1^N$

Name: It is the identification of the symbol. Having more than one name represents synonyms.
Syntax: Word | Phrase

Notion: It is the denotation of the symbol.
Syntax: Sentence

Behavioral Response: It is the connotation of the symbol.
Syntax: Sentence

Figure 2. Scenario model

Scenario: It is the description of a situation in the application domain.
Syntax: Title + Goal + Context + $\{Resources\}_1^N$ + $\{Actors\}_1^N$ + $\{Episodes\}_2^N$ + {Exceptions}

Title: It is the identification of the scenario.
Syntax: Phrase | ([Actor | Resource] + Verb + Predicate)

Goal: This is the aim to be reached in the application domain. The scenario describes the achievement of the goal.
Syntax: [Actor | Resource] + Verb + Predicate

Context: This is the geographical location, temporal location, or precondition.
Syntax: {Geographical Location} + {Temporal Location} + {Precondition}

Resources: They are the relevant physical elements or information that must be available in the scenario.
Syntax: Name + {Constraint}

Actors: These are persons, devices, or organization structures that have a certain role in the scenario.
Syntax: Name

Episode: It is a set of actions that details the scenario and provides its behavior.
Syntax:
<episodes> ::= <group> <group> | <episodes> <group>
<group> ::= <sequential group> | < nonsequential group>
<sequential group> ::= <basic sentence> | <sequential group> <basic sentence>
<nonsequential group> ::= **#** <sequential group> **#**
<basic sentence> ::= <simple sentence> | <conditional sentence> | <optional sentence>
<simple sentence> ::= <episode sentence>
<conditional sentence> ::= **IF** <condition> **THEN** <episode sentence>
<optional sentence> ::= **[** <episode sentence> **]**

Exception: An exception hinders the achievement of the scenario goal.
Syntax: Cause [**(**Solution**)**]

Constraint: It is a scope or quality requirement referring to a given entity. It is an attribute of resources, basic episodes, or subcomponents of context.
Syntax: ([Subject | Actor | Resource] + **Must** [**Not**] + Verb + Predicate) | Phrase

CLOSED-POPULATIONS ESTIMATION

The estimation method in closed populations of any nature such as wild animals, software bugs, and in this case LEL symbols is based on the idea of capturing specimens belonging to the population whose size is unknown more than one time. Initially, this method was applied to wild-animal populations (Otis, Burnham, White & Anderson, 1978). The strategy, sometimes called capture, mark, and recapture, or the tag recapture method, involves capturing and releasing specimens. If the same specimens are mostly captured over and over again, it can be concluded that the population is basically the captured set. On the other hand, when a few of the specimens are recaptured, it can be concluded that the population is actually very large. The impact of the capture-release procedure over the specimens should be as smooth and bloodless as possible.

Initial capture and recapture statistical models assumed that every single wild animal had the same probability to become trapped and that every trap or capture procedure had the same probability to capture specimens. Later, several models considering differences among wild animals and

among other qualitative factors were introduced. A basic model assuming no difference among animals or any other factor is currently identified as M_o. Models M_t, M_b, and M_h introduce the assumption of different sources of unequal probabilities. Model M_t allows capture probabilities to vary by time due to climate, trap location, or even capture procedure. Model M_b allows capture probabilities to vary by behavioral changes caused by previous captures. Finally, M_h allows capture probabilities to vary due to heterogeneity among individual animals.

Models combining more than one source of capture probability variation were also developed such as M_{tb}, M_{th}, M_{bh}, and M_{tbh}. For every one of these models, the independence among qualitative factors is assumed. In other words, the combined probability is determined by the product rule of Bayes' theorem (Papoulis, 1985).

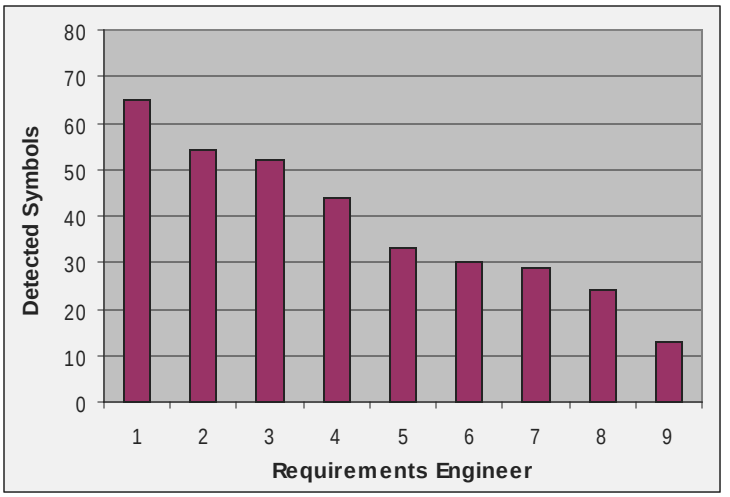
Researchers who applied capture and recapture methods to software inspections (Biffl, 2003; Briand, El Emam, Freimut & Laitenberger, 2000; Petersson, Thelin, Runeson & Wohlin, 2003; Thelin, 2004; Wohlin & Runeson, 1998) mapped the role of wild animals to software bugs and the role of traps or hunters to software inspectors. It became evident that the variation of capture probabilities due to bug behavioral changes caused by more than one inspection is senseless. Then models M_b, M_{bh}, M_{tb}, and M_{tbh} should be discarded using M_o, M_h, M_t, and M_{th} instead. This became so obvious that the authors formerly mentioned (Biffl, 2003; Briand, El Emam, Freimut & Laitenberger, 1997) did not even mention the factor behavior probability change.

CAPTURING REQUIREMENTS

When capture and recapture techniques are applied to the RE domain, the behavior probability-change factor should be carefully watched since it is not clear if it should or should not be disregarded. Actually, this depends upon the source of information used during knowledge elicitation and the acquisition technique applied. For example, if more than one requirements engineer reads the same document to pick LEL symbols, there is no way for such symbols to be influenced by previous readings. On the other hand, if several requirements engineers interview the same client or user during the LEL creation activity, it is conceivable that the interviewed person (who actually holds in his or her way of speaking the information about LEL symbols) may become influenced by previous interviews. This implies that the person being interviewed tends to change after the initial interview. He or she may develop a discomfort toward being interviewed over and over again about the same subject, or he or she may get more involved in the software project, supplying more and more useful information in consecutive interviews.

Preliminary experimental studies showed that the time factor (actually the difference among requirements engineers) behaves in a way similar to what happens in software inspections (Doorn & Ridao, 2003; Ridao & Doorn, 2006). In other words, in both cases, the time factor is more important than in what happened with wild animals. However, a notoriously more important fact became evident: Requirements engineers' probabilities and symbols' probabilities are far from being independent factors. This was not reported during capture and recapture experiences in software inspections.

Figure 3. Number of LEL symbols elicited by different requirements engineers



In other words, an M_{th} model cannot be applied using factor independence assumption. This phenomenon can be easily understood by paying attention to the fact that different people have different biases in their skills. Then it seems there is no such thing as the probability of a symbol to be picked by a requirements engineer and also there is no such thing as the probability of a requirements engineer to pick symbols. What there actually exists is the probability of a given requirements engineer to pick a specific symbol.

Figure 3 depicts the number of LEL symbols obtained by different requirements engineers in a replicated experiment based on a system dealing with savings plans for the acquisition of brand-new cars (Mauco, Ridao, del Fresno, Rivero, & Doorn, 1997; Rivero, Doorn, del Fresno, Mauco, Ridao, & Leonardi, 1998). It works through groups of people who pay monthly fees in order to obtain automobiles. They participate in monthly meetings in which a unit is adjudicated by a drawing or bidding by the participants. The system also includes arbitration in the event of renouncement or a participant's death, lack of payment of the monthly fees, insurance, and contracts with the makers, among others. It is obvious that the time factor must be carefully taken into account.

FUTURE TRENDS

The preliminary experiments should be extended to more study cases not only in LEL but in other models of the process. Metrics to define the granularity levels of the completeness studies should be defined and tested. It is not known whether dealing with the capture of notions or behavioral responses will improve or make the prediction ability of the models difficult. It is also unknown how the completeness of a model will influence the completeness of later models and, more important, over the completeness of the software system requirements.

CONCLUSION

Software requirements validation is a hard task not for the requirements actually understood and modeled, but for those that remain hidden. They will show up in the middle of the software development process with a notorious disturbance power, or they will be discovered when the software is put into service. Its functionality will not be as expected by clients and users.

Since some requirements will remain hidden because the requirements engineer has not seen them, there are few chances in which clients or users discover such missing software specification.

A capture and recapture strategy may help in reducing the amount of hidden requirements by giving the people involved a figure about how many requirements remain unmodeled and perhaps help in the development of better heuristics for the whole requirements engineering process.

KEY TERMS

Capture and Recapture: It is a method to estimate the abundance of members of a given class in a closed environment. Specimens are captured, marked, and released.

Elicitation: This is the activity of acquiring knowledge of a given kind during the requirements engineering process.

Language Extended Lexicon: It is a semiformal model holding the most relevant words or phrases of the language of the application domain carrying a special meaning.

Requirements Engineering: It is an area of software engineering that is responsible for acquiring and defining the capabilities of the software system.

Requirements Management: It is the activity of following up on the evolution of the software system requirements set, and dealing with the allocation of requirements to specific pieces of the software and with the changes in the requirements along time.

Scenario: This is a semiformal model describing observable situations in the current UofD or guessed situations that would take place when the software system is put into operation.

Universe of Discourse: It is the environment in which the software artifact will be used. It includes the macrosystem and any other source of knowledge.

Validation: It is the activity of contrasting a model with the actual world. It should answer the question "Are we creating the right model?"

Verification: It is the activity of checking different parts of a model or different models among them. It should answer the question "Are we creating the model right?"

Complex Organizations and Information Systems

INTRODUCTION

In modern organizations, information, and particularly knowledge, is known to be the most strategically important resource. The defining characteristics of modern organizational forms are purported to be flatter hierarchies, decentralized decision making, greater capacity for tolerance of ambiguity, permeable boundaries, capacity for renewal, self-organizing units, continual change, and an increasingly complex environment (Daft & Lewin, 1993; Warne, Ali, Bopping, Hart, & Pascoe, 2004). Yet, many systems that are developed to support organizational activities continue to fail at an alarming rate (Hart & Warne, 2005; Warne, 2002). Many explanations have been offered for such failures (e.g., DeLone & McLean, 1992; Fortune & Peters, 2005; Lyytinen & Hirschheim, 1987; Sauer, 1993; Warne, 2002), but contradictions and stresses continue to confound organizations and their use of information and communications technology (ICT).

The challenge for information systems (IS) research and practice is to articulate an organizational paradigm, including its structures, forms, and systems, that will enable the organization to be agile, innovative, and have the capacity to learn. This article discusses some of the parameters for a new contemporary model for organizations.

BACKGROUND

A modern paradigm for organizations needs to focus on their ability to support knowledge work practices that integrate thinking and doing (Burstein & Linger, 2003). Such practices address both the production of goods and services and the means of their production. Most importantly, such practices rely on the ability to remember and learn from the past and to use this learning to make sense of current situations. It is these practices that enable organizations to effectively compete in a rapidly changing environment through their ability to respond flexibly to internal and external demands. Such flexibility is derived from the dynamic of a network-centric organizational form, the shift to knowledge as a critical resource, the emphasis on learning, and a recognition and acceptance of complexity as the modern context of organizations.

The 'sensible organization' is an articulation of such an organizational paradigm. The concept of a 'sensible organization' is related to the sense-making view of organizations (e.g., Weick, 1995; Wiley, 1994; Cecez-Kecmanovic & Jerram, 2002). There are three significant levels of sense-making (see Linger & Warne, 2001): individual, organizational, and an intermediate level involving teams, groups, or units. Knowledge has traditionally been understood at the individual level. It is often said that "only people know," and individuals learn as they acquire knowledge from others. At the organizational level we use metaphors of 'organizational learning' and 'organizational memory' in the context of formal knowledge repositories, intranets, databases, and data warehouses that are invariably ICT based. The focus of most knowledge management initiatives is at this organizational level, while less attention has been paid to the collective knowledge at the intermediate level.

The focus of the sensible organization is the intermediate level since the informality, interactivity and adaptability of small teams defines a space for what is traditionally called 'common sense'. Within this space, teams are able to construct shared understanding and take action based on that understanding, amid the accountability and constraints of the formal enterprise. In this sense, teams represent the site of most innovation and creativity in organizations, and consequently where the challenges and potential of a sense-making approach are most apparent. Sensible organizations therefore encourage the emergence of self-directed teams interconnected in a network-centric configuration as described in Warne, Ali, and Hasan (2005b).

What is proposed by the sensible organization is not new but a return to past skills that have often been overtaken by the bureaucratization of the workplace—a process that, in many instances, is itself a result of ICT-driven change.

THE SENSIBLE ORGANIZATION IN CONTEXT

As organizations change in order to maintain their strategic and sustainable position in the broader society, they are adopting flatter forms that require substantial changes in the way people work. These changes are directed to supporting agile teamwork and coordinated group activity that is flexible but also well aligned with the desired organizationally defined outcomes. The sensible organization needs to be understood in the context of its structural and functional forms, and the interdependencies between these forms, in shaping the organization.

On the other hand, IS research will need to increase its understanding of these transformed organizational cultures in order to provide advice on managing organizations where uncertainty and complexity are the norm. Such understanding is a necessary prerequisite to the design and implementation of ICTs that are consistent with the sensible organization. For ICT systems to effectively support the sensible organization, the underlying architecture will need to appropriate social technologies (e.g., Pfaff & Hasan, 2006; Hasan, 2006a) in a manner that empowers knowledge workers and democratizes organizational information.

In order for IS research to understand the sensible organization, it is necessary to examine elements that characterize the sensible organization and its context.

Situating the Sensible Organization—The Complex Environment

Organizations are confronted by increasing complexity and a rapid rate of change (Robbins, 1990), where the nature of change is frequently revolutionary rather than evolutionary. This is exemplified by the impact of ICT, and the Internet in particular, on how organizations work and interact with their environment. The challenge for the sensible organization is to successfully manage this transformative environment as a network of complex entities and to adopt 'systems thinking' (Senge, 1994) in order to recognize and understand emerging patterns of this complex world.

Traditionally, organizations adopted a reductionist approach that attempted to summarize the dynamics, processes, and change that occurred in terms of the lowest common denominators and the simplest, yet most widely provable, applicable, and elegant explanations. For the sensible organization, it is more appropriate to view the world as a complex system that includes numerous elements, arranged in structures, that go through processes of change. These changes are neither describable by a single rule nor are reducible to only one level of explanation and often include features whose emergence cannot be predicted from their current specifications (Hasan, 2006b). This approach is consistent with IS, which intrinsically takes a socio-technical systems view of the situations it investigates as illustrated by 'soft systems methodology' (SSM) developed by Checkland (1991).

For the organization to make sense of a complex system, it needs to accommodate the system's inherent dynamics, including the ability to incorporate unanticipated and unforeseen features that emerge from that dynamic. This requires an innovative means of understanding the longitudinal changes to the organization and the possibilities open to the organization in the future. Frameworks like Snowden's (2002) Cynefin model are useful to reach such understanding.

The Sensible Organization as a Complex System

Complexity itself is characterized by a number of important properties such as self-organization, non-linearity, and emergence. Snowden's (2002) Cynefin framework is a model that presents organizations as a knowledge space with five domains: two domains of order, the known and the knowable; two domains of unorder, complexity and chaos; and the undesirable domain of disorder. Each domain has a different mode of community behavior, and each implies a different form of management, a different leadership style, and the adoption of different tools, practices, and conceptual understanding. For the sensible organization, the 'complex' domain is of particular interest with its characteristics of self-determination, emergence, and organic forms.

Importantly, sensible organizations are not limited to any domain, but exhibit, to a greater or lesser extent, characteristics of each domain. Sensible organizations are often more like ecosystems than machines with one domain predominating in any specific situation. Using the Cynefin model one is able to see how organizations and their information systems can simultaneously be mechanistic and organic. When confronting a complex and changing environment, the sensible organization replaces rational planning with processes that stimulate patterns of propitious emergent activity with an emphasis on sense-making, unstructured decision making, and shared situation awareness. The current reality is that organizational transformations will continue to be a permanent feature and therefore it makes sense to view the organization primarily from the perspective of the Complexity domain.

The Sensible Organization Infrastructure—Socio-Technical Systems to Support Complexity

The characteristic of IS that distinguishes it from other management fields in the social sciences is that it concerns the use of "artifacts in human-machine systems" (Gregor, 2002). Conversely, the characteristic that distinguishes IS

from more technical fields, such as software engineering, computer science, and information technology, is its concern for the human elements in organizational and social systems. A basic premise of this article is that all information system artifacts are essentially socio-technical in nature and continually evolve so that they acquire emergent properties, uses, and impacts. The term *socio-technical* effectively expresses the intricate relationships and interrelationships between the social and technical elements of any information system, particularly within organizations. Taking into account the properties of complex environments, Coakes (2002) describes the goal of socio-technical design as producing systems capable of self-modification, of adapting to change, and of making the most of the creative capacity of the individual for the benefit of the organization. Scholtz (2002) also sees the socio-technical perspective as valuing small independent work groups engaged in highly varied tasks, managing their own activities, and often supported by technology. These descriptions support the notion that socio-technical principles, and their application, help organizations to explore complexity in the human, organizational, and technical aspects of change (Coakes, 2002).

IS draws significantly on the uniqueness of computer-based ICT and their place in shaping recent human, social, and organizational history. The rapid evolution of ICT is continuing to transform firms from relatively simple entities, with solid boundaries and formal hierarchical structures, into a much more complex interconnected set of internal and external relationships. However, many of the anticipated benefits of ICT have not been realized, a reflection of the fact that, in a truly complex environment, patterns emerge that cannot be predicted. The phenomena emerging from developments in ICT, such as 'information overload', are merely symptoms of deeper issues that are less visible but that have greater impact: ICT/IS in organizations has taken away:

- the routine parts of work, and with them the time and space for reflection;
- the hands-on experience of work so that people lose touch with reality;
- much of the face-to-face social interaction so that opportunities for building trust and understanding are diminished; and
- recognition of the importance of, and support for, the invisible, pervasive, informal organization.

It is these issues that present the greatest challenges and opportunities for IS research and practice.

The significance of ICT that could support the less formal, social aspect of teamwork has long been a focus of the field of computer supported cooperative work (CSCW). CSCW explores a wide range of issues concerning cooperative work arrangements and ICT support for those arrangements (Bannon, 1992). Importantly, CSCW focuses on work arrangements grounded in the actual work being performed. When new social technologies (e.g., Wikis and blogs) that support cooperation (Prinz & Kock, 2007) are introduced into the workplace, and used appropriately by organizations, some of the original promise of ICT may be sensibly fulfilled.

INVESTIGATING THE SENSIBLE ORGANIZATION: EMPIRICAL STUDIES

The case for the sensible organization is based on a reinterpretation of the authors' research published over the past 10 years to draw informed lessons from the past to make sense of current trends in order to anticipate, and prepare for, a more sensible future. This research involved field studies of diverse organizations, and used approaches, methods, and theories that were at times developmental, interventionist, and participatory, involving action research arrangements and the collection, analysis, and interpretation of qualitative data. These approaches take a holistic and systemic view, and address the attributes that are the focus of the sensible organization. The studies focus on complexity, dynamics, changing work practices, blending the social with the technical and the cultural, as well as the social aspects of learning, growing, and adapting. The following is the collection of inter-related research projects undertaken by the authors and the focus of each project.

- *Social Learning in the Australian Defense Organization*—Identified the significance of the human dimensions of even the most technical and bureaucratic of organizations (e.g., Ali, Pascoe, & Warne, 2002; Linger & Warne, 2001; Warne, Ali, Pascoe, & Agostino, 2001; Warne, Ali, & Pascoe, 2003; Warne, Hasan, & Ali, 2005a).
- *Perceptions of Middle East Warfighters*—Highlights the importance of networks in modern agile organizations and the need to understand the human side of the network-centric view of organizations (e.g., Ali, 2006; Pascoe & Ali, 2006; Warne, 2006).
- *Weather Forecasting*—Demonstrated the importance of knowledge-based work practices to sense-making at the intermediate, team-based level of the organization (e.g., Iivari & Linger, 2000; Linger & Burstein, 2001).
- *Developing Web Communities*—Established an understanding of voluntary collaboration and natural ways of working together when civil society appropriates the Internet-enabled digital culture (e.g., Connery & Hasan, 2005; Hodgkinson & Hasan, 2006).
- *Corporate Wikis*—Explored the benefits and challenges of appropriating social technologies from the civil digital culture to support social learning in corporations (e.g., Pfaff & Hasan, 2006).

INVESTIGATING THE SENSIBLE ORGANIZATION: LESSONS LEARNED

The issues raised by these studies point to changes that are necessary for transformation to a sensible organization. The complex environment presents organizations with a very large range of problems and opportunities. Organizational response to this diversity of inputs is ideally to become agile, flexible, and adaptable by transforming their structures and processes. Such a response is consistent with Ashby's (1957) Law of Requisite Variety as the organization attempts to construct itself as an entity that can match the variety that it confronts in its environment. Thus, for example, a network-centric structure allows the organization to be more flexible than a more rigid hierarchical command and control structure in order to adapt itself dynamically to changes in the environment. The variety of the network-centric structure is derived from the ability of individual nodes to respond to the environment. These nodes are constrained only by the dynamics of the network. The network-centric structure is dependent on small, autonomous, self-directed, and self-coordinating groupings. Such groups are more apt at recognizing and understanding changes in the activity system for which they have responsibility and have the expertise and authority to act on that understanding. Such action, within a Network-centric structure, impacts on other groups, who in turn take action, and this provides the organization with the requisite variety to dynamically interact with its environment. The organization still preserves the capability to make sense of its situation from a broader, more abstract, and longer-term perspective, and to act on that understanding. This can be contrasted to the monolithic response of the control and command structure that requires considerable lead times in order to undertake the rational process of information gathering and decision making in order to reach its singular response. The response is predicated on the assumptions of "perfect" information and the ability to reach the optimal decision, often without regard to time constraints.

The studies highlight that organizations are transforming by adopting flatter hierarchical structure and combining these with a network-centric configuration. These transformations are challenging because culture change is imposed much more rapidly than it would normally occur. Managers are having to relinquish some of their traditional control to small, self-directed teams while workers need to increase their situational awareness in order to take on more responsibilities and exercise authority within a small, less prescribed group setting. This is a considerable change from the way they would have operated in the past and often there is little training or even understanding of the skills and capability that are needed.

In order to match their volatile environments, most enterprises today espouse the idea that they are a learning organization able to transform themselves as needed in a creative and informed manner. The studies articulate the critical role of social learning to the growth of modern enterprises and the importance of developing a culture of empowerment, trust, forgiveness, openness, commitment, and recognition. On the other hand, many of the knowledge work practices that are essential to the development of expertise and innovation in the socio-technical system are often invisible and are thus not acknowledged nor recognized by the organization. The studies also show that the necessary skills and capabilities required in a network-centric environment can be supported in a mix of face-to-face and online collaborative spaces and viewed holistically as socio-technical systems. Reinforcing the imperative to transform to a network-centric structure, the studies identified that effective teamwork was considered crucial in achieving operational goals. But with this transformation, integrity, maturity, adaptability, flexibility, competency and a sense of humor emerge as highly rated skills and qualities that are important for team members.

FUTURE TRENDS

The sensible organization targets the chaotic, complex environment of the agile, social, networked organization, and related communities, where members are knowledge workers engaged in activities that meld thinking and doing. This requires a new approach to developing supporting technologies. The focus of ICT needs to expand from organizational requirements and individual users to the support needed for employees working in self-directed groups and teams, as well as investigating the appropriation of social software and other emerging technologies to enable more democratic management of collective knowledge.

The exponential growth in the use of technologies like YouTube and Facebook suggest that social software needs to be channeled into organizational applications that support the creative energies of complex environments, encouraging the emergence of innovative new forms of working. Such transformations require a multi-perspective, multi-disciplinary approach together with holistic systems thinking. This is the new challenge for ICT developers.

Organizations need to reinvent their competitive advantage by introducing, or reintroducing, collaboration technologies and practices within and between their internal boundaries (Josserand, 2004). This requires blurring the distinction between organizational systems and those used in civil society, and the corporate appropriation of social technologies. It highlights the need to increase our understanding of the organizational cultures of community networks in civil society in order to understand how to manage organizations where uncertainty and complexity are the norm.

CONCLUSION

Large bureaucratic organizations are facing rapid and substantial changes that require new understandings, skills and the capability inherent in network-centric structures. Many organizations are adopting hybrids of a traditional hierarchy with a limited command and control structure that allow for the emergence of self-directed groups in a network-centric configuration. The sensible organization adopts network-centrism and encompasses the organizational, social and cultural as well as the technical aspects of working in these changing, hybrid environments.

Knowledge workers need the authority, skills, and capability to work effectively and creatively in teams as much as they need the traditional operational skills to do their job. In a sensible organization this creative and cognitive work needs to be overtly recognized and rewarded. Management needs to encourage sense-making and exploration rather than resort to traditional methods of setting objectives and measuring outcomes. A sensible organization is grounded in a culture that promotes social learning, community/team building, and the appropriation of new flexible technologies in emergent socio-technical systems.

In terms of the Cynefin framework, socio-technical systems, and particularly ICT, have a long history of supporting, and even automating, aspects of the *known* and *knowable* domains. The challenge now is to understand the sensible organization in order to design and construct the necessary socio-technical system that will enable the sensible organization to be effective in the *complex* and *chaotic* domains, while it remains efficient in the *known* and *knowable* domains.

Sense-making as a concept underpins a new approach to research. The sense-making approach allows sensible organizations to emerge from much of the chaos that has arisen from a general lack of understanding of the cultural, social, and personal effects of ICT, and more particularly in recent times, social technologies. The emergence of the sensible organization requires cultural investigations as part of requirements analysis to facilitate a sound understanding of existing work practices in terms of both social and functional processes and networks. Research needs to expand its focus to the development of a culture of cooperation and the creation of an environment for innovation through collaborative knowledge work. In this environment, civil society, as well as the government and corporate sector, need to be included as legitimate sites of research.

The sensible organization can define a new organizational paradigm within which socio-technical systems are not only focused on automating work, but also supporting the way it is done and enhancing productivity and the work experience itself**.**

ACKNOWLEDGMENT

The information in this article is largely derived from the authors' own research work and those of their colleagues, and from a paper they have co-authored entitled, "The Sensible Organization: A New Agenda for IS Research," presented at the International Conference on Information Systems (ICIS 2007) in Montreal in December 2007.

KEY TERMS

Collective Activity Systems: The work of groups and teams can be viewed as collective activity systems which are carried out by people in support of their interpretations of their role, the opportunities and resources available to them, and the purpose for which the activity exists. Using the language of activity theory, this is both subjective, in the sense that it is a matter for individual interpretation, and objective, in the sense that the motives, purpose, and context are a vital part of the reality of human work. An activity is defined by the dialectic relationship between a subject (i.e., a person or small group of people) and the object of their work, which includes purpose, motive, and context. An activity both mediates and is mediated by the tools used and the social context of the work activity. This two-way concept of mediation implies that the capability and availability of tools mediates what can be done, and the tool in turn evolves to hold the historical knowledge of how a society works and is organized.

Complexity: Understood as a concept in various ways, yet not definitively defined in the literature. However, in recent times, comprehensive theories of complexity and chaos have become popular in many disciplines of both the natural and social sciences. These theories reflect the tension between the natural tendency for disorder to increase while humans strive to impose order by developing ever more interconnected systems. In business today success is no longer determined by a few single factors, but by systems with multiple interacting relationships. Thus complexity and chaos theories are being applied in organization science where both operations and management in human enterprises are becoming increasingly complicated. The response is frequently to impose greater planning, control, rules, and regulation. At some point, organizations reach a state of complexity where planning and control of mandated work-practices should give way to the provision of a supportive environment that allows innovation and creativity for problem identification and solutions to emerge. The former is likely to be exploitative and bureaucratic, while the latter can be networked and innovative.

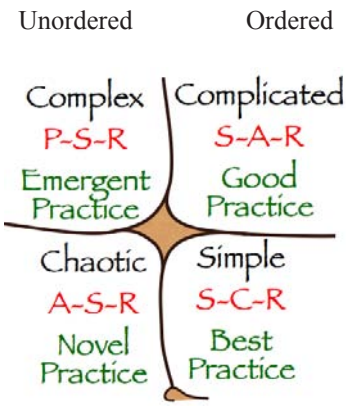
Cynefin (pronounced kun-ev'in)**:** The name of a sense-making framework proposed by Snowden (2002). It is a knowledge space with five domains setting the context for collective decision making which has been used in knowledge management as well as other applications including conflict resolution. The domains are, characterized by the relationship between cause and effect. The first four domains are:

1. **Simple or Known,** in which the relationship between cause and effect is obvious to all; the approach is to *Sense–Categorize–Respond*, and we can apply *best* practice.
2. **Complicated or Knowable,** in which the relationship between cause and effect requires analysis or some other form of investigation and/or the application of expert knowledge; the approach is to *Sense–Analyze–Respond*, and we can apply *good* practice.
3. **Complex,** in which the relationship between cause and effect can only be perceived in retrospect, but not in advance; the approach is to *Probe–Sense–Respond*, and we can sense *emergent* practice.
4. **Chaotic,** in which there is no relationship between cause and effect at systems level; the approach is to *Act–Sense–Respond*, and we can discover *novel* practice.

The fifth domain is **Disorder**, which is the state of not knowing what type of causality exists, in which state people will revert to their comfort zone in making a decision.

Cynefin Framework: Defined by the following figure

(adapted from Wikipedia).



Knowledge Work: The term 'knowledge worker' is attributed to Drucker (1959), who used it to describe someone who adds value by processing existing information to create new information that can be used to define and solve problems. The subsequent development of information and communications technologies has added new meaning to this concept. For the contemporary knowledge worker, managing the collective knowledge about his or her work is an integral part of the work itself, and thus is critical to the performance of the organization. Knowledge work reflects the self-directed work practices of individuals and teams, in almost every industry, who continuously engage in processes that create and exploit knowledge. The modern work activity system is located within a space defined by the doing, thinking, and communicating dimensions (Burstein & Linger, 2003).

Network Centricity/Centrism: Large bureaucratic organizations, and the people who work in them, are facing rapid and substantial changes which require new understandings, skills, and capabilities for the network-centric environment. In some of the early literature, the term 'network-centric' only referred to the connectivity achieved through technological networks, in particular the Internet and Web-enabled applications. However its connotation has expanded as ICT networks and applications are transforming the ways in which people gather, share and process information and knowledge, and consequently, on the ways they make decisions to act. This is having an impact in organizations: on their structures, their ways of working, on organizational learning, as well as on the ways people collaborate and form social networks. Many organizations are now hybrids of a traditional hierarchy, with a limited command and control structure, and a network-centric configuration allowing the emergence of self-directed groups. The domain of network-centrism now encompasses the organizational, social and cultural as well as the technical aspects of working in these changing, hybrid environments.

Requisite Variety: Principle proposed by Ashby (1957) suggesting that the internal diversity of any self-regulating system, such as an organization, must match the variety and complexity of its environment if it is to deal with the challenges posed by that environment. Diversity of knowledge and skill can provide a resource for innovation and learning, at all levels of organizational management. If the systems that regulate do not have enough (or requisite) variety to match the complexity of the regulated, then regulation will fail. The system will be out of control. If an organization is complicated or complex, it is likely to have plenty of variety; if it is simple (e.g., purely hierarchical), the variety is usually low and the organization will struggle with the current complex environment.

Sensible Organization: There are many things about work in today's organizations that just do not make sense. We observe contradictions, stresses, and tensions everywhere. The advancements of science and technologies, which promised to take away the drudgery of the human condition do not seem to have fulfilled their promise. We have replaced 'drudgery' with the new disease of 'affluenza'. We fondly reflect on the creativity and community spirit of pre-industrial age cottage industries and the subsequent de-humanization of the workforce in the assembly line of factories of the industrial age. The notion of 'sensible organization' is a return to the human and social values that have disappeared in the modern workplace. Sensible assumptions about most modern organizations, which have complex hybrid structures consisting of hierarchies and networks, is that they are often more like organic ecosystems than machines. Moreover, it makes sense to adopt the position that this mechanistic-organic hybrid is now a natural state of affairs and should not be resisted. Indeed this creates an ideal context for innovation, creativity, and growth—a context in which rational planning should give way to processes that stimulate patterns of propitious emergent activity with an emphasis on sense-making, unstructured decision making, and shared situational awareness.

Social Learning: Learning that occurs within or by a group, an organization, or any cultural cluster, and it includes:

- the procedures by which knowledge and practice are transmitted across different work situations and across time; and
- the procedures that facilitate generative learning that enhances the enterprise's ability to adjust to dynamic and unexpected situations, and to react creatively to them.

Social learning represents important processes that contribute to individuals' abilities to understand information, create knowledge from that information and share what they know. Social learning is therefore intrinsic to the factors in organizations that enhance and enable the assimilation, generation, sharing, and building of knowledge that transforms an organization into a learning organization.

Social Software (or Social Technology): A new civil digital culture has taken hold, in which so-called 'social' and/or 'conversational' technologies are providing unprecedented opportunities for everyday civil user activities. The attraction of these social technologies is their low cost, intuitive functionality, and connectivity. Social technologies provide computer-mediated environments that use applications such as Weblogs (blogs), Wikis, chatrooms, and various Web-based groupware systems. They support new forms of informal, network-centric interaction and activity between people, allowing and enhancing informal access to create and distribute information. These technologies empower ordinary people to have a global presence for business, political and social purposes. The new social technologies are tools of a rising digital democracy that provide users with a new flexibility and independence to support collective actions, knowledge sharing and decision making by self-directed groups. Social technologies, which support cooperative socio-technical systems, are being appropriated by enlightened enterprises which are transforming from traditional hierarchical structures to more network-centric configurations.

Complexity Factors in Networked and Virtual Working Environments

Juha Kettunen
Turku University of Applied Sciences, Finland

Ari Putkonen
Turku University of Applied Sciences, Finland

Ursula Hyrkkänen
Turku University of Applied Sciences, Finland

INTRODUCTION

Working environments are changing from the traditional model. An increasing amount of work takes place in networked and virtual environments which are not tied to one place and time. The work environment is defined "virtual," when the employee uses information and communication technology (ICT) for collaboration (Vartiainen, 2006). The planning of working conditions becomes challenging task for managers and ICT tool developers, because there is a lack of understanding the consequences of emerging virtual work.

The capacity of workers to percept and process information is burdened with the complexity and high demands of working life. Knowledge of the complexity factors of the overall work system is essential for an in depth understanding of human working capabilities and limitations (Kleiner, 2006). The complexity of work is usually considered as a factor related to the task. At the one end the task is creative and demanding and at the other end it is simple and routine-like. The expanded complexity concept also takes into account the working environment that can be different combinations of physical, virtual, social and cultural spaces.

The purpose of this article is to present a framework to analyse the complexity factors in networked and virtual working environments. The approach developed in this article is intended to be generic in order to be applicable to various kinds of organisations and networks for the purpose of management. It is important that the working conditions of workers can be planned in advance to provide workers with appropriate ICT tools and data networks to enable efficient cooperation in networks in a way that the workload can be limited to a sustainable level. The described framework is assessed using the case of the Turku University of Applied Sciences (TUAS).

BACKGROUND

Organisational Context of the Study

Networked and virtual work are analysed by applying the complexity approach to the Turku University of Applied Sciences. The strategic plan of the TUAS is to react to the changes in a flexible way (Kettunen, 2006, 2007; Kettunen & Kantola, 2006). The interaction of the institution is close with its operational environment. The purpose of the institution is to react to the changes in its environment in a flexible way and to increase its external impact on the region.

TUAS is a multidisciplinary higher education institution founded in 1992. The City of Turku owns the institution, which has 800 full-time employees. The TUAS has six faculties and a Continuing Education Centre. ICT is an important field of education and is combined with business, biotechnology, mechanical engineering, health care, performing arts, communication and many other subjects. Cooperation with other universities is active. One reason is that the ICT education and research of the University of Turku and Åbo Akademi University are located in the same ICT Building.

The TUAS has 9,500 degree students. The institution offers tuition mainly in Finnish but there are also degree programmes, modules and courses in other languages. Internationalisation is one of the focus areas of the institution. The TUAS has wide international networks. The institution has cooperation with several higher education institutions in Europe, Asia and the Americas. Five entire programmes are taught in English. The objective is to improve the students' ability to work in a global environment.

Networked and Virtual Environments

Figure 1 describes the dimensions of networked and virtual work. There are three modes for organising the communication and collaboration of work: traditional organisation,

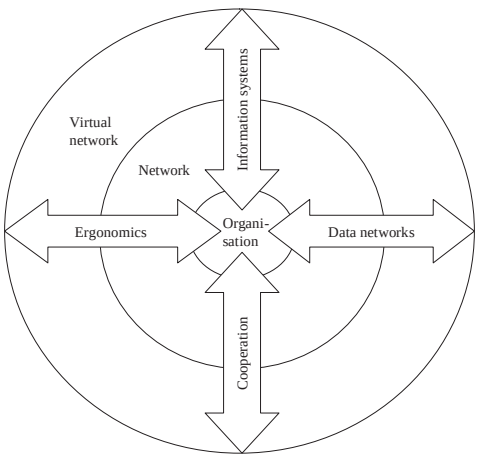
network and virtual network. The concept of the virtual network includes networked and traditionally organised work. Mobility may take place within or outside the organisation. Networked and virtual work can be analysed using the various dimensions that come across the organisation and networked and virtual environments.

Information systems have been typically planned for the organisation, but an increasing amount of information systems have also been designed for the cooperation in networked and virtual environments. Virtual work environments increase the complexity of the work and therefore, various approaches are required to analyse and design the well-being of workers and the performance of the overall work system.

Data networks and ICT reflect the needs of working environments. The traditional organisation-centred work is extended with the mobile work, networked cooperation in diverse locations and virtual systems, which increase the complexity of working environments. Working in these environments requires not only traditional network but also an increasing amount of wireless data networks.

Ergonomics as a discipline is concerned with interactions with human-machine systems. Ergonomics has played a vital role, for example, in the reduction of occupational injuries, improved performance, increased health and safety of workers and end-products. Pheasant (1996) has concluded that the objective of ergonomics is to achieve the greatest possible harmony between the product and its users in the context of the task performed. With complex sociotechnical systems the above is not enough because various subsystems exist and the importance of interactions between them has a significant role. Kleiner (2006) emphasises that the larger work systems have to consider when there is a need to understand human-technology interaction, capabilities and limitations better. Macroergonomics as a subdiscipline of ergonomics is concerned with human-organization interface technology and the optimisation of the overall work system, that is, design of the worker-job, worker-machine, and worker-software interfaces (Hendrick & Kleiner, 2001).

Figure 1. Dimensions of networked and virtual work



ORGANIZATIONAL EXPANSION TOWARD THE VIRTUALITY

Complexity Factors of Networked and Virtual Work

Vartiainen (2006) has described the complexity of working environments by following six dimensions: mobility, geographical dispersion of the workplaces, diversity of actors, asynchronous working time, temporary structure of the working groups and mediated interaction. These six dimensions form, in addition to task complexity, a set of requirements that can also be considered work load factors (Hyrkkänen, 2006). The complexity factors arise from the conjunction of a worker and the particular kind of working environment. We have further developed the complexity model of the networked and virtual work by exploring it taking into account the human and technology related enablers and limitations of virtual work.

Table 1 describes the general concepts of complexity factors for the traditionally organised, networked and virtual work. We suggest this classification as a framework, which can be used for example, as a framework for empirical studies, participatory design projects and consulting processes. The working environments are changing from the traditional model, where the place and time have an important role. An increasing amount of work takes place in networked and virtual environments which are not tied to one place and time. The planning of working conditions becomes challenging, because there is a lack of proper tools for analysing and managing sustainable and safe working conditions.

The information environments and systems can be classified as mechanical, organic and dynamic (Ståhle & Grönroos, 2000; Ståhle & Hong, 2002; Ståhle, Stahle, & Poyhonen, 2003). The information systems in the mechanical information systems increase the efficiency of internal processes and include thoroughly controlled information systems, which are based, for example, on the automation of routines. The organic information system emphasises dialogue, communication and sharing of experience-based tacit knowledge (Kim, Chaudhury, & Rao, 2002; Takeuchi & Nonaka, 2004). The dynamic information systems include information systems which produce innovations and services by self-organisation. The virtual systems, networking, net casting and different portals, are often in connection with

Table 1. General concepts of complexity factors in an organisation, network and virtual network

	Information systems	Data networks	Cooperation	Ergonomics
Organisation	• Mechanical	• Intranet	• Internal working groups	• Microergonomics
Network	• Organic	• Wireless local area networks	• Working in networks	• Sociotechnical systems • Macroergonomics
Virtual network	• Dynamic	• Internet	• Working in virtual environments	• Macroergonomics

more risky, chaotic and innovative environments and online networking platforms (Steinberg, 2006).

Data networks include typically Internet, local wireless networks and Intranet. Mobile devices enable workers access to wireless networks. The emerging and expanding wireless networks enable the use of the data network wirelessly. A wireless local area network (WLAN) enables communication between devices in a limited area. WLAN or Wireless Fidelity (WiFi) is becoming increasingly popular with the rapid emergence of portable devices. Other similar certifications such as Worldwide Interoperability of Microwave Access (WiMAX) offer longer ranges of radio waves.

Cooperation and collaboration is not only within working groups within organisations, but typically in networks and virtual environments. Cooperation in networks is typical in clusters, which are geographic concentrations of interconnected companies, specialised suppliers, service providers, firms in related industries, and associated institutions in particular fields that compete but also cooperate (Porter, 1998). Many of the advantages of clusters involve location-specific business services and networking. Some of the clusters are closely aligned to government and to public institutions (Denison, 2007; Graham, 2005). They include face-to-face contact, close and ongoing relationships and access to information via data networks. Some of the cooperation exists only in virtual networks. A typical example is the development of the Linux, which is one of the most prominent examples of open source development and free software.

Ergonomics can be classified as microerconomics, which focuses on the interfaces between the individual, organisation and other system elements and macroergonomics, which focuses on the design of overall work system. Organisational factors are related to the physical activity of workers, environmental factors and organisational complex factors. When the functioning of the networked working environment is under development, it is advisable to analyse it as a sociotechnical system, covering interaction between workers and technology (Carayon, 2006). Macroergonomics is an approach of work systems which attempts to achieve a fully harmonized work system at both the micro- and macro-ergonomic level by integrating principles and perspectives from industrial, work and organisational psychology (Kleiner, 2006). Typically the complexity of work increases when workers are moving to virtual work environments (Richter, Meyer, & Sommer, 2006).

Networked and Virtual Work at the TUAS

Table 2 describes the complexity factors of work at the Turku University of Applied Sciences. It is not an exhaustive description of all the characteristics of the traditionally organised, networked and virtual work of the institution, but it provides examples of complexity factors of the institution. The approach helps the management of the institution to analyse the complexity factors and take them into account in the work design and human resources planning.

The information systems include the devices and software used in the various information environments. Mechanical information systems include traditional systems such as accounting, personal administration and payroll systems, which are strictly tied to the processes and structures of an organisation. Organic information systems include, for example, query systems which are used to attain feedback from students and employers. They include also the library, project management and management information systems (Kettunen & Kantola, 2005). The dynamic information systems include the courses in the platform of virtual learning, Finnish virtual university portal and services of virtual libraries.

Data networks include, for example, Intranets and Internet. Wireless local area networks are expanding rapidly. An example of the wireless network is the SparkNet. It is

Table 2. Complexity factors of work at the TUAS

	Information systems	Data networks	Cooperation	Ergonomics
Organisation	• Desk computers • Internal phones	• Administration and study intranets	• Working groups in educational development and research	• Face-to-face development of safe, healthy and efficient tools and work environments
Network	• Laptops • Communicator • 3G telephones • VoIP	• WLAN/WiFi (SparkNet) • WiMAX	• Local, national and international networks of higher education and research	• Local, national and international mobility, geographical dispersion of workers and information technology
Virtual network	• Virtual learning environments	• Internet • Finnish University and Research Network (Funet)	• Studying and cooperating in virtual environments	• Communication and interaction are ICT mediated • Temporary and self-organised virtual teams

located in Turku and is the largest and most extensive wireless network solution in Finland with about 100,000 users. The coalition of wireless networks was established in 2003 by the local universities, the City of Turku, MasterPlanet Ltd. and a development company ICT Turku Ltd. The idea of SparkNet is based on exploiting existing network resources wirelessly. The members of the SparkNet coalition build pieces of a public Wireless Fidelity (WiFi) network instead of building their own WiFi network. SparkNet is easy and affordable for the students to pursue their studies wherever they want using Voice over Internet Protocol (VoIP), online courses, video conferencing (Skype) and other systems.

The cooperation and networks of the TUAS are primarily located in Southwest Finland, which is the second largest economic area after the capital of Finland. ICT, biotechnology and mechanical engineering are the strongest clusters of the region, which are engaged in the region in mutually beneficial cooperation with higher education, research, commerce and culture. This emphasises the important role of networking in the clusters of the region. The institution has also national networks with 20 traditional science universities, 28 professional-oriented universities of applied sciences, other education institutions and enterprises and other partner organisations. The annual number of cooperation contacts is 7,000-8,000 including education projects, applied research and development, practical training and administration.

Ergonomic methods are required when the safe, healthy and efficient tools or work environments are designed. The networked work of the TUAS has more enriched job characteristics such as local, national and international mobility, the geographical dispersion of workers and information technology. Typically, the cooperation and collaboration of international activities is complex due to various geographical locations, asynchronous work in different time zone and diversified cultural backgrounds. The workers in virtual environments have a larger amount of organisational tasks, more demanding learning requirements and level of participation than the workers in traditional jobs. Workers' communication and interaction are mainly ICT mediated. A worker participates in several virtual teams at the same time. Teams are often temporal and heterogeneous including people from different cultural backgrounds. Usually, the virtual work environment of the individual worker is not controlled by the managers; it is self-managed by the worker and this causes an additional dimension of complexity.

FUTURE TRENDS

A number of changes are taking place in global business and technology that lead to the increasing complexity of work

systems. Today, "system" in ergonomics means a broad range of working environments from the usage of a simple tool to the performing of a task in a complex sociotechnical environment (Carayon, 2006). Such complexity can be seen in the expansion of virtual organizations and mobile workers.

In the future, especially with complex work systems, a human-centred design approach has to be used as opposed to a technology-centred approach (Hendrick & Kleiner, 2001). Early observation of the system's complexity is an increasingly important managerial task in order to design a work system where the well-being of workers and the overall system performance are in balance. The earlier the input occurs, the greater the impact on costs and schedule. Redesigning an existing work system is expensive and time consuming.

There are some principles concerning how the human-centred design approach can be realised. Hendrick and Kleiner (2001) list three criteria what are essential for an effective work system design approach; (1) joint design, (2) a humanized task approach and (3) consideration of the organization's sociotechnical characteristics. Joint design means that the personnel subsystem and technological subsystem should be developed simultaneously and supported by employee participation throughout the entire design process. Humanized task approach is concerned with human functions and tasks in the work system prior to the decision to allocate tasks to workers or machines. The sociotechnical characteristics of the organisation should be assessed and integrated into the work system's design process. When an evaluation or development methodology fulfils the above mentioned three criteria it is human-centred and macroergonomic.

A working virtual team requires both ICT mediated and face-to-face interactions, at least as long as ICT tools do not include more sophisticated features. The functionality of a virtual team relies on the interactions between team members. A group of people who are working separated by distance or time and have a shared task to perform, is dependent on common tools, information and social dealings. Existing ICT tools such as mobile phones, e-mail and video conferencing are rather well fulfilling the needs of information transmission. However, they have limited features to mediate issues relating to social dealings, that is, when a new team member collaborates it is difficult to identify with the rest of team thorough ICT, because, for example, the development of trust needs a richer communication channel than text or voice only.

According to Edwards and Wilson (2004), when a virtual team is able to cross the organizational, cultural and functional boundaries of a single organization, it can deliver the combined skills and knowledge required to be more competitive in fast-changing markets. In addition, Wilson (2000) emphasises that we should study interactions not simply to design artefacts but to understand the interactions themselves in order to design more sophisticated ICT. These are the fundamental driving forces of the future ICT tool design.

CONCLUSION

This study presented a useful approach to analyse the complexity factors of networked and virtual work. The organisational environment was extended toward networked virtual work, where it is useful to analyse the different complexity dimensions. The dimensions of this study include information systems, data networks, cooperation and ergonomics. The approach can be used in empirical studies, participatory design projects and consulting. This approach can also be extended using other appropriate dimensions.

Networked and virtual work provides new challenges and we can no longer understand the behaviour of workers and their performance at work as we once did. For instance, we should now study interactions between different organisational dimensions, not simply to design new communication tools but to understand the interactions themselves in order to manage the overall work system.

When the functioning of the entire virtual working environment is under development, a human-system interaction and the entire work organization and sociotechnical system have to be taken jointly into consideration. Macroergonomics is an approach of work systems design which attempts to achieve a fully harmonized work system at both the macro- and micro-ergonomic level. In future, macroergonomics should be more common knowledge among managers in order to meet the design and development challenges of complex work environments. This means, for example, that workers should be more involved in the design and implementation of technology and new information and communication systems in organisations.

As organisations expand to virtual environments, the need for experience and special solutions will increase. However, supporting the work of virtual environments is a difficult assignment. Identifying complexity factors is a good start. The existing models of complexity are mainly based on the concept of traditional organisational work. This study contributes to the current discussion by offering one model for assessing the complexity factors of networked and virtual work.

KEY TERMS

Cluster: Clusters are geographic concentrations of interconnected enterprises, specialised suppliers, service providers, firms in related industries, and associated institutions in particular fields that compete but also cooperate.

Human-Centred Approach: This is an approach to human-machine function and task allocation that first considers the capabilities and limitations of the human and whether the function or task justifies the use of a human.

Linux: Linux referes to Unix-like computer systems which have a Linux kernel. The source code of Linux is available to anyone to use, modify and redistribute freely. The Linux was originally developed by Linus Thorwalds.

Macroergonomics: The subdiscipline of ergonomics that focuses on the design of the overall work system. Conceptually, a top-down sociotechnical systems approach to the design of work systems and carry through of the overall work system design characteristics to the design of human-job, human-machine and human-software interfaces to ensure that the entire work system is fully harmonised.

Microergonomics: Those aspects of ergonomics that focus on the design of interfaces between the individual and other system elements, including human-job, hu-

man-machine, human-software and human-environment interfaces.

WiFi: Wireless Fidelity was originally a brand licensed by the WiFi Alliance. It describes the underlying technology of wireless local area networks based on the IEEE 802.11 specifications. It was developed for use in mobile computing devices, such as laptops, in local area networks.

WiMAX: Worldwide Interoperability of Microwave Access promotes conformance and interoperability of the IEEE 802.16 standard. WiMAX is a certification mark given to equipment that meets the certain conformity and interoperability tests.

WLAN: Wireless local area network is used to link two or more computers without using wires. WLAN uses spread-sprectrum technology based on radio waves to enable communication in a limited area.

Computational Biology

Andrew LaBrunda

Cabrini Medical Center, USA

INTRODUCTION

It is impossible to pinpoint the exact moment at which computational biology became a discipline of its own, but one could say that it was in 1997 when the society of computational biology was formed. Regardless of its exact birthday, the research community has rapidly adopted computational biology and its applications are being vigorously explored.

The study and application of medicine is a dynamic challenge. Changes in medicine usually take place as a result of new knowledge acquired through observation and experimentation. When a tamping rod 1-inch thick went through Phineas Gage's head in 1848, his survival gave the medical field an unusual opportunity to observe behavior of a person missing their prefrontal cortex. This observation lead to the short-lived psychosurgical procedure known as a lobotomy, which attempted to change a person's behavior by separating two portions of a person's brain (Pols, 2001). Countless observations, experiments and mistakes represent how almost all medical knowledge has been acquired.

The relatively new field of computational biology offers a nontraditional approach to contribute to the medical body of knowledge. Computational biology is a new field combining biology, computer science, and mathematics to solve problems that are unworkable with traditional biological techniques. It includes traditional areas such as systems biology, molecular biology, biochemistry, biophysics, statistics, and computer science, as well as recently developed disciplines including bioinformatics and computational genomics. Algorithms, which are able to closely model biological behavior, validate the medical understanding of the observed processes and can be used to model scenarios that might not be able to be physically reproduced.

The goal of computational biology is to use mathematics and computer science to model biological systems on the molecular level. Instead of taking on large complex systems, computational biology is starting small, literally. Modeling problems in molecular biology and biochemistry is a far less daunting task. At a microscopic level, patient's characteristics drop out of the equation and all information behavior affecting is known. This creates a deterministic model which, given the same input, will always produce the same output. Some of the major subdisciplines of computational biology are computational genomics, systems biology, protein structure prediction, and evolutionary biology, all of which model microscopic structures.

COMPUTATIONAL GENOMICS

An organism's heredity is stored as deoxyribonucleic acid (DNA) or ribonucleic acid (RNA). Each of the storage methods contains a linear chain of finite elements called bases. In the case of DNA the chain is composed of four bases, adenine, cytosine, guanine, and thymine, and RNA is composed of four bases, adenine, cytosine, guanine, and uracil. This information can be representing in a computer through a series of linked-lists or arrays. The order of bases in DNA/RNA is 99.9% the same between members of the same species and genetic sequencing is the way of determining the order of the bases. Certain regions of DNA, called genes, are used by the body to create proteins. These proteins are used to construct and maintain the organism. Genes can be thought of as blueprint instructions for how to make each unique person. There are long stretches of DNA between the genes the function of which is not well understood. The sum of all the genetic information about an organism is called a genome. When a computer is applied to deciphering an organism's genome, this is known is computational genomics. Computational genomics are used to better understand and compare sequences, identify related organisms, and measure biodiversity.

There are two major challenges in genomic studies. The first is genetic sequencing, (determining the order of the bases that make a strand of genetic material) and the second is localizing the genes within the genome. Sequence comparison is probably the most useful computational tool for molecular biologists. Repositories containing hundreds of genomes have been established and are available for public access. A biologist now has the ability to compare a unique sequence of DNA with the already known genetic sequences from this massive repository. Prior to the application of computers to the problems genomics scientist had to manually attempt to align sequences using ill suited tools such as word processors.

By identifying the genome for several related organisms it is possible to compare the related species and see how genetic mutation could allow one organism to evolve while leaving the other species unchanged. This type of analysis provides scientists with a more accurate descriptive tool to identify differences between organisms rather than relying on physical taxonomy. It also gives scientist an opportunity to see how a species' genetic information changes over time. If a large number of species have a genetic mutation which increases their successfulness, this observation may indicate an environmental change. As an example, if three unrelated species in different parts of the world genetically mutate to grow longer or thicker hair, one could hypothesize that an ice age was beginning.

One of the most important modern molecular genetic advances is the sequencing of specific genes and computational biology is becoming of increasing importance in sequencing studies. In the future, medications may be tailor made to the needs of each individual based on their specific genetic makeup. One of the hurdles that must be crossed to reach this point is a cost effective and accurate computer sequencing technique (Mitchell & Mitchell, 2007). Standardizing the reporting system of gene sequencing would minimize error and give researches a common template from which data can be extracted.

Now, computers have the ability to perform searches using pair-wise or fuzzy logic algorithms. Fuzzy logic allows for the identification of nonintuitive relationships. Identification of such relationships can provide a great deal of insight. The sequence of a gene not only encodes genetic information, but also give clues as to the function of the gene (Gibas & Jambeck, 2001, pp 13-14). Studies are actively being done using fuzzy systems to model genetic processes (Ishibuchi & Nojima, 2006).

NEURAL NETWORKING AND FUZZY LOGIC

A fuzzy system is a control system utilizing a nondiscrete mathematical system to form loosely coupled decision making data structures. Fuzzy logic has many different applications. The most widely accepted solution for pattern matching is that of Neural Networking (NN). Neural networks are simplistic software models of brain function at a cellular level. The nervous system is composed of neurons, which receive input through dendrites and transmit output through axons, all of which communicate through synapses (small spaces between nervous system cells across which chemical messages are transmitted chemically). Hypothetical software models of neural processes can be applied to emulate some of the pattern matching abilities of the brain. For example, a series of lotteries forming words can be fed into a NN system. The NN first "learns" by observing the probability that a sequence of letters will occur will occur. As the NN processes additional input, nonlinear relationships emerge where new data uses a similar set of nodes, representing neurons, during processing. Fuzzy systems accept inputs between 0 and 1 representing a continuum of trueness. This is different from classical discrete computational systems, which only allow inputs of false (0) and true (1). Fuzzy neural-based systems try to maximize accuracy while minimizing complexity.

PROTEIN FOLDING

Proteins are molecules which comprise many of the structural and functional components of living things. They are made by stringing together amino acids. All of the proteins in the human body are made from combination of various quantities of only 20 different amino acids. As proteins are created (by ribosomes) they fold into three-dimensional structures and it is the 3-dimensional interaction of the amino acids that is important. Sometimes a protein may be composed of multiple three dimensional structures interacting to perform a specific function in the body. It is the three-dimensional structure of a protein that determines its function. Many diseases occur when just one amino acid is replaced for another, such as in sickle cell anemia.

Understanding the structure of proteins allows understanding of their function and may someday provide a new therapeutic target for people with disease caused by defects in protein structure.

Research is currently being done using computational biology to understand protein structure in the energy-producing portion of cells called mitochondria (Gabaldon, 2006). Mitochondria are unique in that they are all inherited maternally. Understanding mitochondrial protein structure helps us understand how normal cells function and allows for understanding of diseases caused by mitochondrial dysfunction. Classically, mitochondrial diseases are considered to be uncommon and include diseases such as Leber's hereditary optic neuropathy and Kearns-Sayre syndromes, but more recent evidence has linked mitochondrial function to common diseases such as type 2 diabetes, Parkinson's disease, atherosclerotic heart disease, stroke, Alzheimer's disease, and cancer (Baloyannis, 2006; Folmes & Lopaschuk, 2007). Understanding mitochondrial protein structure will likely provide insight into disease processes for a gamut of pathological processes.

Although no computer model is currently able to accurately replicate the processes of protein folding, the accuracy of models has been improving. Currently, a popular method of protein modeling is to look at the hydrophobic (water repelling) and hydrophilic (water loving) properties of each individual amino acid and modeling the protein structure on a two or three-dimensional grid lattice. The

hydrophobic properties of amino acids are thought to be the most important factor in determining the 3D structure of a protein and advances in lattice selection have allowed for improved accuracy in protein modeling (Böckenhauer & Bongartz, 2007). Surprisingly, accurate models can be generated using only hydrophobic/hydrophilic properties of amino acids when grid technology is used. Grid technology is a system by which multiple computers are linked together and simultaneously work to solve a problem.

Another modeling system has been developed in which "low energy" amino acids are brought together first followed by higher energy amino acids to create a 3-D model (Hockenmaier, Joshi, & Dill, 2007). This is not a perfect model, but represents one of the first steps in using computational biology to model protein folding. Before it is understood how proteins function in diseased states, research must first be done to understand how they function in healthy individuals.

COMPUTATIONAL EVOLUTION

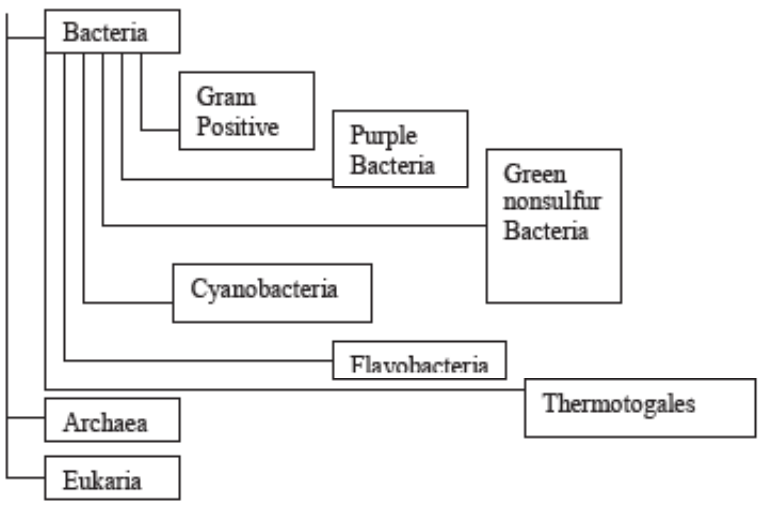
Computational evolution is a subspecialty of computational biology that uses computer technology and mathematics applied to evolutionary processes. Traditionally, evolutionary studies are retrospective. Scientists look backward at extinct species and study current species to try and understand the chronological development of the various species. The discovery of DNA has allowed a new level of understanding of these processes and more accurate classification of organisms. As computational genetics becomes more advanced, it will become clear not only physically where on a strand of DNA changes occurred creating new species, but trends will emerge. Computer mapping of these trends will allow predictions to be made about the evolution of future species (Banzhaf et al., 2006).

Scientific taxonomy emerged in the 18th century and has created a framework of nomenclature from which modern scientists work. This taxonomic classification is based largely on phenotypic relationships. In the modern era, one can extract genetic sequences and find relationships between organisms irrespective of the framework of the existing taxonomy. Often there is discordance between the historical taxonomic structure and the relationship determined through genetic analysis. For example, children are taught in grade school that there is a seven layered naming system for each organism (kingdom, phylum, class, order, family, genus, species). DNA studies provide evidence that there are three large groups of organisms, Bacteria, Archaea (an ancient form of bacteria) and Eukarya (everything else).

Sequencing the entire human genome is a landmark in scientific achievements; however, a future goal of the scientific community is to sequence the genome of every species starting with endangered species (Lesk, 2002, pp. 5-6). It will be understood why certain mutations are more likely than others. Information of this type will eventually allow a prospective study of evolution, meaning that predictions can be made based on where evolution will go in the future.

Maximum parsimony is a new concept in modeling evolution, recently formulated by Nakhleh and colleagues in 2005, and is one of the most popular methods for constructing a phylogenic tree (figure 1). This modeling technique considers as its basis that the edges of the tree should have the least amount of changes. The rational is that a new species has existed for fewer generations and therefore will exhibit less variety in any given set of genetic markers. A tree constructed

Figure 1. Example of a phylogenic tree



in this manner will model a system with the fewest number of mutations. While not without controversy, preliminary work applying maximum parsimony to phylogenic classification systems has yielded interesting results (Jin, Nakhleh, Snir, & Tuller, 2007). The parsimony trees have found genetic relationships between species which do not visibly appear similar but share key genetic similarities.

SYSTEMS BIOLOGY

Systems biology endeavors to understand the cause and effect of a biological system by studying and modeling the interaction of components. By modeling biological systems, one is better able to understand the complex biological relationships and fundamental behavior of living things. As simple models are designed, developed, tested, and validated, researchers will be able to model higher-level processes composed of model-proven subprocesses. This progress will lead to practical innovations in drug development and medical engineering.

One of the major challenges in studying systems biology is that the more complex the system being modeled the less likely the system will successfully represent actual behavior. Biological systems require physical models which are dynamic, continuous, and nondeterministic in nature. Unfortunately, these are the three most difficult characteristics to simulate. As an example, take the infection bacterial endocarditis, an infection of the inner lining of the heart. As the bacteria multiply the friction from blood flow could cause bacteria to dislodge from the heart valves and spread to other parts of the body (Durack, Lukes, Bright, & Duke, 1994). Correctly estimating when the bacteria will detach and how it might spread throughout the body is dependent on many factors. Among them would be the patients INR (International Normalized Ratio), detailed vein, artery, and blood flow characteristics as well as the bacteria's precise rate of reproduction. These nondiscrete values are extremely difficult to know with certainty given their propensity toward continuous change and difficulties in making precise measurements accurate enough to generating models.

At a microscopic level biological information is stored as DNA or RNA then translated into proteins. One of the most active areas of research currently undertaken in the field of systems biology is to model the processes involved in reading and executing the organic instructions that start with a piece of DNA and end in a protein. There are three key processes: 1) replication, the process by which DNA is copied, 2) transcription, which takes a DNA and produces RNA, and 3) translation which takes an RNA and produces a protein.

Replication is seen in cell division and is responsible for creating new copies of cells as old cells die and need to be replaced. For example, making new red blood cells or replacing skin cells. During replication, DNA untwists and the helix separates into two separate strands of DNA. Through a complex set of reactions, each half rebuilds their missing chemical complements, typically with few errors. Of the three processes, this one is the easiest to model.

Transcription uses DNA as a blueprint for creating RNA. Due to the different chemical makeup of RNA, it can exist as a single 3D strand rather than being restricted to the double helix form, as is DNA. Modeling the transcription process and the ensuing behavior of RNA has yet to be achieved. Not only is its transcription process difficult to model, but the type of RNA produced affects the function and behavior. There are three types of RNA that can be produced: messenger, transfer, and ribosomal. Each type of RNA has its own function and modeling challenges.

Translation is the process by which a protein is produced from a strand of RNA. The protein produced as a result of this process can be model to represent a linear chain amino acids as described in detail earlier. The physical 3-D structure of the protein is just as important to the proteins behavior as the chemical composition (Gibas & Jambeck 2001, pp 26-29). A great deal of research is ongoing to understand the physicochemical nature of protein.

Another challenge in systems biology is compiling the ever-growing amount of information into a usable format. New advances are made daily in protein structure, gene mapping and numerous other fields. As data is rapidly generated, the problem becomes how to organize, analyze and utilize the information. One of the goals of systems biology is to organize and catalog new information as it becomes available. These organizational systems must be flexible enough to absorb new types of information and integrate them with the old, but organized enough to separate relevant from irrelevant information. Grids technology is one of the computer resources being applied to systems biology (Strizh, Joutehkov, Tverdokhlebov, & Golitsyn, 2007).

Grid technology is a computer modeling system that allows higher throughput computing utilizing networked computers; essentially making all computers on a network one large distributed machine. This system allows large data sets to be analyzed by breaking them down into smaller ones and running them simultaneously on a number of separate networked computers. For this type of processing to be effective, problems must be discrete, uncoupled, and computable. Although grid computing has been around for years, its application in the field of medicine is only begging to be realized.

CONCLUSION

The field of computational biology is in its infancy. There are many problems that must be overcome before the benefits of the field can be tapped. Headway is being made in the modeling of complex interacting systems at the molecular level. As microsystems are better able to more accurately model biological processes, new tools will be developed to model higher-level systems using the micromodels as a foundation. The hope is one day to accurately model the entire body's biological processes.

Technologies and logic systems such as grid processing, fuzzy logic and maximum parsimony are finding patterns and relationships that couldn't be found through observation alone. The tools and technologies that are now being developed offer a new way to understand the structure of nature. Someday in the distant but foreseeable future, resource consuming experiments may move from the laboratory to the computer, allowing for optimal solutions to complex problems and novel therapeutic modalities.

INTRODUCTION

Computers in the workplace are a given. Although the advantages of computers are well-known and proven, many people still try to avoid using them. It is extremely important to find out which factors influence the success of end-user computing. What are the reasons that some people excel on a computer while others have problems and even build up a resistance toward the use of computers?

This chapter provides a literature-based overview of computer attitude and computer anxiety as factors that influence a user's resistance, commitment, and achievement. A graphic model, according to which the interactions between computer attitude and anxiety, their causes, indicators, and impacts may be understood, is proposed. It is put forth that external strategies to deal with anxiety and a negative attitude are imperative to break down a snowballing effect of cause and effect and to ensure effective end-user computing.

BACKGROUND

Computer Attitude

Gordon Allport (1935) defined the concept of attitude, in general, as follows: "An attitude is a mental and neural state of readiness, organized through *experience*, exerting a directive or dynamic *influence* upon the individual's *response* to all objects and situations with which it is related" (p. 810). In other words, attitude is determined by experience and impacts upon the individual's behavior.

A person's attitude toward a computer is influenced by a variety of aspects, e.g., the social issues relating to computer use (Popovich et al., 1987), computer liking, computer confidence, computer anxiety or comfort (Delcourt & Kinzie, 1993; Loyd & Gressard, 1984a), achievement (Bandalos & Benson, 1990), usefulness, and value (Francis-Pelton & Pelton, 1996).

Computer Anxiety

According to Henderson et al. (1995) anxiety is viewed as "a drive that motivates the organism to avoid the stimulus for anxiety" (p. 24). This implies that an individual will avoid the use of a computer in the presence of computer anxiety and if possible.

Kaplan and Sadock (1998) referred to anxiety as "a diffuse, unpleasant, vague sense of apprehension, often accompanied by autonomic symptoms" (p. 581). Specifically, computer anxiety involves an array of emotional reactions, including fear, apprehension, uneasiness, and distrust of computer technology in general (Negron, 1995; Rohner & Simonson, 1981).

Computer anxiety is also influenced by a variety of aspects, e.g., general anxiety and confidence (Harrison & Rainer, 1992), computer liking (Chu & Spires, 1991; Loyd & Gressard, 1984b), impact of computers on society (Raub, 1981), equipment-related anxiety (Marcoulides, 1989), comfort and value (Violato et al., 1989), and corporate pressure.

The Relationship between Computer Attitude and Computer Anxiety

Computer anxiety is often included as a component of attitude (Delcourt & Kinzie, 1993; Loyd & Gressard, 1984a). Jawahar and Elango (2001) reported, however, that previous studies used the concepts of computer anxiety and negative attitudes toward computers interchangeably. Computer anxiety is, however, not solely responsible for a negative attitude. A person can have a negative attitude toward computers even though he or she is not overly anxious about

using them. This may be because of a negative experience, e.g., an apologizing clerk blaming an erroneous account statement on the computer.

Furthermore, attitude allows for both a negative and a positive grading, whereas anxiety is, by definition, either negative or absent.

MAIN THRUST OF THE CHAPTER: A MODEL FOR INTERACTION

In order to indicate the various influences on the mental states of computer attitude and computer anxiety and the effect they have on a user's ability to execute computer-related tasks effectively, a model for interaction was developed (Figure 1).

The model shows interaction on three levels of abstraction. The right-hand column resembles a typical flow diagram but with an adapted convention. It shows the sequence of mental and operational events when a user is confronted with a task to be done on the computer. The diamond symbols do not represent conscious decisions but rather indicate general user behavior as determined by the user's current levels of computer attitude, computer anxiety, knowledge, and pressure experienced.

As an example of how to read the flow diagram, consider a user who has to perform a computer task. If his or her level of computer anxiety is not above a specific critical level (*D1*), he or she has a positive attitude toward computer tasks (*D2*). If he or she knows how to perform the task (*D4*), he or she will do the task (*P2*). If the user's knowledge is inadequate, this person will go through a process of learning (*P1*) until he or she can do the task. If the anxiety level is high (*D1*), the user will only use the computer if forced to do so (*D3*), or else he or she will opt out of the task or do it without a computer (*P3*).

The middle column in Figure 1 indicates the user's current levels of computer anxiety and computer attitude. The influence that computer anxiety and computer attitude have on each other as well as their influence on user behavior and the processes of learning and task execution is indicated with curved arrows (*E5–E11*). It is also clear that task execution (computer experience, *P2*) impacts computer attitude and anxiety in return (*E12–E13*).

The left-hand column shows the external processes and factors that influence a user's levels of computer attitude and anxiety.

Further discussion in this chapter serves to substantiate the claimed influences from the literature.

Factors that Determine Computer Attitude

Several studies have been undertaken to explore potential factors associated with a positive attitude toward computers (Brodt & Stronge, 1986; Scarpa et al., 1992; Sultana, 1990; Schwirian et al., 1989; Bongartz, 1988; Burkes, 1991). Some of the factors that were considered were level of education, years of experience in the work environment, computer experience, age, gender, and job title (*E3* and *E13*). The only factor that was repeatedly, although not consistently, found to have a positive effect on computer attitude, was computer experience (*E13*).

Causes of Computer Anxiety

According to Torkzadeh and Angulo (1992), there are three perspectives of computer anxiety: psychological (*E1*), sociological (*E1*), and operational (*E1* and *E12*). From a psychological perspective, users may fear that they will damage the computer, feel threatened when having to ask younger workers for help, or feel that they are losing control because computers are perceived as a threat to one's power and influence. From a sociological perspective, people have a need for social contact with other people, and because computers can change existing social patterns, they find the situation unbearable. People may also have a fear of computers replacing them. From an operational point of view, people want to avoid embarrassment connected with their inability to type or to use the keyboard. An initially confident user might be disillusioned with the complexity and sophistication of computer systems and procedures after a first experience (*E12*).

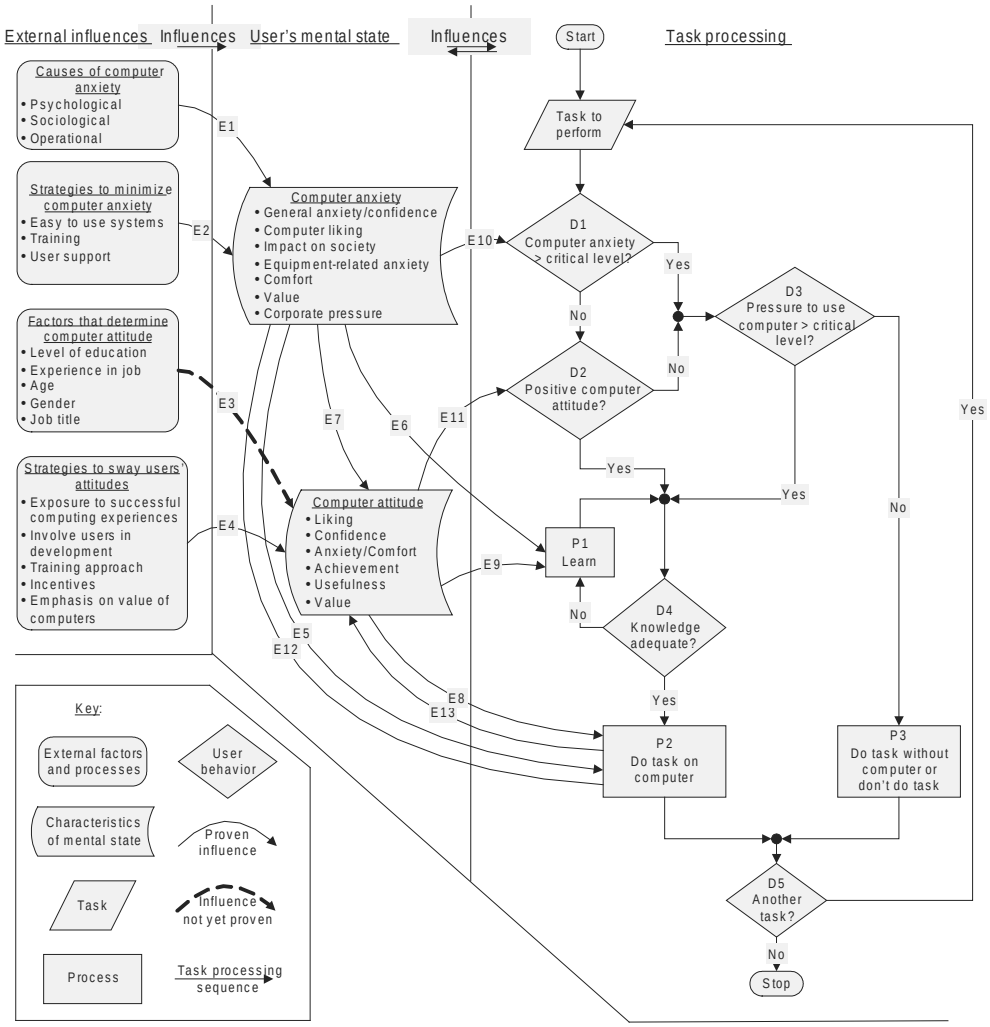
Effects of a Positive Attitude

According to Ngin et al. (1993), individuals with work excitement express creativity, receptivity to learning, and have the ability to see opportunity in everyday situations. Positive attitudes enhance the learning process (Shneiderman, 1980) (*E9*), specifically the motivation to learn and the ability to retain information in a given situation (Jawahar & Elango, 2001).

A negative attitude may lead to computer resistance (Sheiderman, 1980) (*D2*, *D3*, and *P3*), a phenomenon that can be found among experienced as well as inexperienced users (Negron, 1995). A negative attitude may even lead to defamation or sabotage of computer technology (Gibson & Rose, 1986).

A person's attitude toward computers and related technology could determine his or her performance with the technology and the satisfaction he or she draws from the

Figure 1. Model for interaction



experience (*E8*), although contradictory results are reported in the literature. Nickell and Pinto (1986) as well as Jawahar and Elango (2001) found a positive correlation between scores on a computer attitude scale and the final course grades of students enrolled in an introductory computer class. Other studies on students report an inverse relation between attitudes and performance (Hayek & Stephens, 1989; Marcoulides, 1988; Mawhinney & Saraswat, 1991), while still other researchers report no relationship between these two constructs (O'Quin et al., 1987; Kernan & Howard, 1990; Szajna & Mackay, 1995).

It was indicated above that scales to measure computer attitude differ with regard to the components they include. Jawahar and Elango (2001) also indicated that some tests measure attitudes toward working with computers, while others have components measuring general attitudes toward computers. These might be possible reasons for the contradictory results regarding the impact of computer attitude on computing performance. One cannot expect to obtain consistent results if the instruments used differ substantially from one another. This is one area in this field of research where agreement and subsequent standardization are yet to be achieved.

Impact of Computer Anxiety

Anxiety affects people's thinking, perception, and learning (Kaplan & Sadock, 1998). It also produces confusion and distortions of perception relating to time, space, people, and the meanings of events. These distortions usually have a negative effect on learning ability by lowering concen-

tration, reducing recall ability, and impairing the ability to make associations (*E6*).

Specifically, computer anxiety can be recognized by a fear expressed regarding present or future interactions with computers or computer-related technology, negative global attitudes about computers (*E7*), or self-critical internal dialogues during computer interactions (Rosen & Weil, 1995).

People with computer anxiety experience the incidence of physical, phobic symptoms, such as stomach cramps and cold sweats, as well as psychological symptoms, such as a resistance to use and a negative attitude toward a system (Shneiderman, 1980).

Computer anxiety seems to be a good predictor of computer achievement (*E5*). Marcoulides (1988) found that computer anxiety influenced the effectiveness with which college students could utilize the computer. Rosen et al. (1987) also found that computer-anxious undergraduate students enrolled in computer-based courses were twice as likely to drop out of the course and received lower course grades than nonanxious students.

Although anxiety usually has a negative connotation, there appear to be optimal levels of anxiety that help people to function effectively (Higgins, 1989) and that make them more alert and aware of what is going on (Lugo & Hershey, 1981; Beck & Emery, 1985) (*E5*).

Strategies to Sway Users' Attitudes

Previously, it was indicated that a negative computer attitude might lead to computer resistance. It is, therefore, important to identify strategies to enhance or sway users' attitudes toward computer use. Possible strategies are as follows (*E4*):

- Expose the users to successful and positive computer experiences (Yaghmaie et al., 1998).
- Make users aware of the fact that their computer literacy would be an advantage in any future work environment (Emmet, 1988).
- Involve users actively in the implementation of computer systems (Barry & Gibbons, 1990).
- Emphasize the ease with which work can be accomplished using a computer function (Marasovic et al., 1997).
- In training, stress the fact that computer use leads to desired outcomes (Marasovic et al., 1997).
- Include in training programs activities aimed at increasing self-efficacy (Henderson et al., 1995).
- Introduce incentives in order to convince and motivate users (Sultana, 1990).
- Consider the user's attitude and motivation when system designers design the user interface (Galitz, 1997).

Strategies to Minimize Computer Anxiety

Computer anxiety is something that will not just disappear on its own, but it is something that has to be dealt with. It is considered to be a temporal emotional state rather than a permanent personality trait and, therefore, can be remedied through positive computing experiences (Cambre & Cook, 1987). Possible strategies are as follows (*E2*):

- Easy-to-use computer systems (Appelbaum & Primmer, 1990)
- Basic training for the most routine tasks (Cambre & Cook, 1987; Flaughler, 1986; Lewis, 1988)
- Advanced training, which is essential to keep users interested as they progress (Appelbaum & Primmer, 1990)
- User support in the form of manuals, consultants, user groups, and computer specialists (Appelbaum & Primmer, 1990)

FUTURE TRENDS

It was argued above that the variety with regard to components and focus of the scales used by researchers to measure computer attitudes might be responsible for the contradictory results regarding the impact of computer attitude on computing performance. If a measuring scale for both computer attitude and computer anxiety can be standardized, much of the current confusion that exists in the literature could be solved. For example, the definition of computer comfort as it is given under "Terms and Definitions" below is merely the opposite of that for computer anxiety. This means that a standardization of measuring scales would include a consolidation of terminology.

CONCLUSION

The use of a graphic model provides an efficient way of understanding the interaction between computer attitude and computer anxiety, together with their causes, indicators, impacts, and strategies to deal with them.

From this model, it can be deduced that there are two-way interactions between computer attitude and computer anxiety on the one hand and computer task execution on the other. A vicious circle can be established where anxiety inhibits performance (*E5*), which in turn, produces a negative attitude toward the system (*E13*) and further slows the process of learning to use the system (*E9*).

External strategies can be applied to reduce computer anxiety and sway users' attitudes toward the use of computers (*E1–E4*). This will then lead to better achievement (E5

and *E8*), which will, in turn, lead to self-confidence (*E12*) and appreciation of the value of computers in general (*E13*). Less anxiety and a positive attitude will support the learning process (*E6* and *E9*), which will eventually result in better achievement.

Because of the proven effect of computer experience on attitude, moderate pressure can be applied to ensure that users do not avoid the use of computers and, in this way, never get the opportunity to gain experience (*D3*). This pressure can be explicit by means of assignment or by applying measures to create intrinsic motivation so that the user drives him- or herself.

KEY TERMS

Computer Anxiety: A diffuse, unpleasant, and vague sense of discomfort and apprehension when confronted by computer technology or people who talk about computers.

Computer Attitude: A complex mental state that affects a human's choice of action or behavior toward computers and computer-related tasks.

Computer Comfort: The user does not experience any suffering, anxiety, pain, etc., when using a computer.

Computer Confidence: The user is confident that he or she would be able to master a required skill to solve a particular problem using a computer, e.g., learning how to use a specific facility of an application program or learning a programming language.

Computer Liking: The use of a computer to solve problems is enjoyable, stimulating, and even addictive.

Self-Efficacy: Measure of a person's belief and confidence that he or she can perform a certain task.

Usefulness: The user is convinced that the use of computers in the workplace is an efficient and effective means to solve problems.

INTRODUCTION

The old computing is about what computers can do, the new computing is about what people can do. Ben Schneiderman, HCI Researcher (1997)

One of the most intriguing fields of human-computer interaction (HCI) involves the communication aspects of computer music interfaces. Music is a rich communication medium, and computer music is the amalgam of interface science and musical praxis forming a dynamic subset of HCI.

There are structural similarities between the job of a music composer and that of a *user interface designer* (although their objectives may be different). While sound has been used in general purpose interfaces as an *object*, its use has been deteriorated at a primary level, that of a signal-processing approach. However, music composition and performance are highly abstract human activities involving a semantic and a symbolic mechanism of human intellectual activity.

This article analyzes the unique problems posed by the use of computers by composers and performers of music. It presents the HCI predicates involved in the chain of musical interaction with computer devices, commencing from the abstract part of symbolic composition, then coping with usability issues of the graphical user interfaces (GUIs) implemented for musical scripting, and concluding to a synthesis stage which produces digitized sounds that enhance or replace original analog audio signals. The evaluation of HCI elements for computer music under the prism of usability aims at the development of new graphical tools, new symbolic languages, and finally better user interfaces. The advance in technology on this area creates the demand for more qualitative user interfaces and more functional and flexible computer music devices. The peculiarities of computer music create new fields in HCI research concerning the design and the functionality of computer music systems.

BACKGROUND

Computer Music Interfaces

In the early stages of the microcomputer evolution, various protocols had been developed in order to achieve interconnection between computers and instruments. The milestone of computer music proved however to be the musical instrument digital interface (MIDI), which is a communications standard used for transmitting musical performance information (Aikin, 2003). It was developed in 1983 in response to the increasing sophistication, and corresponding complexity, of commercial electronic instruments, especially synthesizers. Therefore, MIDI is a protocol specifying how electronic musical instruments may be controlled remotely. In brief, MIDI is a very successful and inexpensive protocol that has reshaped the computer music landscape. However, it cannot overcome easily its representation limitations, especially on alternative music notations. The common music notation (CMN) scheme along with the MIDI specification is Western music oriented. The problem with CMN has been taken into account in several works: Although CMN is supposed to furnish a model for traditional music in a European style, it is not absolutely supposed that this model is also convenient or suitable for music coming from outside of Western traditions (East Asia, Middle East countries, etc.) (Bellini, Barthelemy, Nesi, & Zoia, 2004). As a result, they are not able to clearly depict alternate musical forms and traditions.

Almost all music recordings today utilize MIDI as a key enabling technology for recording music. In addition, MIDI is also used to control hardware including recording devices as well as live performance equipment such as stage lights and effects pedals. Lately, MIDI has exploded onto the scene with its adoption into mobile phones. MIDI is used to play back the ring tones of MIDI capable phones. MIDI is also used to provide game music in some video games.

MIDI is almost directly responsible for bringing an end to the "wall of synthesizers" phenomenon in 1970-1980s rock music concerts, when musical keyboard performers

were sometimes hidden behind banks of various instruments. Following the advent of MIDI, many synthesizers were released in rack-mount versions, enabling performers to control multiple instruments from a single keyboard. Another important effect of MIDI has been the development of hardware and computer-based sequencers, which can be used to record, edit, and playback performances.

A number of music file formats have been based on the MIDI bytestream. These formats are very compact; often a file of only 10 kilobytes and can produce a full minute of music.

MIDI, albeit the dominant, is not the most expandable and modular interface. Also, other interfaces like the Synthesis toolKit Instrument Network Interface (SKINI) physical modeling interfaces have appeared (Cook, 1996). These interfaces are purely computer software inventions and lack the hardware orientation of MIDI. However, they are more adaptive in expressing alternate musical forms and interfaces.

Computer Music Languages

An *audio programming language* is a programming language specifically targeted to sound and music production or synthesis. Such languages are: ABC, ChucK, CMix, CMusic, Common Lisp Music (CLM), CSound, Haskore, HMSL, Impromptu, jMusic, JSyn, Loco, designed to be for sound what Logo is for graphics, Max/MSP, Music I, Music-N, Nyquist, OpenMusic, Pure Data, Real-time CMix, Soundscrape, SuperCollider, Q-Audio. Each of thoses languages has its own features and objectives. For instance, JSyn is used by JAVA programmers and makes use of simple methods, which are written in C language, for real-time audio synthesis.

Score Writing and Notation Creation

This category of interfaces consists of state-of-the-art, easy-to-use GUIs that provide ways to create, enter, edit, hear, view, lay out, and ultimately print music in staff notation. Usually these programs have complete control over every aspect of music printing and publishing. Generally, they are perceived as mature products, satisfying the musician in the same sense that a good word processing system satisfies the author enough to shift from handwriting to electronic processing.

However, their expression format is staff based, and therefore they can satisfy users' needs as long as the CMN can satisfy the expression of the melody accurately. A typical interface for CMN composition is shown in Figure 1. Figures 2 and 3 show two applications for music notation: Sibellius and Quitar Pro.

There are several methods used to enter music data into notation editors and sequencers.

An attractive method for keyboard players is to enter music by playing it on a MIDI keyboard. Most commercial notation editors allow this method. Unfortunately, automatic identification of rhythms is difficult, so the user must carefully check all notes in order to correct errors. Furthermore, each voice must be entered separately.

Optical music recognition (OMR), the musical equivalent of optical character recognition (OCR), has been used in building some music collections. Unfortunately, OMR is less accurate than OCR, and the scanned music must be carefully checked for errors, a process that often requires a considerable length of time (Rossant & Bloch, 2004).

The most common music entry method is by handling a GUI, using a mouse. The problem is that a mouse provides two-dimensional data entry, with horizontal and vertical coordinates. Music notation, however, is inherently three dimensional, with the horizontal dimension indicating time of note onset, the vertical dimension indicating the frequency of the note, and the shape of the note indicating rhythm, or note duration.

Musical Interfaces for Alternative Music Systems

For Western music users, or for systems that have adapted to CMN, there seems to be little or no problem. However, the world of music is not unified. Especially in the East, we do have alternate musical interfaces which use different semantics. A classical example is that of Byzantine music. This kind of music, apart from having a significant diachrony, serves also as an intuitively alternate interface, since it uses the notification methodology of ancient Delta systems (Margounakis & Politis, 2005).

In Figure 4 ARION is presented, which is a prototypal visual client, the first of its kind, that has served for composition with Ancient Greek music semantics (Politis, Vandikas, & Margounakis, 2005). ARION uses real-time physical modeling, voice reproduction techniques and provides ethnomusicology with an easy-to-use and functional interface for notation-based Ancient Greek music synthesis.

Recording Systems and Production Systems

This category of products, undoubtedly the flagship of the computer music industry, produces complete professional music recording systems. Usually they combine high resolution MIDI recording channels with audio recording in either 16- or 24-bit formats. This way they offer state-of-the-art multi-track, digital input capabilities and thus simulate and gradually replace classical analog recording studios in the meanwhile having the advantage of inherent communication with digital instruments. Although the hardware and

Figure 1. Entry level score writer, cakewalk's notation handling module

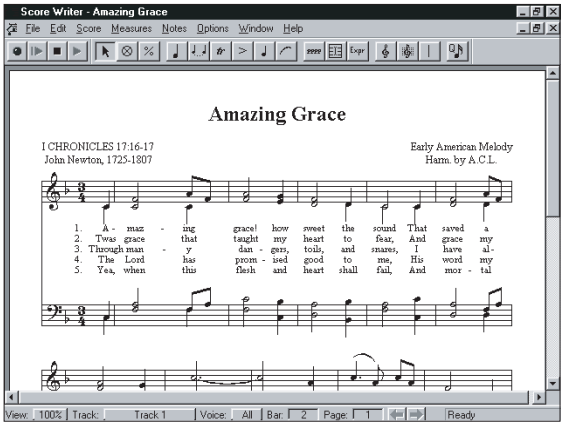

Figure 2. SIBELIUS *is a complete software for writing, playing, printing, and publishing music notation.*

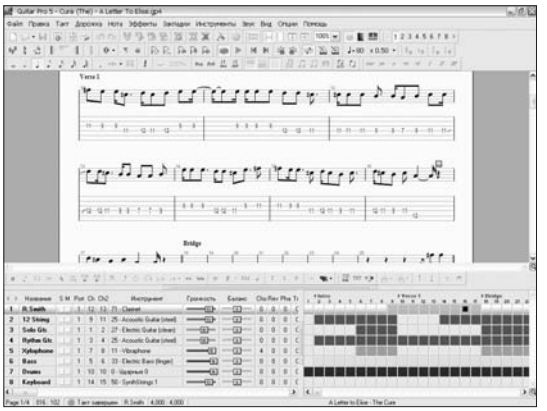
Figure 3. Guitar Pro is a multi-track tablature editor for guitar, banjo, and bass.



the low-level capabilities of these systems rely heavily on the MIDI specification and therefore do not offer substantial improvements over the performance limitations of MIDI, their high-level perception, that is, their GUIs challenge the computer music community for the invention of new conceptually and functionally composing and synthesizing schemas. To a great extent this has been solved with the various plug-ins that accompany and complement the basic systems.

An important attribute of music recording and production software systems is the effective visualization of computer music predicates. Several plug-ins allow this visualization in a spatial and semantically polymorphic way. Another key element of these systems is that they also carry out tasks in real time. This fact makes them straightly comparable to hardware synthesizers. Aikin (2003) compares the advantages of computer-based instruments (software synths) to dedicated hardware (hardware synthesizers) and comes to the conclusion that although music software is an evolving dynamic scene, hardware instruments will always play a vital role in music synthesis.

In musical composition, the strength of these systems lies on the symbolic processing of CMN. However, these systems are not merely notation interfaces that perform via the MIDI specification. Good performance criteria should also apply.

In this field, the advances in HCI challenge for innovations beyond the limited, file-based, single-data-type applications. The momentum is towards models supporting richer data types, visualization paradigms, and distributed storage such as the model behind the rapidly evolving World Wide Web.

The multi-dimensionality of musical data begs for higher dimensions of control and representation impossible with the current "paper on a desktop" metaphor (Freed, 1995) (Figures 5, 6).

Waveform Processing Systems

This category of products, is related with the signal processing aspect of computer music. Although these systems allow the production of virtually *any* sound, they are not short-term composition systems, and they will not be considered.

PROBLEM FORMULATION

The use of computer music interfaces aims at producing melodic pieces. The instrument used in this case is a computer program, perhaps in conjunction with a keyboard hardware interface communicating via the MIDI-IN and OUT ports. Producing melodic lines is a matter of inspiration and not an arbitrary or disciplined procedure. In terms of HCI it means that the computer program used must have

Figure 4. The graphical user interface of ARION

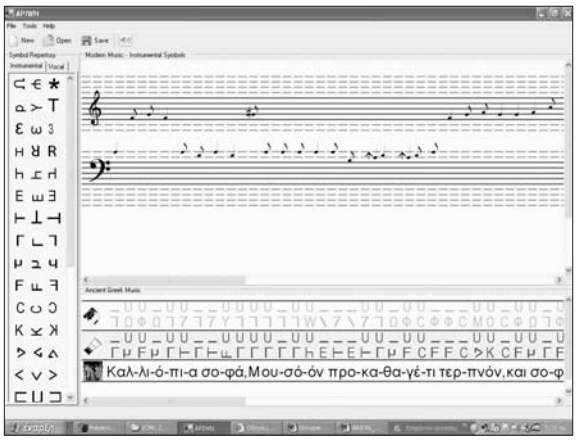


Figure 5. Typical recording systems interfaces implementing the recording console metaphor

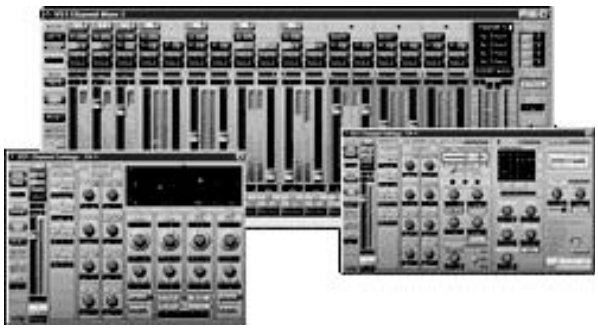

Figure 6. Orion Platinum 6 introduces the impulse response processor, an effect for applying reverbera-tion from captured impulse responses.

functionality and *usability* features that enable the user to record in symbolic form the music he has conceived. Usually, five criteria are used in order to evaluate the usability of an interface according to the ISO/DIS 9241-11 directive (ISO DIS 9241-11, 1996):

1. Learnability for the use of the new system. Five principles that affect learnability are: predictability, synthesizability, familiarity, generalizability, and consistency (Dix, Finlay, Abowd, & Beale, 2004).
2. Effectiveness, that is, the extent to which the intended goals of musical synthesis and composition are achieved. The effectiveness with which users employ a product to carry out a task is defined as a function of two components, the quantity of the task attempted by the users, and the quality of the goals they achieve.

   Effectiveness |= *f*(quantity, quality)

3. Efficiency, when used by experienced and trained users, that is, the amount of resources that have to be expended to achieve the intended goals. This criterion is more procedural than quantitative in computer music. In engineering, the term *efficiency* is uncontentiously understood as the ratio of useful energy output to energy input.
4. Satisfaction, in the sense of the extent to which the user finds the use of the product acceptable and desirable.
5. Capability to use the system from users not familiar with its musical categories and predicates after a long time.

In order to evaluate the performance of computer music systems on alternate musical interfaces a heuristic evaluation will be performed. According to Nielsen (1994) heuristic evaluation is a usability engineering method for finding the usability problems in a user interface design so that they can be attended to as part of an iterative design process. Heuristic evaluation involves having a small set of evaluators, experts in their field, examining the interface and judging its compliance with recognized usability principles (the "heuristics"). For each category of musical interface products, evaluation takes place according to the previously mentioned criteria.

RESULTS

The evaluation of specific computer music interfaces is based on the previously mentioned usability criteria. These criteria however are adjusted to the specific communication content of each interface. The evaluation is calibrated with

Table 1. Usability evaluation of computer music protocols on their ability to simulate alternate musical sounds

Protocol	Simulation	Interconnection	Expandability	Acceptability	Learnability
MIDI (Industry standard)	+/-	+	-	+	+
PM	+	+	+	-	+
Extended MIDI	+	+	+/-	+/-	+

Table 2. Usability evaluation of computer music software modules on their ability to track down alternate musical predicates and to produce adequate sounds

Product group	Alternate symbolic representation	learnability	Simulation effectiveness	Expandability	Efficiency	Satisfaction
CMN based	-	+/-	-	+/-	-	-
System based	-	+/-	+/-	+	+/-	+/-
Alternate	+	+	+	-	+	+

the following ratings of confidence whether a task can be performed:

- : weak confidence, +/- : plausible, + : strong confidence.

Interfaces

The usability criteria for the category of computer music protocols and specifications has to do mainly with the ability to simulate a broad range of musical data, to present them in an acceptable way, and to expand to alternative musical forms. An evaluation of some schemas is shown in Table 1.

The term *simulation* describes the ability to render musical sounds close to the real-time performance data.

The term *interconnection* implies the ability to communicate with other digital musical devices. The term *expandability* describes the ability to engulf alternate musical systems and events.

The term *acceptability* measures the propagation of the protocol to alternative musical traditions users. The term *learnability* implies how easily the users of a specific product learn to produce alternative musical sounds and predicates.

Score Writing and Production

In this combined category, the evaluation criteria are adjusted to the pool of computer music users attempting to compose not abstract CMN melodies but melodies which will be performed and propagated to listeners of alternate musical systems. Modern Greek Pop music has been taken into account.

Hardware incarnations of such systems were also considered; the basic criterion for their acceptance is the existence of a corresponding software module which can at least create notation or symbolic scripting of the performed music. For instance, if we have a keyboard performing Arab or Byzantine tunes, it is a prerequisite to have a software module that can write melodic lines according to this system. It is desirable but not obligatory for these systems to communicate.

The comparison of such systems is performed in Table 2. The well-known ISO/DIS 9241-11 (ISO DIS 9241-11, 1996) usability criteria are applied.

Some variations and extension of these criteria have to do with:

1. whether the system has room for symbolic representation of the alternate musical form;
2. whether the system is learnable for users expressed mainly in alternate forms and not in CMN;
3. whether the produced sound or the symbolic scripting of a melody are close to the alternate music predicates;
4. whether the system is modular and can cooperate with other computer music instruments and gadgets;
5. whether expert users of computer software and alternate music theory and practice can produce alternative music; and
6. whether the listeners of alternate music forms accept the audio result of the simulation.

FUTURE TRENDS

Virtual Music Environments

The concept of the virtual music environment (VME) is a generalization of a virtual music instrument, in which the virtual world itself acts as a source of multimodal (e.g.,

visual, audio, haptic) feedback, and at the same time, a place of interaction. Naturally, the two important issues in designing a VME are: (1) the display content and (2) the control interface. These two issues are in fact interrelated as music performance is seen as a closed loop system composed of the user and the VME. The control interface must be designed to be as natural and easy-to-use as possible for quick responses to the ongoing music, and the world around the user must contain the right information and convey it to the user in an intuitive manner for acceptable controllability. The display must also be "vivid" in the sense that it must leave the user with a strong musical impression so that one remembers the "essence" of the musical content. Several virtual music environments have been proposed (Broersen & Nijholt, 2002; Valbom & Macros, 2003).

Interaction with Computer Music Systems

In an effort for more natural interaction with the computer music systems, we need support for input devices with higher control bandwidth and dimensionality than the mouse that may lead to a faster, more natural, and more fluid style of interaction for certain tasks (Wu & Balakrishnan, 2003). There is also need to integrate new kinds of keyboards and a broader range of physical gestures and nonhuman control sources. Several works are related to new gesture input devices (Malik & Laszlo, 2004; Wilson, 2004; Wilson & Cutrell, 2005).

Many musicians find the interface (mouse, computer keyboard and/or synthesiser keyboard) less natural than the traditional pencil and manuscript, so alternatives are an active area of research. Pen-based systems for data entry are rapidly developing, driven by their popularity with users. As a consequence, pen-based systems for music tasks are designed (Phon-Amnuaisuk, 2004). A set of gestures for the pen entry of music was reported in 1996. One of the most important pen gestures is *Presto1* and *Presto2* by Presto.

Most electronic music controllers that have been created are based on existing acoustic instruments, such as the piano keyboard. Such electronic controllers have the obvious advantage of being used relatively easily by "traditionally" trained musicians. However, there is an emergence of whole new types of controllers and new ways of performing music (Masui, Tsukada, & Siio, 2004; Orio, Schnell, & Wanderley, 2001). Obviously, this also highlights the need for evaluation of these new types of devices (Wanderley & Orio, 2002).

CONCLUSION

Already several prototypal and research projects have been focusing on alternate music representation, authoring, and scripting. It is expected soon that the advances in GUI software engineering will enable the production of commercial products that can compete the more than a decade old Western music counterparts. Since the Western music interfaces have a very interesting evolution from the HCI point of view, a first performance evaluation on their outsourcing capabilities has been achieved.

KEY TERMS

Alternative Music Systems: Music systems that are not conformed to Western music features (notation, scales, consonance, timbre, rhythm, etc.). Byzantine and Oriental music are two examples of such systems.

Computer Music (CM): A field of study that examines both the theory and application of new and existing technologies in the areas of music, sound design and diffusion, acoustics, sound synthesis, digital signal processing, and psychoacoustics.

Computer Music Languages: Programming languages specifically targeted to sound or music production and synthesis.

Human-Computer Interaction (HCI): The study of the interaction between people and computers.

Interface Design: The design of software applications with the focus on the user's experience and interaction.

Musical Praxis: Musical practice; exercise or discipline for a specific purpose or object (here music composition and performance).

Prototypal: Representing or constituting an original type after which other similar things are patterned.

Usability: The extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use. In order to evaluate usability, five criteria are used: (1) learnability, (2) effectiveness, (3) efficiency, (4) satisfaction, and (5) capability.

Computer-Aided Diagnosis of Cardiac Arrhythmias

INTRODUCTION

In this chapter, the field of computer-aided diagnosis of cardiac arrhythmias is reviewed, methodologies are presented, and current trends are discussed. Cardiac arrhythmia is one of the leading causes of death in many countries worldwide. According to the World Health Organization, cardiovascular diseases are the cause of death of millions of people around the globe each year. The large variety and multifaceted nature of cardiac arrhythmias, combined with a wide range of treatments and outcomes, and complex relationships with other diseases, have made diagnosis and optimal treatment of cardiovascular diseases difficult for all but experienced cardiologists. Computer-aided diagnosis of medical deceases is one of the most important research fields in biomedical engineering. Several computer-aided approaches have been presented for automated detection and/or classification of cardiac arrhythmias. In what follows, we present methods reported in the literature in the last two decades that address: (i) the type of the diagnosis, that is, the expected result, (ii) the medical point of view, that is, the medical information and knowledge that is employed in order to reach the diagnosis, and (iii) the computer science point of view, that is, the data analysis techniques that are employed in order to reach the diagnosis.

BACKGROUND

Arrhythmia can be defined as either an irregular single heartbeat (arrhythmic beat), or as an irregular group of heartbeats (arrhythmic episode). Arrhythmias can affect the heart rate causing irregular rhythms, such as slow or fast heartbeat. Arrhythmias can take place in a healthy heart and be of minimal consequence (e.g., respiratory sinus arrhythmia), but they may also indicate a serious problem that may lead to stroke or sudden cardiac death (Sandoe & Sigurd, 1991). Ventricular arrhythmias may be categorized broadly as premature ventricular contractions (PVCs) and ventricular tachyarrhythmias, the latter including ventricular tachycardia (VT) and ventricular fibrillation (VF). Atrial fibrillation (AF) is the most prevalent arrhythmia in the western world, affecting 6% of the individuals over age 65 and 10% of those over age 80.

REVIEW OF THE PROPOSED METHODS

There are several aspects that can be addressed in order to review the proposed methods for computer-aided diagnosis of cardiac arrhythmias. The type of the diagnosis is the most important since cardiac arrhythmia is a very complex problem, having several different characteristics that need to be considered before reaching a safe diagnosis. Also, the electrocardiogram (ECG) analysis that is employed for this purpose is another important aspect. Finally, the data analysis and classification algorithms that are used define the accuracy and robustness of each approach.

Type of Diagnosis

Concerning the type of the diagnosis, two main approaches have been followed in the literature: (i) arrhythmic episode classification, where the techniques focus on the total episode and not on a single beat, and (ii) beat-by-beat classification, in which each beat is classified into one of several different classes related to arrhythmic behavior. Arrhythmic episode classification was performed in most of the methods proposed early in the literature, addressing mainly the discrimination of one or more of ventricular tachycardia (VT), ventricular fibrillation (VF), and atria fibrillation (AF) from normal sinus rhythm (NSR). More recent approaches mainly focus on beat-by-beat classification. In each case, a much larger

number of different types of cardiac arrhythmic beats are considered. A combination of these two different approaches has been proposed by Tsipouras (Tsipouras, Fotiadis, & Sideris, 2005), where beat-by-beat classification was initially performed and the generated annotation sequence was used in order to detect and classify several types of arrhythmic episodes.

Medical Data and Knowledge

In what concerns medical information, the main examination that leads to cardiac arrhythmia diagnosis is the ECG recording; thus, the majority of the methods proposed in the literature are based on its analysis. In the early studies, the ECG waveform was directly used for the analysis from it. However, more recent approaches are based on ECG feature extraction. In this case, features are mainly on the time and frequency domains in the early studies, while more complex time-frequency (TF) and chaos analysis are employed in the more recent studies, trying to access the nonstationary dynamic nature of the signal. Related to morphological features, QRS detection is the easiest to apply and the most accurate ECG processing method and thus, the most commonly used in the literature: almost all proposed methods include QRS detection in some stage of their analysis. Several other morphological features, inspired from the physiology of the ECG signal, have been employed in the proposed studies. However, the detection and measurement of all morphological features is seriously affected by the presence of noise, with the R peck being the least distorted. The identification of the importance of the heart rate variability has led to the development of methods based solely on the RR-interval signal and features that are extracted from it, for cardiac arrhythmia assessment.

Medical knowledge has been used in most of the proposed methods, mainly defining the features that carry sufficient information to be used for the classification. Rule-based medical knowledge has been employed in limited studies; instead mainly data-driven approaches have been developed. Thus, medical knowledge have also been employed for the generation of the annotation of the datasets, since data-driven approaches require an initial annotated dataset in order to be trained. In Tsipouras (Tsipouras, Voglis, & Fotiadis, 2007), a hybrid technique has been proposed in which both knowledge-based rules and training based on annotated data have been integrated into a single fuzzy model.

Data Analysis and Classification Algorithms

The general scheme that dominates the proposed methods for arrhythmia diagnosis is a two-stage approach: feature extraction from the ECG and classification based on these features. For the feature extraction stage, time and frequency analysis techniques have been gradually replaced by TF and chaos analysis. TF distributions and wavelet transform (WT) are commonly employed to measure the signal's energy distribution over the TF plane. In addition, combination between features originated from two or more different domains, has become a common practice. However, the major shift has emerged in the classification stage: the initial threshold-based techniques and crisp logic rules have been replaced with complex machine-learning techniques and fuzzy models. Most of the proposed approaches are based on several variations of artificial neural networks (ANNs) for the final classification and, in addition, hybrid approaches employing several ANNs and combining their outcomes have also been widely used. Support vector machines (SVMs) have also been incorporated, while fuzzy logic has been employed, either as part of the classification mechanism or for the definition of the fuzzy classifiers.

PROPOSED APPROACHES FOR COMPUTER-AIDED DIAGNOSIS OF CARDIAC ARRHYTHMIAS

Several researchers have addressed the issue of automated computer-based detection and classification of cardiac rhythms. We present methods that are considered in the literature as the most cited in the field. Thakor et al. (**Thakor,** Zhu, & Pan, **1990)** proposed a sequential hypothesis testing (SHT) algorithm for the detection of VT and VF. The detection is based on the evolution of a binary signal, generated using a threshold crossing interval (TCI) technique. The algorithm was tested in a database consisting of 170 ECG recordings (half from each category) having 8-sec length, and the results indicate that the detection was 94.12% for VT and 82.35% for VF after 4 sec, while the results increase to 100% for both arrhythmic types after 7 sec. An improvement of this approach was proposed by Thakor et al. (Thakor, Natarajan, & Tomaselli, 1994), named multiway SHT algorithm. In this case, three types of rhythm are considered, VT, supraventricular tachycardia (SVT), and NSR. The algorithm is evaluated in a dataset including 28, 31, and 43 segments for each type of rhythm and its accuracy is 98% after 1.6-, 5-, and 3.6-sec evolution time of the episode for VT, SVT, and NSR, respectively. Chen et al. (Chen, Clarkson, & Fan, 1996) applied the SHT algorithm, on the malignant arrhythmia subset of the MIT-BIH database (MITADB), resulting in much lower results. Thus, they have proposed a modification for this technique, employing dubbed blanking variability as basis for discrimination. Testing both the initial SHT technique and their modified approach to a subset of the database (30 episodes of VF and 70 episodes of VT), the classification accuracy improved from 84% to 95%. A similar approach

was proposed by Zhang et al. (Zhang, Zhu, Thakor, & Wang, 1999). Again, a binary signal is generated from the ECG recording using a threshold, and then the normalized complexity measured is calculated. Then, minimum, maximum, mean, and standard deviation features are extracted from it, for a specific window length, and are used for classification using statistical analysis. The classification is performed for three types of cardiac rhythm, VT, VF, and NSR. The dataset was the same as the one used in Thakor (1990), while 34 ECG recordings of NSR were added from the MITADB. A comparative study was performed with respect to the length of the window length, which varied from 1 to 8 sec. Results indicated 100% sensitivity and specificity for all categories when 7-sec window length is reached.

The problem of VF detection was also addressed by Alfonso and Tompkins (1995), using TF analysis of ECG recordings. They compared short-time Fourier transform (STFT) and two TF distributions, smoothed pseudo Wigner Ville distribution (SPWVD) and cone-shaped kernel distribution (CSKD), in order to identify the TF analysis that provided more discriminatory features for VF vs. NSR. Recordings of NSR were obtained from the MITADB, while VF recordings were extracted from the Stanley database. Based on these, the authors demonstrated that TF distributions can provide a more detailed inside of the VF than STFT. Khadra et al. (Khadra, Al-Fahoum, & Al-Nashash, 1997) proposed a more spherical approach for the arrhythmic episode classification problem, addressing the classification of VT, VF, atrial tachycardia (AT), and NSR. Their approach was also based on TF analysis, applying WT to ECG recordings in order to produce the TF representation, and measuring the signal's energy distribution in specific time intervals and frequency subbands (related to ECG physiology), thus producing three features. The final classification was provided using these features with a rule-based classifier. Forty-five ECG recordings of 2-sec length were selected from the MITADB and the ECG database of the electronic engineering department of the Yarmouk University (YUDB), with 12 associated with VF, 13 with VT, 12 with AT, and 8 with NSR, to evaluate the proposed technique and the obtained accuracy is 88.89%. A similar approach was proposed by Al-Fahoum and Howitt (1999). In this case, six features were extracted measuring the signal's energy distribution in specific time intervals related to ECG physiology and frequency subbands. Classification was performed using radial basis functions neural network (RBFNN), based on the leave-one-out evaluation strategy. The employed ECG recordings had 1-sec length, thus focusing on a single beat rather than a group of beats. For the evaluation of the method, 49 beats of VF, 49 beats of VT, 21 beats of AF, and 40 beats of NSR (in total 159 beats) were selected from the MITADB, the YUDB, and the Marquette medical systems ECG database. Comparative analysis was performed between nine different wavelets and the results indicated accuracy ranging from 81.1%-97.5%. TF analysis was also employed by Tsipouras and Fotiadis (2004) for the classification of ECG segments as normal or arrhythmic. In this study, time and TF analysis were used to extract features from the RR interval signal while classification was performed based on mixture-of-classifiers approach, using the combined results of several artificial neural networks (ANNs). In the time domain, six known heart rate variability (HRV) features were extracted, such as standard deviation of the RR intervals and standard deviation of the HRV, and all different combinations among them were used to train the ANNs. In the case of TF analysis, STFT and 18 time-frequency distributions were used to generate the TF representation and then, for each of them, features were extracted representing the signal's energy distribution over the TF plane and based on these, an ANN was trained. The evaluation was performed based on 32 RR intervals segments (corresponding to approximately 30-sec ECG recordings), extracted using all recordings from the MITADB. Classification sensitivity and specificity were 87.53% and 89.48%, respectively, for the time domain features, and 89.95% and 92.91%, respectively, for TF domain features.

Beat-to-beat classification was addressed by Simon and Eswaran (1997). In their work, analysis of each ECG waveform was performed using discrete cosine transform (DCT) and using the extracted coefficients as an input into a set of ANNs, each of them identifying a specific classification category, while the final classification was defined combining the outputs of all ANNs. The proposed method was used to identify beats belonging to five categories, while using data from the MITADB, the Glasgow database, and scanned waveforms, training and test sets were comprised, including 54 beats for training and 1,040 beats for testing. The evaluation of the method indicated an average sensitivity of 96.04%. Hu et al. (Hu, Palreddy, & Tompkins, 1997) have presented a method for beat classification, based on a mixture of experts approach, which is also a technique based on combining outcomes of ANNs. In this case, the ECG beat waveform was used as input for two ANN-based classifiers, one trained using data from several patients (global expert), and a second using data from a specific patient (local expert), and the combination of their outputs, using a gaiting network, provided the final classification. Although, the authors use a four-category dataset extracted from the MITADB, evaluation is based on the identification of only two categories, namely PVCs and normal (N) beats. Evaluation was based on 43,897 N beats and 5,363 PVC. The reported accuracy was 95.52%. Beat morphology and interval features were also used by Chazal et al. (Chazal, O'Dwyer, & Reilly, 2004) for cardiac beats classification. The extracted features are used with a linear discriminants classifier, based on maximum likelihood, to classify heart beats into five categories. The MITADB was used for training and evaluating the proposed method: 51,020 beats were used for training and 49,711 for testing, obtaining 86.2% accuracy.

Beat-by-beat classification was also addressed by Miniami et al. (Miniami, Nakajima, & Toyoshima, 1999), for supraventricular rhythm (SVR), ventricular rhythm (VR), and ventricular flutter/fibrillation (VFF). The spectrum of each QRS complex is accessed using FT, extracting five spectral components (features) fed into an ANN, which provides the final classification. The dataset included 700 QRSs, including 200, 100, and 200 for SVR, VR, and VFF, respectively, used for training the ANN and 100, 50, and 100 QRSs used for evaluation. Results indicated 90.33% average sensitivity and 95.33% average specificity. Dokur and Olmez (2001) also exploited beat-by-beat classification based on ANNs. Frequency domain features are extracted from the ECG beat waveform, using two different approaches, one based on FT and the second based on WT. Classification is performed for 10 categories of arrhythmic beats, adopted from the MITADB annotations. A hybrid ANN was trained for each of the two approaches for feature extraction, using 150 beats from each category for training while evaluation was performed using again 150 beats from each category. The obtained results indicated 65.4% and 88% classification accuracy for the FT and WT feature sets, respectively. Osowski and Lihn (2001) developed a method for ECG beat classification based on ANNs. In this case, statistical features were derived from each ECG beat waveform and, based on them, a fuzzy hybrid ANN was used to generate the final classification. The classification categories were 7, again originated from the MITADB annotations, while 4.035 beats were used for training and 3.150 for testing the method, which reported 96.06% classification accuracy. Ge et al., (Ge, Srinivasan, & Krishnan, 2002) proposed a method for classification of cardiac beats into six categories: NSR, artial premature contractions (APC), PVC, SVT, VT, and VF. The ECG waveform is analyzed using autoregressive (AR) modeling, and the estimated AR coefficients were used in a generalized linear model to classify the cardiac arrhythmias. Using 856 cardiac beats, obtained from the MITADB, the proposed approach presented 96.85% classification accuracy. In a second approach, Osowski et al. (Osowski, Linh, & Markiewicz, 2004) addressed this problem, using again statistical features, but also a second set of features based on Hermite basis functions (HBF) extraction, while SVMs were employed. The number of categories increased to 13 and the train and test sets were comprised from 6.690 and 6.095 beats, respectively. The average sensitivity was 93.72%, in the case of statistical features, 94.57% in the case of HBF features, and 95.91% when both classifiers were integrated.

Ham and Han (1996) proposed the discrimination of N beats and PVCs based on fuzzy adaptive resonance theory mapping (fuzzy ARTMAP). Their approach was based on the analysis of three features, extracted from each cardiac beat: two linear predictive coding coefficients and the mean square value of the QRS complex. Then, a fuzzy ARTMAP, which is an ANN classifier, was employed for the final discrimination. For training purposes, and to test the described method, 12,123 N beats and 2,868 PVCs were used, resulting in 99.88% sensitivity and 97.43% specificity. Fuzzy logic was also employed in the approach proposed by Weibien et al. (Weibien, Afonso, & Tompkins, 1999) for the same problem. In this case, features were extracted from each cardiac beat related to heart rate, morphology, and TF characteristics of the QRS, accessed using a filter-bank for analysis and a fuzzy rule-based classifier was employed for the final classification. For training, 8,089 N beats and 1,080 PVCs were used, and 77,374 and 5,900, respectively, for testing, reporting average sensitivity 74.6% and average positive predictivity of 66.5%. Wang et al. (Wang, Zhu, Thakor, & Xu, 2001) addressed the problem of classification of ECG records in three categories: VT, VF, and AF. The analysis was based on features representing the short-time generalized dimensions of multifractal analysis, while classification was provided by a fuzzy Kohonen network. The test set comprised from 60 ECG recordings of each category, 6- or 8-sec long, while the average sensitivity and specificity were 97.2% and 98.63%, respectively.

Acharya et al. (Acharya, Bhat, Iyengar, Rao, & Dua, 2003) presented a classification method based solely on the RR interval signal. Four features are extracted from the RR interval signal, the average heart rate, two features representing signals energy on specific frequency subbands and the correlation dimension factor, extracted from 2-D phase-space plot of the signal. Based on these, a fuzzy equivalence relation classifier is generated, for four classification categories: ischemic/dilated cardiomyopathy, complete heart block, sick sinus syndrome, and NSR. Two hundred and seventy six ECG segments were used for training the classifier and 66 for testing. The average sensitivity was 95%. Acharya et al. (Acharya, Kumar, Bhat, Lim, Iyengar, Kannathal, & Krishnan, 2004) also presented a similar approach for eight classification categories, the four mentioned previously, and additionally left bundle branch block, PVC, AF, and VF. In this case, three features from the RR interval signal were employed, the spectral entropy, geometry of the 2-D phase-space plot of the signal, and the largest Lyapunov exponent, while the classifier was the same. Two hundred and seventy nine ECG segments were used for training the classifier and 167 for testing; the average sensitivity was 85.36%. Another approach for arrhythmic beat classification and arrhythmic episode detection and classification which is also based on the RR-interval signal, is proposed by Tsipouras et. al. (Tsipouras, 2005). A three RR-interval sliding window is used in the arrhythmic beat knowledge-based classification algorithm. Classification is performed for four categories of beats: N, PVCs, VFF, and 2o heart block (BII). The beat classification is used as input of a knowledge-based

deterministic automato to achieve arrhythmic episode detection and classification. Six rhythm types are classified: ventricular bigeminy, ventricular trigeminy, ventricular couplet, VT, VFF, and BII. The achieved scores for all beats of the MITADB (approximately 110,000 beats) indicate high performance: 94% average accuracy for arrhythmic beat classification and 94% average accuracy for arrhythmic episode detection and classification. For the same arrhythmic beat classification problem, Tsipouras et al. presented a second approach (Tsipouras, 2007), based on fuzzy logic. A similar knowledge-based initial set of rules was employed, which was then transformed into a fuzzy model, and an optimization technique was used to tune its parameters. Comparative analysis was performed for different fuzzyfication functions and realizations of the fuzzy operators used in the fuzzy model. The same dataset was used for evaluation, indicating 96.5% average accuracy.

FUTURE TRENDS

Based on the presented works, there should be no doubt that several challenges remain concerning the computer-aided diagnosis of cardiac arrhythmias. From the medical point of view, a major limitation in all proposed methods is that they are based solely on the analysis of ECG recordings. Other medical information related to the patient, such as medication and medical history, are not included. Genomic data, such as single nucleotide polymorphisms related to cardiac disorders, can also have a significant impact on the diagnostic value of such systems if they are incorporated. From the computer science point of view, several of the proposed techniques are based on "black box" approaches for the classification, such as ANNs, which cannot provide interpretation of the produced diagnosis. This is a very important aspect, since providing a clear insight of their inner process for decision-making mechanism is essential for physicians in order to incorporate such systems in their clinical practice. Moreover, experts rely more on systems that contain, to some extent, established medical knowledge in their decision-making mechanism. Thus, machine learning techniques that can generate transparent classification mechanisms and can also integrate established medical knowledge are the key to creating computer-based arrhythmia diagnosis systems that will be widely used.

CONCLUSIONS

Several computer-based methods for the automated diagnosis of cardiac arrhythmias have been presented. The methods indicate that, under special conditions, they can provide the doctors with diagnosis of arrhythmias. However, most of the methods have been evaluated in existing datasets and not in clinical conditions, where usually the signals are noisy and not easily interpretable. It seems that methods based on knowledge, in general, do not provide with the best results, but the doctor could be helped since the decisions made are easily interpretable. All methods to become a real tool need further refinement in terms of facing real clinical conditions, real-time operation, and extensive evaluation.

KEY TERMS

Artificial Neural Network (ANN): An interconnected group of artificial neurons that uses a mathematical or computational model for information processing based on a connectionist approach to computation. It has the ability to learn from knowledge, which is expressed through interunit connection strengths, and can make this knowledge available for use.

Atrial Fibrillation (AF): Disorganized, high-rate atrial electrical activity.

Atrial Premature Contractions (APCs): Single or paired extrasystoles that originate in the atrials.

Electrocardiogram (ECG): Recording of the electrical activity of the heart.

Fuzzy Logic: Derived from fuzzy set theory dealing with reasoning that is approximate rather than precisely deduced from classical predicate logic.

Heart Rate Variability (HRV): The alterations of the heart rate between consecutive heartbeats.

Premature Ventricular Contractions (PVCs): Single or paired extrasystoles that originate in the ventricles.

QRS Detection: Procedure for detecting the QRS complexes in the ECG signal.

RR-Interval Signal: The signal representing the durations between consecutive R waves of the ECG.

Ventricular Tachyarrhythmias: Repetitive forms of three or more consecutive ventricular ectopic beats.

Computing Curriculum Analysis and Development

Anthony Scime
State University of New York College at Brockport, USA

INTRODUCTION

Information technology (IT) is an umbrella term that encompasses disciplines dealing with the computer and its functions. These disciplines originated from interests in using the computer to solve problems, the theory of computation, and the development of the computer and its components.

Professionals from around the world with similar interests in IT came together and formed international professional organizations. The professional organizations span the disciplines of computer engineering (CE), computer science (CS), software engineering (SE), computer information systems (CIS), management information systems (MIS), and information technology (IT) (Freeman & Aspray, 1999). Note that information technology is both an umbrella term and a specific discipline under that umbrella.

These organizations exist to promote their profession and one method of promotion is through education. So, these professional organizations defined bodies of knowledge around the computer, which have been formalized and shaped as model curriculums. The organizations hope that colleges and universities will educate students in the IT disciplines to become knowledgeable professionals.

Because of the common interest in computing, there is a basic theory and a common technical core that exists among the model curricula (Denning, 1999; Tucker et al., 1991). Nevertheless each of the model curricula emphasizes a different perspective of IT. Each fills a different role in providing IT professionals. It falls upon the colleges and universities to select and modify the corresponding curriculum model to fit their needs.

BACKGROUND

Currently, there are a number of model curricula for computing (Table 1). A Joint Task Force on Computing Curricula created by the Association for Computing Machinery (ACM), and the IEEE Computer Society (IEEE-CS) developed Computing Curricula 2001 (CC 2001). This model focuses on programs in theoretical and applied computer science with various areas of emphasis in all areas of computing including computer engineering (CE), the engineering of computer hardware, and computer science (CS), the theory and design of hardware and software (Computing Curricula, 2001).

The field of information systems (IS) can be divided into the management of information systems (MIS), the engineering of computer information systems (CIS) and the use of existing commercial software applications to solve organizational problems or information technology (IT). The Information Resource Management Association (IRMA) and the Data Administration Managers Association (DAMA) have a curriculum model for MIS known as the Information Resource Management (IRM) model. It takes a management of data approach to information systems (Cohen, 2000). For a strong accounting and management MIS orientation, the Information Systems Auditing and Control Foundation has developed an interdisciplinary curriculum known as the Information Systems Auditing at the Undergraduate and Graduate Levels (ISA) model (ISACF, 1998).

IS 2002 (Information Systems, 2002) is a model curriculum developed through the joint efforts of the ACM, the Association for Information Systems (AIS), and the Association of Information Technology Professionals (AITP). This curriculum model focuses on information systems development as well as on management (Gorgone, Davis, Valacich, Topi, Feinstein, & Longenecker, 2002). The Information Systems Centric Curriculum (ISCC '99) model was developed by a task force that included members from academe and industry. It is oriented to large-scale system design and implementation. The focus is on the construction of the tools necessary for information management (Lidtke, Stokes, Haines, & Mulder, 1999).

The IT education special interest group of the ACM (SIGSITE) has developed a curriculum proposal. This curriculum is oriented toward the use of computing applications to solve organizational problems (IT Curriculum Proposal – Draft, 2002). An existing IT model is the Organizational and End User Information Systems (OEIS) model developed by the Office Systems Research Association. It is aimed at IT support of end-users. (Office Systems Research Association, 1996).

The Software Engineering Institute (SEI) has developed a model that follows the engineering approach of design first in the construction of software for embedded, large, and critical systems. The model strongly suggests specialization in a specific application domain (Bagert, Hilburn, Hislop, Lutz, McCracken, & Mangal, 1999).

Table 1. IT professional organizations and curriculum models

Professional Organization	Curriculum Models
Association for Computing Machinery (ACM)	Computing Curricula 2001 (CC 2001)
	Information Systems 2002 (IS 2002)
Association for Information Systems (AIS)	Information Systems 2002 (IS 2002)
Association of Information Technology Professionals (AITP)	Information Systems 2002 (IS 2002)
Computing Society of the Institute of Electrical and Electronic Engineers (IEEE-CS)	Computing Curricula 2001 (CC 2001)
Data Administration Managers Association (DAMA)	Information Resource Management (IRM)
Information Resources Management Association (IRMA)	Information Resource Management (IRM)
Information Systems Audit and Control Association (ISACA)	Information Systems Auditing at the Undergraduate and Graduate Levels (ISA)
International Federation for Information Processing (IFIP)	Informatics Curriculum Framework 2000 (ICF-2000)
Office Systems Research Association (OSRA)	Organizational and End User Information Systems (OEIS)
Software Engineering Institute (SEI)	Software Engineering Institute (SEI)
Special Interest Group in Information Technology Education (SITE) of the ACM	Information Technology Curriculum Proposal (IT)
An independent group of Academics and Professionals	Information Systems Centric Curriculum ’99 (ISCC ’99)

Internationally, the International Federation for Information Processing (IFIP) in coordination with the United Nations Educational, Scientific and Cultural Organization (USESCO) has developed a framework within which schools can develop an IT curriculum (Mulder & van Weert, 2000). The Informatics Curriculum Framework 2000 (ICF-2000) considers the needs of developing countries for IT knowledgeable workers. These needs are balanced against the country’s educational resources. The result is a tailored IT curriculum based on the established models.

CONSIDERATIONS IN DEVELOPING A CURRICULUM

To select or develop a curriculum, a school needs to assess their objectives and capabilities in providing graduates to the IT work force. A school with a strong liberal arts tradition has a different philosophy than a technically oriented school. A large university may have schools of computing and business; the focus of each may produce different information technology professionals. Some schools prepare students for further study while others are oriented to the job market. Schools with an international or national focus have different objectives than schools providing entry-level professionals locally.

The resources of a school may limit the curriculum as well. Time is a critical resource. Some model curricula require a student begin studying information technology courses in the first semester, others require only 4 or 5 semesters of IT and begin in the 3rd year of study. IT disciplines vary on the requirement for facilities. Courses requiring hands-on hardware to test theory or practice application require laboratories similar to those in an electrical engineering department. Some curricula stress practical application in commercial settings. This requires the school have close working relationships with local sponsors. The interests of the IT faculty also have an impact on curriculum development. Ideally, IT departments are well balanced in faculty expertise. However, it is possible for a balanced department to have a greater interest in the development of IT artifacts versus the management of those artifacts. IT is a very large discipline, for one small department to be able to provide expertise in all facets of IT is unlikely.

Having considered the previously mentioned considerations, a school should also consider the role for which they are preparing graduates. Students require different knowledge dependent upon the role they will perform within IT. The

Table 2. Technical core and role emphasis by discipline and curriculum model

Discipline		CIS		MIS		IT		SE	CE	CS

curriculum studied helps determine the graduate's role. All information technology education consists of various technical, computer-oriented topics ranging from a theoretical understanding of computing, through the design and support of practical applications for complex computer systems. The depth of knowledge in these topics varies with the specific IT discipline and model curriculum (Scime, 2002b).

The fundamental knowledge in all the information technology disciplines involves the development, modification, support, conceptualization, and management of software and hardware artifacts (Freeman & Aspray, 1999; Information Technology Association of America, 1997). Developers work with programming and modeling languages. Developers need multiple courses in at least one of these areas. Modifiers need strength in programming or application tools. Supporters need to understand the end-users as well as the technology. Although conceptualizers typically have graduate degrees, at the undergraduate level this thinking begins with a strong theory component and by relating IT to the real world. Finally, IT managers are also conceptualizers by bringing together the IT professionals to satisfy an organization's need for information.

Not emphasizing the same common technical core of IT knowledge is what makes the IT disciplines differ from one another. Some areas of the core are emphasized in different model curricula, and provide an orientation of knowledge toward one or more of the professional roles. By considering the number of required and elective courses for an element of the technical core in a model the strengths of the model can be estimated. The relationship of the emphasis of tech-

nical topics, and the IT disciplines and professional roles supported by the curriculum models is of value in selecting a model as a beginning to program development (Table 2) (Scime, 2002b).

FUTURE TRENDS

The ACM and IEEE-CS are currently working on extending their model (CC 2001) to include other computing disciplines. They expect to create four volumes of curriculum models. These will include a model for computer engineering, software engineering, and information systems, as well as the current model for computer science. The software engineering work is currently in first draft. The computer engineering model is currently a preliminary draft. The information systems model is expected to closely match AIS/AITP/ACM's current IS 2002 model.

As computing becomes more and more ubiquitous, the use of the computer and its theoretical basis will continue to expand and infiltrate other disciplines. Expansion will manifest itself as the creation and clear definition of subdisciplines, such as CE, SE and IS are today. Infiltration is the inclusion of IT into the sciences, arts, and humanities, for example, the use of graphical information systems in earth science and criminal justice.

CONCLUSION

The constantly changing world of computing and the constantly changing world of business leads to the enviable weakness of computing education (Lidtke, Stokes, Haines, & Mulder, 1999). Each school needs to assess their educational philosophy and student needs to create the curriculum best for them. By closely following a model, a school's prospective students, student's potential employers, and graduate schools know the type of education received by the graduates. The school administration is assured that the IT department is providing a curriculum, which covers all of the central topics of IT and emphasizes the chosen information technology discipline (Scime, 2001, 2002a, 2002b).

Although the disciplines differ in emphasis, all businesses that use information (and they all do) will need information technologist from each of the disciplines. All are necessary, but not all need to be provided from the same source.

(1991). Computing Curricula 1991: Report of the ACM/IEEE-CS Joint Curriculum Task Force, Association of Computing Machinery.

KEY TERMS

Computer Engineering (CE): The engineering of computer hardware.

Computer Information Systems (CIS): Concerns information systems with an emphasis on information as an enterprise resource, and its design, development, implementation, and maintenance of information systems. Sometimes referred to as information systems.

Computer Science (CS): Hardware and software theory and design.

Computing Curricula 2001 (CC 2001): Developed by the Joint Task Force on Computing Curricula created by the ACM and the IEEE-CS. This model focuses on programs in theoretical and applied computer science (Computing Curricula, 2001).

Information Resource Management (IRM): Curriculum model 2000 of the IRMA and the DAMA focuses particularly on the disciples of information resource management and management information systems. It takes a management of data approach (Cohen, 2000).

Information Systems (IS): Use data to create information and knowledge to assist in operational, management, and strategic organizational decision-making. It is also an umbrella term for computer information systems, management information systems and information technology.

Information Systems 2002 (IS 2002): Model curriculum developed by the efforts of the ACM, AIS, and AITP. This curriculum model focuses on information systems development and management (Gorgone, Davis, Valacich, Topi, Feinstein, & Longenecker, 2002).

Information Systems Auditing (ISA) at the Undergraduate and Graduate Levels: Model developed by the ISACF Task Force for Development of Model Curricula. It is an interdisciplinary approach with a strong accounting and management orientation. (ISACF, 1998).

Information Systems Centric Curriculum (ISCC '99): Model developed by a task force that included members from academe and industry. It is oriented toward large-scale system design and implementation as opposed to automata theory and programming. The focus is on the construction of the tools necessary for information management (Lidtke, Stokes, Haines, & Mulder, 1999).

Information Technology (IT): Uses existing commercial software applications to solve organizational problems. Sometimes refer to as information systems. It is also the umbrella term for all the disciplines involved with the computer.

IT Curriculum Proposal: Being developed by SIGSITE, the curriculum is oriented toward the use of computing applications to solve organizational problems (IT Curriculum Proposal – Draft, 2002).

Management Information Systems (MIS): The management of information systems and data including management of the design, development, implementation, and maintenance of information systems. Sometimes referred to as information systems.

Organizational and End User Information Systems (OEIS): Model developed by the OSRA is aimed at IT support of end-users (Office Systems Research Association, 1996).

Software Engineering (SE): The engineering of software for embedded, large, and critical systems.

Software Engineering Institute (SEI) Model: Model developed at SEI that follows an engineering approach of design first. The model suggests specialization in a specific domain (Bagert, Hilburn, Hislop, Lutz, McCracken, & Mangal, 1999).

Concept-Oriented Programming

Alexandr Savinov
University of Bonn, Germany

INTRODUCTION

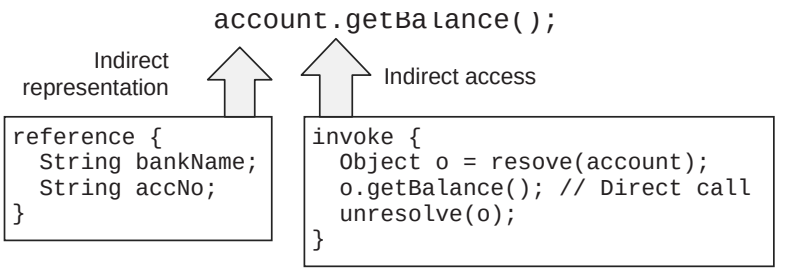
In the concept-oriented programming (CoP) (Savinov, 2005, 2007), the main idea is common to many other approaches and consists in raising the abstraction level of programming by introducing new language constructs and mechanisms. The distinguishing feature of CoP is that it aims at automating the way objects are represented and accessed (ORA). More specifically, one of the main concerns in CoP is modeling the format of object references and the procedures executed during object access.

For example, if we need to retrieve the current balance stored in a bank account object then we make the following simple method call: `account.getBalance()`. In object-oriented programming (OOP), it results in an *instantaneous* execution of the target method because this variable contains a *primitive* reference which is supposed to provide *direct* access to the represented object. In CoP, it is not so and everything depends on the format of the reference used to represent this account object. References in CoP have an arbitrary custom format defined by the programmer and hence objects are represented *indirectly* using abstract identifiers from a virtual address space. In this case, the real procedure executed during access depends on what is stored in the variable `account`. In particular, it may well happen that the account object is stored on a remote computer in another organization. Then, its reference can be rather complex and include such fields as `bankName` and `accNo` (Figure 1). Object access to such an indirectly represented account will involve many intermediate operations like security checks, transaction management, network packet transfer and operations with persistent storage. However, all these intermediate actions will be executed behind the scenes so that we have the illusion of instantaneous action. Then the programmer is still able to use the target objects as if they were local directly accessible objects, at the same time having a possibility to inject any intermediate code responsible for object representation and access (ORA).

References in CoP are as important as objects because both have arbitrary structure and behavior associated with them. If OOP deals with objects then CoP deals with both objects and references. The main role of references consists in representing objects, that is, they contain some data that makes it possible to access the object. Thus, references are *intermediate* elements which are activated each time the represented object is about to be accessed. For example, each time we read or write a field, or call a method, the object reference intercepts these requests and injects its own actions. Thus, any object access can trigger a rather complex sequence of intermediate actions which are executed behind the scenes. In large programs this hidden functionality associated with references can account for a great deal or even most of the overall complexity. The main task of CoP in this sense consists in providing adequate means for effectively describing this type of hidden intermediate functionality which has a cross-cutting nature. OOP does not provide any facilities for describing custom references and all objects are represented and accessed in one and the same way. CoP fills this gap and allows the programmer to effectively separate both concerns (Dijkstra, 1976): explicitly used business logic of objects and intermediate functions executed implicitly during object access.

The problem of indirect object representation and access can be solved by using such approaches as dynamic proxies (Blosser, 2000), mixins (Bracha & Cook, 1990; Smaragdakis & Batory, 1998), metaobject protocol (Kiczales et al.,

Figure 1. Indirect method call via custom references and intermediate operations



1991; Kiczales et al., 1993), remoting via some middleware (Monson-Haefel, 2006), smart pointers (Stroustrup, 1991), aspect-oriented programming (Kiczales et al., 1997) and others. However, CoP is the only technology that has been developed for precisely this problem and solves it in a principled manner. It is important that CoP generalizes OOP by providing a possibility of smooth transfer to the new technology.

BACKGROUND

Hierarchical Address Space

A concept-oriented program can be viewed as a set of nested spaces (Figure 2). Each space has one parent where it is identified by some local address. The parent space itself is identified by some address relative to its own parent and so on till the root. Thus, any element is identified by a sequence of local addresses where each next address identifies the next space. Such an identifier is referred to as a *complex address* while its constituents are referred to as *segments*. This structure is analogous to the conventional postal addresses where cities are identified by names within countries and streets have unique names within cities. For example, an element in the postal address space could be identified by the following complex address: `<"Germany," "Bonn," "University of Bonn">`.

An important consequence of such a design is that objects can interact only by intersecting intermediate space borders. An access request such as a method call or message cannot *directly* (instantaneously) reach its target. Instead, it follows some access path starting from the external space and leading to the internal target space (Figure 2). In order to access an element of the space it is necessary to resolve all segments of its complex reference starting from the high segment and ending with the low segment, which is the target object. The resolution procedure is responsible for locating the element identified by one segment in the context of the parent space. Thus, each intermediate border along the access path executes some special functions, which are triggered automatically as an access request intersects this border.

The same approach is used in CoP where objects are identified by complex references defined by the programmer rather than using primitive references. For example, if account reference consists of two segments—bank name and account number—then the balance could be obtained as usual by applying a method to this complex reference:

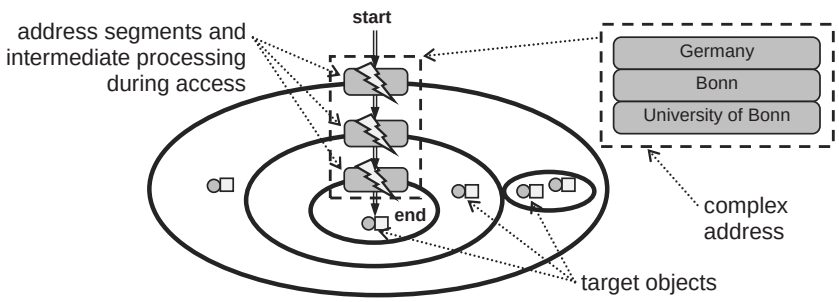
```
Account account = <"MyBank," "98765432">;
double balance = account.getBalance();
```

Since objects in CoP are represented by complex references each access requires several intermediate steps for locating the object. For example, in order to resolve the account object represented by its bank name and account number it is necessary to find the bank object and then to find the account object. Notice that the method applied to the reference is only the last step in this indirect access procedure. An important assumption of the concept-oriented approach to programming is that most of the functionality in large programs is concentrated on intermediate space borders. Target methods in this case account for a relatively small portion of the overall complexity. The goal of CoP in this sense can be formulated as providing support for describing such a hierarchical space at the level of the programming language rather than in middleware or hardware. The programmer then is able to describe an arbitrary *virtual address space* which serves as a container for objects. Such addresses are virtual because they are not directly connected with the real object position and hence they provide an additional level of abstraction.

References and Objects

In OOP, the programmer models objects by classes while all references have one and the same type. Thus we cannot influence how objects are represented and how they are

Figure 2. A program can be viewed as a hierarchical space



accessed. In CoP, the programmer deals with two types of things—references and objects—as opposed to OOP where only objects are considered. This means that any concept-oriented program consists of and manipulates custom objects and custom references both having arbitrary structure and behaviour. However, objects and references are not considered separately. Instead, they are thought of as two sides of one and the same thing. In other words, in CoP, there are no such things as an isolated reference and an isolated object—they can only exist within one element as two its sides or flavors. Thus any concept-oriented system consists of and manipulates object-reference pairs. The space of all elements is then broken into two parts: the *identity world* consisting of references and the *entity world* consisting of objects (Figure 3). For example, a city has two sides: city name and city object. A bank account also has two sides: account reference (with properties like account number), and account object (with properties like balance). The two worlds of references and objects can be viewed as cross-cutting concerns separated in a principled manner within CoP. The functions of objects and references are orthogonal but on the other hand these two elements cannot exist separately because they are two sides of one and the same thing.

Both references and objects have their own structure and functions defined by the programmer however their roles are different. References are intended to represent objects. They are always passed by-value while objects are passed by-reference. Thus references do not have their own locations and exist only in transient form. Reference represents part of reality which is directly comprehendible while object is a thing-in-itself which is not observable in its original form and hence is radically unknowable. So the only way to get information about an object or to interact with it consists in using its reference which stays between us and objective reality.

Elements of the program (reference-object pairs) exist in a hierarchical space where each element has a parent element as described in the previous section. This hierarchical structure is described by *inclusion relation*, that is, we say that an element is included into its parent element. For example, Bonn is included in Germany and accounts "456789" and "987654" are included in "MyBank" element identifying some bank.

Additionally, it is assumed that any element substitutes for some primitive element and this structure is described by means of *substitution relation*. For example, DNS computer names substitute for IP addresses and Java references substitute for memory handles. Finding the primitive reference substituted by this reference segment is referred to as *reference resolution*. The resolution procedure allows us to translate virtual address into real addresses and to get direct access to the represented entity.

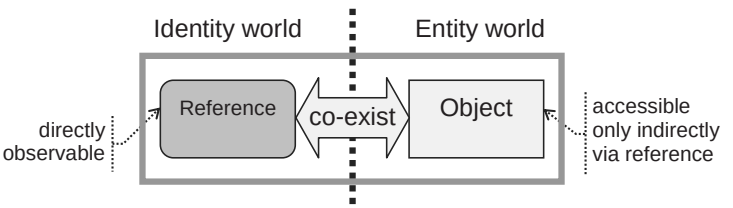
FROM CLASSES TO CONCEPTS

Concepts and Inclusion Relation

Any concept-oriented program manipulates reference-object pairs. Since both constituents have their own structure and behavior they can be described by means of conventional classes. This means that references are described by *reference classes* and objects are described (as usual) by *object classes*. However, since references and objects are two sides of one element these two classes are constituents of one construct, called *concept*. Thus, concept is defined as a pair of two classes: one reference class and one object class. If concept has empty reference class then it is equivalent to normal classes as used in OOP and therefore concepts can be viewed as a generalization of classes. For example, a concept of bank account could be defined as follows:

```
concept Account
 reference { // Reference class
   char[8] accNo;
   double getBalance() { ... }
   Person getOwner(Address address) { ... }
   ... // Other reference class members
 }
 object { // Object class
   double balance;
   double getBalance() { ... }
   Person getOwner(Address address) { ... }
   ... // Other object class members
 }
```

Figure 3. Two crosscutting concerns: The world of identities and the world of entities



Here the reference class is declared using keyword 'reference' while object class is marked by keyword 'object.' Concepts are used where classes are used in OOP, namely, for declaring types of variables, parameters, fields, return values and other elements of the program. In the above example method `GetOwner` takes one parameter of type `Address` and returns an element of type `Person`. However, since it is a concept-oriented program, these two types are names of concepts. As a consequence, any element stores a custom reference with the format defined in the corresponding concept rather than a primitive reference. For example, the return value might store a person unique number or full name and birthday depending on how concept `Person` defines its reference class.

When a concept is instantiated then two instances are created: an instance of the reference class, called reference, and an instance of the object class, called object. The reference is stored in the variable (in code) while the object is created in some storage (in data) like memory. Actually, objects can reside anywhere in the world because they are represented by *virtual* addresses. References are always stored and passed by-value while objects are stored and passed by-reference. In other words, references do not have their own references and their role consists in indirectly representing objects. Thus, we always manipulate references which indirectly represent objects.

It is important that a reference always intercepts any access to the represented object. This means that if we call a method which is defined in both reference class and object class then the reference method will be executed before object method. The reference method can then call its object method if necessary. In the following example, reference method `getBalance` simply calls its object counterpart (dual method) using keyword 'object' and the object method `getBalance` then returns the value of its field:

```
concept Account
 reference { // Reference class
   char[8] accNo;
   double getBalance() {
     print("===> Reference method");
     return object.getBalance();
   }
 }
 object { // Object class
   double balance;
   double getBalance() {
     print("---> Object method");
     return balance;
   }
 }
```

If we apply method `getBalance` to an account reference

```
Account account = findAccount(person);
account.getBalance();
```

then the following output will be produced:

```
$ ===> Reference method
$ ---> Object method
```

In OOP, any method invocation results in an immediate execution of its body defined in the object class. In CoP variables store custom data according to the reference class structure. Therefore, object method cannot start immediately and reference methods play a role of intermediate processing points which take control before the represented object can be reached. When an object method is executed it can use functions of its reference by means of keyword 'reference.' For example, object method `getBalance` from the previous example could print its account number as follows:

```
print("---> Account: "+reference.accNo);
```

Just as classes in OOP can inherit base classes, concepts are defined within a hierarchy. The difference is that concepts use *inclusion relation* for describing their hierarchy, that is, a concept can be included in a parent concept. Inclusion relation generalizes inheritance and its main distinguishing feature is that it describes a hierarchy of elements, that is, concept instances exist within a hierarchy at run-time. In other words, if classes in OOP are connected by means of IS-A relation, then concepts in CoP are connected via IS-IN relation. For example, one bank account may have many (internal) savings accounts which are described by concept `SavingsAccount` included in parent concept `Account`:

```
concept SavingsAccount in Account
 reference { // Reference class
   char[2] subAccNo; // Sub-account id
   double getBalance() { ... }
   ...
 }
 object { // Object class
   double balance;
   double getBalance() { ... }
   ...
 }
```

Here we use keyword 'in' to declare the parent concept. Sub-accounts are identified by two digits stored in a field of its reference class. However, it is important to understand that this identifier is local, that is, it uniquely identifies its objects only in the context of some parent account. In order to get a complete reference we need to store two segments: one parent reference consisting of eight digits and one child reference consisting of two digits. For example, if we get an account for some person:

```
SavingsAccount account = findAccount(person);
double b = account.getBalance();
```

then variable `account` will contain a *complex reference* consisting of two segments: `<"12345678," "01">`. High segment identifies the main account (concept `Account`) while low segment identifies some its sub-account (concept `SavingsAccount`). Thus concepts and inclusion relation allow us to control what is stored in variables and passed in parameters rather than only the object format in OOP. Notice that the programmer does not have to know where the objects really reside because variables store virtual addresses and finding the object is the task of the corresponding concept. In particular, we can still use variable `account` as if it contained a primitive reference for calling various methods like `getBalance` in the previous example. Such access may trigger rather complex intermediate behavior (security, transactionality, persistence, etc.) which is however hidden in the definition of concepts `Account` and `SavingsAccount`.

Reference Resolution

References in CoP are virtual addresses and hence they represent objects only indirectly by substituting for some primitive reference which provides direct access. Accordingly, in order to access the target object, it is necessary to resolve its indirect (virtual) reference, which is an instance of some concept reference class defined in the program. It is assumed that any reference class is responsible for resolving its instances (references) into primitive references. This resolution logic is implemented in a special method of the reference class, called *continuation method*. Whenever an object of this concept is about to be accessed, the compiler automatically calls the continuation method of its reference. The resolved reference is then used to directly access the object state and functions. For example, continuation method (called `continue`) could be implemented as shown in the following code fragment:

```
concept Account
 reference { // Reference class
   char[8] accNo;
   void continue() {
     print("===> Account: Start resolution");
     Object primitive = loadFromDb(accNo);
     primitive.continue(); // Proceed
     storeInDb(accNo, primitive);
     print("<=== Account: End resolution");
   }
 }
 object {
   double balance;
 }
```

Here continuation method of concept `Account` prints a message when it starts and loads the account object in memory from some database using its number as a primary key. Then it uses the obtained primitive reference (with the type `Object`) in order to pass control to the object and it is precisely the point where the target method is called or the object is otherwise accessed. When the access is finished, the continuation method stores the state of the object back to the database and finally prints a message. For example, the following output will be produced each time the account balance is read:

```
$ ===> Account: Start resolution
$ <=== Account: End resolution
```

Effectively, any access to the object is wrapped into the reference resolution procedure implemented in the continuation method however these actions will be executed implicitly. An advantage is that our code does not depend on how objects are represented and accessed, i.e., these concerns are separated. If later we change the format of references or the location of objects then the code that uses them will remain the same. Thus we can work with indirectly represented objects located anywhere in the world as if they were directly accessible local objects.

Normally concepts are defined as included in some parent concept and hence their objects are represented by complex references consisting of several segments. In this case each reference segment has to be resolved individually by its own continuation method. The resolution procedure in this case consists of several nested steps. It starts from resolving the very first (high) segment corresponding to the parent concept. Then it resolves the second segment and so on down to the last (low) segment corresponding to the type of the object. Each resolved primitive reference is stored on top of a special data structure called *context stack*. When the complex reference is completely resolved the context stack contains direct primitive references of all the object segments. It is important that when the next segment is resolved all its parent objects can be directly accessed using their primitive references from the context stack. Parent objects can be accessed using keyword 'super.' Notice however that one parent object can be shared among many child objects while in OOP for each child there is one parent. Normally parent object is used to store information about the location of its children.

For example, let us assume that an account has many internal savings accounts which are described by concept `SavingsAccount` included in concept `Account`. Parent concept `Account` can resolve its references as shown in the previous example by loading account objects from some persistent storage. Savings accounts have to resolve their own references (two digit number) in the context of their main account. In particular, we can store the mapping

between sub-account numbers and object primitive references in a field in the parent object as shown in the following code fragment:

```
concept Account
 reference { // Reference class
   char[8] accNo;
   void continue() {
     // Precisely as in the pervious example
   }
 }
 object {
   double balance;
   Map map; // Used by child objects
 }

concept SavingsAccount in Account
 reference { // Reference class
   char[2] subAccNo; // Sub-account id
   void continue() {
     print("  ===> SavingsAccount: Start resolution");
     Object primitive = super.map.get(subAccNo);
     primitive.continue();
     print("  <=== SavingsAccount: End resolution");
   }
 }
 object { // Object class
   double balance;
 }
```

Notice that here parent concept `Account` has one additional field `map` in its object class which stores the mapping from virtual sub-account identifiers to their primitive references. Child concept `SavingsAccount` accesses this field from its continuation method using 'super.' If a savings account needs to be accessed then its main account number will be resolved by concept `Account` and then its sub-account number will be resolved on the second step by concept `SavingsAccount`. For each such access the following output will be produced:

```
$ ===> Account: Start resolution
$   ===> SavingsAccount: Start resolution
$   <=== SavingsAccount: End resolution
$ <=== Account: End resolution
```

Dual Methods and Overriding

A concept can provide two definitions of one method in its reference class and object class, which are called *dual methods*. In addition, parent and child concepts can as usual define one and the same method. For example, if concept `SavingsAccount` is included in concept `Account` then both concepts can implement method `doAction` in their reference classes and object classes. Thus there are 4 implementations of this method in two concepts. Earlier we postulated that references intercept method calls to their objects but in this case objects are represented by two reference segments implementing method `doAction`. In order to resolve this ambiguity CoP follows the following principle: *parent reference methods have precedence over (override) child reference methods*. This means that if we apply a method to a multi-segment reference then its high segment will intercept this call by executing its version of this method. This principle is quite natural because for entering some internal space it is necessary to cross its external border. For example, in order to reach some city we have to intersect the country border. This principle of overriding is analogous to the mechanism of inner methods (Goldberg, Findler, & Flatt, 2004) used in the Beta programming language (Kristensen, Madsen, Moller-Pedersen, & Nygaard, 1987). In the following example concept `Account` implements method `doAction` in its reference class and hence it will be executed each time this method is applied to a reference of any sub-concept including `SavingsAccount`:

```
concept Account
 reference { // Reference class
   char[8] accNo;
   void doAction() {
     print("===> Account: Reference method");
     sub.doAction();
     print("<=== Account: Reference method");
   }
 }
 object { // Object class
   double balance;
   void doAction() {
     print("---> Account: Object method");
     super.doAction();
     print("<--- Account: Object method");
   }
 }
```

By means of this mechanism parent reference methods can override child reference methods. It is useful if it is necessary to control access to internal scope. Once a parent reference method got control it can decide how to continue. Normally, parent methods perform some actions and then delegate the method call further to its child reference. Child reference segment is available via special keyword 'sub' which is opposite to the conventional 'super' for accessing parent objects.

Applying a method to keyword 'sub' means that control is passed to the next segment of the complex reference. In our example reference method `doAction` of concept `SavingsAccount` will be called. This method can delegate request further to a possible child reference but in the example below it calls the same object method using keyword 'object:'

```
concept SavingsAccount in Account
 reference { // Reference class
  char[2] subAccNo; // Sub-account id
  void doAction() {
   print("  ===> SavingsAccount: Reference method");
   object.Action();
   print("  <=== SavingsAccount: Reference method");
  }
 }
 object {
  double balance;
  void doAction() {
   print("  ---> SavingsAccount: Object method");
   super.doAction();
   print("  <--- SavingsAccount: Object method");
  }
 }
```

Once we are in an object method, it is possible to call methods of parent object using keyword 'super' precisely as it is done in OOP. Here we use the dual principle formulated as follows: *child object methods have precedence over (override) parent object methods*. For example, object method `doAction` of concept `SavingsAccount` calls its parent object method (method of the context). Notice that parent objects are accessed directly using primitive references from the context stack. Here, the output produced during invocation of method `doAction` for a savings account object is shown:

```
$ ===> Account: Reference method
$   ===> SavingsAccount: Reference method
$   ---> SavingsAccount: Object method
$ ---> Account: Object method
$ <--- Account: Object method
$   <--- SavingsAccount: Object method
$   <=== SavingsAccount: Reference method
$ <=== Account: Reference method
```

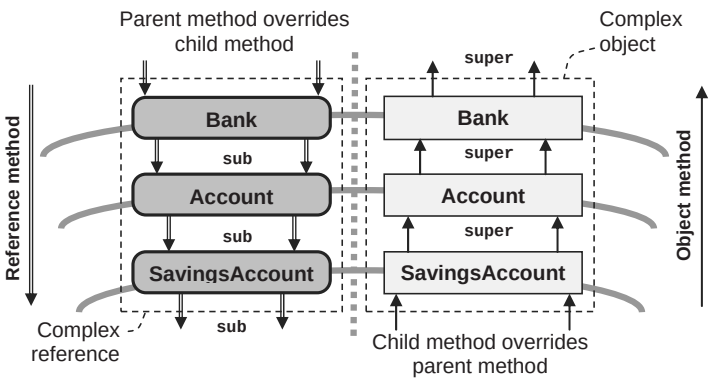
The sequence of access via dual methods is shown in Figure 4. It is assumed that concept `SavingsAccount` is included in concept `Account` which in turn is included in concept `Bank`. Thus the element has three reference segments (on the left) and three object segments (on the right). If some method is applied to such a complex reference then the parent reference segment intercepts it and then the same method of the child reference segment is called. Thus we can move down through reference segments using keyword 'sub.' At some moment the reference method can call its object method and the process switches to the right half of the diagram (entity world). Here the process propagates upward through the object segments using keyword 'super.'

FUTURE TRENDS

In future this approach will be developed in the direction of defining concrete programming languages and introducing elements of the concept-oriented programming in existing languages. In order to implement the described approach it is necessary to develop such mechanisms as complex references, context stack, reference length control and others. One general problem here is that there are two approaches to using concepts which are called CoP-I (Savinov, 2005) and CoP-II (Savinov, 2007, 2008; this article). Hence it is necessary to understand what are their advantages and disadvantages when used in programming languages.

Another direction for research consists in integrating this approach with the concept-oriented data model (CoM) (Savinov, 2006, 2009) which is based on the same principles. The challenging goal here consists in unifying programming with data modeling. This model uses the formalism of nested ordered sets when describing data semantics and such operations as projection and de-projection for data manipulations. However, identity modeling in CoM is completely analogical to CoP. In particular, data can be described by concepts and inclusion relation. Any data item is uniquely identified by its complex reference from a virtual address space which can be stored in other data items as a property.

Figure 4. Duality of method overriding



CONCLUSION

For the past several decades, programmers have been modeling things in the world with trees using hierarchies of classes and object-oriented programming languages. This abstraction works out pretty well because most of the world is hierarchical and in most cases things can be easily fit into a hierarchy. Yet, there is one serious problem with this approach: classes allow us to model only entities (objects) but not identities (references). Thus identity modeling and references were considered second class citizens in the area of computer programming, data modeling, analysis and design. The concept-oriented paradigm fills this gap by introducing concepts and inclusion hierarchy which generalize classes and inheritance. Now the world is still described using a hierarchy but such a model reflects the dual nature of things which consist of one entity and one identity. Such a generalization is informally analogous to introducing complex numbers in mathematics. Just as concepts in CoP, complex numbers have two constituents: a real part (object or entity) and an imaginary part (reference or identity). Yet these two constituents are always manipulated as one whole and this makes mathematical expressions much simpler and more natural. The same effect we get in programming when concepts are introduced: program code gets simpler and more natural because two sides or flavors are manipulated as one whole.

KEY TERMS

Complex Reference: A sequence of references, called segments, where each next segment represents an object within the context of the previous segment. Complex references are used to represent objects in a hierarchical address space. The format of one segment is defined by the reference class of the corresponding concept.

Concept: A pair consisting of one object class and one reference class. Instances of the object class are referred to as objects and are passed-by-reference. Instances of the

reference class, called references, are passed by-value and represent objects.

Continuation Method: A special method of the reference class which is intended to resolve this reference by translating its field values into the substituted primitive reference which can be then used for direct access.

Context Stack: A stack of resolved references to parent objects (contexts). A reference on top of the context stack provides direct access to the target object and is obtained by resolving the last (low) segment of a complex reference. A reference at the bottom is obtained by resolving the first (high) segment of the complex reference.

Dual Methods: These have the same signature but different definitions in the object class and the reference class of a concept. Dual methods are used as usual by specifying their name and parameters.

Primitive Reference: A reference provided by the compiler depending on the run-time environment. Structure and functions of primitive references cannot be changed by the programmer and therefore it is assumed that they provide direct access to objects.

Reference Class: A class which is intended to describe structure and behavior of object identifiers. Its instances, called references, are passed by-value and indirectly represent objects by substituting for some primitive reference.

Concepts and Dynamics of the Application Service Provider Industry

Dohoon Kim
Kyung Hee University, Korea

INTRODUCTION: SOFTWARE AS A SERVICE

The enterprise intelligence through e-transformation is one of the cornerstones of the next-generation e-business era where the Internet constitutes the core business resource. Furthermore, the severe competitive landscape of e-business makes firms focus on their core capability and farm out staffing functions such as IT. Under this circumstance, enhancing intelligence and synergy through e-transformation will be accomplished by IT outsourcing via ASPs (application service providers). The ASP industry now provides an essential infrastructure for the Internet-based e-business transactions, thereby accelerating corporate e-transformation.

An ASP is generally defined as a third-party service firm that deploys, manages, and/or remotely hosts a software application through centrally located servers in a lease agreement. ASPs started their business by providing online application programs such as ERP (enterprise resource planning) and CRM (customer relationship management) solution packages to corporate customers. The first customers were small companies or local branches of multinational companies where IT outsourcing was the only option to deploy IT resources due to financial or regional constraints. As seen in these cases, the biggest merit of employing ASPs is that corporate customers do not have to own the applications and take responsibilities associated with initial and ongoing support and maintenance. Consequently, ASPs are differentiated from the existing IT services in that ASPs provide IT resources to multiple corporate clients on a one-to-many basis with a standardized service architecture and pricing scheme.

BACKGROUND: INDUSTRY VALUE CHAIN

The industry value chain does not allow a single service provider to control the entire service delivery process. Even if we confine our attention to the software delivery process in the value chain, the complexity does not reduce significantly. In order to deliver applications over the Internet, we need a mechanism to establish and maintain collaboration among independent functional divisions. Analysis of this nature of the value chain shows how the industry is likely to evolve and gives some insights into the strategic meaning of special types of convergence. In particular, we should point out two critical aspects of the value chain, which are required to survive in the market: a large customer base and stable relationship with other functional divisions. The structure of partnership among the players in the value chain is one of the major elements to classify emerging ASP business models. Table 1 summarizes key players in the ASP value chain.

There are a number of factors that are frequently cited as fueling or dashing the growth of the ASP market (Burris, 2001; Factor, 2002; Kim, 2002; Sparrow, 2003; Toigo, 2001). One of the striking characteristics observed so far is that immaturity of the industry is the most representative challenge in terms of the market factor: for example, the uncertainty as to whether existing and emerging ASPs are winning enough customers to validate an ASP business model for highly sophisticated enterprise applications. While some ASPs are gaining momentum with early adopters, there are many client companies that are unwilling to rent ERP applications due to the lack of trust in the industry itself in Korea (Kim & Choi, 2001). Moreover, it is security control and remote monitoring systems, SLA (service level agree-

Table 1. Key players in the ASP value chain model

- Software Vendors: including ISVs (independent software vendors), content providers (CPs), and so forth
- Network Infrastructure Providers: including telecommunication operators, ISPs (Internet service providers), and so forth
- Application Service Providers: as an intermediary or an organizer between software vendors and customers
- Individual and Corporate Customers: subscribers (end users) of the ASP services

Table 2. Drivers and challenges of the ASP industry

Category	Drivers	Challenges
Technology	◆ Reduce risk of technological obsolescence due to rapidly changing IT ◆ Provide a chance to utilize best-of-breed applications ◆ Avoid IT staffing shortage	◆ Unsolved security concerns ◆ Emerging, new technological requirements from the clients: e.g., SLA with client participation ◆ Unproved service reliability: e.g., network problems, system scalability and performance
Market	◆ Minimize up-front TCO (total cost ownership) ◆ Provide predictable cash flows	◆ Unproved client momentum ◆ Failure in giving clients sufficient trust due to unstable ASP industry

Table 3. ASP business models and capability profiles

Basic Types	Characteristics and Value-Added Components	Basic Capability
H-ASP (Horizontally Specialized ASP)	◆ Develop deep expertise within a given functional area (as opposed to one-stop shop): Substantial consulting services are possible ◆ ISV's need of partnership with systems integration and distribution companies ◆ Should be Web-based software provider ◆ Either own the software or develop proprietary integration in a specific field	◆ Well positioned to expand customer basis quickly ◆ Hard to copy the domain-specific knowledge
V-ASP (Vertically Specialized ASP)	◆ Industry-specific applications (in contrast to one-stop shop) ◆ Vertically oriented template methodology: easily deploy across multiple clients in the same industry	◆ Strong advantage in customized solutions ◆ Hard to copy the industry-specific knowledge
AIP (Application Infrastructure Provider)	◆ Originated from telecommunication company that owns networks and has operations experience ◆ Provide infrastructure management to ASPs ◆ Provide system management services including SLA ◆ Alleviate client concerns regarding network reliability, etc.	◆ High investment costs as an entry barrier: easy to protect their market share
XSP (Extended Service Provider)	◆ Provide total services from front end to back end with systems integration consulting ◆ Create new business process by rearranging suppliers and customers ◆ Help customers and even other service providers enter new markets, deploy services, and improve profitability easily while minimizing risk ◆ Build and integrate customized applications, thereby enabling clients to avoid the need to handle multiple ASP solutions	◆ Going back to one-stop-shop idea: Improved flexibility will be the core competitive edge for XSP

ment; Lee & Ben-Natan, 2002; Sturm, Morris, & Jander, 2000) management, and the global standardization process that should be further developed to support proliferation of ASPs. In the end will survive only a few successful ASPs that adapt themselves to the market requirements and take the most advantage of the competitive landscape.

ASP BUSINESS MODELS

The industry's short history raises the following questions. What changes will happen? Who will be the winners and losers? To answer these questions, Table 3 clarifies different types of the ASP business domains that are currently emerging. ASP's common value proposition to improve total benefits from IT outsourcing has been giving rise to various trials in designing the service delivery processes, each of which corresponds to a business model suggested in the table. Therefore, this classification plays a key role in identifying and analyzing the collaborative networking structure in the ASP value chains.

FUTURE TRENDS: INDUSTRY DYNAMICS AND EVOLUTION

The guiding principles of the industry evolution, which have been leading the industry to face proliferation of ASP business models, are summarized into (a) economies of scale through positive feedback from the market and (b) integration across the value chain for attaining cost reduction and differentiation.

First, it is the economies of scale or increasing return that serves as the core economic guiding principle for ASPs. A survey on the Korean IT outsourcing market reveals that, in terms of the TCO (total cost ownership) of a typical ERP package, IT outsourcing through ASPs enables clients to save roughly 20% of their up-front license fee and 80% of the implementation and maintenance service costs (Kim & Choi, 2001). Accordingly, ASPs that host these applications basically seek to lower this 80% portion of the TCO upon the notion of a one-to-many relationship between an ASP and its clients. An ASP is usually able to leverage standardized solutions across multiple clients. Attaining client momentum and reducing the overall costs per client are the major economic motivations for ASPs to compete with each other, thereby creating a positive feedback mechanism through network externality on the demand side. In sum, the competition keeps going for the expansion of a customer base or market share, which provides a good surrogate measure of profit for this case.

Second, the competitive landscape is also defined by the unique nature of a service system market where independent hardware and software resources are combined and reorganized into a new package in alignment with partners along the value chain and even a customer's business process. These offerings aim at designing a seamless and proprietary service delivery process to sharpen the competitive edge while raising the entry barrier. This essential feature of integration in the service delivery process makes the various possible business models reduce into the different types of service product combinations along the value chain as presented in Table 1. The integration, however, should be verified by achieving savings in TCO, though it is not easy to measure the amount of cost reduction by a certain partnership structure. Accordingly, the cutthroat competition fueled by business domain integration not only drives down the price to an acceptable market price, but also creates diverse market segmentations based on the service product differentiation.

Furthermore, increasing switching costs and rising entry barriers, two basic phenomena regarding the guiding principles and competitive landscape, are common to all the business models. As a result, efforts to penetrate into different market segments and build new customer relationships at the niche will inevitably run into strong resistance from the incumbents. Some events like technological breakthroughs will be required in order for a specific ASP model to consolidate another. Therefore, various business models will thrive over a period of time before some giant players in each business model emerge. Despite a unique coexistence of diverse ASP business models, some hypotheses on the industry structure change and evolution can be derived from those observations together with the guiding principles.

First, the general trend will be that the total number of ASPs in the industry will reduce since the customer base is not large enough to keep all the incumbent ASPs alive. Cash flows generated from the market give winners resilience to possible occasional failures and allow them to better manage risk by diversifying a portfolio of value components to open a new market niche. It is this kind of positive feedback loop (Arthur, 1989; Nelson & Winter, 1978) from the economies of scale that accelerates the exit of losers from the market and shapes the industry structure (Shy, 2002).

Second, the industry has been concentrating more around horizontally and vertically specialized ASPs than around the pure ASPs (that is, a simple partnership with an ISV). The primary concern of the emerging ASPs is to build some value-added components to the service architecture, thereby making it hard for competitors to replicate their business model and for customers to replace the current provider. However, reliance on third-party ISVs could make it more difficult to resolve underlying performance issues that have been the subject of customer scrutiny. On the other hand, looking up the capability profiles of the ASP business models, we can conclude that both H-ASPs and V-ASPs hold a dominant position from this standpoint. If some technical constraints such as SLA and security requirements come to rise to the surface, AIP will gain technological competitiveness since delegating the control of core enterprise applications to an external provider requires ASPs to prove their capability of reliable and stable operations.

Last, we predict that the rate-of-demand increase will affect the industry structure: the pattern of market segmentation, the market share of each ASP type, and so forth. The speed of the market expansion will affect ASPs' selection of competitive priorities.

CONCLUSION

The ASP industry will shape the future e-business transactions, providing a great flexibility in redeploying a firm's resources. Although the industry is currently at its early stage of the industry life cycle, much attention is now paid to vertical or domain-specific expertise and flexible capabilities in addition to the basic offerings. In order to assess both the market and the supply side, classified are emerging ASP business models together with some driving forces shaping the evolutionary path. Some careful observations disclosed that (a) the capability of an ASP model hinges on the differentiation of service products to a large degree and

(b) economies of scale play a key role in the dynamically evolving market mechanisms. ASPs that originally developed their proprietary solutions will be better positioned in terms of ultimate performance and scalability. Those ASPs will increase the chance to succeed in the market irrespective of how critical a given solution is to their client's day-to-day operations. Last, some technical factors that may affect the evolution path (for example, SLA regulation and security) should be considered in the near future.

KEY TERMS

AIP: An application infrastructure provider (AIP) is a type of ASP, which is usually originated from telecommunication operators that run their own networks and IDCs (Internet data centers). AIP focuses on server hosting and network infrastructure management for other ASPs and corporate clients, and provides value-added services based on its technology leadership, for example, online security and e-payment services.

ASP: An application service provider (ASP) is a third-party service firm that deploys, manages, and/or remotely hosts a software application through centrally located servers in a lease agreement.

Economies of Scale: Economies of scale are the achievement of lower average cost per unit through increased production, or the decrease in the marginal cost of production as a firm's extent of operations expands.

Horizontal ASP: Horizontal ASPs provide online applications for a specific business function such as human resource management, procurement, customer relations, and so forth.

IT Outsourcing: IT outsourcing is the outsourcing of enterprise information systems and management to computer manufacturers or software companies (the term outsourcing stems from using an outside resource). Companies can save purchasing cost, maintenance cost, and labor cost by outsourcing and paying for those services. Outsourcing has become a common practice in the US where companies are faced with uncertain returns of massive investment in IT resources.

SLA: A service level agreement (SLA) is a contract between a supplier and a customer that identifies (a) services supported at each of three layers—application, host (system), and network—(b) service parameters for each service, (c) levels of service quality, and (d) liabilities on the part of the supplier and the customer when service quality levels are not met.

Vertical ASP: Vertical ASPs provide online applications customized for a specific industry such as staff or operations scheduling for hospitals, material procurement for the steel industry, and so forth.

Value Chain: A value chain is a chain of activities in a group of collaborators who are designed to meet market demand. They are vendors involved in value chains across purchasing, procurement, manufacturing, warehousing, distribution, and sales of components, equipments, raw materials, and so forth to manage a series of resource and information flow.

XSP: An extended service provider (XSP) provides total IT-related services from online applications through maintenance and reengineering of IT resources to business process consulting for its clients. Success of the XSP model should presume the rapid proliferation of the ASP services in an overly complex market. If the ASP service demand grows explosively in a short period of time, the XSP model will debut in the market earlier on, increasing the possibility of XSPs dominating the industry as they have scale advantage in terms of cost.

Conceptual Commonalities in Modeling of Business and IT Artifacts

Haim Kilov
Stevens Institute of Technology, USA

Ira Sack
Stevens Institute of Technology, USA

INTRODUCTION

The proverbial communication gap between business and IT experts is mostly due to the fact that what is considered obvious to some business experts might not be obvious or even known to IT experts, and might substantially differ from what is considered obvious to other business experts. Thus, different stakeholders may understand the business domain and problems in tacit and quite different ways, and at the same time might be unaware of these differences. This leads to business-IT misalignment, and therefore to many serious information system failures, from life-threatening to financial or simply very annoying (loss of customers' trust and patience).

The article provides a concise overview of the topic, includes definitions of some essential concepts and constructs together with industrial examples of their use in modeling and in fostering business-IT alignment, and shows how a small subset of UML has been successfully used to represent the essential structure of a model.

BACKGROUND

Creating business and IT system models readable and understandable to all stakeholders is possible only if the system of concepts underlying such models is well-defined, understandable to the model *readers*, and does not require extensive and painstaking explanations. Because the experiences of different stakeholders are usually quite different, the fundamental underlying concepts should be invariant with respect to the specific business (or IT) domain of interest.

Fortunately, a *system* of simple and elegant *abstract* modeling concepts and constructs exists and has been stable for centuries. Precise definitions of its semantics come from exact philosophy, mathematics, programming, and systems thinking. It has been successfully used in theory, in industrial practice (including international standards such as the Reference Model of Open Distributed Processing (ISO/IEC, 1995)), and in teaching of business and IT modeling. It includes such generic concepts as system, model, abstraction, structure, relationship, invariant, state, action, behavior, conformance, type, composition, template, name in context, and so forth, thus providing a solid foundation for systems of appropriate domain-specific concepts, such as contract, trade, confirmation, derivatives, options trade, and so forth, for the financial domain.

Why are we reusing concepts from exact philosophy? As Mario Bunge observed, "all factual sciences, whether natural, social, or mixed, share a number of philosophical concepts…and a number of philosophical principles" (Bunge, 2001). Moreover, philosophers "won't remain satisfied with examples [...]; they will seek general patterns" (Bunge, 2004). The work of such outstanding systems thinkers as Mario Bunge and F.A. Hayek includes clear and concise definitions and descriptions of such concepts and of some fundamental patterns which are essentially the same as those formulated—independently—in the best IT-based sources. Specifically, the concept of a *relation* is indispensable for understanding a system:" so long as the elements... are capable of acting upon each other in the manner determining the structure of the machine, their other properties are irrelevant for our understanding of the machine" (Hayek, 1952), and "the structure of a system is the set of all the relations among its components, particularly those that hold the system together" (Bunge, 2003). The same kinds of generic relations hold together very different systems, thus providing a solid foundation for bridging the communication gap between business and IT experts.

E.W. Dijkstra observed decades ago (Dijkstra, 2007) that "it is the sole purpose of the specifications to act as the interface between the system's users and the system's builders. The task of "making a thing satisfying our needs" as a single responsibility is split into two parts– "stating the properties of a thing, by virtue of which it would satisfy our needs" and "making a thing guaranteed to have the stated properties." These considerations apply both to the "business side" and to the "IT side" of any application development (or purchase) project.

Some examples of simple and elegant generic specifications understandable to their readers include the relational data model (Codd, 1970), certain high-level programming languages (Wirth, 1995), and the Macintosh user interface. The underlying implementations may have been complex,

but it was of no importance to the users of these systems: the "internals" were not exposed. However, in too many instances businesses have been unnecessarily restricted by "requirements" imposed by inadequate IT systems. As a well-known example, consider restrictions imposed on data by IT systems that require a set of predefined manual codes (without any business meaning) and prohibit the use of business-specific aliases. These restrictions—a typical example of business-IT misalignment—still result in serious losses for businesses, although excellent IT-based solutions to these problems were described more than 30 years ago, for example, in Gilb and Weinberg (1977).

A SYSTEM OF REUSABLE ABSTRACT CONCEPTS

A business model ought to be abstract enough to be understood, and therefore, while being precise, it should not be excessively detailed. But it also *cannot* be too detailed: as observed by Hayek, in any complex system "of life, mind and society" it is possible to "determine only the general character of the resulting order and not its detail." The purpose of a (high-level) model of a complex domain is to "bring about an abstract order – a system of abstract relations – concrete manifestations of which will depend on a great variety of particular circumstances which no one can know in their entirety" (Hayek, 1985). Such a model is essential for strategic decision making; and because tactical and operational decision making are determined by strategic decisions, such a model becomes essential for any kind of business decision.

As early as 1605, Bacon noted that "amongst so many great foundations of colleges in Europe, I find strange that they are all dedicated to professions, and none left free to Arts and Sciences at large." This is what "systems thinking" is about, and it has been around, under different names, for millennia. It is based on mathematics and exact philosophy–areas of human endeavor that have also been around for millennia (see, for example, the eloquent presentation in (Russo, 2004)). Furthermore, if the business stakeholders did not state the requestes properties of the IT "thing" (also sometimes known as "business rules") for any reason–for example, they were never asked, "everyone knew" what these properties were supposed to be, or it was not known "how to ask"– then the developers make these properties up and often specified them only in their code (very often unreadable to anyone except–prehaps–the developers themselves), so that as a result the IT thing has an important but not too useful property "it does what it does".

William Kent presents (Kent, 1978) an approach in which asking apparently trivial questions (like "What is an information systems thing?" "What is a Real World thing?" "What does 'the same thing' mean?" "What is a name?" etc.) leads to substantial clarification of a business domain and of business problems. This is an essential component of the framework for business-IT alignment because understanding and articulation of questions and problems is much more important than answering or finding solutions: "deeper understanding of the real features of a problem ... is an essential prelude to its correct solution" (Johnstone, 1977). Understanding a problem is possible only when the business domain for that problem is demonstrably understood in the same manner by all stakeholders, in order for the (inevitably) different viewpoints of different stakeholders to be conceptually compatible. More specific questions asked about a business domain, such as "what is a bank?" and "what is a margin call?" proposed by Dines Bjørner (Bjørner, 2006), lead to understanding of a business domain and articulating that understanding. As one of many examples of failures due to inadequate understanding, consider *The Spectator*'s assessment (Vincent, 2007) of hedge fund modeling: incomplete models for which invariants were not made explicit and too much was left outside as tacit assumptions led to very expensive failures of quantitative hedge funds due to violations of these assumptions: "shares were moving in ways that hadn't been programmed into the computer models." No wonder that, as a result, *Financial Times* (Davies & Tett, 2007) described the "Flight to simplicity" and understandability requested by users or potential users of financial instruments who wanted to return to "old fashioned banking" sketched in the article in exactly the same manner as in Dunbar (1901); for a simple example, a credit card is conceptually the same as a letter of credit a century ago.

Clearly, using abstraction is a prerequisite for understanding and for separating the concerns of various business and IT stakeholders. But this is not sufficient: As observed by F.A. Hayek: "Until we have definite questions to ask we cannot employ our intellect; and questions presuppose that we have formed some provisional hypothesis or theory about the events" (Hayek, 1985). A domain model, or its fragment, is just such a provisional theory. If it does not exist yet for the specific domain of interest, we may try to use appropriate generic models that almost always do exist; and if no generic models exist, then we can try to compose such a model out of appropriate business patterns.

This concept of business patterns is not new at all. Adam Smith eloquently presented it about 250 years ago in *The Theory of Moral Sentiments*:

When a number of drawings are made after one pattern, though they may all miss it in some respects, yet they will all resemble it more than they resemble one another; the general character of the pattern will run through them all; the most singular and odd will be those which are most wide of it; and though very few will copy it exactly, yet the most accurate delineations will bear a greater resemblance to the most careless, than the careless ones will bear to one another.

Relationships—from fundamental such as composition to business-specific such as foreign exchange option trade—are well-known examples of business patterns.

The concepts of a structure in general and of a relationship in particular are central in analysis and understanding of any system, be it a business or an IT one; moreover, they are the basis of business-IT alignment. Fortunately, there are only a few generic relationships, and their definitions—coming from exact philosophy and mathematics—have been around for centuries, if not millennia. For example, in the third century BC, the Stoics explicitly distinguished between different kinds of composition based on different ways of emergent property determination (Russo, 2004).

Property determination is the essential aspect of characterizing the semantics of different types of interesting generic relationships.

The *composition* relationship is defined as "[a] combination of two or more [items] yielding a new [item], at a different level of abstraction. The characteristics of the new [item] are determined by the [items] being combined and by the way they are combined" (ISO/IEC, 1995). Whereas in some cases the values of emergent properties may be easily determined by a computer-based system (e.g., the total number of pages in a book composed of chapters), in more interesting cases the values of the emergent properties can be determined only by human valuation, which is always subjective (Mises, 1949) (e.g., the abstract of such a book, or a binary-valued emergent property "do I want to buy it?"). The article (Davies & Tett, 2007) also refers to inadequate determination of emergent properties of the exotic and not very transparent financial instruments, presumably due to inadequate models. Different kinds of composition help us to understand business systems better and to articulate that understanding: for example, the distinction between a traditional and a modern corporation (or a traditional and modern industry) (Drucker, 2001) may be illuminated as the distinction between a hierarchical and a nonhierarchical composition of parts of that corporation (Kilov, 2002).

A *subtyping* relationship is that between a supertype and its subtypes, such that each instance of a subtype has all properties of its supertype and some additional (subtype-specific) properties. For example, a foreign exchange option trade contract is a subtype of a derivative contract which, in turn, is a subtype of a trade contract which, in turn, is a subtype of a contract.

A *reference* relationship is that between a reference and maintained items, such that some properties of the maintained item are determined by the properties of its reference item. As an example (based on Bjørner, 2006), a seller's action is subtyped into a seller's follow-up and delivery to an unprepared customer, while the seller's follow-up (that may be subtyped further) has a reference relationship to the customer's confirmed order.

The three generic relationships are analogous to the three control structures in classical programming: sequence ("like" reference), selection ("like" subtyping), and iteration ("like" composition).

It is important to observe that, firstly, these relationships have been used to define both traditional businesses and IT systems, and, secondly, that the participants in these relationships need not be only "things" but may also be actions (also known as "processes" or "steps"). Thus, the structure of any system, of any (business or IT) domain, or any (business or IT) process may be defined using the same underlying fundamental constructs; generic relationships with precisely defined semantics. In particular, changing a business process (i.e., a partially ordered composition of steps), including (sub)components of the change implemented by means of IT systems, may be understood, specified, and explained to all interested parties using these constructs.

A business or IT model should be simple to read, but creating it is not easy at all. While modeling ought to be based on a solid theoretical foundation (some fragments of which were sketched above), "...the task of recognizing the presence in the real world of the conditions corresponding to ... our theoretical schemes is often more difficult than the theory itself... We cannot state simple, almost mechanical criteria by which a certain type of theoretical situation can be identified, but we have to develop something like a sense for the physiognomy of events" (Hayek, 1969).

The most important characteristics of a graphical language chosen to represent models or requirements are its simplicity and well-defined semantics. With respect to simplicity, the best approach is to follow the advice of E.W. Dijkstra for programming languages:

"...all knowledge of one's programming language can conveniently be formulated on a single sheet of paper and can be gotten across the limelight in about twenty minutes lecturing... only then real difficulties of understanding and solving real problems can be dealt with; that activity requires the ability to think effectively more than anything else (Dijkstra, 2007).

The same considerations apply to modeling languages, and even to a greater extent because the backgrounds of all programmers include (or are at least supposed to include) the same system of common fundamental concepts, while the backgrounds of business and IT stakeholders may be very different. The notation-independent and buzzword-invariant system of fundamental concepts used in systems thinking and described—independently!—by such apparently diverse authors as Bunge (2003, 2004), Codd (1979), Hayek (1969), Hoare (1975), Smith and Smith (1977) ,Weinberg (1982) and others, as well as in RM-ODP and in modeling texts such as Kilov (2000) and Kilov (2002), may be (and has been) explained to and understood by business and IT

stakeholders without any problems. With respect to well-defined semantics, too many diagrams "...appeared precise, but the meaning of the boxes and arrows was fuzzy: it was quite easy for two people to draw the same diagram with very different intent" (Parnas, 2001). Thus, in choosing the subset of UML (Unified Modeling Language) to represent understandable business and IT models, it is essential to concentrate on a very small, simple, and powerful subset of language constructs (not restricted by any technological considerations) having a well-defined semantics. Such a small subset of UML, with relationship semantics precisely defined as described above, exists and became an OMG standard: See www.omg.org/cgi-bin/doc?formal/2004-02-07.

FUTURE TRENDS

The problem of business-IT alignment has been around for decades and still has not been successfully solved. However, with the substantially increasing importance of all-pervasive information technology, a critical mass of users request simple, elegant, and usable IT systems. It has become acceptable and even fashionable to speak about going "back to basics," and the need for simplicity in IT emphasized by such computing science founders as Dijkstra and Hoare became acknowledged both by businesses and by some IT stakeholders: "Simplicity is the unavoidable price which we must pay for reliability" (Hoare, 1975).

In a market economy, the demand for a currently scarce type of a product or service, such as understandable IT systems, leads to additional design and development of products or services of that type. The strive for simplicity, together with appearance of elegant IT products and services (such as the well-known Google®, iPod®, iPhone®, and others) described not only in industrial publications but also in the *Wall Street Journal*, *The Economist*, *The Spectator*, and so forth, demonstrates that in future users, perhaps starting with consumers, but eventually—and soon—also business enterprises, will have more and better information technology choices. The foundations for such developments are already there.

CONCLUSION

The system of reusable abstract concepts, based on well-known ideas from mathematics, exact philosophy, and systems thinking and discussed here, provides a sound basis for understandable, complete, and rigorous models of businesses or IT systems. These models are based on the semantics of the appropriate domain rather than on existing or planned systems, products, or solutions. Therefore, they are an excellent—and essential—framework for business-IT understanding and alignment, including decision making demonstrably based on a solid foundation.

A business domain model clearly defines the structure of the domain. It is an abstract and precise road-map of a fragment of a business or IT system, or of a product, with appropriate refinements. Such business models have been successfully used for making demonstrably justified strategic, tactical, and operational decisions in all kinds of business and IT system environments, and thus for successful business-IT alignment (Kilov & Sack, 2007).

The reference list presents a lot of interesting and useful material for further reading. Textbooks like Kilov (2002) and Morabito, Sack, and Bhate (1999) provide a good starting point for becoming a good analyst able to write models understandable and usable by all stakeholders.

KEY TERMS

Analysis: "breaking down a whole into its components and their mutual relations" (Bunge, 2003).

Composition: A relationship between a composite and several components, such that some (emergent) properties of the composite are determined by the components and by the way they are combined.

Generic Relationship: Composition, subtyping, or reference.

Reference: A relationship between a reference and maintained items, such that some properties of the maintained item are determined by the properties of its reference item.

Reference Model of Open Distributed Processing (RM-ODP): an international standard defining the semantics of fundamental concepts and constructs used for specification of any system independently of a specific methodology, technology, or tool.

Relationship: A collection of items together with the invariant referring to the properties of the items.

Subtyping: A relationship between a supertype and its subtypes, such that each instance of a subtype has all properties of its supertype and some additional—subtype-specific—properties.

Type: A predicate (ISO/IEC, 1995).

INTRODUCTION

Integrating data from different sources consists of two main steps, the first in which the various relations are merged together, and the second in which some tuples are *removed* (or *inserted*) from the resulting database in order to satisfy integrity constraints. There are several ways to integrate databases or possibly distributed information sources, but whatever integration architecture we choose, the heterogeneity of the sources to be integrated causes subtle problems. In particular, the database obtained from the integration process may be inconsistent with respect to integrity constraints, that is, one or more integrity constraints are not satisfied. Integrity constraints represent an important source of information about the real world. They are usually used to define constraints on data (functional dependencies, inclusion dependencies, etc.) and have, nowadays, a wide applicability in several contexts such as semantic query optimization, cooperative query answering, database integration, and view update.

Since the satisfaction of integrity constraints cannot generally be guaranteed, if the database is obtained from the integration of different information sources, in the evaluation of queries, we must compute answers that are consistent with the integrity constraints. The following example shows a case of inconsistency.

Example 1: Consider the following database schema consisting of the single binary relation *Teaches (Course, Professor)* where the attribute *Course* is a key for the relation. Assume there are two different instances for the relations *Teaches*, D1={(c1,p1),(c2,p2)} and D2={(c1,p1),(c2,p3)}. The two instances satisfy the constraint that *Course* is a key, but from their union we derive a relation that does not satisfy the constraint since there are two distinct tuples with the same value for the attribute *Course*.

In the integration of two conflicting databases simple solutions could be based on the definition of preference criteria such as a partial order on the source information or a majority criterion (Lin & Mendelzon, 1996). However, these solutions are not generally satisfactory, and more useful solutions are those based on (1) the computation of "repairs" for the database, and (2) the computation of consistent answers (Arenas, Bertossi, & Chomicki, 1999).

The computation of repairs is based on the definition of minimal sets of insertion and deletion operations so that the resulting database satisfies all constraints. The computation of consistent answers is based on the identification of tuples satisfying integrity constraints and on the selection of tuples matching the goal. For instance, for the integrated database of *Example 1*, we have two alternative repairs consisting in the deletion of one of the tuples *(c2,p2)* and *(c2,p3)*. The consistent answer to a query over the relation *Teaches* contains the unique tuple *(c1,p1)* so that we do not know which professor teaches course *c2*. Therefore, it is very important, in the presence of inconsistent data, not only to compute the set of consistent answers, but also to know which facts are unknown and if there are possible repairs for the database.

BACKGROUND

Several proposals considering the integration of databases as well as the computation of queries over inconsistent databases have been provided in the literature (Agarwal, Keller, Wiederhold, & Saraswat, 1995; Arenas et al., 1999; Arenas, Bertossi, & Chomicki, 2000; Bry, 1997; Dung, 1996; Greco & Zumpano, 2000; Lin, 1996; Lin & Mendelzon, 1996; Lembo, Lenzerini, & Rosati, 2002; Lenzerini, 2002; Wijsen, 2003). Most of the techniques for computing queries over inconsistent databases work for restricted cases, and only

recently have there been proposals to consider more general constraints. This section provides an informal description of the main techniques proposed in the literature.

- Lin and Mendelzon (1996) proposed an approach taking into account the majority view of the knowledge bases in order to obtain a new relation that is consistent with the integrity constraints. The technique proposes a formal semantics to merge first order theories under a set of constraints.
  However, the "merging by majority" technique does not resolve conflicts in all cases since information is not always present in the majority of the databases, and, therefore, it is not always possible to choose between alternative values. Moreover, the use of the majority criteria involves discarding inconsistent data and hence the loss of potentially useful information.
- Arenas et al. (1999) introduced a logical characterization of the notion of consistent answer in a possibly inconsistent database. The technique is based on the computation of an equivalent query $T_\omega(Q)$ derived from the source query Q. The definition of $T_\omega(Q)$ is based on the notion of residue developed in the context of semantic query optimization.
  More specifically, for each literal B, appearing in some integrity constraint, a residue *Res(B)* is computed. Intuitively, *Res(B)* is a universal quantified first order formula that must be true, because of the constraints, if B is true.
  The technique, more general than the previous ones, has been shown to be complete for universal binary integrity constraints and universal quantified queries. However, the rewriting of queries is complex since the termination conditions are not easy to detect and the computation of answers generally is not guaranteed to be polynomial.
- Arenas et al. (2000) proposed an approach consisting in the use of a Logic Program with exceptions (LPe) for obtaining consistent query answers. An LPe is a program with the syntax of an extended logic program (ELP), that is, in it we may find both logical (or strong) negation ($\neg$) and procedural negation (not). In this program, rules with a positive literal in the head represent a sort of general default, whereas rules with a logically negated head represent exceptions. The semantic of an LPe is obtained from the semantics for ELPs, by adding extra conditions that assign higher priority to exceptions. The method, given a set of integrity constraints ICs and an inconsistent database instance, consists in the direct specification of database repairs in a logic programming formalism. The resulting program will have both negative and positive exceptions, strong and procedural negations, and disjunctions of literals in the head of some of the clauses, that is, it will be a disjunctive extended logic program with exceptions. As shown by Arenas et al. (1999), the method considers a set of integrity constraints, IC, written in the standard format $\vee_{i=1}^{n} P_i(x_i) \vee \vee_{i=1}^{m} (\neg Q_i(y_i) \vee \varphi$, where φ is a formula containing only built-in predicates, and there is an implicit universal quantification in front. This method specifies the repairs of the database, D, that violate IC, by means of a logical program with exceptions, Π^D. In Π^D, for each predicate P a new predicate P' is introduced, and each occurrence of P is replaced by P'.
  The method can be applied to a set of domain independent binary integrity constraints *IC*, that is, the constraint can be checked w.r.t. satisfaction by looking to the active domain, and in each *IC* appear at most two literals.
- Calì, Calvanese, De Giacomo, and Lenzerini (2002), Lembo et al. (2002), and Lenzerini (2002) proposed a framework for data integration that allows to specify a general form of integrity constraints over the global schema, and it is defined a semantics for data integration in the presence of incomplete and inconsistent information sources. Moreover, it is defined as a method for query processing under the previous semantics when key constraints and foreign key constraints are defined upon the global schema.
  Formally, a data integration system I is a triple $<G, S, M_{G,S}>$, where G is the global schema, S is the source schema, and $M_{G,S}$ is the mapping between G and S. More specifically, the *global schema* is expressed in the relational model with both key and foreign key constraints; the *source schema* is expressed in the relational model without integrity constraints; and the *mapping* is defined between the global and the source schema, that is, each relation in G is associated with a view, that is, a query over the sources. The semantics of a data integration system is given by considering a source database D for I, that is, a database for the source schema S containing relation r^D for each source r in S.
  Any database G is a *global database* for I, and it is said *legal* w.r.t. D if:
  - It satisfies the integrity constraints defined on G.
  - It satisfies the mapping w.r.t. D, that is, for each relation r in G, the set of tuples r^B that B assigns to r is a subset of the set of tuples $\rho(r)^D$ computed by the associated query $\rho(r)$ over D: $\rho(r)^D \subseteq r^B$.

  In this framework, the semantics of I w.r.t. a source database D, denoted $sem^D(I, D)$, is given in terms of a set of databases. In particular, $sem^D(I, D) = \{ B \mid B$ *is a legal global database for I, w.r.t. D}*. If $sem^D(I, D) \neq \emptyset$, then I is said to be consistent w.r.t. D.

In this setting, a query *q* posed to a data integration system *I* is a conjunctive query over the global schema, whose atoms have symbols in *G* as predicates. A tuple $(c_1, .., c_n)$ is considered an answer to the query only if it is a *certain* answer, that is, if it satisfies the query in every database that belongs to the semantics of the data integration system.

The *retrieved global database*, denoted by *ret(I, D)*, is obtained by computing for each relation *r* of the global schema r^D; the query $\rho(r)$ is then evaluated the query over the source database *D*. Note that the *retrieved global database* satisfies all the key constraints in *G*, as it is assumed that $\rho(r)$ does not violate the key constraints; thus, if *ret(I,D)* also satisfies the foreign key constraints, then the answer to a query *q* can be done by simply evaluating it over *ret(I,D)*. If it is the case that *ret(I,D)* violates the foreign key constraints, then tuples have to be added to the relations of the global schema in order to satisfy them.

Obviously in general there are an infinite number of legal database that are coherent with the retrieved global database, even if it is shown that there exists one, the *canonical database*, denoted *can(I,D)*, that represents all the legal databases that are coherent with the retrieved global database. Thus formally the answer to a query q can be given by evaluating can(I, D). Anyhow, the computation of the canonical database is impractical, as generally the database can be infinite; thus, Calì et al. (2002) defined an algorithm that computes the certain answers of a conjunctive query q without actually building can(I, D).

- Wijsen (2003) proposed a general framework for repairing databases. In particular the author stressed that an inconsistent database can be repaired without deleting tuples (*tuple-based* approach), but using a finer repair primitive consisting in correcting faulty values within the tuples, without actually deleting them (*value-based* approach).

Example 2: Suppose to have the following set of tuples reporting the dioxin levels in food samples:

Sample	Sample Date	Food	Analysis Date	Lab	DioxinLevel
110	Jan 17, 2002	poultry	Jan 18, 2002	ICI	normal
220	Jan 17, 2002	poultry	Jan 16, 2002	ICB	alarming
330	Jan 18, 2002	beef	Jan 18, 2002	ICB	normal

Dioxin Database

and the constraint:

$$\forall s, d_1, f, d_2, l, d(\text{Dioxin}(s, d_1, f, d_2, l, d) \rightarrow d_1 \leq d_2)$$

that imposes the date of analyzing a given sample cannot precede the date the sample was taken.

The first tuple in the Dioxin Database says that the sample 110 was taken on January 17, 2002, and analyzed the day after at the ICI lab, and that the dioxin level of this sample was normal. While the sample 110 respects the constraint, the sample 220 violates it. An inconsistency is present in the database, and the author claims to "clean" it in a way that avoids deleting the entire tuple, that is, acting at the attribute level and not at the tuple level.

Given an inconsistent database, a consistent answer can be obtained by letting the database in its inconsistent state, and by propagating in the answer the consistent portion of the database, that is, the set of tuples matching the query and satisfying the constraints. As the repair work is deferred until query time, this approach is called *late-repairing*. In this framework an alternative technique is proposed consisting in a *database transformation*. Given a satisfiable set of constraints Σ, that is, a set of finite constraints, and a relation I, apply a database transformation $h_\Sigma : I \rightarrow I$ such that for every query Q, $Q(h_\Sigma(I))$ yields exactly the consistent answer to Q on input I and Σ.

Observe that $h_\Sigma(I)$ is not necessarily a repair for I and Σ; it can be thought of as a "*condensed representation*" of all possible repairs for I and Σ that is sufficient for consistent query answering. The practical intuition is that an inconsistent database I is first transformed through h_Σ in such a way that the subsequent queries on the transformed database retrieve exactly the consistent answer; since databases are modified prior to query execution, this approach is called *early-repearing*.

Clearly for a given set of satisfiable constraints Σ, early and late repairing should yield the same set of consistent answers, hence $f_\Sigma(Q)(I)=Q(h_\Sigma(I))$, for every query and every relation.

A NEW TECHNIQUE FOR QUERYING AND REPAIRING INCONSISTENT DATABASES

Greco, Greco, and Zumpano (2001, 2003) and Greco and Zumpano (2000) proposed a general framework for computing repairs and consistent answers over inconsistent databases with universally quantified variables. The technique is based on the rewriting of constraints into extended disjunctive rules with two different forms of negation (negation as failure and classical negation). The disjunctive program can be used for two different purposes: compute "repairs" for the database, and produce consistent answers, that is, a maximal set of

atoms that do not violate the constraints. The technique is sound and complete (each stable model defines a repair, and each repair is derived from a stable model) and more general than techniques previously proposed.

Specifically, the technique is based on the generation of an extended disjunctive program LP derived from the set of integrity constraints. The repairs for the database can be generated from the stable models of *LP*, whereas the computation of the consistent answers of a query *(g,P)* can be derived by considering the stable models of the program $P \cup LP$ over the database *D*.

Let *c* be a universally quantified constraint of the form:

$$\forall X [B_1 \wedge ... \wedge B_k \wedge \text{not } B_{k+1} \wedge ... \wedge \text{not } B_n \wedge \phi \supset B_0]$$

then, *dj(c)* denotes the extended disjunctive rule

$$\neg B'_1 \vee ... \vee \neg B'_k \wedge B'_{k+1} \vee ... \vee B'_n \vee B'_0 \leftarrow (B_1 \vee B'_1), \ldots, (B_k \vee B'_k), (\text{not } B_{k+1} \vee \neg B'_{k+1}), \ldots, (\text{not } B_n \vee \neg B'_n), \phi, (\text{not } B_0 \vee \neg B'_0),$$

where B'_i denotes the atom derived from B_i, by replacing the predicate symbol *p* with the new symbol p_d if B_i is a base atom otherwise is equal to false. Let *IC* be a set of universally quantified integrity constraints, then $DP(IC) = \{ dj(c) \mid c \in IC \}$, whereas *LP(IC)* is the set of standard disjunctive rules derived from *DP(IC)* by rewriting the body disjunctions.

Clearly, given a database *D* and a set of constraints, *IC*, $LP(IC)_D$ denotes the program derived from the union of the rules *LP(IC)* with the facts in *D*, whereas $SM(LP(IC)_D)$ denotes the set of stable models of $LP(IC)_D$, and every stable model is consistent since it cannot contain two atoms of the form *A* and $\neg A$. The following example shows how constraints are rewritten.

Example 3: Consider the following integrity constraints:

$\forall X [p(X) \wedge \text{not } s(X) \supset q(X)]$
$\forall X [q(X) \supset r(X)]$

and the database D containing the facts p(a), p(b), s(a), and q(a).
The derived generalized extended disjunctive program is defined as follows:

$$\neg p_d(X) \vee s_d(X) \vee q_d(X) \leftarrow (p(X) \vee p_d(X)) \wedge (\text{not } s(X) \vee \neg s_d(X)) \wedge (\text{not } q(X) \vee \neg q_d(X)).$$
$$\neg q_d(X) \vee r_d(X) \leftarrow (q(X) \vee q_d(X)) \wedge (\text{not } r(X) \vee \neg r_d(X)).$$

The previous rules can now be rewritten in standard form. Let *P* be the corresponding extended disjunctive Datalog program. The computation of the program P_D gives the following stable models:

$M_1 = D \cup \{ \neg p_d(b), \neg q_d(a) \},$

$M_2 = D \cup \{ \neg p_d(b), r_d(a) \},$

$M_3 = D \cup \{ \neg q_d(a), s_d(b) \},$

$M_4 = D \cup \{ r_d(a), s_d(b) \},$

$M_5 = D \cup \{ q_d(b), \neg q_d(a), r_d(b) \}$ and

$M_6 = D \cup \{ q_d(b), r_d(a), r_d(b) \}.$

A (generalized) extended disjunctive Datalog program can be simplified by eliminating from the body rules all literals whose predicate symbols are derived and do not appear in the head of any rule (these literals cannot be true). As mentioned before, the rewriting of constraints into disjunctive rules is useful for both (1) making the database consistent through the insertion and deletion of tuples, and (2) computing consistent answers leaving the database inconsistent.

FUTURE TRENDS

As a future trend, an interesting topic consists in specifying preference criteria so that selecting among a set of feasible repairs the preferable ones, that is, those better conforming to the specified criteria. Preference criteria introduce desiderata on how to update the inconsistent database in order to make it consistent; thus they can be considered as a set of desiderata that are satisfied *if possible* by a generic repair. Therefore, informally a preferred repair is a repair that better satisfies preferences. Preliminary results have been published by Greco, Sirangelo, and Trubitsyna (2003).

CONCLUSION

In the integration of knowledge from multiple sources, two main steps are performed, the first in which the various relations are merged together, and the second in which some tuples are removed (or inserted) from the resulting database in order to satisfy integrity constraints.

The database obtained from the merging of different sources could contain inconsistent data. In this article we investigated the problem of querying and repairing inconsistent databases. In particular we presented the different techniques for querying and repairing inconsistent databases (Agarwal et al., 1995; Arenas et al., 1999; Greco & Zumpano, 2000; Lin & Mendelzon, 1996).

KEY TERMS

Consistent Answer: A set of tuples, derived from the database, satisfying all integrity constraints.

Consistent Database: A database satisfying a set of integrity constraints.

Data Integration: A process providing a uniform integrated access to multiple heterogeneous information sources.

Database Repair: Minimal set of insert and delete operations that makes the database consistent.

Disjunctive Datalog Program: A set of rules of the form:

$$A_1 \vee \ldots \vee A_k \leftarrow B_1, \ldots, B_m, not\ B_{m+1}, \ldots, not\ B_n, \quad k+m+n>0,$$

where $A_1,\ldots, A_k, B_1,\ldots, B_n$ are atoms of the form $p(t_1,\ldots, t_h)$, p is a predicate symbol of arity h, and the terms $t_1,\ldots, t_h$ are constants or variables.

Inconsistent Database: A database violating some integrity constraints.

Integrity Constraints: A set of constraints that must be satisfied by database instances.

Constructionist Organizational Data Mining

INTRODUCTION

Scientific or organizational knowledge creation has been addressed from different perspectives along the history of science and, in particular, of social sciences. The process is guided by the set of values, beliefs, and norms shared by the members of the community to which the creator of this knowledge belongs, that is, it is guided by the adopted paradigm (Lincoln & Guba, 2000). The adopted paradigm determines how the nature of the studied reality is understood, the criteria that will be used to assess the validity of the created knowledge, and the construction and selection of methods, techniques, and tools to structure and support the creation of knowledge. This set of ontological, epistemological, and methodological assumptions that characterize the paradigm one implicitly or explicitly uses to make sense of the surrounding reality is the cultural root of the intellectual enterprises. Those assumptions constrain the accomplishment of activities such as construction of theories, definition of inquiry strategies, interpretation of perceived phenomena, and dissemination of knowledge (Schwandt, 2000).

Traditionally, social realities such as organizations have been assumed to have an objective nature. Assuming this viewpoint, the knowledge we possess about things, processes, or events that occur regularly under definite circumstances, should be an adequate representation of them. Knowledge is the result of a meticulous, quantitative, and objective study of the phenomenon of interest. Its aim is to understand the phenomenon in order to be able to anticipate its occurrence and to control it.

Organizations can instead be understood as socially constructed realities. As such, they are subjective in nature since they do not exist apart from the organizational actors and other stakeholders. The stable patterns of action and interaction occurring internally and with the exterior of the organization are responsible for the impression of an objective existence. The adoption of information technology applications can reinforce or disrupt those patterns of action and interaction, thus becoming key elements in the social construction of organizational realities (Lilley, Lightfoot, & Amaral, 2004; Vaast & Walsham, 2005).

BACKGROUND

The Rational and Emotional Nature of Personal Knowledge

Individual knowledge is actively constructed by the mind of the learner (Kafai & Resnick, 1996).

We make ideas instead of simply getting them from an external source. Idea making happens more effectively when the learner is engaged in designing and constructing an external artifact, which is meaningful for the learner, and he or she can reflect upon it and share it with others. From this constructionist description of the learning process, we can emphasize several elements associated with the creation of knowledge, namely, *cognition*, *introspection*, *action*, *interaction*, and *emotion*.

Through *cognitive* processes, humans construct mental representations of external and mental objects. *Introspection* is a specific type of cognition that permits the personal inquiry into subjective mental phenomena such as sensory experiences, feelings, emotions, and mental images (Damásio, 1999; Wallace, 2000). Through *action* and *interaction*, we create our experiences of the world we live in. The effective construction of personal knowledge requires the building of relationships between concepts and other mental constructs, in profoundly meaningful experiences (Shaw, 1996). All human experience is mediated by *emotions*, which drive our attention and concentration in order to help us to process external stimuli and to communicate with others.

The Historical and Socio-Cultural Context of Knowledge

A social reality is a construction in continuous reformulation that occurs whenever social actors develop social constructions that are external and sharable.

By the mere fact that people interact, influencing each other's mental constructs, social reality is in constant reconstruction. In this context, learning of new concepts and practices is happening continuously, either intentionally or unintentionally.

Learning happens inside specific mental and social spaces, meaning that what a group can learn is influenced by:

- The concepts, schemata, values, beliefs, and other mental constructs shared by the group.
- All knowledge we create about external things, events, and relationships is based on and constrained by our mental constructs and the tools we use to experience that external world.
- The creation of knowledge is founded on the historical and socio-cultural context of its creators, providing a shared basis for the interaction inside a group. The continuous interaction of the group members, happening in a common environment, leads to similar mental constructs, a common interpretation of events, and the creation of shared meaning structures and external constructions, such as new tools that change how the external word is experienced.
- There is no viewpoint outside human subjectivity or historical and socio-cultural circumstances from which to study phenomena and to judge the inquiry process and the knowledge produced.

ODM AND KNOWLEDGE CREATION: PROBLEMS AND OPPORTUNITIES

ODM (organizational knowledge discovery) has been defined as the process of analyzing organizational data from different perspectives and summarizing them into useful information for organizational actors who will use that information to increase revenues, reduce costs, or achieve other relevant organizational goals and objectives (Fayyad, Piatetsky-Shapiro, & Smyth, 1996; Matheus, Chan, & Piatetsky-Shapiro, 1993).

Data mining is a sub-process of the knowledge discovery. It leads to the finding of models of consumer behavior that can be used to guide the action of organizational actors. The models are built upon the patterns found out among data stored in large databases that are backed by statistical correlations among that data. Those patterns are extracted by specific mechanisms called data mining algorithms.

Attached to the discourse around the data mining tools, there is the idea that in the future, new and more powerful algorithms will be developed that will be capable of finding more valuable patterns and models, independently from human subjectivities and limitations. If it ever becomes possible to integrate the knowledge of the relevant business domain into the system, the algorithm would be able to decide about the usefulness and validity of discovered patterns, correlations, and models, as well as to grow in sophistication by integrating these models in its knowledge of the business. The decision-making process would become extensively automated and guided by the objective reasoning of clear and rational rules implemented in a computer-based system.

However, this view has several drawbacks, namely:

1. Since all human knowledge has a tacit and non-expressible dimension, it will never be possible to integrate all relevant business knowledge in a repository to be analyzed by a data-mining algorithm.
2. The diversity of views about the business activities and their context is what allows for the emergence of organizational creativity and development and the challenge of taken-for-granted concepts and practices (Bolman & Deal, 1991; Morgan, 1997; Palmer & Hardy, 2000). The stored knowledge representations are those around which there is some degree of consensus. This is important for the stability of work concepts and practices and to support organizational cohesion. However, they may also trap organizational actors in those concepts and practices, even when evidence shows they are threatening organizational success.
3. The relevance of knowledge representations stored in organizational repositories changes according to changes in the socio-cultural circumstances that offer the context for making sense of the representations. Only the organizational actors can understand those contexts and are able to give meaning to knowledge representations.
4. It is still believed that decision-making is or should be an essentially rational process, guided by cognitive processes such as planning, resolution of problems, and creativity (Sparrow, 1998). However, recent experiments in neurobiology show that emotion is an integral part of reasoning and decision-making (Damásio, 1999). Thus, only organizational actors can make decisions. The full automation of the process is not a realistic objective.

Instead of the present focus on the technological side of ODM, it would be interesting to adopt a constructionist approach and to focus on the social process of knowledge construction that makes ODM meaningful. With this new focus on people and the way they create and share knowledge, the main concern would be to mobilize the knowledge of organizational actors so the whole organization can benefit from it. This concern is justified by the awareness that the organization, seen as a community, is more intelligent than each one of its members, including any of its leaders.

LEVERAGING KNOWLEDGE CREATION IN ORGANIZATIONS: SOME CONSTRUCTIONIST GUIDELINES FOR ODM

With ODM there is a special focus on knowledge about consumer behavior to support decision and action. ODM

Table 1. A summary of constructionist guidelines for ODM

Using data mining tools	Creating rich learning environments
Data mining results will support insight and creativity when organizational actors have enough time to reflect upon them, to change their actions accordingly, to learn with the consequences of their own and others' actions.	Work relationships must be strengthened in order to create the social cohesiveness needed for the ongoing production of shared constructions that engage the organization in developmental cycles.
Effective formal and informal communication must be fostered in order for it to become possible to discuss each others' interpretations of past and present experience in the light of perceived enduring changes in organizational agents' work context.	The construction of knowledge about customers' preferences and their future needs and reactions must be guided by the shared purposes of the specific communities of practice that constitute the organization.
Data mining tools may be used to seek dissonance between the usual representations of consumer behavior and the evidence of actual behavior. This dissonance usually triggers the need to reestablish consonance by adopting more effective work practices.	Organizational repositories, data mining tools, and the results of data mining are social artifacts that should be used to make ideas tangible, to negotiate meanings, and to facilitate communication between organizational actors.
The search and interpretation of patterns and models of consumer behavior should be guided by a multi-dimensional knowledge of the business domain, and work concepts and practices.	Knowledge representations were created and stored under specific historical and socio-cultural circumstances of which their readers must be aware in order to be able to understand relevance or inadequacy of those representations.

assists the organization in knowing the preferences of its customers and in anticipating their needs and reactions. The construction of this knowledge must be guided by the specific purposes of the several communities of practice that constitute the organization.

ODM and the knowledge it helps to create are social constructions. Repositories, data mining tools, and the resulting patterns, correlations, and models are social artifacts that should be used to make ideas tangible, to negotiate meanings, and to facilitate communication between organizational actors. As such, they may become catalysts for the development of shared knowledge about consumer behavior, when they are used in the contexts of meaningful projects.

Data mining systems may become empowering tools in the sense that they make viable the analysis of large organizational repositories of knowledge representations. These knowledge representations are social constructions that connect organizational actors to a common view of the business concepts and practices that shape their intentions and interactions. Problems in the performance of organizational tasks or in organizational adaptation to environmental changes may reside in the inappropriateness of knowledge representations or in the tools used to extract rules and patterns from them. Knowledge representations were created and stored under specific historical and socio-cultural circumstances of which their readers must be aware in order to be able to understand their relevance or inadequacy.

Table 1 summarizes the constructionist guidelines for ODM, grouping them in two categories:

- guidelines that should be considered for the creation of rich learning environments in which data mining systems are used as social artifacts that leverage continuous learning, and
- guidelines that should be considered when using a specific data mining tool.

These guidelines are given from constructionist theories developed and applied in areas such as psychology, education, and organization theory.

FUTURE TRENDS

According to the assumptions of the constructionist perspective, ODM should be designed to involve organizational actors in the social construction of something external and sharable. The designing of a marketing campaign, the making of a decision, and the transformation of work representations and practices are examples of social construction processes for which ODM could be viewed as relevant.

As a result of the process, the individual and shared knowledge will become more sophisticated, empowering the action of individuals and groups, and facilitating interaction. In this way, organizational actors consciously create cohesive and pluralist work environments, more prone to deal with problems and difficult decisions associated with consumer behavior. This perspective is more realistic than the traditional view of ODM as a process of making knowledge

neutral and independent of the knower and social contexts in which is created, in order to support decision-making processes idealized as inherently rational.

The tools used to support ODM fundamentally shape and define the process. Lack of appropriate tools impoverishes a social setting and makes social construction difficult. Future research is needed to study how current data mining tools support (1) the transformation of work practices and representations concerning consumer behavior and (2) the definition of effective practices to deal with opportunities and threats perceived in actual consumer behavior. It will also be important to create practical experiences of designing and implementing the ODM process in specific organizational settings so that learning from a constructionist perspective can be supported.

CONCLUSION

This article describes ODM as a process for the social construction of knowledge. As such, the focus changes from the technology used to discover patterns in the stored data to the human and social issues surrounding knowledge creation in organizations.

Managers should provide the resources and the conditions for the emergence of rich learning environments in which data repositories and data mining tools sustain collective cognitive processes such as memory, reasoning, language, and attention. In this way ODM becomes a key organizational process in the construction of organizational representations of external realities. These representations will guide organizational decision and action. In accordance with this view, the article provides a summary of constructionist guidelines for ODM to help managers leveraging knowledge creation in organizations.

KEY TERMS

Constructionism: A set of theories that defines the human beings as active constructors of their own learning and development. This learning and development of knowledge happens more effectively when individuals are involved in the construction of something external, something that can be shared, or both.

Objective Social Reality: It has an independent existence from any account of it.

Objectivism: A set of theories that views true knowledge about external realities, and the process of its creation, as neutral and independent of the knowledge creator.

Rich Learning Environment: A learning environment in which the learner is empowered to create a strong connection with the reality of interest by directly experiencing with it in order to develop mental constructs that are deep, complex, pluralist, and emotionally rich.

Socially Constructed Reality: It is created through purposeful human action and interaction. This reality is shaped by the individual's subjective conceptual structures of meaning. It is reconstructed by the human interactions that support continuous reinterpretations and change of meanings. The social institutions are the means through which meanings are stabilized and the social reality assumes an objective appearance.

Social Constructions: External and sharable concepts, associations, artifacts, and practices that people actively develop and maintain in their social settings. An organization is an example of a social construction that interconnects its members in a specific social setting, in which many other social constructions are continuously being developed and maintained.

Constructivism in Online Distance Education

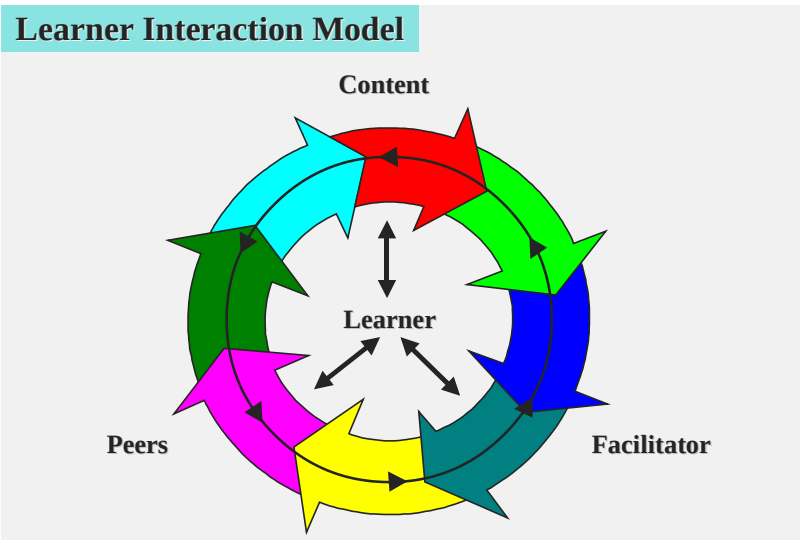
INTRODUCTION

The past two decades have ushered in a very pronounced gravitation toward a constructivist approach to teaching and learning in all realms of society and most particularly in the online distance education environment. Augmenting communication in and among those in the academic, business, and military communities, the exponential advancement of science and technology has availed vast amounts of information to virtually millions of people around the globe. In conjunction with this knowledge explosion has been a growing concern for the democratization of the learning process, with constructivism driving much of the educational agenda. This article examines the resurgence of this approach to teaching and learning, its convergence with rapidly changing technological advances, and how it forecasts future trends in online pedagogy.

BACKGROUND

While the constructivist method has been highly emphasized in the more recent literature (Jonassen, Davidson, Collins, Campbell, & Haag, 1995; Rovai, 2004; Tenenbaum, Naidu, Jegede, & Austin, 2001), it is not a new approach to learning. Presenting an early example, Socrates facilitated discourse with students asking directed questions to assist them in realizing the weaknesses in their logic and critical thinking. This enabled them to share in the responsibility of their learning through active participation while negotiating meaning in the creation of shared understanding. In contrast, over time, most professors in Western culture often served as primary repositories of information along with the scrolls and velum texts found in the limited number of physical libraries available to educators. This role included the important function of disseminating information, as well as assisting students in

Figure 1. © 2000, Grooms, L.D.



shaping and forming that knowledge. The lecture served as the quickest and easiest way to reach both small and large groups of individuals.

While the lecture method was the norm of information delivery for centuries in Western culture, the knowledge explosion of the 20th century demanded more active learner participation. In light of this constant and rapid flux of information and knowledge, students became lifelong learners compelled to use metacognitive skills to constantly evaluate and assimilate new material into their respective disciplines. As this implies, knowledge was no longer viewed as a fixed object; rather, learners constructed it as they experienced and co-created an understanding of various phenomena by collaborating and working with peers and professors as well as with the information. Based on the work of Kidd (1973), Long (1983), Moore (1989), and Palmer (1993), Grooms' (2000) Learner Interaction Model (see Figure 1) illustrates that in the constructivist culture, the learner perpetually interacts with these three components of learning.

Now, rather than strictly acquiring information, Duffy and Cunningham (1996) explicated that "learning is an active process of constructing…knowledge and…instruction is a process of supporting that construction" (p. 171). Critical in this process is recognizing the shifting role of the professor who becomes the *guide on the side* or content facilitator and is no longer the proverbial *sage on the stage* or content provider. The student's role also has changed from being a passive receiver of information to an active participant in the knowledge-making process (Weller, 1988), aligning with Bandura's (1977, 1994) concept of the autonomous learner, an important dimension of the constructivist model. Table 1 delineates these two approaches to learning.

Of special interest in Table 1 is the role of community. The constructivist approach recognizes that students do not learn strictly within the limited confines of an educational institution, but rather within the broader context of their personal lives. Consequently, the boundaries between the educational institution and the larger community become blurred, creating a unique set of challenges.

As people work collaboratively in the learning activities, they bring their own worldviews and experiences to each situation, often creating a plethora of perspectives. During this collaborative learning process, they must negotiate and generate meaning and solutions to problems through shared understanding. Thus, education moves from a single, solitary pursuit of knowledge to a collaborative learning community that shapes and informs responses to the environment. As noted by Fuller and Söderlund (2002), this challenges the common metaphor of the university as a self-contained village.

RAPIDLY CHANGING DISTANCE LEARNING TECHNOLOGIES

Over the years, educators have experimented with and successfully employed multiple media for distance learning. As early as the 18th century, print material was used and even today still serves an important role in distance education.

Table 1

Approaches to Learning		
	Traditional	**Constructivist**
Professor	Sage on the Stage	Guide on the Side
	Content Provider	Content Facilitator
Learner	Passive Recipient	Active Participant
Knowledge	Fixed Object	Fluid
Organization of Learning	Ordered & Structured	Open & Often Chaotic
Communication	Uni-directional	Multi-directional
Primary Resource	Text & Professor	Multiple Sources
Method	Lecture	Active Process
Media	Print	Blended
Format	Individualized	Collaborative
Activities	Goal-oriented	Problem-centered
Focus of Learning	Knowledge & Understanding	Application, Analysis, Synthesis, & Evaluation
Assessment	Recall	Alternative Assessment
Community	Educational Institution	Integrated with Life

After the 1930s, other media became significant with audio, including radio and audiotapes, and video, including public broadcasting, satellite, and cable, dominating much of the 20th century.

Much of this education was one-way based on a mass communication or one-to-many educational model. Basically, it was a rigid structure with information flowing in one direction, from the powerful and knowledgeable instructor reaching to a large group of students. It included elements of limited feedback through the use of such things as the penny post in the 19th century and the addition of telephone and fax in the 20th century. Limited opportunities for face-to-face interaction were also incorporated with some programs. Thus, much of distance learning during these times remained mainly non-interactive.

By the 1990s, the advent of the Internet presented new opportunities in distance education. The result was the evolution of a new type of collaborative learning, in which the potential for interaction between the professor and the learner increased exponentially with wide-area networks accommodating synchronous and asynchronous communication. While exploring computer-mediated activities of the online learning environment, Santoro (1996) highlighted three broad categories: (a) computer-assisted instruction, which allows the computer to serve as teacher by structuring information delivered to the human user, (b) computer-based conferencing, which includes e-mail, interactive messaging, and group conference support systems, and (c) informatics, which refers to online public access libraries and interactive remote databases. This proliferation of the Internet unlocked the door for educational institutions to reach beyond their four walls, making services accessible to students around the world through online activities.

In their work with the U.S. Department of Education, Waits and Lewis (2003) reported that in the 2000 to 2001 academic year, 56% of the nation's degree-granting 2- and 4-year institutions offered courses at a distance with another 12% planning to do so within the next year. Although the communication technologies of the 21st century—print, audio, video, and the Internet—cover a broad spectrum of distance education mediums, this exponential growth in science and technology has catapulted the Internet into rapidly becoming the preferred delivery platform. Researchers such as Cotton (1995) and others who have been tracking this information over the last decade along with scholars such as Bocarnea, Grooms, and Reid-Martinez (2006) continue to explore not only the trends in distance education, but also the understanding of and the issues involved in aligning the environment with student needs. Typical factors include (a) the characteristics of the discipline, (b) the degree of interactivity sought in the distance learning process, (c) learner characteristics, (d) instructor traits, (e) the expansiveness of the distance education initiative, (f) the desired level of accessibility and flexibility of the delivery platform, (g) the availability of technical support, and lastly (h) the potential for growth.

In addition to the global reach of the Internet, the lines *among* communication technologies have swiftly blurred. Today, in the convergence of technologies, computers, telephones, and cameras are no longer distinct entities, but can be found bundled into one small handheld gadget through the fusion of technology (McCain & Jukes, 2001). Through this fusion, communicating with students and colleagues has become more integrated, vastly expanding the means of feedback.

With such rapid technological advances, today's educators are dropped into what Jacque Ellul (1964) described as the intersection of tension between humanity and technology. This struggle with the latent and manifest, and intended and unintended consequences of technology exists as students and professors wrestle with new Web-enabled devices that seem to expand learning media at exponential rates. These include, but are not limited to, online courseware and portals, interactive media (edutainment), video and telephone conferencing, podcasting, vodcasting, phonecasting, instant messaging, blogging, moblogging, linklogging, vlogging, and photologging.

This new technology facilitates greater flexibility and customization in the learning process. For example, combining metatagging and object tagging with some of these media automates the process in highly specialized ways that create cost and human resource efficiencies. Other advances supporting increased efficiency in communities of practice include knowledge management, learning objects, and electronic performance support systems (EPSS).

Instructional designer Don Morrison (2004) demonstrated how the aforementioned learning channels can be established within parameters and policies that most appropriately align with the primary strengths and weaknesses of each medium. He noted that among others, cost, time constraints, delivery speed, and infrastructure help determine appropriate application. Morrison's work also pointed to ways in which educational models can be designed to marry traditional and online means of moving from the simple to the more complex methods of learning.

Citing that the mix of traditional and online learning depends upon the student, the context, the available channels, and the time constraints in which the education takes place (Morrison, 2004), one such marriage is blended learning. Although the typical example of blended learning evokes images of traditional classes combined with an online component, this is not the only alternative. While images of the traditional precipitate thoughts of coaching and mentoring, collegial relationships, seminar participation, and workshops, and the virtual environment conjures visions of referencing manuals and online communities, any combination of these means constitute blended delivery.

From blended to distance learning, these new electronic forms of communication have forced a paradigm shift in education. This move is most avidly seen in distance learning, where even the terminology has shifted from distance education to online or e-learning. This new term more clearly indicates the way in which learners can use computer-mediated hypertext multimedia communication to easily collaborate in a continuous integration of knowledge and social capital.

FUTURE TRENDS

As previously discussed, the rapid growth of technology continues to herald unprecedented opportunity for distance learning, and when wed to a constructivist approach, it presents opportunities for online pedagogy that can transcend traditional modes of education. From this marriage emerges three primary factors that define the new online pedagogy: (a) community building through networks that cross time and geographic boundaries, (b) structure through technology that manages, and (c) collaborative opportunities for shared knowledge and wisdom in response to the complexities of a global society (Reid-Martinez, 2006).

Community

As Bocarnea et al. (2006) note, today's technologies launch a new paradigm of online learning and pedagogy, which has the potential to be communal in nature. Primarily, these technologies allow for interaction between students and professors, students and peers, and the broader community in unprecedented ways. For example, Wojnar (2002) and Young (2002) confirm that students in Web-based courses have greater instructor access through e-mail and e-learning platforms than they would often have in traditional lecture halls.

In fact, Young (2002) highlights the differences between the boundaries embedded in his traditional face-to-face class and that which he encounters online. This suggests that guidelines and boundaries following good business practices are essential to prevent online instructors and students from feeling overwhelmed by the 24-7 opportunity for interaction. As this suggests, these technologies provide opportunities for networking and building strong virtual learning communities that can transcend geographic boundaries and extend far beyond the duration of the student's formal education.

In addition, this communal nature of the virtual learning environment provides opportunity for students to bring their local community context into the learning experience in direct ways as well as immediately allowing them to apply what they have learned through their study. For example, students in leadership programs can be employed full-time in leadership positions and take their learning experiences directly into their work environment through well-designed course assignments. The professor is no longer someone whom the student must wait to see in class later in the week, but rather is readily available in the e-learning platform to serve as consultant and mentor as the student applies the principles studied that week. The professor has become the "guide on the side." This triangulation of student-professor-content points to the need for well-designed learning experiences developed from a constructivist perspective to meet the challenges and needs of today's students. Indeed, uniting the new technology with this approach appears to be a marriage made in heaven for contemporary students working in a rapidly changing and highly demanding global environment.

Unfortunately, this opportunity for such rich learning experiences is not always the case. For example, Schweizer (1999) noted that many online courses have been cited as unsound, lacking pedagogical clarity and adequate design. While some scholars such as Wang and Newlin (2002) make certain that pedagogy guides the design of their online courses, all too often technology rather than pedagogy has driven the computer-mediated learning experience instead of simply serving as the delivery mechanism.

In fairness to contemporary educators, the rapid advancement of technology creates a moving-target challenge for course developers who often find themselves reacting to the technological advances rather than proactively establishing the technology's relationship to the learning process. As Bocarnea et al. (2006) observe, theory typically "follows technology in desperate attempts to describe the impact of an already existing and rapidly fading…technological reality" (p. 385).

This suggests that staying focused on strategy and content design remains the dominant challenge for curriculum developers. Online pedagogy, the science of and about online education, provides perspective to assist the developers in focusing and maintaining the balance necessary for creating excellent online learning experiences. Furthermore, online pedagogy allows designers to be proactive as they can be in constant reflection and introspection about the technological processes involved in online learning.

Structure

Heralded just over 14 years ago by Negroponte (1995), the information age is collapsing on itself as the amount of online information is becoming unbearable. After the scramble to have everything digitized, the primary challenge today is how to create meaningful knowledge from such massive amounts of data. The quality of knowledge in contrast to quantity drives the heart of this concern. In light of this overload, structure is essential to online knowledge development.

Related to the structure is the development of open-source initiatives. While most often understood as software that is

open for use and modification by the public, the phrase has become a recognized attribute ascribed to multiple endeavors, such as knowledge-building. The open-source nature of online initiatives pushes a new model for managing learning and knowledge-building through the communal process. It allows diverse individuals from various locations to combine information from multiple sources into distributed knowledge networks. Through this open-source structure, participants interact to share experiences and knowledge, thereby expanding their awareness of new concepts and differing approaches to problem solving as they modify the information in the open-source environment and redistribute it back to fellow participants (Bocarnea et al., 2006).

As this suggests, through interaction, participants build complex webs of knowledge in the open-source cyberspace. The technology provides the structure to create and maintain webs of knowledge, and it also grants ease of access globally to those in the public interested in that knowledge. In the process, knowledge is given away to others who in turn begin to use it in multiple ways while beginning the next evolution of knowledge development as they add to and transform the knowledge base they accessed through the open-source structure. With this transformation is the transference of power and control that becomes less centrist and more distributed globally.

Collaborative Knowledge-Building

As noted above, interaction is the key for the development of open-source knowledge-building. While scholars such as Cederblom and Paulsen (2001) posit learning as a behavioral change, others hold that it is simply when learners meet needs and establish goals for attaining knowledge (Ponton & Carr, 2000). Referring to this process as an implied contract, Keirns (1999), along with the above scholars, suggests that if online learning is used, structure is critical to allow students to advance in their knowledge.

The design of the online course becomes the principal structure to assure learners' goals are achieved. In that course design, structured interaction must be at the core. Not only does this interaction provide for knowledge development, but Blair (2002) claims that online threaded discussions can serve as primary places for faculty to prompt students' critical thinking. Furthering this thought in comparison with on-campus courses, she cites that online learners exemplify a greater degree of reflection and depth in their questions. This is likely because in most cases, online learners have more time to process and research their responses. Moreover, the delay in feedback in the asynchronous learning environment also allows learners to be less inhibited, to take greater chances, and thus to offer more in-depth analysis (Smith, Ferguson, & Caris, 2002).

One way of establishing structured interaction is through required dialogue participation (Klemm, 1998). As earlier noted, the online classroom creates greater access for participation (Cummings, 1998; Wojnar, 2002; Young, 2002), which Blair (2002) suggests often forges stronger relationships due to increased interaction frequency. This increased interaction also relates to higher learner commitment due to the socialization the learner goes through to be a participant in the knowledge-building process. Thus, learner perception of the degree of interaction plays an important role in student achievement, satisfaction, and course quality (Roblyer & Ekhaml, 2000).

Again, in the collaborative nature of the constructivist online culture, interaction perpetually occurs between learners and content, learners and instructors, and learners and peers, with each type of interaction reinforcing and fostering collaborative knowledge-building for both the learner and the faculty. With this in mind, online course designers must decide how to best structure courses capitalizing on this collaborative interaction.

CONCLUSION

As the above suggests, the advent of online learning as a new form of distance education has not just provided opportunity to disseminate information in a new medium, but it has radically adjusted the distance learning paradigm in terms of distribution methods, community-building, and pedagogy. The use of 21st century technology is rapidly closing the gap of the communication immediacy essential in developing communities of practice for knowledge-building. With their open-source networks, these new technologies encourage and actively support constructivist pedagogy in the new distance education paradigm. Most of all, distance education can now fulfill its greatest potential, which is to reach every learner who desires to participate in the knowledge-building process. The result is a democratization of education not previously seen, allowing for shifts in power and control throughout societies.

KEY TERMS

Autonomous Learning: The process in which individuals take responsibility for their learning.

Collaborative Learning: The process in which individuals negotiate and generate meaning and solutions to problems through shared understanding.

Computer-Assisted Instruction: The computer serves as the "teacher" by structuring information delivered to the human user.

Computer-Based Conferencing: E-mail, interactive messaging, and group conference support systems.

Constructivism: An approach in which students share responsibility for their learning while negotiating meaning through active participation in the co-creation of shared understanding within the learning context.

Distributed Knowledge: Information dispersed throughout a community of practice and not held by any one individual.

Informatics: Online public access libraries and interactive remote databases.

Interaction: Mutual communicative exchange between individuals.

INTRODUCTION

Computer programming involves more than thinking of a design and typing the code to implement it. While coding, professional programmers are actively on the lookout for syntactical glitches, logic flaws, and potential interactions of their code with the rest of the project. Debugging and programming are therefore not to be seen (and taught) as two distinct skills, but rather as two intimately entwined cognitive processes. From this perspective, teaching programming requires instructors to also teach students how to read code rigorously and critically, how to reflect on its correctness appropriately, and how to identify errors and fix them.

Recent studies indicate that those students who have difficulties in programming courses often end up coding without intention (Gaspar & Langevin, 2007). They search for solved exercises whose descriptions are similar to that of the new problem at hand, cut and paste their solutions, and randomly modify the code until it compiles and passes the instructor's test harness. This behavior is further exacerbated by textbooks, which only require students to modify existing code, thus ignoring the creative side of programming. Breaking this cognitive pattern means engaging students in activities that develop their critical thinking along with their understanding of code and its meaning.

This article discusses constructivist programming activities that can be used in undergraduate programming courses at both the introductory and intermediate levels in order to help students acquire the necessary skills to read, write, debug, and evaluate code for correctness. Our constructivist apprenticeship approach builds on earlier field-tested apprenticeship models of programming instruction that successfully address the learning barriers of the new generations of novice programmers. We go one step further by realigning such approaches to the genuine difficulty encountered by students in a given course, while also addressing some pedagogical shortcomings of the traditional apprenticeship instructional practice. This is achieved by introducing a strong pedagogical constructivist component at the instructional level through so called antagonistic programming activities (APA). We conclude with a manifesto for a new multidisciplinary research agenda that merges the perspectives on learning found in both the computing education and evolutionary computation research communities.

BACKGROUND

Novice Programmers and their Learning Barriers

The study of the learning barriers encountered by novice programmers is critical to the computing education research community. Recent studies describing the misconceptions and preconceived notions held by novice programmers (Chen, Lewandowski, McCartney, Sanders, & Simon, 2007; Kolikant, 2005) indicate that these learning barriers evolve with each new generation of students. In this context, a phenomenon known as "programming without intention" has been identified as an attempt by students who encounter difficulties in programming to mechanize the programming thought process. Their heuristic boils down to the following: (a) reading the description of the program to write and look up available documentation (solved exercises, Google, Krugle, etc.) for another similar, already-solved exercise, (b) cutting and pasting the solution to that exercise as a starting point for the current assignment, and (c) compiling and running the program and, since it most likely does not do what is expected, modifying it. Due to the lack of understanding of the solution being reused and the lack of time devoted to understand the programming activity from the ground up (e.g., learn the syntax, learn the role of statements, learn when to use which), these modifications often boil down to a series of almost random changes until the program seems to execute according to the requirements.

This obviously random-based development approach has very little to do with programming and leaves students unable to explain why a particular statement is in their code. In some occurrences, students stated, "I have the code now for this assignment; I need to understand it." This indicates a complete reversion of the programming thought process leading from ideas to implementations. Instead, intentionality is lost, and statements are manipulated in an almost mechanical manner without second thoughts. Essentially, students are utilizing skills at the lower end of the knowledge framework by demonstrating cognitive functions that Bloom (1956) would have termed as knowledge or understanding with no ability to analyze, synthesize, or evaluate the programming process itself.

Criticizing this approach is, however, insufficient. Understanding what reinforces our students' belief that they are problem solving when developing code this way is what can really help us lead them to overcome this particular learning barrier. The nature of the exercises typically found in some introductory programming courses might be partly responsible for this situation. Often, novice programmers are only required to reuse already working programs and modify them slightly (under heavy guidance) to do something new. While analogical thinking is essential to the professional developer when learning new languages, technologies, and paradigms, it is not safe for it to be the only conceptual tool developed by students during their first programming experience. Creative thinking, critical thinking (e.g., debugging), and problem solving are all essential components of the programming thought process, which, if not given proper attention from the beginning, might fuel the misconception that programming is just a matter of pattern matching in a big book of existing solutions.

Leveraging Apprenticeship in Programming Courses

This learning barrier can be addressed by an apprenticeship model of teaching (Kolling & Barnes, 2004), which can take on several distinct forms. The most obvious one is instructor-led live coding: An instructor presents a problem to her or his students, lets them work on it for a definite time, and then introduces the solution. Instead of presenting students with a detailed explanation of the complete solution, the instructor builds the solution from scratch in front of his or her audience. This diverges from the usual instructional pattern, which leads students to build a dictionary of problem-solution pairs that were introduced in class. Such courses encourage students to memorize data in the hopes that they will be able to simply regurgitate it at the next exam. If a question dares differ from a previously solved problem in any significant way, they will then attempt to fit the memorized solution to this new problem by applying a couple of minor adjustments, which could be stumbled upon almost randomly. By developing the solution in front of the students, the instructor's teaching is aligned with the learning outcomes of the course: the programming thought process itself vs. its outcomes. This approach is clearly illustrated in the work of the BlueJ team and their textbook (Kolling & Barnes, 2004).

Other implementations of the apprenticeship model of teaching are closer to problem-based learning approaches; students are taught the programming thought process by applying it frequently to solve new problems from scratch. This learn-by-programming or learn-by-doing approach also leads students to realize the importance of creative and critical thinking in the programming activity while reducing the benefits of memorization-only or analogy-only strategies. In complement, these pedagogical strategies are often coupled with peer learning approaches (McDowell, Hanks, & Werner, 2003; Willis, Finkel, Gennet, & Ward, 1994).

These apprenticeship pedagogical strategies address the above-mentioned learning barriers by aligning the skills being practiced by students during exercise sessions with the authentic learning outcomes expected from an introductory programming course. This in itself complements nicely with constructive alignment theory (Biggs, 2003), which aligns assessment tools with expected learning outcomes.

From Apprenticeship to Constructivist Apprenticeship

Despite these significant pedagogical achievements, the apprenticeship model of instruction can be further improved from the instructional method perspective. Let us take a critical look at the above-mentioned apprenticeship activities: instructors demonstrating the programming thought process while solving a problem live, classmates developing code while other students play the role of a peer programming observer, students coding against each other in a game-based learning environment (e.g., Bierre, Ventura, Phelps, & Egert, 2006).

These activities are essentially instructivist in nature; students are presented with a problem, they work on it, and then the instructor (or their peer) corrects them or even develops a complete solution for them. Even though the thought process is the focus of the demonstration rather than the solution itself, the teaching process is mostly unilateral. The "sage on the stage" (or next seat) strikes again and leads students to adopt a rather passive attitude as they receive their instruction.

Besides the motivational or attention-span issues that such approaches can cause, the work invested by students to develop their own solution is completely ignored in the instructional process (a hallmark of instructivist pedagogies). They are therefore never corrected, improved, or even

leveraged to understand how the student learns. The student is instead required to replace his or her misconceptions with the correct ones. This process is not transformative and often leaves students wondering why their own solutions were incorrect. Down the road, students will commit errors when trying to apply a knowledge that was accepted on top of very blurry foundations.

In such a scenario, the quality of instruction is expected to make up for this lack of connection with the students' cognitive models. Its quality is based on the instructor's past experience with similar student populations or on the instructor's knowledge of studies published on traditional learning barriers encountered by sometimes significantly different student populations. While necessary, this knowledge too often fails to capture the authentic learning barriers encountered by students in the classroom being currently taught. Indeed, such studies do not account for the evolution of the learning barriers, cognitive models, and preconceptions with which each single generation of students arrives. If they did, the computing education research community would have certainly converged by now toward an optimal pedagogical strategy for novice programmers. This misleadingly portrays the pedagogy of programming research as a static problem that might end up being solved once and for all for the ages to come regardless of the evolution of students' learner profiles and the programming technologies and methodologies themselves.

We suggest that the next step in improving the apprenticeship model of learning and teaching resides in developing and replacing inherent instructivist dynamics with constructivist ones. This work led us to define constructivist apprenticeship as a general pedagogy. In the context of computing education research, this pedagogical strategy proved to be particularly suited for introductory and intermediate programming courses in which it could be implemented as antagonistic programming activities (Gaspar & Langevin, 2007).

CONSTRUCTIVIST APPRENTICESHIP AS A PROGRAMMING PEDAGOGY

Constructivist Apprenticeship and Antagonistic Programming Activities

While the constructive alignment theory (Biggs, 2003) aligns assessments with learning outcomes, constructivist apprenticeship completes it at two levels. First, it aligns the learning activities themselves (focus on programming thought process and apprenticeship) with these same learning outcomes. Second, it aligns, through constructivism, the pedagogy of instruction with the authentic learning barriers students encounter (as opposed to the assumed ones). In a programming course, such a pedagogical strategy can be implemented through programming activities that adhere to the following principles. First, the activity must develop programming skills and prevent students from reaching acceptable results through mere cut-and-paste strategies. Second, it must reduce the instructivist dimension of the learning experience by fostering a symmetrical dialog between instructor and student (or among students for peer learning). Last, it must reduce this instructivist dimension by de-emphasizing the importance of showing students the "right way." The last two principles led us to consider the benefits of situations in which students work against one another. This reflection led us to experiment with various classes of antagonistic programming activities.

APAs are programming activities aimed at honing the students' critical thinking and troubleshooting skills in order to develop authentic programming skills at the higher levels of Bloom's (1956) taxonomy. These active learning activities enable groups of students to work together but with antagonistic goals, in face-to-face or distance education settings, under the instructor's supervision or purely as peer learning. These activities also leverage constructivist teaching methods in so far that very little of the solution is communicated to students; instead, their errors are pointed out by the instructor or their peers, but left to be fixed by them. The following sections examine the core idea of each APA variant, provide application examples, and discuss their salient features.

APA 1: Student-led live coding (design-focused variant). Many instructors have already realized the benefits of developing solutions in front of their students (live coding). This apprenticeship teaching (Kolling & Barnes, 2004) successfully refocuses the teaching effort on the programming skills themselves instead of the memorization of finished code solutions. However, students are still passively taught the correct thought processes and accept it as they would have accepted a complete solution, while their own errors are still left out of the learning experience.

In response to the instructor-led live coding's shortcomings, one can let students solve problems in front of their classmates. This student-led live-coding variant requires, for each exercise, the teacher to pick a student who will operate the podium PC with a wireless keyboard (Hailperin, 2006). The student's work is projected, thus enabling the instructor to solicit classmates for corrections, improvements, and discussions about the thought process itself and not the complete finished solution only (unlike most peer learning pedagogies). Most importantly, the students' errors provide the instructor with an authentic understanding of his or her students' problems on which to base the lecturing and class

discussions. This marks an improvement compared to the way instructors usually base their pedagogy on their own past experience or published studies, which, while statistically significant, might relate to a population significantly different from their current students. This is also the trademark of a constructivist approach, which values and integrates the students' errors as part of their learning experience.

APA 2: Student-led live coding (alternative-focused variant). In the alternative-focused variant, one student is still given the wireless keyboard. However, while this student develops his or her own solution, others work independently on their own. This allows for more independence and therefore enables the emergence of radically different solutions while still enabling those having difficulty to peek at the chosen student's early work. During the activity, the instructor walks among students, helping them with their individual solutions, answering questions, and assessing the variety of strategies being implemented. After a set time, students are invited to look back at the chosen student's work and contribute comments, fixes, and suggestions for alternative approaches. The instructor can then lead a hands-on discussion while the code is being modified to evaluate the various strategies (good or bad) that were explored independently by students. The following exercise was given as such as an in-class activity for the fourth week of an intermediate programming course right after a recursion lecture:

> *Implement an iterative and recursive version of a function that will return how many times its (strictly positive integer) argument can be divided by 2 until you get a nonnull remainder. For instance, F(4) will display 2 time(s), F(5) will display 0 time(s), and F(6) will display 1 time(s).*

Students came up with a wide range of solutions including iterative ones (e.g., *while* loop), recursive ones building their results on call returns (expected as the closest of the lecture's examples), and recursive ones building their results during the call (using an extra parameter). This resulted in discussions about tail recursion optimization and detailed explanations (based on program execution stack diagrams) of each solution to ensure they were understood by all. Finally, students also generated unanticipated solutions involving global and static local variables, which motivated a minireview session on these topics. This variant illustrates how a slight protocol change can foster significantly different learning dynamics, which can be further supported by open-ended exercises.

APA 3: Test-driven peer code reviews. So far, APA relied on instructors to serve as a central hub, coordinating the students learning. In larger classes, it becomes difficult for a single instructor to coordinate many students while still allowing all of their voices to be heard. In such settings, peer learning strategies are generally more successful. The very principles of constructivist apprenticeship can also be leveraged in a peer learning context by enabling students to correct each other in a noninstructivist manner. Most peer learning pedagogies rely on collaboration between peers of equivalent levels. In practice, the peers might end up exchanging complete solutions unilaterally or, in a less extreme dysfunctional scenario, exchange corrected code fragments or partial solutions. Even if this teaching and learning dynamic is not unilateral, each peer's contribution too often ignores the others' and boils down to a "your code doesn't work, mine does" reaction. How can we switch this learning dynamic to something more balanced (both students get to develop their solution and improve them) and more constructivist (their individual attempts are matured in a satisfying solution rather than ignored in the acceptance of correct solutions)? The following exercise, adapted from the Javabat applets (Parlante, n.d.), illustrates how this can be done.

The students were paired and given a problem description:

The squirrels in Palo Alto spend most of the day playing. In particular, they play if the temperature is between 60 and 90 (inclusive). Unless it is summer, then the upper limit is 100 instead of 90. Using Raptor, write a flowchart which is going to ask the user to provide a temperature value (between 0 and 130) and a number summer which will be equal to 0 or 1. Depending on the values that were passed to you by the user, you will determine whether the squirrels are playing or not and display on the screen an appropriate message.

In each pair, both students developed their own solutions independently along with a test harness. A test harness, in this case, was simply a written list of tests to be performed on the programs along with their expected and observed outcomes. Once satisfied with their code, students applied their test harnesses to their peer's code. As they did so, they read the code itself, taking note of which tests failed and adding new tests to capture flaws they spotted in their peer's code. Then, they exchanged again their programs to improve them based on the failed tests. This process was reiterated until both programs were successful through each test harness.

The main pedagogical benefit of this APA is its constructivist nature; students instruct each other without exchanging code and without directly fixing errors (a more subtle form of instructivism). Instead, each peer can only adapt their test

harness to reflect the flaws they perceived in both programs. This allows students to develop their critical thinking and debugging skills without being shown how to improve directly. Misconceptions in students' minds, along with their incarnation as bugs in their respective programs, are therefore addressed without relying on an instructivist exchange.

The activity is also antagonistic; students "attack" each other's code through test harnesses. However, unlike most game-based educational activities (Bierre et al., 2006), students are not allowed to confuse "learning by blasting" with "learning to blast. In many competitive learning settings the task at hand (e.g., piloting a tank) ends up overpowering the educational outcome (e.g., learning to program). Code quality, sometimes even correctness, become secondary to performing well in the game. Depending on the game itself, the winning strategy can cost students their learning experience. In our activities, this obstacle is removed by having students compete on code correctness through test harnesses instead of programs' outcomes.

FUTURE TRENDS

Constructivist apprenticeship realigns the pedagogy of contents with learning outcomes and the pedagogy of instruction with the authentic learning barriers experienced by students, thus complementing the achievements of constructive alignment theory. From the applicability perspective, this principle is extremely flexible, and its benefit can reach beyond the programming courses (introductory and intermediate) we have been focusing our discussion on so far. Any course conveying a problem-solving skill to students can benefit from this pedagogical strategy (e.g., accounting, software engineering, algorithms design, etc.). In this expanded context, live coding and code peer review activities can be more broadly perceived as peer-reviewed problem solving. Besides its application to a wider range of courses and disciplines, constructivist apprenticeship has also the potential to serve as ambassador for a new interdisciplinary research agenda bringing together the understanding of learning dynamics from two apparently unrelated fields: evolutionary computation and computing education. The following example illustrates how APA can draw inspiration from and leverage evolutionary computation techniques to inform and improve educational practices.

Using test harnesses in APA allowed us to leverage constructivist peer learning dynamics. Instructors can use similar strategies to teach students by, for instance, crafting an array of values to fail a student's sorting algorithm. Such an approach convinces students of their errors without forcing a solution, which would fail to explain why their codes are not acceptable. Interestingly, similar strategies are used when coevolving artificial neural networks. The way students develop iteratively new test cases meant to fail their peer's code as it is being improved from its confrontation with previous test harnesses can be seen as a coevolutionary dynamic. Test harnesses and programs are defining their respective fitness (i.e., goodness) as a function of how they perform against one another. Similar coevolutionary dynamics can be found in predator-prey models, leading each species to improve under the selective pressure of their counterpart's own evolutionary drive. This dynamic has also been successfully applied to the design of artificial neural networks (Mayer, 1998). A series of neural networks are created randomly, thus forming a population that will be opposed to another population made of training samples, that is, a set of input-output pairs that represent the expected behavior neural networks are expected to learn. The two populations undergo an evolutionary computation transform mimicking the mutation, recombination, and selection scheme found in natural evolutionary systems (Holland, 1992). The quality of a neural network is then quantified in terms of the number of training samples it can successfully solve. Inversely, the quality of a training sample is measured by the number of neural networks it can cause to produce a wrong error. By improving the quality of one of the two populations, we improve the quality of the other, thus leading to a so-called coevolutionary scheme.

CONCLUSION

This article describes constructivist apprenticeship and its applications to programming courses through antagonistic programming activities. We stressed the potential of this approach to help students overcome a learning barrier characterized by a loss of intentionality when designing programs and its applicability to both instructor-focused and peer-learning scenarios. Ramifications and synergies with other educational theories were discussed as well as the potential for constructivist apprenticeship to benefit other computing courses, or even disciplines, that focus on teaching problem-solving skills. Besides the educational framework in which this approach has been developed, we see constructivist apprenticeship as a herald of an interdisciplinary research agenda bringing into the computing education research field an understanding of learning dynamics from the perspective of evolutionary computation researchers. As discussed, results in the latter can mature into and inspire improved pedagogical strategies.

KEY TERMS

Antagonistic Programming Activities: These are programming learning activities meant to motivate students by leveraging competitive dynamics focused on scrutinizing, critiquing, improving, and troubleshooting classmates' code. These activities embody the constructivist apprenticeship principles as applied in both instructor-supervised and peer-learning contexts.

Apprenticeship: An apprenticeship is an educational approach historically employed to train crafts practitioners adapted to computing education as a way to teach programming skills through instructor-led demonstrations of from-scratch problem solving (instructor-led live coding).

Constructive Alignment Theory: It is an alignment of learning and teaching activities with the course outcomes and constructivist principles. It was introduced by Professor John Biggs (2003)

Constructivist Apprenticeship: This is a variant of the apprenticeship model of teaching that realigns the teaching practice to incorporate constructivist educational practices. It is applied to programming courses through antagonistic programming activities.

Evolutionary Computation: It is the field of research that deals with the design, and application to engineering problems (e.g., optimization, learning), of bio-inspired algorithms that embody the quintessential characteristics of natural evolutionary systems.

Student-Led Live Coding: It is an antagonistic programming activity in which a student's programming thought process is made visible to all in order to enable an apprenticeship learning based on the authentic learning barriers encountered by students (as opposed to the assumed ones).

Test-Driven Peer Code Review: It is an antagonistic programming activity that pairs students to work on a given exercise, yet allows them to develop their own solutions independently, thus ensuring the symmetrical involvement of

both peers. Solutions are then exchanged and test harnesses developed to fail the peer's code. These test cases are the only instructive information exchanged between peers, thus ensuring a constructivist learning dynamic.

Contactless Payment with RFID and NFC

INTRODUCTION

The radio frequency identification (RFID) reading technology enables the transfer, by radio, of information from electronic circuit to a reader, opened up some interesting possibilities in the area of e-payment (Domdouzis, Kumar, & Anumba, 2007). Today, the near field communication technology (NFC) opens up even more horizons, because it can be used to set up communications between different electronic devices (Eckert, 2005).

Contactless cards, telephones with NFC capacities, RFID tag have been developed in industry and the services (Bendavid, Fosso Wamba, & Lefebvre, 2006). They are similar, but, some major differences explain the specificity of these three applications and the corresponding markets. The label, or marker, is a small size electronic element that transmits, on request, its numerical identification to a reader.

The RFID identification makes it possible to store and recover data at short distance by using these miniature markers or labels (see Figure 1) associated to the articles to identify. The cost of the label is only few centimes. An RFID system is made of labels, readers connected to a fixed network, adapted software (collection of information, integration, confidentiality...), adapted services, and management tools that allow the identification of the products through packing.

Contactless smartcards (see Figure 2) contain a microprocessor that can communicate under a short distance with a reader similar to those of RFID technology (Khu-smith & Mitchell, 2002).

The originality of NFC is the fact that they were conceived for the protected bilateral transmission with other systems. NFC respects the standard[a] ISO-14443 (Bashan, 2003) and thus, can be used as a contactless card. It can be used as a contactless terminal communicating with a contactless card or another NFC phone (ISO-18092). Services available through NFC are very limited today, but many experiments are in progress and electronic ticketing experiences (subways and bus) started in Japan[b].

There are two types of NFC phones:

- The mono chip composed of only one chip for GSM services (called the SIM) and NFC services. In that case, an NFC service is dependent of the phone operator.
- The dual chip shows a clear separation of the two functions within two different chips. That completely

Figure 1. Some examples of RFI label

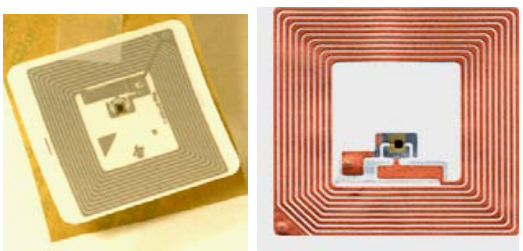

Figure 2. Example of a contactless bank card

isolates the operator and allows independent NFC services…

We define the technology standards, the main platforms and actors in the background section. The main trust develops some contactless payment applications, and analyses the benefits and constraints of the different solutions. The future trends section concerns the research and technology evolution in contactless payment applications.

BACKGROUND

The major interest of contactless cards is to facilitate access control, micropayment… Another interest refers to the usury of card; it is insensible to contact oxidation. We detail briefly the international standards that are involved in RFID and NFC.

Standards

ISO-14443

This standard is the international one for contactless smartcards operating at 13.56 MHz in close proximity of a reader antenna. This ISO norm sets communication standards and transmission protocols between a card and a reader to create interoperability for contactless smartcard products. Two main communication protocols are supported under the ISO-14443 standard: Type A and B. Other protocols were only formalized: Type C (Sony/Japan), Type D (OTI/Israel), Type E (Cubic/USA), Type F (Legic/Switzerland).

This norm is divided in four parts and treats Type A and Type B cards:

- ISO-14443-1 defines the size and physical characteristics of the antenna and the microchip;
- ISO-14443-2 defines the characteristics of the fields to be provided for power and bi-directional communication between coupling devices and cards;
- ISO-14443-3 defines the initialization phase of the communication and anticollision protocols;
- ISO-14443-4 specifies the transmission protocol.

ISO-14443 uses different terms to name its components:

- PCD: proximity coupling device (or reader);
- PICC: proximity integrated circuit card (or contactless card).

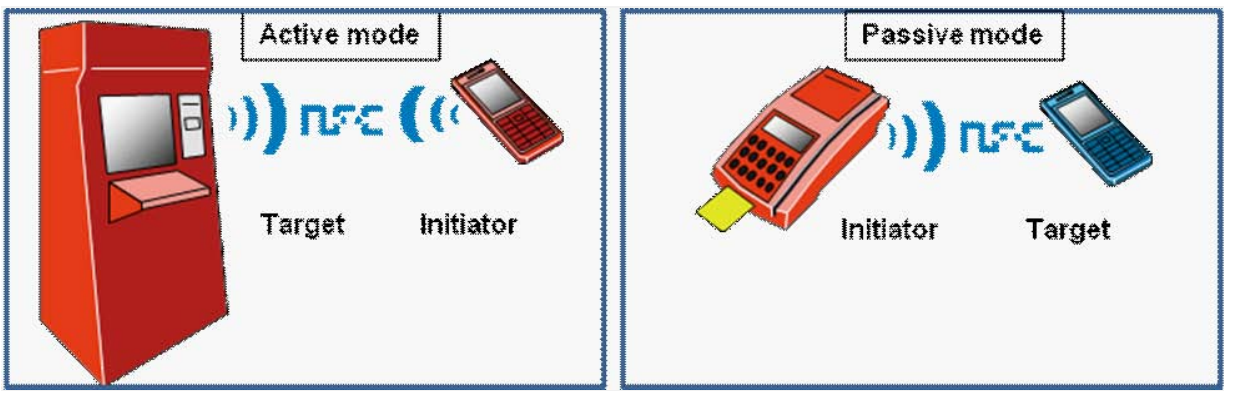
ISO-18092

NFC is a short-range (10 to 20 centimeters) wireless communication technology that enables the exchange of data between devices over a short distance. Its primal goal is the mobile phones usage. This open platform technology is standardized in ISO-18092 norm NFC Interface protocol-1[c]. In NFC technology, two communication modes exist: passive and active communication modes of NFC interface protocol to realize a communication network using NFC devices for networked products and also for consumer equipments (see Figure 3).

ISO-21481

The ISO-21481 standard (NFC interface protocol-2[d]) is derived from Ecma-356 (interconnection) standard. It specifies the selection mechanism of communication mode in order to not disturb communication between devices using ISO-

Figure 3. The two NFC communication modes



18092, ISO-14443 (contacless interface - proximity), and ISO-15693 (contacless interface - vicinity).

Application Platforms and Major Actors

There are major actors in the field of contactless applications; we distinguish two important platforms using the contactless technology: Mifare and FeliCa. This chapter does not focus on more details about these platforms technology, but is more about their applications.

Current actors in payment applications, namely MasterCard and Visa, stay alert, and intend to play a major role in future payment applications. They have already joined the movement and launch many developments over contactless payments. They begin to agree to a common communications protocol for contactless payment devices. This is based on the MasterCard PayPass™ protocol. MasterCard made the first step with a contactless credit card (see Figure 4) (Olsen, 2007).

The Visa PayWave technology is rather largely deployed within many European countries. They both intended the American market to future deployments (Turner, 2006).

Visa and MasterCard technologies comply with the EMV (Europay Mastercard Visa) standard. This standard defines the interoperation between smartcards and terminals for authenticating credit and debit cards. It defines strong security measures and provides a strong authentication along the process.

Mobile specifications are still in an early stage of development. Those who want to follow the development can do it at the EMVCo Web site[e]. Contactless cards that define the EMV standard over contactless communication does not differ so much with contact cards. The differences will be in the usages and applications.

Figure 4. Payment with a contactless card

MAIN FOCUS OF THE CHAPTER

The main focus of the chapter is an analysis of the benefits and limitations of RFID authentication for electronic payment (Tajima, 2007). This part deals with the particular constraints of banking (computation time, security…) for this kind of authentication process (Chen & Adams, 2004). The use of radio frequency and the small distance allows some security weakness that leads to security reinforcements.

Contactless Cards in Banking Applications

We have seen that MasterCard and Visa have an agreement to share a common transmission protocol and experimentation for the contactless payments by radio frequency in the points of sale.

Contactless payments, as conceived in the programs MasterCard PayPass and Visa PayWave[f], make it possible for the cardholders to carry out fast payments by a simple passage of their card in front of a terminal, thus, avoiding them giving their payment card to a merchant or handling cash. Contactless payments are much more practical for the consumers and are particularly adapted in environments of purchase where the speed is essential, like fast food, the gas station, but also theaters. They also offer new appropriate payments by using a card in unusual environments of purchase, like slot-machines or tolls. To make a payment, a user presents his/her card near the front of a terminal (a beep is emitted by the terminal). A request for an online authorization is sent. The payment is carried out.

There exist two types of PayPass cards:

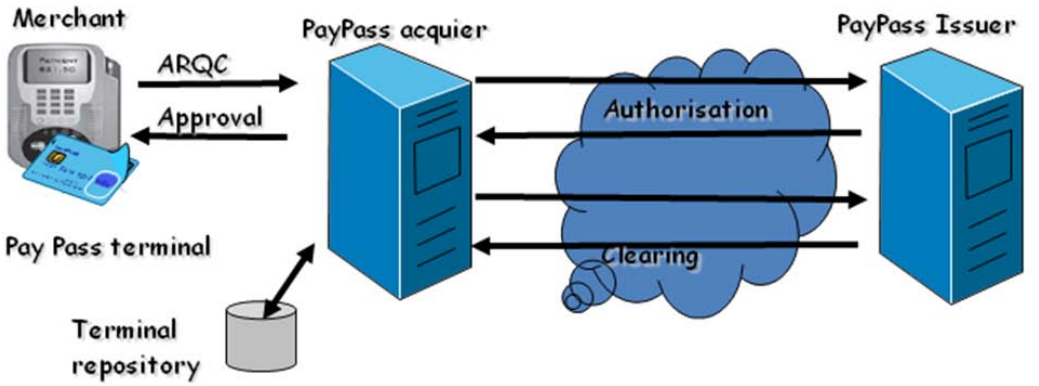
- Contactless with a magnetic stripe ;
- Contactless with a chip that is EMV compliant (dual-use card).

For the European market, Visa is planning on using RFID-enabled dual-use debit cards, based on its own Visa Contactless payment technology. It aims, in particular, at European countries already using EMV compliant cards. But, Visa is also understood to be in talks with mobile manufacturers to use NFC technology that will enable a phone to be used instead of a card.

For the US market, the contactless PayPass is not EMV compliant, so, the target is to limit the authorization requests (see Figure 5). How does it work?

- For a small amount (as for illustration <$30), an authorization of $30 is requested, then debited of the small amounts carried out;
- The payments lower than the authorization threshold, decrement of the preceding payments, are not online transaction object;

Figure 5. Delayed clearing and settlement



- As soon as the cumulated ceiling of preauthorization is reached, a new preauthorization is required.

When the amount exceeds $30, for example, an authorization request is always sent with the following exchange. The security of the transaction is guaranteed, first, by the use of some information stored in the card such as the card number, and second, through the secure transfer with the terminal by using the RSA algorithm: For the EMV countries, cards have contactless capability and EMV compliance. The transaction has another scheme.

NFC

NFC can be used as a terminal or a simple contactless card (Remédios, Sousa, Barata, & Osório, 2006). Before NFC, contactless applications, like payment or control access, were only implemented on cards. These developments were limited because the card has no battery power supply. Mobile phone is a possible solution in face of this problem because it is auto-provided with energy. Lots of new applications can be charged on an NFC phone, but not on a contactless card.

In opposition to credit card, mobile phone memory is not safe enough for storing secret data and critical applications. That is why these applications can be embedded on a separate chip. The security and confidentiality of data are ensured by encryption, which is handled by the chip itself.

The chip can be located in several places (Mallett, Millar, & Beane, 2006):

- Into the phone: The drawback is that the chip is not transferable; it is integrated in the phone. This system is named dual chip and has many advantages: telecom operators independence, security… This solution has been chosen by the ITEA research project called SmartTouch (SmartTouch, 2005) whose objective is to study and promote the use of NFC mobile phones for different applications including payment ;
- In the SIM card: The problem of this solution is that there is no standardization yet, and the telecom operator is responsible for all applications on its SIM card, thus responsible for the NFC part.

NFC mobile can be used as a terminal with a contactless card or another phone (ISO-18092), or it can be used as a contactless card (ISO-14443). Mobile screen, key pad, and connectivity features can be used to create more and more user friendly applications.

NFC Phone as a Contactless Credit Card

The NFC mobile phone can be used as a contactless credit card. In this case, NFC technology does not bring anything more than a contactless card (except for dematerialization of card, which is more useful).

An example of these applications is the proximity payment. The merchant, who has an NFC terminal, enters the amount of the transaction. The mobile owner then puts the phone near the terminal and information about his/her transaction are displayed on his/her mobile screen. If the owner agrees the transaction, he/she validates and enters his/her PIN code. He/she puts the phone on the terminal to send all information (number bank account…). He/she finally can take his/her ticket, since the transaction is closed.

In Japan, this payment solution is actually used. Lots of taxis adopted NFC payment system in their vehicle, which secures transactions for taxi and users do not need any cash money[g]. Some gas stations are already equipped for the NFC payments with mobile phone. Lots of research programs are based on NFC technology (Jaring, Törmänen, Siira, & Matinmikko, 2007).

FUTURE TRENDS

Future trends stress the different research topics that should participate to solve some still existing problems in contactless payment (Chen & Adams, 2004). We can consider that there are two main actors involved in the NFC payment with different objectives and limits.

The Mobile Phone Operators

An entity, either the mobile phone operator or a third-party vendor, sells the mobile phone and produces the correct information required to personalize the SIM. The responsibility of the personalization of the SIM is given to the mobile phone operator. The mobile phone operator prefers using a second chip than a single one because there is no exchange with the environment of the phone without it permits it (and more, it bills it). In that case, if a banking actor tries to modify the parameter of the SIM to implement the secrecy of the bank to allow the payment, it can do it only with the agreement of the mobile phone operator, who is the owner of the secrecy of the SIM.

That relation between the mobile phone operator and the bank can only be nowadays, with a one-to-one agreement that is incompatible with a generalization of that solution. Today, to start experimentations, the solution is to externalize the personalization to a specialized third partner well known by the mobile phone operators and by the banks. For each cardholder, the third party will receive the secret keys and software from the cardholder's mobile phone operator and the cardholder's bank, and will personalize the SIM with that information (Pasquet, Reynaud, & Rosenberger, 2008). That solution is tested by the three mobile phone operators and by five major banks in France in the Pegasus project on two French cities (Strasbourg and Caen).

In the future, it is necessary to modify the SIM architecture and to create some virtual shelters inside the SIM, protected by keys communicated by the SIM operator to the bank to allow the bank a remote personalization. The global platform specifications (new standard for smartcards infrastructure) are on the way to allow that secure remote personalization, but it will take more or less 2 or 3 years[h].

A second solution is possible with an NFC mobile phone; it is to not deal with a bank, and to pay a service by the costumer's mobile phone bill. These payment types, already used to buy bell rings for the customer phone, can also be used for NFC payments.

The Banks

Ten years ago, some banks tried to develop, with mobile phone manufacturers, some mobile phone with a special slot to insert banking cards[i]. They have given up that solution; very secured but expensive.

Another possibility is the use of NFC dual chip mobile phone where the SIM is completely separated from the NFC chip. The SIM is bought by the customer and installed in the mobile phone (Remédios et al., 2006).

The phone manufacturers are interested in that solution but the question is: which actors will commercialize the mobile phone if the operators disagree with the dual chip solution? Experimentations are in progress in few countries in the world (Finland, France…), but it will be difficult to convince the whole mobile phone operators to share the income of such solution.

Except that problem, the banks have just to personalize the NFC mobile phone. But, the phone must be in front of the antenna of the personalization equipment. This leads to two solutions: the banks can give the NFC mobile phone (within the partnership with a mobile phone operator and a manufacturer) to their clients (which model, which color…?), or the banks develop some personalization equipments and install them to personalize the NFC mobile phone of their clients. The two solutions impose some high investments for the banks.

CONCLUSION

Which technology is the best regarding traceability and security (identification and authentication)? As regard to the identification, the RFID, the smartcard, and the NFC, after the barcode, are today in competition. All actors develop their technology, until the moment when the aspect of universality or cost price is called into question by new considerations.

It appears that each technology is worth only according to the markets that are open for him/her, and for which industrial series allow a good profitability of use of the associated products. The convergence of the new networks will bring, by association with other technologies (cryptology, reduction in price and volume of the memories, particular modulations...), elements suitable to stimulate this dynamics.

KEY TERMS

Contactless Cards: The contactless smartcards contain a microprocessor that can communicate under a short distance with a reader similar to those of RFID technology

EMV: Europay, MasterCard and Visa specifications. This is a standard for interoperation between smartcards and point of sale terminals and also automated teller machine.

Felica: That platform owned by Sony Corporation, originally proposed as ISO-14443 type C but refused, is now compliant with the ISO-18092.

IC: Integrated circuit Miniaturized electronic circuit also known as microcircuit, chip, or microchip.

Myfare: That platform owned by NXP semiconductors, is compliant with the ISO-14443 type A standard.

NFC: Near field communication A short-range high frequency wireless communication technology, an extension of the ISO-14443 proximity-card standard for mobile phones.

RFID: Radio frequency identification Automatic identification method relying on storing and retrieving data using devices called RFID tags.

Smartcards: Card equipped with a chip or integrated circuit card (ICC). It defines any pocket-sized card with embedded integrated circuits which can process information.

Tags: Miniature markers or labels emitting a unique number or other information.

Contemporary Concerns of Digital Divide in an Information Society

Yasmin Ibrahim
University of Brighton, UK

INTRODUCTION

The social issue of the "digital divide" has courted much political and scholarly attention in the last decade. There is, however, less consensus over the origin of the term, even though it is generally associated with the advancement and diffusion of information technology. According to Jan Steyaert and Nick Gould (2004), the concept of the digital divide is believed to have gained media and academic currency in the mid-1990s. In 1998, the United Nations labelled the digital divide as a new type of poverty that was dividing the world (cf. Hubregtse, 2005). A UNDP (United Nations Development Programme) report in 1999 (cf. Norris, 2000) stated that "the network society is creating parallel communications systems" that increase the divisions between rich and poor nations (p.3). The term, in effect, captures the social inequality of access to technology, particularly the Internet, as well as the long-term consequences of this inequality for nations and societies.

The significance of the term is embedded within the notion of an information society, where information is an important component of the global economy in terms of production, development, and social enrichment of societies and nations. The diffusion of technologies, such as the Internet, has meant the surfacing of various social issues including technology's impact on society, its relationship with older media forms, and its immediate impact on people's social and political lives (Robinson, 2003, p. i). New technologies, such as the Internet, are seen as transforming the globe into an information society with the ability to promote new forms of social identity and social networks while decentralizing power (Castells, 1996, p. 2001). Robin and Webster (1999, p. 91), nevertheless, are of the view that the contextualization of the digital divide debates within the issue of information revolution is misleading, for it "politicises the process of technological development by framing it as a matter of shift in the availability of and access of information."

The term digital divide conveys the broader context of international social and economic relations and in particular, the centre-periphery power configuration marked by American dominance over the rest of the world (Chen & Wellman, 2004, p. 41). In fact, rhetoric and literature on technology and information have always emphasized this divide (see Galtung & Ruge, 1965), not to mention the debates that were sparked in the 1980s by UNESCO's proclamation of the New World Information Order (cf. Norris, 2000). The term has been analysed both at global and regional levels, and has involved the investigation of socioeconomic contexts, global governance, policy issues, as well as cultural elements. The analysis of the digital divide on a global level may entail comparisons of large regions, between developed and developing countries, and between rural and urban areas. In modern consciousness, the phrase captures the disadvantages and inequalities of those who lack access or refrain from using ICTs in their everyday lives (Cullen, 2003).

BACKGROUND

The imbalances between North and South in the field of communications and information were published in the Macbride Report in 1980, under the auspices of the United Nations Educational, Scientific, and Cultural Organization (UNESCO). The report concluded that there were stark discrepancies between industrialised and developing countries with regard to information flows and capacticites for active participation in the communication process (Modoux, 2002, p.2). The report was instrumental in the formation of a New World Information and Communication Order (NWICO), led by the United Nations and UNESCO to address the imbalances. With the appropriation of the NWICO as a "Cold War" agenda and the illumination of information and communication as a key tool of control and propaganda, the debates about the information and communication imbalances became subsumed under this climate of political hostility. In the 1970s and 1980s, the fear that development in the communication field might predominantly benefit the authoritarian regimes in the South (Modoux, 2002, p. 7) mediated much of the rhetoric and, as such, the global political context was important in situating debates on communication and information disparities.

The digital divide, as an issue, dominated the G8 summit in Okinawa in 2000, and has also dominated similar discussions at the first World Social Forum in Porto Alegre in Brazil and the Davos World Economic Forum (Menou, 2001, p. 112). In the same vein, the "World Bank has, from the early 1990s, published a number of reports on information technology and the Internet, stressing it as a major area

of concern for the world. Other global initiatives naturally include the World Summit on Information Society (WSIS) meetings in Geneva in 2003 and Tunis in 2005" (Luyt, 2006, p. 276). In July 2001 at the Genoa Summit, the G8, comprising the most highly industrialized countries, adopted a plan to clarify the role of information and development strategies and their contribution to the fight against poverty. In its agenda, the "Genoa Plan of Action" embraced intiatives aimed at "creating conditions such that everyone, in the years ahead, should be able to participate in the 'information society' and share its benefits." The agenda, as Luyt notes (2004, 2006), to position the digital divide as a global issue, has been shaped by powerful corporations, governments, and civil society organisations. International agencies such as the World Bank, UNDP, and ITU (International Telecommunications Union) have reiterated the need for central government, local government, nonprofit organizations, and the private sector to bridge the global divide.

According to the ITU report (2005), the digital divide, in the last 10 years, has been shrinking in terms of the number of fixed phone lines, mobile subscribers, and Internet users throughout the world. However, there remain significant disparities from nation to nation in terms of access to such technology. According to ITU estimates, some 8,000,000 villages-representing one billion people worldwide-presently lack connection to any kind of ICTs. Statistics also revealed that in 2004 fewer than 3 out of every 100 Africans used the Internet, compared with an average of 1 out of every 2 inhabitants of the G8 countries (Canada, France, Germany, Italy, Japan, Russia, the UK, and the US). In addition, in 2004 there were approximately the same total number of Internet users in the G8 countries as in the rest of the world combined. This translates into 429m Internet users in G8 countries and 444m users in non-G8 countries.

The digital divide is often measured by the degree of access to ICTs and the Internet. With the rapid proliferation of information and communication technologies, there is growing concern over the disproportionate number of users concentrated in developed countries. In 2001 for example, 169m Americans were online, accounting for 60% of the US population and 29% of the world's Internet population (Chen & Wellman, 2004, p. 40). According to a 2005 ITU report, the present digital divide not only refers to inequalities of access to telephones and the Internet, but also to mobile phones, RFID (radio-frequency identification), and sensors. The report stressed that far from there being a single digital divide, there is instead a terrain of varying levels of access to ICTs that may widen the gulf between developed and developing countries if the latter do not actively invest in these fields. Martin and Robinson (2004, p. 2) point out that researchers and policy makers agree that there are presently profound differences in Internet use across incomes, educational levels, races, and ages both in the US and other nations, and often the disagreement is over how long these differences will persist or what these trends will be.

THE MAIN ISSUES

Beyond the contemporary currency of digital divide, the unequal development between rich and poor nations in technology and science had been termed by Hans Singer as "international technological dualism" more than three decades ago (cf. Gudmunsdottir, 2005). The digital divide captures the relationship between the Internet and social inequality, and as the Internet becomes more important in society, those who remain off-line (Martin & Robinson 2007, p. 1). The term situates two meta-issues: on the one hand it focuses on the issue of access and connectivity, and on the other it ventures beyond access issues into media literacy and associated skills and on to issues of social cohesion, civic engagement, and participation (Sciadas, 2002, p. 4). The problem of global information imbalance is often seen beyond the technology paradigm, and is often equated with cultural hegemony (Kema, 2005).

The digital divide refers mainly to the division between the information rich and the information poor, whether they be individuals or societies. It is also common to deploy the term to divide the globe geographically, as in the "North-South" dichotomy or the "West and the rest" (Gudmunsdottir, 2005, p. 3). At a global level, the digital divide results from the fact there is a huge and growing gap between the more advanced countries and the rest regarding the size and intensity of their ICT applications (Menou, 2001, p. 112). According to Rowena Cullen (2001, p, 311), "the digital divide has been applied to the gap that exists in most countries between those with ready access to the tools of ICTs, and the knowledge that they provide access to, and those without such access or skills. This may then be attributed to socioeconomic factors, geographical factors, educational, attitudinal and generational factors." Van Dijk (1999) lists four barriers of access that can impact on digitial divide, and this can include mental access (i.e., the lack of interest), material access (i.e., the lack of infrastructure), skills access (i.e., lack of literacy), and usage acess, which refers to the ability to embrace opportunities to access technology. Others, such as Warschauer (2004), have categorised these impediments as human resources, social resources, digital resources, and physical resources. Similar to Van Dijk's categories, these refer to the lack of infrastructure, language barriers, media literacies and skills, and additionally they focus on the social resources such as the agencies offered through the context of the community, as well as institutions that can mediate policy and deployment of technology.

From a social constructionist perspective, Luyt argues (2006, p. 279; Sciadas, 2002) that the global digital divide is not a social or policy problem but one technological condition among many in a world with divisions of many kinds. According to Luyt, what makes the lack of access to ICTs a policy problem is the work of claim makers who have generated much publicity about the condition and the

negative consequences for those experiencing it. Carsten Fink and Charles Kenny (2003, pp. 16-17) argue that a widening absolute gap in per-capita ICT access does not necessaily imply that poor countries are falling behind. They call for researchers to look at relative rates of growth due to the fact that "if poor countries experience faster rates of growth in ICT usage and access levels, it is mathematically inevitable that in the short term the absolute gap may continue to widen even though they may surpass the rich world at some point." Comparing growth rates for users in rich and poor countries since the early 1990s till 2000, Fink and Kenny (2003, p. 17) conclude that the gap between the countries in terms of usage has been shrinking in relative terms and hence the most striking feature of the digital divide is not how large it is but how rapidly it is closing. For example, in the mid 1990s over 90% of Internet hosts were found in North America and Western Europe while Asia only had a share of 3% of the global Internet hosts. However, by 2001 Asia had 144 million users compared to 180 million and 155 million users in North American and Western Europe, respectively (cf. Hao & Chao, 2004)

As mentioned, the digital divide can equally refer to both the lack of resources and infrastructure as well as the lack of media proficiency (i.e., literacy) and support infrastructure (i.e., education, policies and communal networks), which can create disparities between nations in the information age. The disparity between the digitally empowered and disempowered is expected to intensify without some degree of intervention at the global level. Language issues can also present a barrier to democratizing the digital revolution. This is mainly due to the fact that only about half of the world's Internet users are native English speakers and about three-quarters of all Web sites are in English (cf. Chen & Wellman 2004, p. 42). Besides linguistic barriers, various other factors including socioeconomic status, gender, life stage, and geographical locations can affect people's use and appropriation of new media technologies (Chen & Wellman, 2004, p. 42, Stayert & Gould, 2004). Bearing these five factors in mind, De Han and Rijken (2002) emphasise that the digital divide is another aspect of social exclusion in societies where barriers to accessing new media are no different from barriers to accessing other needs such as health, education, and employment.

Various factors can influence the diffusion of technology in developing countries and these can include infrastructure, government policies, regulations, economic development, culture, and language (cf. Bazar & Boalch, 1997; Cullen, 2003). The digital divide in countries may then be influenced by and reflect social demographics as well as public policies and social issues. As such, the marginalised or those with less social mobility may require public policy interventions to close the gap. In the US, for example, Afro-Americans, Latinos, and North American Indians have been identified as needing public programmes to widen their inclusion (Cullen, 2001, p. 312; Norris, 2000). Martin and Robinson (2007, p.1-2) point out that income inequality is a distinctive economic barrier to Internet use. According to Paul Dimaggio et al. (cf. Martin & Robinson, 2007, p. 2), persons of higher socioeconomic status employ the Internet more productively and to greater economic gain than their less privileged but still connected peers. Analysts (cf. Chowdhury, 2004; Cullen, 2001) point out that while improved access to ICTs and the Internet are important, one should not assume that they alone can solve all the problems that accompany the digital divide within and between countries. For example, new figures from the European Union's Official Statistics body reveals that in 2004, on average, 85% of European students used the Internet compared with only one in eight retired people (eGov Monitor). Secondly, as Cullen (2001, p. 312, 2003) reiterates, new technology does not always replace the old, and in the process of coexisting, they may enhance the range of human experience even if users opt not to favour newer technologies over older ones.

Jos De Haan (2004, pp. 67-68) postulates that social inequality lies at the heart of the debate on the rise of the information society, but too often these discussions are limited to, and centre on, access without fully analysing the consequences of differences in IT access. He argues that Internet access is seen as binary (i.e., whether one is a user of the Internet or not), and this hinders earlier theoretical progress in understanding the influence of communication processes of social change. Instead, he suggests a multidimensional model that includes motivation, possession, and digital skills. Motivation looks at attitudes, interests, the will to use technology, and the fears surrounding it. Possession accounts for access not just in the home, but in other places a user may find himself or herself . The third component looks at the extent to which potential users are able to handle IT. As such, De Hann stresses the need to analyse cultural and attitudinal factors in shaping consumption and behaviour towards technology.

Kubicek (2004) points out that within the developing world the digital divide is growing, as there are discrepancies between urban and rural populations. In addition to geographical remoteness, lack of relevant content and lack of technological support can constitute barriers for the use of the Internet in disadvantaged communities (Chen & Wellman, 2004). The issue of the digital divide is also bound up with the availability of telecommunications infrastructure along with technical capacities (i.e., telephone lines, broadband, satellite services, etc.) Wiring up rural areas entails major investments of capital, and often governments may opt to liberalise the telecommunications industry to allow private investments in these sectors. Where telecommunications industries are privately owned there may be reluctance on the part of investors to inject capital into areas that do not maximize their revenue stream, and this may include rural areas.

In most Western countries, governments actively engage and devise policies to ensure citizens' access to and consumption of ICTs to enable participation in social, educational, and economic activities (Cullen, 2001, p. 113, 2003). The Clinton administration, in 2000, proposed a new plan in which tax breaks were offered to private companies to help close the digital divide between the haves and the have-nots. Clinton's programme also included other support infrastructure such as teacher training programs and Community Technology Centres. As such, public programs are deemed just as important as investing in technical infrastructure to ensure access to the Internet. Other Western European countries have also harnessed public and private resources to achieve increased Internet literacy and access. Rao et al. (cf. Norris, 2000) also point to private and public initiatives to include rural areas in South Asia through remote access, community centres, and Internet kiosks.

The rhetoric of the digital divide distracts the world community from concentrating on society's more urgent needs such as health care and education (Cullen, 2001, 2003; Menou, 2001). Cullen (2001, p. 312) stresses that bringing the Internet to Africa and associating it with better education and increased awareness "concentrates on the wrong end of the technology spectrum as the Internet in itself is not education, does not develop literacy or skills to access and interpret information found." A better alternative, Cullen (2001) suggests, would be to "use basic technologies to promote traditional forms of education, enhance the delivery of health care and improve animal husbandry and crop management. Conversely, Internet technologies can provide different forms of benefits as in the sharing of expertise in health and farming initiatives as well as in tourism, trade and e-commerce"(p. 114).

On the other hand, information technology is deemed crucial in enabling less developed nations to participate in the global market place, to create networks and connections with the global communities. As Norris (2000) points out, "the effect of the Internet in broadening and enhancing access to information and communication may be greatest in poorer nations as it can allow the developing world to enter global trading markets directly irrespective of the traditional barriers of distance, costs of advertising and the intermediate distribution chains" (p. 2). In this sense, the Internet can highlight the concerns of developing societies in the international arena by connecting disparate social movements with global civic society.

Measures to restrict access to technologies such as the Internet can take a number of forms, and these can include financial, technical, administrative, or legislative issues in different countries (Modoux, 2002, p. 5). China, for example, imposes strict censorship laws on the Internet, and users can face severe sanctions if they transgress these regulations. There were an estimated 137 million Internet users in China in 2007, which is second in number to the United States (cf. Fallows, 2007). China, like Singapore, is a paradox due to the fact that despite increasing Internet access it has harsh censorship laws. As such, increasing Internet penetration may not equate to equal access to information when compared to other states with more liberal policies. Digital divide can then manifest in a myriad of forms, and can be politicised differentially in the national and global context. Additionally, China, like other countries, has an urban-rural divide, with only 17% of the total Internet population accruing from rural areas in 2007 (Fallows, 2007).

The lack of infrastructure is a major obstacle to the diffusion of technology. For example, the lack of telephone lines and electricity in many villages in India and the shortage of telephone lines in main cities of Kazakhstan, Uzbekistan, Tajikistan, and Turkemenistan (cf. Hao & Chan, 2004) exercabate the discrepancies between populations in rural and urban areas.

FUTURE TRENDS

The digital divide underpins a degree of vulnerability for those who do not have access to technology, however, the debates become confounded when users, particularly those in the developed world, refuse to engage with technology even when access is not an issue. According to research firm Point Topic, 44% or 11.2 million households in the UK refuse Internet connections and out of these, over 40% have little or no intention of getting connected to the Internet, and as the number of Internet households increase, those that are left are increasingly resistant to its appeal (BBC). As De Haan (2004, p. 84) observes, at the heart of inequality in the information society lies the question of the differential behavioural consequences of inequalities in IT access.

Beyond the attitudinal issues, it will remain a challenge for the global community and less developed countries to keep the digital divide on the global agenda in the coming years. While there is consensus, the narrowing of the digital divide should be a global issue rather than one left to indigenous governments and to the political interests of powerful stakeholders who will continue to mediate the issues and concerns raised at the global level. With much concern over the dominance of the US in the governance of the Internet, developing countries have voiced concerns over the political economy of the global resource that is the Internet.

Beyond being a cliche of the differentials and inequalities in society, the term can be positively enforced in both policy making and global consciousness to enforce equity and deter exploitation. As observed by Fink and Kenny (2003, p. 20), the digital divide paradigm can be used to "promote good policy as in the regulation of private comptetition in information infrastructure provision to ensure improved ef-

ficiency, lower costs and increased access." Inversely, they warn that it can lead to countries having an ill-conceived or over-ambitious infrastructure target leading to excessive competition, and which thwart the objectives of national policies and imperatives.

The endeavour to close the gap between the digitally empowered and the disempowered will inevitably entail high costs, and often it has to be weighed against other serious and pressing issues such as poverty and disease; it is difficult to argue that the digital divide is a bigger concern or threat to the people in developing worlds.

CONCLUSION

The issue of the digital divide has been raised as a global concern in the last decade to highlight yet another type of social inequality that could have future consequences for the world. The concept is tightly aligned with the emergence of a postindustrial or information society in which information is seen as a key resource that enables new modes of production, commerce, and civic engagements. The assumption that underpins the digital divide is that societies would be disadvantaged socially, politically, and culturally if they did not respond by ensuring that their citizens have access to technology and to information. Interventions to remedy the problems of the digital divide would include investments in infrastructure as well as public programmes to promote media literacy and digital skills. In both developed and developing countries, these have involved private and public partnerships, as well as the liberalization of the telecommunications market to encourage private investments in infrastructure. The reliance on private-sector investments to build infrastructure has, in many instances, sustained inequalities between urban and rural areas. Additionally, in many countries, digital inequality has mirrored the patterns of socioeconomic inequality. The digital divide as a term, then, addresses both the lack of access as well as the long-term social consequences of not utilizing new technologies that create the potential for global connectivity, as well as new forms of social and political engagements. For developing countries, the term has often led to a false belief that it will remedy the existing problems of poverty or disease, mirroring old debates where technology is perceived to be a panacea for complex social problems. However, as more governments reconfigure politics and civic engagements through new technological platforms, the issue of the digital divide will involve not just literacy, but cultural and attitudinal factors that shape interactions with both technology and politics.

KEY TERMS

Digital Divide: The separation between the information rich, or haves, and information poor, or have-nots.

ICTs: Information and communication technologies, which are seen as the driving force of globalization and new forms of connectivity.

Information Society: The transition from the modern and industrial age in which modes of production, exchange, and social capital are increasingly defined through information

Network Society: The rise of the information society will see the emergence of a network society in which information and technology will enable the formation of networks and strategic planning.

Contemporary Instructional Design

Robert S. Owen
Texas A&M University-Texarkana, USA

Bosede Aworuwa
Texas A&M University-Texarkana, USA

INTRODUCTION

This article discusses the principles of two qualitatively different and somewhat competing instructional designs from the 1950s and 1960s, *linear programmed instruction* and *programmed branching*. Our hope is that an understanding of these ideas could have a positive influence on current and future instructional designers who might adapt these techniques to new technologies and want to use these techniques effectively. Although these older ideas do still see occasional mention and study (e.g., Brosvic, Epstein, Cook, & Dihoff, 2005; Dihoff, Brosvic, & Epstein, & Cook, 2004), many contemporary instructional designers are probably unaware of the learning principles associated with these (cf., Fernald & Jordan, 1991; Kritch & Bostow, 1998; McDonald, Yanchar, & Osguthorpe, 2005).

BACKGROUND

An important difference between these instructional designs is associated with the use of feedback to the learner. Although we could provide a student with a score after completing an online multiple-choice quiz, applications that provide more *immediate feedback* about correctness upon completion of each individual question might be better. Alternatively, we could provide *adaptive feedback* in which the application provides elaboration based upon qualities of a particular answer choice.

Following is a discussion of two qualitatively different instructional designs, one providing immediate feedback regarding the correctness of a student's answer, the other providing adaptive feedback based on the qualities of the student's answer. Suitability of one design or the other is a function of the type of learner and of the learning outcomes that are desired.

SOME CLASSIC CONCEPTS OF INSTRUCTIONAL DESIGN AND OUTCOMES

Although the idea of non-human feedback would seem to imply a mechanical or electronic device, other methods could be used. Epstein and his colleagues, for example, have used a multiple-choice form with an opaque, waxy coating that covers the answer spaces in a series of studies (e.g., Epstein, Brosvic, Costner, Dihoff, & Lazarus, 2003); when the learner scratches the opaque coating to select an answer choice, the presence of a star (or not) immediately reveals the correctness of an answer. Examples of the designs discussed next are based on paper books, but they are easily adaptable to technologies that use hyperlinks, drop-down menus, form buttons, and such.

Linear Programmed Instruction

The programmed psychology textbook of Holland and Skinner (1961) asked the student a question on one page (the following quote starts on page 2) and then asked the student to turn the page to find the answer and a new question:

> A doctor taps your knee (patellar tendon)
> with a rubber hammer to test your _____.

The student thinks (or writes) the answer and turns the page to find the correct answer ("reflexes") and is then asked another question.

Questions or statements are arranged in sequentially ordered *frames* such as the previous single frame. A frame is completed when the student provides a response to a stimulus and receives feedback. Skinner contended that this method caused learning through *operant conditioning*, provided through positive *reinforcement* for stimuli that are designed to elicit a correct answer (c.f., Cook, 1961; Skinner, 1954, 1958).

Skinner (and others who use his methods) referred to his method as *programmed instruction*, which incorporates at least the following principles (cf., Fernald & Jordan, 1991; Hedlund, 1967; Holland & Skinner, 1961; Skinner, 1958; Whitlock, 1967):

- Clear learning objectives.
- Small steps; frames of information repeat the cycle of stimulus-response-reinforcement.
- Logical ordered sequence of frames.

- Active responding by a student who works at his/her own pace.
- Immediate feedback to the response in each frame with positive reinforcement for correct answers.

A technique in programmed instruction is to help the student a great deal at first, and then gradually reduce the cues in latter frames; this is called *fading* (Fernald & Jordan, 1991; Reiff, 1980). If correct responding suggests that a student is learning at a quick rate, *gating* can be used to skip over frames that repeat prior information (Vargus & Vargus, 1991). The programmer is expected to use information about student performance to make revisions; if the student is not succeeding, then it is due to a fault of the program, not to an inability of the student (Holland & Skinner, 1961; Vargus & Vargus, 1991).

Programmed Branching

Crowder (e.g., 1959, 1963) and others (e.g., Pressey, 1963) were critical of Skinner's approach, arguing that students not only learn from knowing a correct answer, but also learn by making mistakes. Crowder distinguished between his *automatic tutoring device* and the Skinner-type *teaching machine*, proposing that the automatic tutoring device is more flexible in allowing the student to receive an explanation when an error is made. Crowder (1959, pp. 110-111) provides an example of how this approach could be used in a programmed textbook:

> In the multiplication of $3 \times 4 = 12$, the number 12 is called the product and the numbers 3 and 4 are called the
>
> Page 15 quotients.
> Page 29 factors.
> Page 43 powers.

In this *programmed branching* method of Crowder, the student is taken to one of several possible discussions depending on the qualities of the answer.

While Skinner's design would be expected to work only when stimuli elicit correct answers, Crowder's design allows for mistakes and must be designed to anticipate particular mistakes. Crowder believed that this method caused learning through *cognitive reasoning*. Whatever answer is chosen by the student, the programmed textbook (or machine) makes a *branch* to a discussion associated with issues relevant to the answer that was chosen. This is followed by a return to the same question if the student had made an incorrect choice, or a jump to new a *frame* containing the next question if the student had made a correct choice.

Learning Outcomes

Many issues have been raised over the years about programmed instruction methods. Reiff (1980) discussed several criticisms:

- It does not take into consideration the sequence of development and readiness to learn (e.g., children of different ages or children vs. adults).
- It develops rote learning skills rather than critical thinking skills.
- Students can in some implementations cheat.
- The encouragement to respond quickly could develop bad reading habits.

Crowder's *programmed branching* design, which has received far less attention and study than Skinner's ideas, would seem to answer at least some of these criticisms. Crowder's design provides an explanation to both correct and incorrect answers, so the learner is not rewarded for cheating or working too quickly. Since the explanation is tied to the learner's thinking at the time a choice was made, Crowder's design would appear to be better to develop critical thinking skills, but might not be so good at developing rote learning skills. Crowder's design would appear to be better suited to students who have a greater readiness to learn, while perhaps not so well suited to a student who is at an earlier stage of learning a subject.

The previous discussion suggests that each of these designs is useful, but that each is useful in different kinds of situations and that the *learning outcomes* of each approach might be different. Skinner's teaching machine, for example, might be more useful in situations where students are learning lists and definitions. The automatic tutoring device, on the other hand, might be more useful when the student is already at a higher level of understanding whereby s/he can now use reasoning to derive an answer, or in situations where the student understands that there are degrees of right and wrong without concrete answers. The Skinner-type teaching machine might be better suited to "lower-order" levels of learning, while the Crowder-type automatic tutoring device might be better suited to "higher-order" levels of learning.

Although many ideas have been proposed with regard to a hierarchical perspective on "lower" and "higher" levels of learning, the most well-known, "Bloom's Taxonomy" (A Committee of College and University Examiners, 1956), originated in about the same timeframe as the ideas of Skinner and Crowder. "Bloom's Taxonomy" proposes that the objectives of learning lie on a hierarchical continuum: (1) knowledge of terminology and facts, (2) comprehension of translation and paraphrasing, (3) application, (4) analysis, (5) synthesis, and (6) evaluation.

"Bloom's Taxonomy" is actually only Part I of a two-part work. The previously mentioned first part is known as the *cognitive domain*. Part II (Krathwohl, Bloom, & Masia, 1964) focuses on the *affective domain*: (1) willingness to receive ideas, (2) commitment to a subject or idea, (3) feeling that an idea has worth, (4) seeing interrelationships among multiple ideas, and (5) the integration of ideas as one's own.

FUTURE TRENDS

Fernald and Jordan (1991) discussed several reasons as to why programmed instruction might have fallen out of use since the decades of the 1950s and 1960s:

- It was seen to dehumanize the teaching process.
- Educators feared that it might be too effective and threaten their jobs.
- The importance of the learning principles was not understood.
- Applications were often not effectively designed.

Technology, economics, and attitudes have since changed. As economics and student demand push us to use distance education methods, the first two arguments would seem to become more diminished in the future.

It is hoped that this article assists in diminishing the latter two arguments by introducing instructional designers to the principles discussed in this article and by encouraging instructional designers to create more effective designs with regard to appropriateness for a particular student audience and with regard to the type and level of learning outcomes that are desired. By better understanding the past, we can better affect the future.

Curiously, there has been less attention devoted to Crowder's ideas of adaptive feedback than to Skinner's ideas of immediate feedback and reinforcement. We continue see occasional research devoted to related issues, such as issues of immediate vs. delayed feedback (e.g., Brosvic et al., 2005; Dihoff et al., 2004; Kelly & Crosbie, 1997) or of allowing students to keep selecting answers from a multiple-choice set until the correct answer is finally discovered (Epstein et al., 2003). However, we still can only speculate with regard to conditions under which a Skinner-style of instructional design would be better and when a Crowder-style of design would be better. It is hoped that this article generates greater awareness of and use of these designs in new technologies, but also that greater interest in these ideas will stimulate more research into the learning mechanisms associated with them.

CONCLUSIONS

New technologies such as Web browsers now make it relatively easy for educators with the most modest of skills to present instructional frames in a linear sequential ordering or as branches that are dependent on the student's selection of answers from a list. In adapting some of these older ideas to newer technologies, we hope that instructional designers will be better equipped to select appropriate methods by considering:

- the student's level of readiness for learning
- the basis for learning when different instructional designs are used
- the qualitatively different kinds of learning outcomes that are possible with different instructional designs

KEY TERMS

Adaptive Feedback: Immediate feedback in the form of an explanation or discussion that is tailored to the qualities of the student's answer.

Automatic Tutoring Device: A device that uses programmed branching and adaptive feedback. Learning results from cognitive reasoning.

Cognitive Reasoning: Learning through the process of thinking about an issue; the student learns new ideas and relationships by relating an issue to previously learned material.

Frame: A small piece of information or a statement to which the student is exposed, such as a page with a single question. In linear programmed instruction, a frame includes a stimulus, a response, and reinforcement (positive feedback).

Hierarchy of Learning: The concept that learning can be sequentially ordered along a continuum from lower-order to higher-order. "Bloom's Taxonomy" is one of many that have been proposed.

Linear Programmed Instruction: A design whereby a series of frames are presented to the student in a specific sequential order. The student actively responds to stimuli in each frame and receives immediate feedback to that response. Learning results through operant conditioning.

Operant Conditioning: Learning through immediate positive feedback (reinforcement) regarding the correctness of an answer; the student learns to respond in a particular way to a particular question or issue (stimulus). Fading can be used by gradually reducing stimulus cues in subsequent frames when material is repeated.

Programmed Branching: A method whereby the student is taken to one of several possible explanations or discussions depending on the qualities of an answer that is given to a question. Gating is a simple skip of frames that repeat prior information when a student's answers suggest that the material has been adequately learned.

Teaching Machine: A device that uses linear programmed instruction whereby frames present a question followed by feedback of the correct answer. Learning results from reinforcement of the student's correct answer.

Contemporary Issues in Teaching and Learning with Technology

Jerry P. Galloway
Texas Wesleyan University, USA
University of Texas at Arlington, USA

INTRODUCTION

To speak of contemporary issues in instructional technology is like counting wave crests in a stormy ocean: they are changing quickly all the time. New technologies and new issues present themselves daily. Educators struggle with both the instructional integration of computing and developing the skills and knowledge necessary to use technology effectively (Lipscomb & Doppen, 2005). Why, after over 30 years of having computers in schools, are educators still having such difficulties?

Today's population is much more accustom to electronics, yet knowledge is weak, concepts are misunderstood, and the difficulties of teaching with technology seem as serious and convoluted today as ever before. The great physicist and thinker, Richard Feynman, offered some critical comments about the challenges of educators. "What happens is that you get all kinds of statements of fact about education, about sociology, even psychology — all kinds of things which are, I'd say, pseudoscience" (Feynman, 1999, p. 242). Today, we understand "more about education [but] the test scores are going down…we just don't understand it at all. It just isn't working" (p. 243). Being critical of how the scientific method is applied to education, Feynman's comments highlight how the study of teaching and learning yields limited or questionable results. Teacher trainers take their best guess on how to prepare teachers to use technology.

BACKGROUND

Educational computing is a relatively new discipline compared to mathematics and science. While the earliest uses of computers might have been by departments of mathematics, it quickly became important for virtually all teachers to become computer literate. But what exactly that entails was not exactly clear (Galloway, 1985) for learning and in society (Beaty & Tucker, 1987).

Microcomputer technology, primitive by today's standards, lacked user-friendly applications, any sort of consistent user interface, or easy-to-use telecommunications and interconnectivity. There was an early division between those who learned to program computers vs. those who focused more exclusively on applications software. Conceptual development, improvement of problem solving, and higher-order thinking skills in computing have been directly linked to the inclusion of Logo programming (Allen, 1993; Battista, 1994; Borer, 1993; Dalton & Goodrum, 1991) and BASIC programming (Overbaugh, 1993). Yet, in spite of an overwhelming need to operate early microcomputers through programming, educators focused instead on the actions and procedural tasks of specific applications (Galloway & Bright, 1987).

With this as a foundation, decades of training have followed in which educators have tried to master new devices and software. So, how long does it take to reach a point of nationwide competency, to develop the protocols of effective use, to establish the knowledge of how best to learn computing? Compared to centuries of science and mathematics, perhaps our 30-plus years do not seem so long.

EDUCATORS LEARN COMPUTING: A PROBLEM OF PERSPECTIVE

Our collective perspective on what it means to learn computing affect what goals we pursue and how we proceed. For example, the use of rubrics or portfolios were not commonly emphasized in education 30 years ago. Today, they are an accepted or at least popular tool for preparing educators (Galloway, 2006; Rural School and Community Trust, 2001). Does this represent progress or perhaps just a symptom of changing fads? Is this a function of real knowledge or mere opinions? This is again reminiscent of a Feynman (1999) criticism, as he suggests that professionals 30 years ago have as much right to a correct opinion as we have today, "to equally unscientifically come to a conclusion" (p. 243)—even if wrong.

Preparing Teachers

It is unlikely that educators younger than their mid-40s graduated high school without having computers in their education. There has been, since the late 1970s, a continual focus on the needs of teachers to learn and adapt to a technology-based profession.

Our attempt over the years to change educators into computer-literate professionals essentially failed. Many

will argue the point, as clearly there are countless success stories. But, with the exception of the techies and innovative pioneers, educators across the profession a generation ago did not, have not changed their basic approach to integrate technology.

Compared to in-service classes, college courses, training, or other options, an overwhelming majority of teachers maintain that their primary methods of learning computing was through self-study and personal experimentation (Galloway, 1997). It can be argued that teachers must assume a responsibility for advancing their technological knowledge and be engaged learners.

When taking a computer class, one must go beyond the prescribed activities. For example, it is not likely that one would be assigned the experience of losing a file or opening a file with the wrong program. These frustrations can be a very necessary part of learning. Far too often educators are passive and restrict their involvement to occasional and discrete enrichment offered through someone else's initiative. Delays and intermittent and partial commitments inhibit learning.

As an analogy, when this author was young, rock-n-roll music was still the choice of the young, but grandfather did not relate and found it quite distasteful. In elevators in 1968, one would hear music from Lawrence Welk and such. This author believed that if elders could simply understand and learn about rock-n-roll and what the artists were attempting to express musically that society could change and the music would be accepted. Today, one is likely to hear McCartney, Dillon, The Beatles, Buddy Holly, or many of the other artists that were objectionable in those earlier years. One might think that, indeed, things changed.

However, the point is that this did not occur because the elders were influenced or convinced. The younger, rock-n-roll generation did not change anyone. The elders were not convinced. No metamorphosis occurred. The young simply grew older and brought their music with them. As the elders died off, the young with a new culture replaced the old.

The same seems true for the computer-using generation. Our efforts a generation ago were ineffective. We have simply waited around while a new generation grows older bringing their technology-based lifestyle with them. Until our children have time to take their place, today's teachers are still introduced to computing as beginners.

Training vs. Education

What do current educators expect from computer training? If we accept that it is difficult to teach someone who does not want to learn, what do students expect from their training? Unfortunately, the most popular notion in instructional technology is that teachers are to be trained, not educated. More than mere semantics, teaching tends to emphasize *showing teachers how to use* technology — rather than facilitating insight, understanding, and conceptual development. In-service programs and college curricula emphasize only what teachers are expected to use rather than what might develop good concepts. Omitting programming is a classic example where teachers as end users of software never see the construction process or design methods behind what they are supposed to learn. Today's design tools (for Web pages and such) are a modern example of where these issues still apply.

Teaching for conceptual understanding and higher-order thinking skills should not be only a part of teaching programming (Tu & Falgout, 1995), but also a fundamental goal of instruction for beginners in computing. Skills and even performance standards can still fail to generate important understandings, perspectives, concepts — integrated knowledge — that all contribute a fundamental and critical basis for problem solving and adaptability.

Focusing on conceptual development will still involve procedures and tasks just as focusing on discrete skills will likely yield some insights and discoveries. But instruction should yield a more complete, fundamental understanding of computing. Most programs and perspectives fail to recognize this important viewpoint and instead pursue skills and competencies to the detriment of understanding, insight, and problem solving.

It is common in other disciplines to speak of *education* rather than *training.* Conceptual development is often the primary focus in the study of science (Trumper, 1997). Even when the preparation of teachers is described in terms of training, science concepts are emphasized, not skills (Thompson & Schumacher, 1995). In spite of the procedures and skills inherent in science and mathematics, students are guided toward the development of a conceptual understanding as they are educated — not trained.

A training model targets activities and the software teachers will use. Much like an airline reservations clerk must learn the keystrokes and procedures for prescribed tasks, educational computing is similarly conceived. An education model, on the other hand, calls for activities and experiences that will yield a deeper kind of learning. Keystrokes and software familiarity would be incidental to the more important yield of experiences, much like those in science and mathematics, that develop understanding, concepts, problem solving, and critical thinking skills. An education-based program would provide experiences because of their educational value regardless of whether they are part of an anticipated skill set. Skill sets, tasks, and the procedural rituals of training will inevitably change and evolve far beyond the scope of any training experience.

Student teachers can be part of the problem as they, very often, prefer the training model. Contrary to any real value or longevity of such an approach, a more involved education presents an undesirable challenge. They prefer to simply be shown what to do. Guided tasks, prescribed procedures,

and discrete tasks are all a matter of doing, not becoming. However, an education calls for change.

Acquiring mindless task sequences is often viewed by educators as success. Improved teaching is then viewed as having more complete checklists for more tasks. This *recipe mentality* of discrete procedural rituals ignores the need for discovery learning, transfer, and adaptability, and could be responsible for continuing the inhibited progress of the past 30 years.

Integration

Limiting factors for the integration of technology include funding, professional development, support for experimentation, and inadequate technology planning (Mehlinger & Powers, 2002). As Galloway (1997) examined technology adoption, it was learned that effective usage is related to the combination of both professional and personal adoption of technology. Virtually no one used technology in their classrooms where personal adoption was not combined with professional use.

It has been said that teachers exist only for the children. They express the sentiment that student needs are the primary, if not the only mission of teachers. It is easy, however, to draw the wrong conclusions from such a self-evident premise. For instructional technology, consistent with this perspective, trends have been directed away from empowering teachers, focusing instead on classroom integration. This may seem justified, but a serious problem remains: it is not reasonable to teach non-computer users to use technology in the classroom. Educating teachers to become computer-using, technology-competent professionals would more likely yield classroom integration as a matter of natural consequence.

While there are training programs targeting classroom integration, what success can be had if teachers are not computer literate or have never adopted computing in their lives? In other words, one must adopt technology as a life-changing metamorphosis. The approach of the past, training over education and rituals over holistic adoption, may likely continue the inhibited progress in integration and technological mastery.

Learning and Working

Everyone agrees that students must be prepared for a technological future, but perceptions vary widely on exactly how to achieve that. This is a challenge of pedagogy.

Computers have been perceived as tools (Beaty & Tucker, 1987) and have been used in that fashion. An alternative view might suggest that the computer is not a tool at all. As a tool might be selected or discarded based on a particular need, technology is too often viewed as independent from everyday life powered-up if the need is sufficiently demanding. Instead, computers are perhaps best viewed as a complete *environment.* It is where we live, work, and play. It is the medium of our planning, our creativity, and an extension of both our short-term and long-term memory. This thinking places different expectations on educators than has traditionally been made. The notion that one can remain a non-computer-using person while merely executing discrete tasks as needed must change.

FUTURE TRENDS

How has learning changed and what is *learning* in the modern tech-based world? Learning is far too often viewed by teachers as a matter of acquiring information. Teachers deliver information to the students who in turn sit on it for a period of time only to hand it back to teachers again in some form of quiz or standardized test. If students regurgitate and return the information accurately, they are said to have *learned.* In fact, students assume this is what is expected of them and resist anything more personally demanding. The notion that they must change, must invent, or synthesize is foreign to them.

Learning is no longer about the acquisition of information. We have information. It is possible to find the average price of a hang guilder, the architect of the Brooklyn Bridge, design plans for a new home, or a translation of the Dead Sea Scrolls in mere minutes — all while sitting in a hotel lobby or even lying in bed in a dormitory room. Acquisition of information is neither the problem nor the goal. Learning to think is the real challenge. Education has become about skill development with demonstrable competencies rather than about becoming smarter or learning to think. Education, as distinct from training, should improve problem-solving abilities, critical thinking abilities, developing an understanding, learning to discriminate and make good choices, and developing a contextual intuition.

Computing students do not want to have to explore and discover, wanting instead to be shown how to execute procedures. Alluded to earlier, this amounts to distributing recipes for subsequent replication. Being ready for tomorrow's computing world depends on understanding, problem-solving skills, and the ability to adapt to the unknown, not on knowing procedures in some software program.

Technology continues to develop faster than anyone can sufficiently learn it. Merely being able to operate the functions and tools in a program is usually considered a success. But achieving a deeper knowledge of how best to adopt, integrate, and teach in a world of technology is quite a different thing.

The Distant Future

Does today's science fantasy help to create the reality of tomorrow? That is of course debatable, but at least imagi-

nation does its part on one side of the evolution equation. Clearly, our children will experience amazing and incredible advancements that today seem like science fiction.

So, extend your vision to consider the following: a kind of futuristic electronic *bubble* as a kind of spherical energy shell that would surround one's head and face. The shell might not be spherical and could instead extend vertically downward in front of the face and chest somewhat like a large energy shield in front of the body. Generally, it may be maintained and kept active throughout the waking hours.

The shell or *e-bubble* would be generated by a multi-functional microchip and would act like a virtual outer skin or electronic membrane extending perhaps 10 to 12 inches in front of the body. Perhaps the orientation of the membrane (up/down, sections, areas, etc.) could be determined by detecting and interfacing with an electrical field from the heart or brain, much like an electrocardiogram or electroencephalogram. This would be important to establish a directional configuration since a microchip might be located more on convenience or medical necessity. The e-bubble should maintain a functional orientation to the body. The membrane can function in sections, quadrants, or areas, as well as operating as a whole or singular entity.

The e-bubble would serve as a communications interface for all sorts of input and output in work, learning, and recreation. The microchip and power supply might be worn as external hardware, like in a necklace, belt buckle, or collar. Perhaps the electronic membrane might exist in the form of a mere hologram projection from specialized glasses. Today's military pilots see electronic projections of critical data superimposed on their natural view of their environment during flight. Some hardware today can feed visual information into one eye, leaving the other eye normal as the brain integrates the two views. The integration of visual and auditory hardware with the body has already begun its prosthetic progression from the separate and independent technologies of yesterday's cathode-ray tube (CRT) and today's plasma flat screens.

Eventually, the development of the e-bubble would evolve beyond the independent device carried in hand. Even with the convenience of a wristwatch or techno-necklace, such devices are external and thus their service to our lives is an add-on not truly integrated and natural. The e-bubble will evolve beyond a separate prosthetic to such a size and state that it becomes an implant no more intrusive than an inner ear replacement.

Images displayed in the membrane fields would include all of the variations we know of today: pictures, graphics, text, color, and of course, full-motion video. One can imagine that these fields appear from the back side, viewed by others, as opaque with no detail or instead translucent with imagery appearing in reverse.

One can imagine interactive fields for drawing, writing, or other tactile manipulations. Perhaps an image might be relocated in the field matrix to open or power another area for a secondary purpose. The various fields might provide a multi-tasking experience of work and play, business and entertainment, or integrated learning and study experiences.

It is really an extension of what has already occurred. Star Trek and many other sources of imagination today illustrate not just an exciting possibility but an inevitable reality.

CONCLUSION

Are we to continue passively as followers of our children or step up as leaders, which the nobility of our profession demands? The overwhelming theme of the past 30 years is that training for discrete tasks must be replaced by holistic adoption and education. Being successful at computing is not a function of memorized procedures or specific skill sets. Procedural rituals, however conveniently arranged or exhaustively accounted, cannot substitute for intuition, problem solving, and a deeper understanding of computing.

The future depends on adaptability and learning transfer, which again attest to the inadequacy of mere training. It will be an exciting future, but challenging to us all. To quote Peter Drucker, 20th-century business pioneer, "The best way to predict the future is to create it."

KEY TERMS

Computer Literacy: The ability to effectively use computer technology to solve problems and efficiently meet personal and professional needs.

Education: Contrary to mere training, the process engaging in supportive and generative experiences for acquiring the broader understanding and mastery.

Educational Computing: Full range of uses of computers pursuant to conducting the profession.

Instructional Technology: The broader field of studying the use or related issues of all technologies in education.

Integration: The effective, instructional use of technology in the classroom.

Learning: Contrary to the acquisition of mere facts, and more than acquiring discrete skills and competencies, learning is the development of knowledge, conceptual understanding, and critical thinking abilities in a prescribed context.

Science Fiction: Imagining future developments in technology and the human-machine interface, including living and working in virtual worlds.

Training: Limited and highly specific instruction for learning discrete tasks and procedural rituals.

Contemporary IT-Assisted Retail Management

C

Herbert Kotzab
Copenhagen Business School, Denmark

INTRODUCTION

Retailing can be defined in two ways, either as a set of functions that adds value to products/services that are sold to end users (functional understanding of retailing) or as a specific institution within a marketing channel that executes retail functions (institutional understanding). The functional view explains retailing as an exchange activity in order to connect a point of production with a point of consumption. These exchange processes refer to (see Kotzab & Bjerre, 2005):

- Marketing processes, including all activities that provide a customized set of products/services as demanded by customers/consumers (which is basically known as offering a customer-oriented assortment in terms of quality and quantity)
- **Logistics** processes, including all activities that help to transfer this specific set of products/services to the markets (such as transportation, breaking bulk and inventory management)
- Assisting processes, which refer to all activities that facilitate a purchase (such as credit function, promotion or advice function).

The orchestration of these functions leads to various types of retail formats such as store-based retailers (e.g., hypermarkets or category killers), non-store-based retailers (e.g., mail-order retailing or electronic commerce) and hybrid retailers (e.g., home delivery services) (Coughlan et al., 2006).

Retailing plays a vital role in today's economy, but many retailing companies face economic pressure as they operate predominantly in mature and stagnant markets (e.g. Seth & Randall, 2001). In order to face these specific challenges, retailing companies adapt strategies that allow them to gain economies of scale by offering highly customized solutions to their customers (see Table 1).

These strategies are built upon the latest developments in information technology (IT) and are therefore called IT-assisted retail management strategies. The following chapter presents an overview to contemporary IT-based retail business models and frameworks that show how IT has created a new mandate for retail management. IT is defined here as the hardware and software that collects, transmits, processes and circulates pictorial, vocal, textual and numerical data/information (e.g., Hansen & Neumann, 2005; Chaffey, 2004).

The following IT is of special interest in relation to IT-assisted retail management:

- Mobile data capturing terminals, light pens, bar code readers, EAN.UCC 128, labels, disks, chip cards, RFID, EPC, sensors to collect information
- Data base systems, tapes, CDs, DVDs, optical disks, Document Retrieval Systems to store information
- PCs, Information Retrieval, Decision support systems, Expert systems: MIS, EIS, MSS, ESS to process information
- Services (e.g., fax, email, EDI, web-EDI, FTP, WAIS, WWW, SMTP, TCP/IP, XML, VAN, GPS), networks (videoconferencing, teleconferencing, voicemail, ISDN, LAN, WAN, fiber optic, intra-, inter- and extranet) and devices (e.g., phones, TV, radio, fax machine, PC, PDA) to transmit information

The increasing use of these technological possibilities has led to major changes in the strategic management of distribu-

Table 1. Cornerstones of contemporary IT-based retail management (see Kotzab & Bjerre, 2005)

IT-based retail marketing strategies	IT-based retail logistics systems
• Re-engineered IT-driven retail formats, allowing for a customized shopping experience • Development of new retail channels, (e.g., Internet-based retail formats to address new customer segments) • Category management, in order to offer client-oriented sets of products, resulting from a joint-planning process with manufacturers based on real-time accessed client data	• The implementation of just-in-time-oriented replenishment systems by connecting the electronic point-of-sale- (EPOS) systems with the manufacturers' ERP-systems • The execution of IT-driven distribution center operations with no-inventory-holding transit terminal structures • The realization of Vendor-Managed-Inventory-Programs on a continuous replenishment basis to reduce inventory levels and to improve order cycles

tion channels as the layers are compressed and the distances between the first and last echelon of the channel are reduced (e.g., Porter, 2001 or Coughlan et al., 2006). Leading retailers are aware of these possibilities and have implemented customized POS-data based marketing strategies (IT-based retail marketing) and demand-synchronized replenishment systems (IT-based retail logistics).

BACKGROUND

IT-Based Retail Marketing Processes

Business practice shows a huge variety of IT-based retailing marketing strategies including the use of smart cards, theft prevention, self-check-out systems, web-kiosks and/or merchandise planning systems. The common goal of all these strategies is to obtain better information on consumer behavior in order to improve customer service. In that sense IT-based retail marketing affects all retail areas from the sales floor to the back offices (Kotzab et al., 2003a; Kotzab & Bjerre, 2005).

IT influences the layout and the atmosphere of a retail store by optimizing the link between sales productivity and consumer excitement (Nymphenburg, 2001) as the following examples show:

- Metro operates the future store concept that promotes technologically-driven innovations in IT-assisted retail marketing as offered by the combined use of RFID, electronic shelf labels, self check out systems, personal shopping agents, instore media such as info terminals, loyalty cards, personal shopping assistant for shoppers, personal digital assistant for employees and intelligent scales (e.g., Metro, 2003, Kotzab & Bjerre, 2005).
- Rewe Austria operates an outlet in Purkersdorf (nearby Vienna), where shoppers self register their purchases via self scanning devices (see Kotzab et al., 2003a). Rewe also uses the "communicating" shopping cart WATSON, which uses a technology based on radio frequency. Whenever passing a "labeled" shelf, the cart announces a message to the shopper (Atlas New Media, 2001).
- Since 2004, Spar-Austria has run a modern supermarket in Mattighofen (near the city of Salzburg) with self-check-out, cash-back terminals, instore-videos and intelligent scales (Spar, 2004).
- Zielpunkt/Plus of the German Tengelmann-Group installed self-check-out systems and cash-back terminals in one Viennese store (Weber, 2004).
- Carter & Lomas (2003) present the Sainsbury store in Hazelgrove (UK) and the Darty store in France, that both represent the state-of-the art of technology driven store layout.
- Weber (2006) reports on the experiences of Belgium Delhaize group which has used Wincor-Nixdorf handheld self-scanning devices since 1997 in their stores which allow customers to scan their items while they are shopping. According to Delhaize, 26 % of all sales are registered with those systems. Mobile self-scanning has allowed Delhaize to install quick shopping lanes within the stores in order to increase throughput times of customers.
- The French retailer Auchan is testing in France so-called scan & bag technology, which is an automated cash-desk system. Auchan operates 166 self-service cash-desks in different stores in Italy (Weber, 2006).

IT has also changed the organizational set up from hierarchical to hybrid/borderless arrangements such as category management (CM) (Gruen, 2002). CM is a joint retailer and manufacturer effort that involves managing product categories as business units and customizing them on a store-by-store basis to satisfy end-user needs (Dussart, 1998). The purpose is to identify those combinations of products that make up consumers' expectations. CM replaces traditional product focused strategies (e.g. brand management) and allows retailers and suppliers to faster react to shifts in the market place (Schröder, 2003). The increasing use of data warehousing and data mining approaches helps to use the scanner data more efficiently in order to establish customer-oriented assortments (Chen et al., 2000). Recently, Kahler & Lingenfelder (2006) were able to identify a strong relationship between the category value for money and store loyalty as CM incorporates the consumers' views and perceptions.

Finally RFID-technology is not only going to retail marketing but also logistics dramatically (Finkenzeller, 2003). Metro's future store concept shows that self scanning processes can be replaced by RFID which reduces waiting times for customers. Du Mont & Hoda (2006) present the case of the Japanese Mitsukoshi who uses RFID technology for an intelligent fitting room in order to enhance customer service. Especially industrial initiatives such as the EPC-Global, a joint venture between EAN International and the UCC, have developed so-called electronic product codes (EPCs), which will increase the diffusion of RFID-technology in the retail industry (see Jordan & Adcock, 2006). EPC is an RFID-based advanced UPC-bar code with the benefit of being able to identify articles at the item level uniquely (Verisign, 2004). The power of such a code can be illustrated by the following quote: "Using this EPC, members of the supply chain can thus identify and locate information about the manufacturer, product class, and instance of a particular product. Depending on the type of tag, EPC can be used to uniquely identify up to 268 million unique manufacturers, each with 16 million types of products. Each unique product can include up to 68 billion individual items, meaning the format can be used to identify hundreds of trillions of unique items" (Verisign, 2004, p.2).

IT-Based Retail Logistics Processes

Logistics in a retailing context refers to multi-echelon logistics systems with many nodes from the original supplier to the final store destination (Kotzab & Bjerre, 2005). The use of specific IT in retail logistics, such as EDI (e.g., EANCOM), barcodes (e.g., EAN/UCC), scanner technology, RFID-technology (e.g., EPC) and XML has converted traditional retail logistics systems into just-in-time-oriented lean retail supply chain management systems. A chain-wide use of technology allows harmonization and synchronization of logistics operations between retailers and their suppliers and has given retailers additional profitability as such systems operate on a pull instead of a push base. Consequently, the total bullwhip effect in such channels is reduced (Lee & Whang, 2002).

The major IT-assisted retail logistics processes are cross docking and continuous replenishment (Kotzab & Bjerre, 2005) on a retail level and collaborative planning forecasting and replenishment (CPFR) on a retail-supplier level (Skjoett-Larsen et al., 2003).

Cross docking is the meta-term for all IT-related flow-through activities within a distribution center that provide tailor-made deliveries on a just-in-time basis. Different vendors deliver full truckloads of their goods to a retailer's transit terminal (a re-engineered distribution center; also called a transshipment point). There, the goods are then consolidated and/or broken to vendor-integrated POS-required smaller delivery units (see Figure 1).

The basic idea of Cross docking is to avoid inventory at the distribution center level, which leads to a replacement of stock holding activities through sorting, transportation and handling activities, which are controlled by increased use of IT (e.g., EAN/UCC 128 in combination with EANCOM messages). The relevant literature offers various types of cross docking operations depending on whether vendors deliver pre-labeled units to the distribution center, full pallets or cases or customized mixed or non-mixed pallets (e.g. Napolitano, 2000).

While cross docking refers to IT-assisted logistics at a distribution center level, vendor managed inventory (VMI) or continuous replenishment (CRP) refer to all cooperative forms of inter-firm automated replenishment programs where the common goal is the automatic reinforcement of the supply of goods and the transfer of the burden of responsibility of storage from a retailer to a vendor.

Within any VMI/CRP setting, retailers re-transfer the inventory competence back to their vendors by agreeing on certain average inventory levels at distribution center level, service levels and/or other arrangements like the reduction or avoidance of out-of-stock-situations (Raman et al., 2001). Within VMI/CRP the former one-to-one relationship (where a seller and a buyer individually represented the goals of their companies') is replaced by inter-departmental, inter-organizational teams, which are responsible for the ordering process (Kotzab & Bjerre, 2005).

A further development in IT-based retail logistics can be seen in the use of CPFR that is defined by the Voluntary

Figure 1. Basic cross docking operation (Kotzab & Bjerre, 2005)

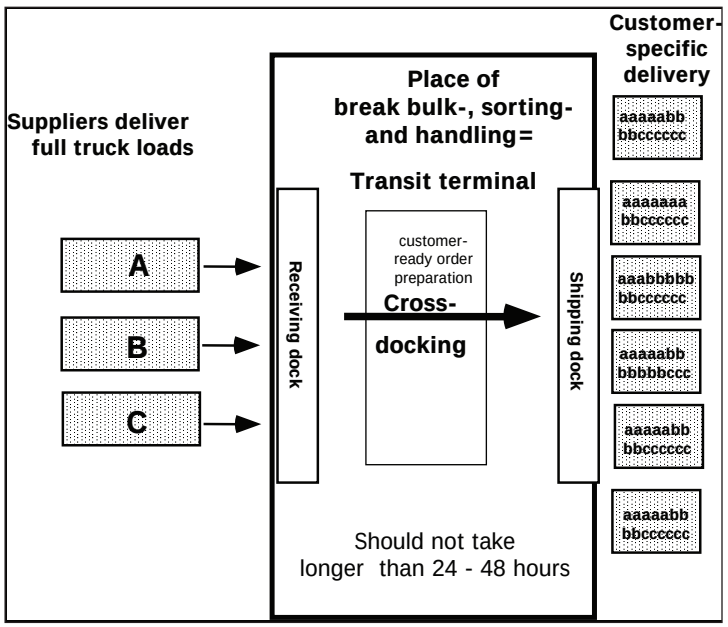

Figure 2. Basic continuous replenishment process in an ECR-environment (Glavanovits & Kotzab, 2002)

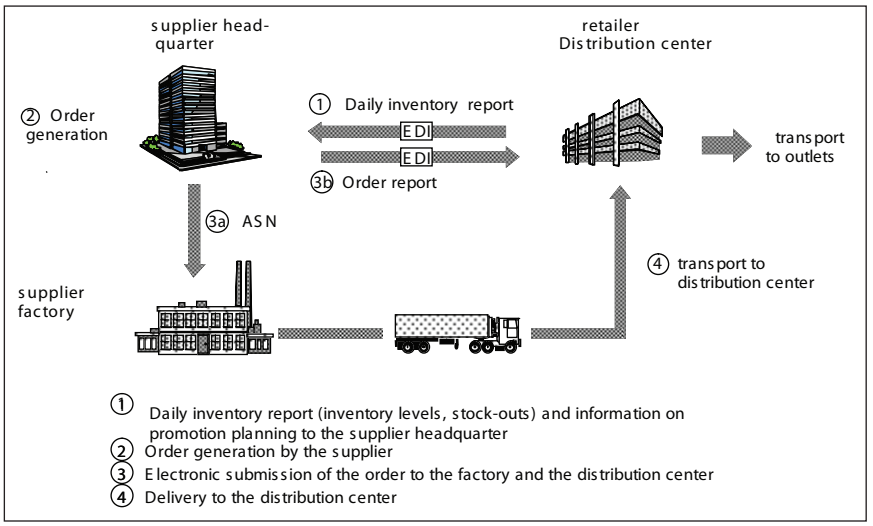

Table 2. CPFR-implementation guideline (see Kotzab et al., 2003b)

Step	Activity	Description
1	Develop front-end agreement	A front-end agreement is developed; criteria for success are established; identification of the CPFR project owners in the companies; financial reward and contribution system is agreed upon.
2	Create joint business plan	A joint Business Plan for the areas of collaboration is created Plans regarding advertising campaigns etc.
3-5	Sales forecast collaboration	The parties get together with each of their customer demand prognoses to establish a common prognosis. In case of deviation from forecast the partners meet to discuss deviations and to update the common forecast.
6-8	Order forecast collaboration	The partners share replenishment plans and discuss deviations and constraints.
9	Order generation	The reordering process/goods flow is initiated. Result data is discussed (POS, orders, shipments). Forecast deviation and stock level problems are identified and solved.

Interindustry Commerce Standards (VICS) as "a collection of new business practices that leverage the Internet and electronic data interchange in order to radically reduce inventories and expenses while improving customer service" (VICS, 1998a). This definition suggests that the Internet and electronic data interchange (EDI) are substantial prerequisites of CPFR.

VICS also crafted guidelines in the form of a nine-step model detailing how to implement CPFR (www.cpfr.org; VICS, 1998b; see Table 2).

These steps can be seen as a "cyclic and iterative approach to derive consensus based supply chain forecasts" (Fliedner, 2003, p. 15). The CPFR process builds to a large extent on the exchange of information among collaboration partners. This exchange of information can be carried out through the use of various technologies such as electronic data interchange (EDI), private networks or the Internet (XML). For the processing of information a large number of software programs have been developed to support the CPFR processes (e.g., Syncra, Logility, Manugistics; i2 Technologies, E-Millennium, E3, J.D. Edwards, Numetrix og Excentric, SAP, Oracle, Baan or Peoplesoft) (see Kotzab et al., 2003b).

FUTURE TRENDS

The Internet is going to revolutionize retailing. The challenge for e-tailing is logistics as the most prominent of Tesco.com shows. Consumer Direct Services (Corbae & Balchandani, 2001) will be more and more demanded, which will increase the number of single-purchase deliveries to the end-users' homes. The total home delivery market in the grocery industry is expected to be over 100 billion Euro, including over 900 million deliveries per year to over 35 million households.

IT-assisted home delivery concepts try to optimize the last mile to the consumer, which is the most expensive part of the total supply chain. There are plenty of home delivery systems, which either deliver the products directly to the home or where customers collect their purchased goods at certain pick-up-points (e.g., Pflaum et al., 2000, Punikavi et al., 2001). Tesco.com, however, goes a different way by serving consumer needs directly from their stores instead of installing special home-delivery distribution centres.

CONCLUSION

The chapter described the consequences of the use of IT in the field of retailing. It was shown how IT can be used in retail marketing to re-engineer retail formats in order to allow for a customized shopping experience. IT-assisted retail logistics refers to just-in-time-oriented demand synchronized delivery systems. The increased use of such systems will lead in the future to more hybrid retail management strategies, where the organizational borders between retailers, suppliers and even consumers will disappear.

KEY TERMS

Barcodes: Simple form of optical character recognition, where information is encoded in printed bars of relative thickness and spacing. RFID combines this technology with radio frequency.

Continuous replenishment systems: Automated order retrieval systems which reduce out-of-stock situations at the point of sales by linking Electronic Point of Sales Systems with supplier factories.

Cross docking: Just-in-time flow through operations in a distribution center which transform incoming deliveries as fast as possible to customer specific outgoing deliveries.

Electronic Data Interchange (EDI): Meta-term for a multitude of different electronic message standards that allow a computerized and highly structured low error communication between computers. A "merge" between EDI and Internet technology can be recently observed by the upcoming of web-based EDI solutions, where on EDI-partner does not have to install EDI but use common web browsers to communicate via EDI.

Electronic Product Code (EPC): RFID-based product identification standard that developed from bar codes. EPC is managed by EPC Global Inc., which is a subsidiary of EAN.UCC. EPC numbers are able to accommodate all EAN.UCC keys.

Electronic Shelf Labels: Price tags that provide accurate pricing due to electronic linkage between the shelves and the checkout system. The technology is based on radio-frequency, infra-red and/or WLAN linking a master check-out with the shelves.

Intelligent Scale: A scale that is equipped with a special camera and identification software. Based on an object's structure, size, color and thermal image, the scale automatically recognizes the item, weighs it and prints out a price tag.

RFID (Radio Frequency Identification): Form of automated radio frequency based identification of objects. RFID systems consist of an antenna, a transceiver for reading radio frequency and to transfer information, a processing device and a transponder.

Scan & Bag: Special application of a self-check-out-system.

Scanner: Electronic devices that convert barcode information into digitized electronic images.

Self Check Out Systems: Self check out systems can occur at the end but also during shopping processes whenever cash-desk operations are 'outsourced' to consumers. In that case, consumers self register their items with specific scanning devices.

Virtual Shopping Assistant: Small mobile computer with a touch screen and bar-code scanner that can be installed to a shopping trolley and can serve as a personal shopping advisor (e.g., offering the customized shopping list).

Content-Based Image Retrieval

INTRODUCTION

With the rapid growth of Internet and multimedia systems, the use of visual information has increased enormously, such that indexing and retrieval techniques have become important. Historically, images are usually manually annotated with metadata such as captions or keywords (Chang & Hsu, 1992). Image retrieval is then performed by searching images with similar keywords. However, the keywords used may differ from one person to another. Also, many keywords can be used for describing the same image. Consequently, retrieval results are often inconsistent and unreliable.

Due to these limitations, there is a growing interest in content-based image retrieval (CBIR). These techniques extract meaningful information or features from an image so that images can be classified and retrieved automatically based on their contents. Existing image retrieval systems such as QBIC and Virage extract the so-called low-level features such as color, texture and shape from an image in the spatial domain for indexing.

Low-level features sometimes fail to represent high level semantic image features as they are subjective and depend greatly upon user preferences. To bridge the gap, a top-down retrieval approach involving high level knowledge can complement these low-level features. This articles deals with various aspects of CBIR. This includes bottom-up feature-based image retrieval in both the spatial and compressed domains, as well as top-down task-based image retrieval using prior knowledge.

BACKGROUND

Traditional text-based indexes for large image archives are time consuming to create. A domain expert is required to examine each image scene and describe its content using several keywords. The language-based descriptions, however, can never capture the visual content sufficiently because a description of the overall semantic content in an image does not include an enumeration of all the objects and their properties. Manual text-based annotation generally suffers from two major drawbacks: (i) content mismatch, and (ii) language mismatch. A content mismatch arises when the information that the domain expert ascertains from an image differs from the information that the user is interested in. When this occurs, little can be done to recover the missing annotations. On the other hand, a language mismatch occurs when the user and the domain expert use different languages or phrases to describe the same scene. To circumvent language mismatch, a strictly controlled set of formal vocabulary or ontology is needed, but this complicates the annotation and the query processes. In text-based image query, when the user does not specify the right keywords or phrases, the desired images cannot be retrieved without visually examining the entire archive.

In view of the deficiencies of text-based approach, major research effort has been spent on CBIR over the past 15 years. CBIR generally involves the application of computer vision techniques to search for certain images in large image databases. "Content-based" means that the search makes use of the contents of the images themselves, rather than relying on manually annotated texts.

From a user perspective, CBIR should involve image semantics. An ideal CBIR system would perform semantic retrievals like "find pictures of dogs" or even "find pictures of George Bush." However, this type of open-ended query is very difficult for computers to perform because, for example, a dog's appearance can vary significantly between species. Current CBIR systems therefore generally make use of low-level features like texture, color, and shape. However, biologically-inspired vision research generally suggests two processes in visual analysis: bottom-up image-based analysis and top-down task-related analysis (Navalpakkam & Itti, 2006). Bottom-up analysis consists of memoryless stimulus-centric factors such as low-level image features. Top-down analysis uses prior domain knowledge to influence bottom-up analysis. An effective image retrieval system should therefore combine both the low-level features as well as the high level knowledge so that images can be classified automatically according to their context and semantic meaning.

EXISTING CBIR SYSTEMS AND STANDARDS

The best-known commercial CBIR system is the QBIC (Query by Image Content) system developed by IBM (Flickner et al., 1995). Image retrieval is achieved by any combination of color, texture or shape as well as by keyword. Image queries can be formulated by selection from a palette, specifying an example image, or sketching a desired shape on the screen. The other well-known commercial CBIR systems are Virage (Gupta & Jain, 1997) which is used by AltaVista for image searching, and Excalibur (Feder, 1996) which is adopted by Yahoo! for image searching. Photobook (Pentland, Picard, & Sclaroff, 1996) from MIT Media Lab is the representative research CBIR system. Like QBIC, images are represented by color, shape, texture and other appropriate features. However, Photobook computes information-preserving features, from which all essential aspects of the original image can be reconstructed.

In 1996, the Moving Picture Experts Group (MPEG)–a working group (JTC1/SC29/WG11) of the International Organization for Standardization (ISO) and the International Electrotechnical Commission (IEC)—decided to start a standardization project called MPEG-7 (Manjunath, Salembier, & Sikora, 2002). The aim is to provide a quick and efficient identification and management of multimedia content so that audio-visual information can be easily searched.

The MPEG-7 specifies the descriptors, description schemes and a description definition language. The descriptors is a representation of features at different levels of abstraction, ranging from low-level visual features like shape, texture and color to high level semantic information such as abstract concept and genres. The descriptor defines the syntax and semantics of the feature representation.

The description schemes specify the structure and semantics of the relationships between its components such as descriptors. The scheme provides a solution to model and describe content in terms of structures and semantics. The description definition language allows the creation of new description schemes as well as descriptors. This allows extension and modification of existing description schemes.

The MPEG-7 standard has eight parts. Of these, Part 3 specifies a set of standardized low-level descriptors and description schemes for visual content which includes shape descriptor, color descriptor, texture descriptor and motion descriptor. Note that the MPEG-7 specifies the descriptors only, and their extraction are not specified as part of the MPEG-7 standard.

CBIR METHODOLOGY

A CBIR system has three key components: feature extraction, efficient indexing and user interface:

- **Feature extraction:** Image features include *primitive features* and *semantic features*. Examples of primitive features are *color*, *texture*, and *shape*. Primitive features are usually quantitative in nature and they can be extracted automatically from the image. Semantic features are qualitative in nature and they provide abstract representations of visual data at various levels of detail. Typically, semantic features are extracted manually. Once the features have been extracted, image retrieval becomes a task of measuring similarity between image features.
- **Efficient indexing:** To facilitate efficient query and search, the image indices needed to be organized into an efficient data structure. Because image features maybe interrelated, flexible data structures should be used in order to facilitate storage/retrieval. Structures such as *k-d-tree*, *R-tree*, *R*-tree*, *quad-tree*, and *grid file* are commonly used.
- **User interface:** In visual information systems, user interaction plays an important role. The user interface consists of a query processor and a browser to provide an interactive environment for querying and browsing the database. Common query mechanisms provided by the user interface are: *query by keyword*, *query by sketch*, *query by example*, *browsing by categories*, *feature selection*, and *retrieval refinement*.

In *query by example*, the user specifies a query image (either supplied by the user or chosen from a random set), and the system finds images similar to it based on various low-level criteria. In *query by sketch*, the user draws a rough sketch of the image he/she is looking for, for example, with blobs of color at different locations, and the system locates images whose layout matches the sketch. In either case, features are first extracted automatically from this query image to form a query image signature. A matching with all other images in the archive is performed by measuring the similarity between their signatures. It can be seen that the matching result is heavily influenced by the choice of features.

BOTTOM-UP CONTENT-BASED RETRIEVAL IN THE SPATIAL DOMAIN

Content-based retrieval makes use of low level image features computed from the image itself for matching. Commonly used

features are *color*, *texture* and *shape* which can be obtained directly from the spatial domain representation.

Color Signature

Color is one of the most widely used features as it is relatively robust to translation and rotation about the angle of view (Deng et al., 2001). One of the often used color features is color histogram. It partitions color distribution into discrete bins and can be used to show the overall color composition in an image. The MPEG-7 specifies six color descriptors: color space descriptor, dominant color descriptor, scalable color descriptor, group of frames or group of pictures descriptor, color structure descriptor and color layout descriptor. Among these six descriptors, two are related to the color histogram. For example, the dominant color information is defined as, $F = \{(\vec{c}_i, p_i, \upsilon_i), s\}$, $i = 1,2,...,N$, where N is the total number of dominant colors, $\vec{c}_i$ is a vector storing color component values, p_i is the fraction of pixels in the image corresponding to color $\vec{c}_i$, υ_i is the color variance representing the color variation in a cluster surrounding the color $\vec{c}_i$ and s is a number representing the overall spatial homogeneity of the dominant colors in the image. The color structure information is obtained from the localized color histogram using a small structuring window so that local spatial structure of the color can be characterized.

Texture Signature

Texture is one of the basic attributes of natural images. Commonly used methods for texture characterization are divided into three categories: statistical, model-based and filtering approaches. Statistical methods such as co-occurrence features describe tonal distribution in textures (Wouwer, Scheunders & Van Dyck, 1999). Model-based methods such as Markov random field (Cross & Jain, 1983) provide description in terms of spatial interaction while filtering approaches including wavelet, Gabor-filters and directional filter-bank (DFB) characterize textures in frequency domain (Chang & Kuo, 1993; Manjunath & Ma, 1996). It has been shown that directional together with scale information is important for texture perception. As texture patterns can be analyzed at various orientations with multiple scales using Gabor-filters, good texture descriptions can be obtained. However, Gabor-filter involves nonseparable transform which is computationally expensive. Recently, Contourlet transform and multiscale directional filter bank have been proposed to solve this problem by combining the DFB with Laplacian pyramid (LP) (Cheng, Law, & Siu, 2007). Although the LP is somehow redundant, the combined approach is still computationally efficient while providing a high angular resolution. As a result, efficient texture descriptors can be obtained.

There are three texture descriptors in MPEG-7: a homogeneous texture descriptor, a texture browsing descriptor and an edge histogram descriptor. The homogeneous texture descriptor adopts Gabor-like filtering for the texture description. The texture browsing descriptor provides a perceptual texture characterization in terms of regularity, coarseness and directionality of the texture pattern. The edge histogram descriptor is obtained by analyzing spatial distribution of edges in an image.

Shape Signature

Shape is one of the key visual features used by human for distinguishing visual data. Compare with color and texture, shape is easier for users to describe in a query, either by example or by sketch. However, because shapes of natural objects in a 2D image can be obtained from different views of the same object, shapes can be rotated, scaled, or skewed. Hence, an effective shape representation should be rotation, translation and scaling invariant, as well as invariant to affine transform to address the different views of objects.

Two of the common approaches for shape representation are boundary-based and region-based approaches. The boundary-based approach works on the edges/outlines of the image while the region-based approach considers the entire regions. In fact, the MPEG-7 standard defines three shape descriptors: region-based shape descriptor, contour-based shape descriptor and 3D shape spectrum descriptor. The region-based descriptor is based on a complex 2D angular radial transformation which belongs to a class of shape analysis techniques using Zernike moments. The contour-based descriptor is based on extracting features such as contour circularity and eccentricity from the curvature scale-space contour representation. The 3D shape descriptor is based on a polygonal 3D meshes object representation.

Bottom-Up Content-Based Retrieval in the Compressed Domain

Features used in retrieval are often extracted from the spatial domain. This is in contrast to the fact that images are usually compressed using JPEG or JPEG 2000 to reduce their size for storage and transmission. Retrieving these kinds of compressed images then requires reconversion to the uncompressed spatial domain for feature extraction. This approach requires many decompression operations, especially for large image archives. To avoid some of these operations, it was proposed that feature extraction be done directly in the transformed domains.

JPEG employs the discrete cosine transform (DCT) for image compression (Pennebaker & Mitchell, 1993). Low-level features such as color, shape and texture have been proposed to be extracted directly by analyzing DCT coefficients. For example, DCT coefficients can be reorganized into a tree structure capturing the spatial-spectral characteristics for retrieval (Climer & Bhatia, 2002; Ngo, Pong, & Chin, 2001). JPEG 2000 is a new compression standard which compresses images using wavelets (Taubman & Marcellin, 2002). As wavelets provide a multiple resolution view of an image, several indexing techniques have been proposed to extract wavelet coefficients for coarse-to-fine image retrieval (Liang & Kuo, 1999; Xiong & Huang, 2002).

One of the major concerns in the compressed domain feature extraction is that they are domain specific. Different compression techniques result in different transformed coefficients. This implies that features that can be extracted in the compressed domain depend greatly on the compression scheme used. As a result, the retrieval system can only be used to retrieve images from a particular compression format. To extract features in the compressed domain irrespective of the compression format, a common framework called the subband filtering model has been proposed (Au, Law, & Siu, 2007). Using this subband model, the block-based DCT coefficients are concatenated to form structures that are similar to the wavelet subbands. This would allow similar features to be extracted for retrieval purposes. It has been proved that similar features can always be extracted in the JPEG and JPEG 2000 domains for retrieval, irrespective of the values of the compression ratio.

Top-Down-Based Retrieval Using Prior Knowledge

Although the visual mechanism is still not well understood, biological visual system research generally suggest two processes involved in visual analysis: bottom-up image-based analysis and top-down task-related analysis. Bottom-up analysis consists of extraction of low-level features described above. Top-down analysis refers to those high-level concepts that cannot be extracted directly from the image, but instead from the semantics of objects and image scenes as perceived by human beings. These conceptual aspects are subjective and are more closely related to users' preferences.

Low-level image features fail to represent high-level semantic image features because they are only the basic components to build cognitive features. A human always focus on the interesting part of an image based on what he or she is trying to look for. The cognitive features of an image play the most important role in the semantic understanding of images.

Whereas low level features are usually context-free, high level semantic features are context-rich. The relationship (spatial or conceptual) between image objects is a strong constraint for semantic image description. In Hare et al. (2006), a semantic space is used to describe the spatial relationships between image objects and hence the scene content. User's domain knowledge can be used to constrain such a semantic space, for example, a mountain scene would consists of blue sky on the top portion of the image, mountains in the middle portion of the image, and grassland or forest in the foreground.

To incorporate high level knowledge incrementally, *relevance feedback* was proposed to interactively refine retrieval results (Rui, Huang, Ortega, & Mehrotra, 1998). In particular, the user indicates to the retrieval system whether the particular retrieved result is "relevant," "not relevant" or "neutral." With the use of some learning algorithms such as Support Vector Machines, a set of possibly better retrieved results can be obtained after a few rounds of this feedback mechanism.

FUTURE TRENDS

A major challenge in CBIR research is to develop a semantic-sensitive retrieval system. Semantic similarity is an important image matching criterion in human and is related to how we interpret image content. An effective image retrieval system should combine both low-level features as well as high level semantic knowledge so that images can be classified according to their context and meaning. However, very little research has been done on high-level semantic features. A possible reason is that high level knowledge are difficult to define and formulate because they are highly subjective and are closely related to viewers' expectations of scene context. There are some attempts to segment an image into different regions using homogenous low level features and then combine them together with context information to form a model for image indexing and retrieval. However, meaningful segmentation is often difficult to obtain in practice.

The major problem in semantic-sensitive CBIR is to define and extract the semantic concept behind the image. The concept can be related to the image categories such as buildings and gardens. It can also be tailored to certain application domains, such as detecting human faces and intruders. Once the concept is extracted and associated with certain low-level features, content-based image retrieval becomes concept matching, which is semantically more meaningful than low-level features matching. Performing concept matching instead of low-level features matching could also speed up the retrieval process.

Machine learning techniques can be used to learn the high level semantic knowledge automatically. Relevance feedback has been proposed to improve the retrieval results. The major challenge here is to develop an effective and efficient algorithm for automatic concept learning and representation. Due to the fuzzy nature of semantic concepts,

probabilistic graphical models such as Bayesian network or relevance network could find applications here.

CONCLUSION

With the rapid growth of Internet and multimedia systems, the use of visual information has increased enormously such that image-based indexing and retrieval techniques have become important. In this article, an overview of CBIR is given. Current CBIR systems mainly extract low-level features such as color, texture, and shape from an image for image classification and retrieval. However, it is well known that these low-level features cannot capture image semantics. In contrast, human performs image searching by relying heavily on the semantic concepts behind the image. In order to close this semantic gap, much more research effort is needed to find ways to define and incorporate high level semantic knowledge onto the CBIR system. We have discussed two major challenges in this area, including (1) semantic concept formulation and extraction from images and (2) the development of effective machine learning algorithms for concept learning and representation.

KEY TERMS

Bottom-Up Image Analysis: This refers to the use of low-level features, such as high luminance/color contrast or unique orientation from its surrounding, to identify certain objects in an image.

Compressed Domain Feature Analysis: This refers to the process of image signature extraction performed in the transform domain. Image features are extracted by analyzing the transform coefficients of the image without incurring a full decompression.

Content-Based Image Retrieval: This refers to an image retrieval scheme which searches and retrieves images by matching information that is extracted from the images themselves. The information can be color, texture, shape and high level features representing image semantics and structure.

Feature Descriptors: A set of features that is used for image annotation and indexing. The features can be keywords, low-level features including color, texture, shape, and high level features describing image semantics and structure.

High Level Semantics: This refers to the image context as perceived by humans. It is generally subjective in nature and greatly depends on user's preferences.

Image Retrieval System: A computer system for users to search images stored in a database.

Image Signature: This is the same as feature descriptors used for image annotation and indexing.

Keyword-Based Image Retrieval: This refers to an image retrieval scheme which searches and retrieves images by using metadata such as keywords. In this scheme, all images are annotated with certain keywords. Searching is then performed by matching these keywords.

Relevance Feedback: This provides an interactive way for humans to refine the retrieval results. Users can indicate to the image retrieval system whether the retrieved results are "relevant," "irrelevant" or "neutral." Retrieval results are then refined iteratively.

Spatial Domain Feature Analysis: This refers to the process of image signature extraction performed in the spatial domain. Image features are extracted by analyzing the spatial domain image representation.

Top-Down Image Analysis: This refers to the use of high level semantics, such as viewer's expectations of objects and image context, to analyze and annotate an image.

Content-Based Retrieval Concept

INTRODUCTION

Because of the demand for efficient management in images, much attention has been paid to image retrieval over the past few years. The text-based image retrieval system is commonly used in traditional search engines (Ratha et al., 1996), where a query is represented by keywords that are usually identified and classified by human beings. Since people have different understandings on a particular image, the consistency is difficult to maintain. When the database is larger, it is arduous to describe and classify the images because most images are complicated and have many different objects. There has been a trend towards developing the content-based retrieval system, which tries to retrieve images directly and automatically based on their visual contents.

A similar image retrieval system extracts the content of the query example $\boldsymbol{q}$ and compares it with that of each database image during querying. The answer to this query may be one or more images that are the most similar ones to $\boldsymbol{q}$. Similarity retrieval can work effectively when the user fails to express queries in a precise way. In this case, it is no longer necessary to retrieve an image extremely similar to the query example. Hence, similarity retrieval has more practical applications than an exact match does.

Content-Based Image Retrieval Systems

In a typical content-based image retrieval system, the query pattern is queried by an example in which a sample image or sketch is provided. The system then extracts appropriate visual features that can describe the image, and matches these features against the features of the images stored in the database. This type of query is easily expressed and formulated, since the user does not need to be familiar with the syntax of any special purpose image query language. The main advantage is that the retrieval process can be implemented automatically (Chen, 2001). The scope of this article is circumscribed to image abstraction and retrieval based on image content.

Human beings have a unique ability that can easily recognize the complex features in an image by utilizing the attributes of shape, texture, color, and spatial information. Many researchers analyze the color, texture, shape of an object, and spatial attributes of images, and use them as the features of the images. Therefore, one of the most important challenges in building an image retrieval system is the choice and representation of the visual attributes. A brief overview of the commonly used visual attributes shape, texture, color, and spatial relationship will be illustrated as follows.

Commonly Used Image Features in Content-Based Image Retrieval Systems

Shape characterizes the contour of an object that identifies the object in a meaningful form (Gevers & Smeulders, 2000; Zhang & Lu, 2002). Traditionally, shapes are described through a set of features such as area, axis-orientation, certain characteristic points, and so forth. These systems retrieve a subset of images that satisfy certain shape constraints. In the shape retrieval, the degree of similarity between two images is considered as the distance between the corresponding points.

Color attribute may simplify the object's identification and extraction in the image retrieval (Galdino & Borges, 2000; Gevers & Smeulders, 2000). Color may provide multiple measurements at a single pixel of the image, and often enable the classification to be done without complex spatial decision-making. Any resulting difference between colors is then evaluated as a distance between the corresponding color points. The color-based retrieval system measures the similarity of the two images with their distance in color space.

Texture attribute depicts the surface of an image object (Yao & Chen, 2002; Zhang & Tan, 2003). Intuitively, the term refers to properties such as smoothness, coarseness, and regularity of an image object. Generally, the structural homogeneity does not come from the presence of a single color or intensity, but it requires the interaction of various intensities within a region.

Retrieval by spatial constraints facilitates a class of queries based on the 2-D arrangement of objects in an image (Chang Erland & Li, 1989; Chang & Li, 1988; Chang, Shi & Yan, 1987; Lee & Hsu, 1992). The query is composed by placing sketches, symbols or icons on a plane where every symbol or icon is predefined for one type of objects in an image. The relationships between the objects can be broadly

classified as either directional (also referred as projective) (Chang & Li, 1988; Chang, Shi & Yan, 1987) or topological (Lee & Hsu, 1992). Directional relationship is based on the relative location and the metric distance between two image objects. Topological relationships are based on set-theoretical concepts like union, intersection, disjunction and so forth. Spatial information is a higher-level attribute, which is increasingly more specific. For example, facial features are frequently presented in terms of spatial information (Sadeghi, Kittler & Messer, 2001).

Briefly, color attribute depicts the visual appearance of an image, characterized by the luminance and chrominance histograms of the image. Texture attribute refers to three components: bi-dimensional periodicity, mono-dimensional orientation, and complexity obtained through world decomposition. Shape attribute sketches the geometrical properties of objects in images. Spatial attribute represents the relative position relationships between objects of an image.

TYPICAL IMAGE RETRIEVAL SYSTEMS

This section briefly overviews the image retrieval systems based on the most commonly used image features: color, shape, texture, and spatial content.

The Color-Based Image Retrieval Systems

Generally, the color-based image retrieval system does not find the images whose colors are exactly matched, but images with similar pixel color information. This approach has been proven to be very successful in retrieving images since concepts of the color-based similarity measure is simple, and the convention algorithms are very easy to implement. Besides, this feature can resist noise and rotation variants in images.

However, this feature can only be used to take the global characteristics into account rather than the local one in an image, such as the color difference between neighboring objects in an image. For example, if a landscape image with blue sky on the top and green countryside at the bottom is employed as a query example, the system that retrieves the images with similar structures based on these global features often gives very unsatisfactory results. In addition, the color-based image retrieval system often fails to retrieve the images that are taken from the same scene in which the query example is also taken from under different time or conditions, for example, the images of a countryside taken at dusk or dawn under a clear or a cloudy sky. In another scenario, the same scene may be imaged by different devices. Using one image taken by one device as the query example may fail to find the same scene taken by other devices.

The Shape-Based Image Retrieval Systems

A shape-based image retrieval system is used to search for the images containing the objects, which are similar to the objects specified by a query. Since an object can be formed by a set of shapes in most cases (e.g., a car can be made of some little rectangles and circles), most similar objects have a high correlation in their set of shapes (Gevers & Smeulders, 2000; Zhang & Lu, 2002). The shape-based image retrieval system extracts the shapes of objects from images by segmentation, and classifies the shapes, where each shape has its own representation and variants to scaling, rotation, and transition.

Some criteria on shape representation and similarity measure for a well performing content-based image retrieval system should be achieved. Firstly, the representation of a shape should be invariant to scale, translation, and rotation. Secondly, the similarity measure between shape representations should conform to human perception; that is, perceptually similar shapes should have highly similar measures. Thirdly, the shape representation should be compact and easy to derive, and the calculation of similarity measure should be efficient.

However, how to locate and how to recognize objects from images is a real challenge. One of the obstacles is how to separate the objects from the background. Difficulties come from discrimination, occlusions, poor contrast, viewing conditions, noise, complicated objects, complicated backgrounds, and so forth. Moreover, the shape-based image retrieval system can only deal with the images that have simple object shapes. For complex object shapes, the region-based method has to build a binary sequence by using smaller grid cells, so that results that are more accurate can be obtained; nevertheless, the storage of indices and retrieval time may increase tremendously.

The Texture-Based Image Retrieval Systems

Literally, texture relates to the arrangement of the basic constituents of a material. In digital images, texture describes the spatial interrelationships of the image pixels. Texture similarity can often be useful in distinguishing the areas of objects in images with similar color, such as sky and sea as well as leaves and grass. Texture queries can be formulated in the manner that is similar to the color queries by selecting an example of desired textures from a palette, or by supplying an example query image. The system then returns the images which are most similar to the query example in texture measures.

Making texture analysis is a real challenge. One way to perform content-based image retrieval using texture as

the cue is by segmenting an image into a number of different texture regions and then performing a texture analysis algorithm on each texture segment. However, segmentation can sometimes be problematic for image retrieval. In addition, texture is quite difficult to describe and subject to the difference of human perception. No satisfactory quantitative definition of texture exists at this time.

The Spatial-Based Image Retrieval Systems

There are two kinds of spatial-based image retrieval systems: retrieval by spatial relationships (RSRs) and spatial access methods (SAMs). The RSR image retrieval system is to retrieve the images from a database that are similar to the query sample based on relative position relationships between the objects in the images. Hence, a physical image can be regarded as a symbolic image, each object of which is attached with a symbolic name. The centroid coordinates of the object with reference to the image frame are extracted as well. By searching for the logical images, the corresponding physical images can then be retrieved and displayed. Therefore, image retrieval can be simplified to the search of symbolic images.

Chang, Shi, and Yan (1987) used a 2D string representation to describe a symbolic image. Objects and their spatial relationships in a symbolic image can be characterized by a 2D string. An image query can be specified as a 2D string too. Consequently, the problem of image retrieval then turns out to be the matching of a 2D string. Subsequently, a great number of other image representations popped out that were derived from a 2D string, such as 2D G-string (Chang, Erland & Li, 1989), 2D B-string (Lee, Yang & Chen, 1992), 2D C-string (Lee & Hsu, 1992), and so forth. These representations adopt the description of orthogonal projection to delineate the spatial relationships between objects.

The SAM image retrieval systems are to manage large collections of points (or rectangles or other geometric objects) in the main memory or on the disk so that range queries can be efficiently answered. A range query specifies a region in the address space, requesting all the data objects that intersect it. They divide the whole space into several disjoint sub-regions, each with no more than P points (a point may represent a rectangle). P is usually the capacity of a disk page. Inserting a new point may result in further splitting a region. The split methods can be classified according to the attributes of the split (Gottschalk, Turney & Mudge, 1987).

Color attribute is most intuitive and straightforward for the user. Texture analysis systems are often developed to perform filtering in the transform domain in order to obtain feature images. The use of global color or texture features for the retrieval of images tends to be misleading, especially in homogeneous image collections. Though shape and texture are the essential visual attributes to derive potentially useful semantic information, there exists less understanding of the benefits to implement these attributes as compared to color, for efficient image retrieval. This approach apparently focuses on global frequency content of an image; however, many applications require the analysis to be localized in the spatial domain.

FUTURE TRENDS

Many visual attributes have been explored, such as color, shape, texture, and spatial features. For each feature, there exist multiple representations that model the human perception of the feature from different perspectives. There is a demand for developing an image content description to organize the features. The features should not only be just associated with the images, but also be invoked at the right place and the right time, whenever they are needed to assist retrieval.

Human beings tend to apply high-level concepts in their daily lives. However, most features, the current computer vision techniques automatically extracting from images, are low-level. To narrow down this semantic gap, it is necessary to link the low-level features to high-level concepts. On the high-level concept, it should allow the user to easily provide his or her evaluation of the current retrieval results to the computer. It is likely for different people to give an identical name; therefore, generating the representation by automatically extracting the objects from an original image is very difficult. Therefore, the spatial relationships between objects cannot be extracted automatically without human interaction with the current techniques of image understanding and recognition. More recent research emphasis is given to "interactive systems" and "human in the loop".

Due to the perception subjectivity of image content, it is difficult to define a good criterion for measuring the similarity among images. That is, the subjectivity of image perception prevents us from defining objective evaluation criteria. Hence, it is urgent to find an appropriate way of evaluating the system performance guiding the research effort in the correct direction.

Establishing a well-balanced large-scale test bed is an important task too. A good test bed must be huge in scale for testing the scalability (for multidimensional indexing), and be balanced in image content for testing image feature effectiveness and overall system performance.

Human beings are the ultimate end users of the image retrieval system. This topic has attracted increasing attention in recent years, aiming at exploring how humans perceive image content and how one can integrate such a "human model" into the image retrieval systems. Recently, more studies of human perception focus on the psychophysical aspects of human perception.

CONCLUSION

A successful image retrieval system requires the seamless integration of the efforts of multiple research communities. To achieve a fast retrieval speed and make the retrieval system truly scalable to large-size image collections, an effective multidimensional indexing module is an indispensable part of the whole system. The interface collects the information from the users and displays back the retrieval results to the users in a meaningful way. To communicate with the user in a friendly manner, the query interface should be graphics-based.

In the iconic image representation, an icon is used to represent an object in an image. The iconic image representation has two advantages. First, once the images in the database are analyzed, it is not necessary to analyze the image again in a query processing. Secondly, since the size of the symbolic image is much smaller than that of the original image, this representation can be well suited to be distributed to database environments where a large number of image transmissions between distant nodes are required.

Typically, color, shape and texture attributes provide a global description of images, but they fail to consider the meaning of portrayed objects and the semantics of scenes. The descriptions of objects and the relative positions among objects provide a spatial configuration and a logical representation of images. Combining approaches for content-based image retrieval systems could be considered as complementary.

KEY TERMS

Color Feature: Analyzing the color distribution of pixels in an image.

Geometric Hashing: The technique identifying an object in the scene, together with its position and orientation.

Query by Example: The image retrieval system where a sample image or sketch can be provided as a query.

Shape Feature: Characterizing the contour of an object that identifies the object in a meaningful form.

Spatial Feature: Symbolizing the arrangement of objects within the image.

Symbolic Image: Consisting of a set of objects; each object stands for an entity in a real image.

Texture Feature: Depicting the surface of an image object.

A Content-Sensitive Approach to Search in Shared File Storages

Gábor Richly
Budapest University of Technology and Economics, Hungary

Gábor Hosszú

Ferenc Kovács
Budapest University of Technology and Economics, Hungary

INTRODUCTION

The article presents a novel approach to search in shared audio file storages such as P2P-based systems. The proposed method enables the recognition of specific patterns in the audio contents, in such a way it extends the searching possibility from the description-based model to the content-based model. The targeted shared file storages seam to change contents rather unexpectedly. This volatile nature led our development to use real-time capable methods for the search process.

The importance of the real-time **pattern recognition** algorithms that are used on audio data for content-sensitive searching in stream media has been growing over a decade (Liu, Wang, & Chen, 1998). The main problem of many algorithms is the optimal selection of the reference patterns (*soundprints* in our approach) used in the recognition procedure. This proposed method is based on distance maximization and is able to choose the pattern that later will be used as reference by the pattern recognition algorithms quickly (Richly, Kozma, Kovács & Hosszú, 2001).

The presented method called ***EMESE (Experimental MEdia-Stream rEcognizer)*** is an important part of a light-weight content-searching method, which is suitable for the investigation of the network-wide shared file storages. This method was initially applied for real-time monitoring of the occurrence of known sound materials in broadcast audio. The experimental measurement data showed in the article demonstrate the efficiency of the procedure that was the reason for using it in shared audio database environment.

BACKGROUND

From the development of the Napster (Parker, 2004), the Internet-based communication is developing toward the **application level network**s (**ALN**). On the more and more powerful hosts, various collaborative applications run and create virtual (logical) connections with each others (Hosszú, 2005). They establish virtual **overlay**, and oppositely to the older **client/server model** they use the **peer-to-peer** (**P2P**) communication. The majority of such systems deal with file sharing (Adar, Huberman, 2000), that is why their important task is to search in large, distributed shared file storages.

A large amount of effort is dedicated for improving their searching (Yang & Garcia-Molina, 2002) and downloading capability (Cohen, 2003; Qiu & Srikant, 2004), however, the searching is quite traditional, it is based on the descriptive metadata of the media contents, as the file name, content description, and so forth. Such method has an inherent limitation, since the real content remains covered and even in case of the mistake of the file description this search can fail. Oppositely to the widely used description-based seeking, the content-based searching has been the topic of the research, only. Its main reason is that the content and its coded representation have a huge variety that is why a comprehensive method has not developed yet.

The novel system, EMESE, is dedicated for solving a special problem, where a small but significant pattern should be found in a large voice stream or bulk voice data file in order to identify known sections of audio. The developed method is light-weight, meaning that its design goals were the fast operation and the relatively small computing power. In order to reach these goals, the length of the pattern to be recognized should be very limited, and the total score is not required.

This article deals mainly with the heart of the EMESE system, the pattern recognition algorithm, especially with the creation of the reference pattern, called *reference selection*.

THE PROBLEM OF THE PATTERN RECOGNITION

In the field of sound recognition there are many different methods and applications for specific tasks (Coen, 1995; Kondoz, 1994).

The demand for working efficiently with streaming media on the Internet increases rapidly. These audio streams may contain artificial sound effects besides the mix of music and human speech. These effects furthermore may contain signal fragments that are not audible by the ear. As a consequence, processing of this kind of **audio signal** is rather different from the already developed methods, as for example, the short-term predictability of the signal is not applicable.

The representation of digital audio signal as individual sample values lacks any semantic structure to help automatic identification. For this reason, the audio signal is transformed into several different orthogonal or quasi-orthogonal bases that enable detecting certain properties.

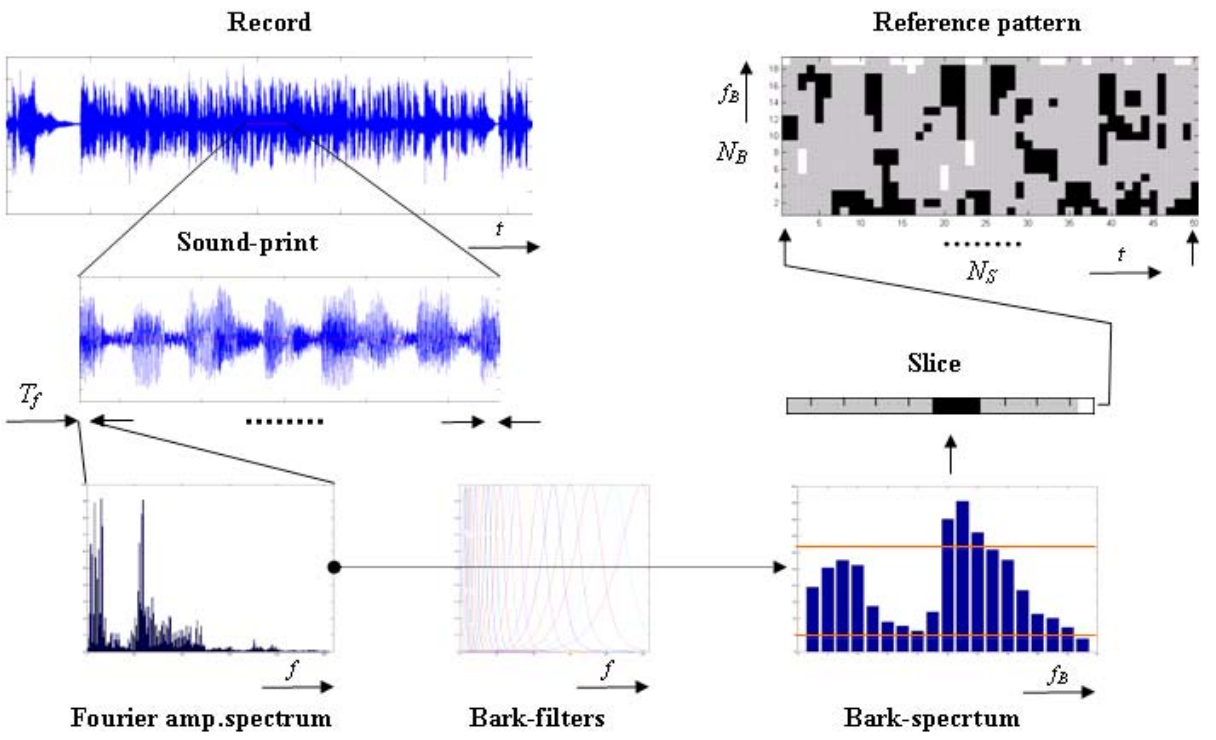
Already, there are solutions for classifying the type of broadcast on radio or television using the audio signal. The solution in Akihito, Hamada, and Tonomura (1998) makes basically a speech/music decision by examining the spectrum for harmonic content, and the temporal behavior of the spectral-peek distribution. Although it was applied successfully to that decision problem, it cannot be used for generic recognition purposes. The paper (Liu et al., 1998) also describes a scheme classifying method where the extracted features are based on the short-time spectral distribution represented by a bandwidth and a central frequency value. Several other features, for example, the volume distribution and the pitch contour along the sound clip, are also calculated. The main difficulty with this method is its high computation-time demand, so real-time monitoring is hardly possible, when taking the great number of references to be monitored into account.

A similar monitoring problem was introduced in Lourens (1990) and the used feature, a section of the energy envelope of the record signal (*reference*) was correlated with the input (*test*) signal. The demand on real-time execution drove the development of the recognition scheme introduced in Richly, Varga, Hosszú, and Kovács (2000), and Richly, Kozma, Kovács, and Hosszú (2001) that is capable of recognizing a pattern of transformed audio signal in an input stream, even in the presence of level-limited noise. This algorithm first selects a short segment of the signal from each record in the set of records to be monitored.

THE SOUND IDENTIFICATION IN THE EMESE

The reference selection algorithm needs a well understanding of the recognition method. The audio signal, sampled at f_s=16kHz is transformed into a spectral description because

Figure 1. The sound representation in the recognition system

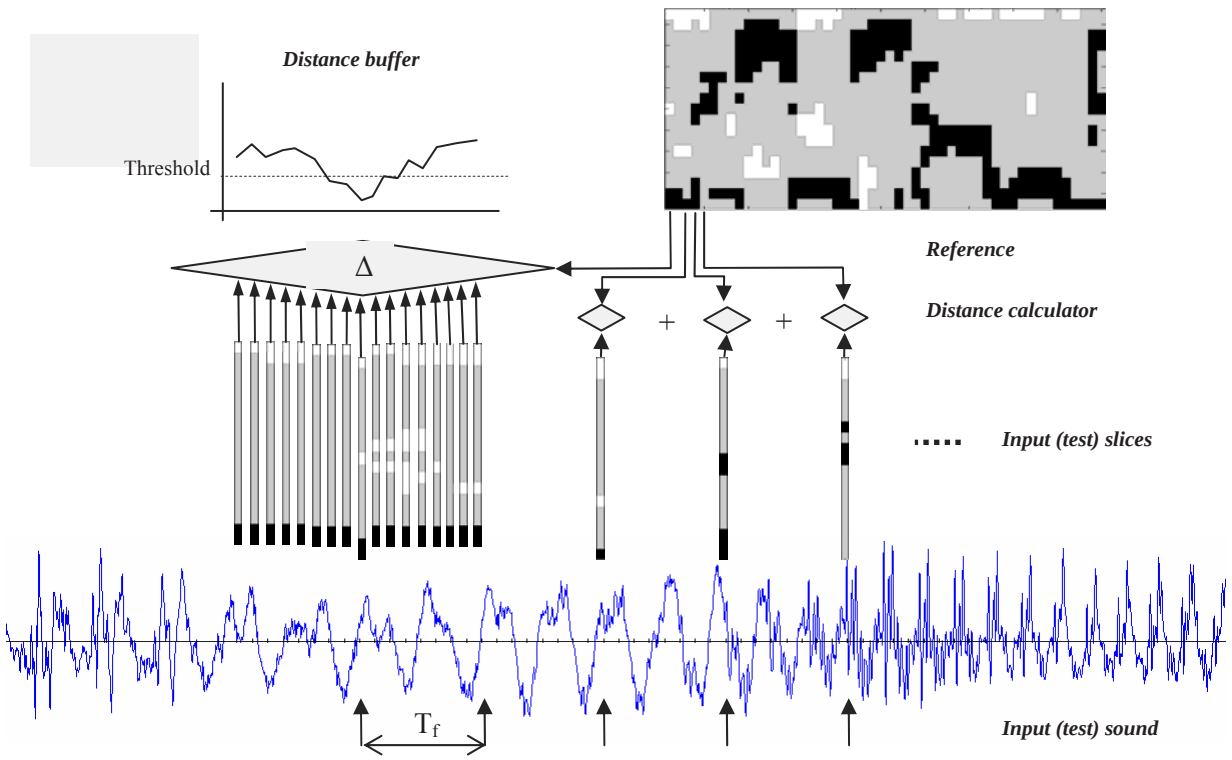


time-domain representation of sound is more sensitive to even light, non-audible distortions. A sound interval is transformed into a block of data, where the columns are vectors computed from a short, atomic section of the sound, where its spectral content can be assumed static. This section of time-domain data is called a *frame* ($N=256$ samples, $T_f=16ms$). First, the absolute value of the complex Fourier spectrum, the amplitude spectrum is computed from the frame. Then, amplitude values of neighboring frequencies are averaged to project the spectrum onto the Bark-scale, a non linear frequency scale. The reason for this is to speed up the later comparison stage by reducing the amount of relevant data and to include a well established emphasizing tool used in audio processing, the perceptual modeling of the human auditory system. As a result, we get a vector with $N_B=20$ values computed from the samples of a frame. In the next step, the vector is normalized and quantized. Two levels are determined in each transformed frame. The levels are the 10% and 70% of the peak value of the amplitude spectrum. We name the transformed frame a *slice* to indicate the applied column-vise recognition method of a reference. In every reference, there are N_S=50 slices of non-overlapping consecutive frames and the audio section, from which the reference was made, is called the soundprint of that specific record ($T_{SP} = T_f * N_S = 800ms$).

The scheme of the recognition algorithm is to grow the already identified parts of the reference patterns continuously, according to the input. This means that the algorithm takes a frame from the input signal, executes the previously described transformation series, and compares the resulting slice to the actual one of every reference. The actual slice is the first one in every reference initially and if it is decided to be similar to the slice computed from the input stream (a slice-hit occurs), the next, non-overlapping input slice will be compared to the next slice of that reference. If an input slice is decided to be non-similar, the actual slice of that reference is reset to the first one. The similarity is evaluated by calculating the weighted Manhattan-distance of the two slices. Manhattan-distance is the sum of the absolute element-vise differences in the slice vectors. This distance metric was chosen at the initial state of the project to avoid multiplication, since the system was developed for low-resource microcontroller and ASIC realizations. Weighting is introduced to emphasize the relevant differences in the used strong quantized environment.

For achieving more accurate alignment between the test and reference signals, the initial slice-hit in a reference is evaluated using a distance buffer, as demonstrated on Figure 2. In this circular-memory, the distances of that first reference slice to overlapping test slices are stored and the middle of the buffer is examined whether it contains the lowest value in the buffer. In case it does, and it also satisfies the threshold criteria, the identification of the reference proceeds to the next reference slice. This method intends to align the iden-

Figure 2. The synchronization mechanism



tification process to the "distance-pit" described in the next section (Richly, Kozma, Hosszú, & Kovács, 2001).

After successfully identifying the last slice of a reference, we successfully identified that record in the monitored input.

THE METHOD OF SELECTING THE REFERENCE PATTERNS

The selection algorithm uses the previously described weighted Manhattan-distance for measuring the similarity of the audio segments. In the vicinity of the reference's beginning, there have to be frames that vary a lot in the sense of the applied distance metric. This has to be fulfilled because the pattern recognition algorithm cannot synchronize to the given reference otherwise, since the record may appear anywhere in the monitored signal. This way a robust

Figure 3. The "distance-pit" around the reference position

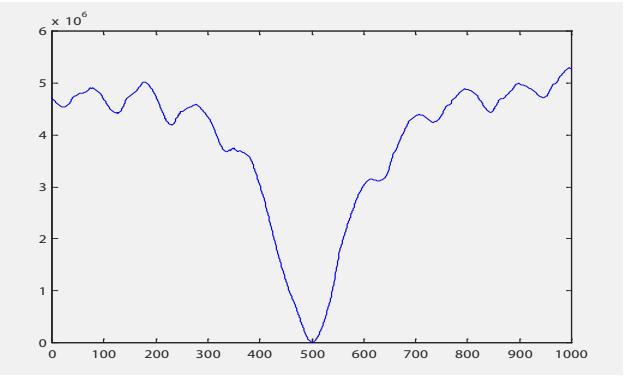


Figure 4. The width of the pits around the sound-print candidate

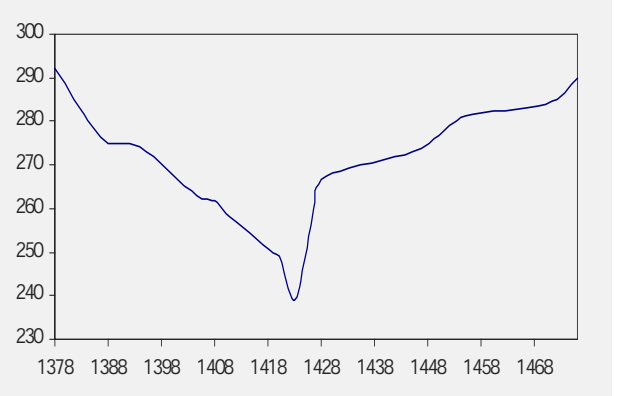

synchronization can be realized that is also successful in the presence of noise.

If we take a long sound-print (reference candidate) from a record to be monitored and calculate the distance of this section all along the record, then it can be observed that the distance function has a local minimum, a *pit* around the candidate's position (Richly, Kozma, Hosszú, & Kovács, 2001). This is demonstrated in Figure 3, where the x-axis shows which frame of the record is compared with the selected candidate, while the y-axis shows the Manhattan-distance values.

To achieve robust synchronization during the recognition, we must guarantee large Manhattan-distance between the candidate and its vicinity. This is assured if the slope of the pit, as showed on Figure 3, is as big as possible. For selecting the best distance-pit and its corresponding candidate section, we should determine the steepness of the pit-side. However, because it is generally not constant, so as an alternative we calculate the width at a given value. Figure 4 shows pit-width of 100 candidate sections, where the sections are extracted from the same record so that their first samples are consecutive in the record. In Figure 4 the horizontal axis is the sample position of the candidate in the record, while the vertical axis is the width of the pits at a record-adaptive level.

Our reference selection algorithm is based on the same principle, but since our pattern recognition method uses the first frame as kernel and grows from the first record, we observed this pit-width for one frame long candidates. The minimum value has to be found in this function without calculating every point of it.

We must also assure that our selected reference does not occur any more in the record again or in any other records. Using database terminology, we would say that the reference must be a key. To avoid unambiguous identification we must try to identify the selected reference in all the other records and if it is not a unique key then a new reference must be selected.

The exact solution would require us to compare every one of the reference-candidates to every other one. This would mean a lot of comparisons even in the case of a few records that could not be done in a conceivable time period.

In the presented algorithm we tried to keep the number of comparisons as low as possible. To do so we examine only the vicinity of the reference candidate in a region having the width w, where w is expressed in number of samples. Also we do not examine all possible reference candidates, only every 100th. The algorithm is listed in Table 1.

RESULTS

Using this algorithm we selected references from 69 advertisements that previously were recorded from a live Internet audio stream. During the tests, we monitored these 69 adver-

Table 1. The reference selection algorithm of the EMESE

1. In the first turn, the reference candidate is selected from the $\frac{w}{2}$th sample of the first region of the given record (The *region* is w=5000 samples). The first region begins on the first sample of the record, and it will define the first sample of the frame.
2. The frame is compared to all possible frames in the region according to the distance metric mentioned above. As a result we get $d(i)$, where $i=0\ldots w-N$, as shown on Figure 1.
3. The next region is selected $k*N$ samples forward in the record, and step 2 is repeated. We select further regions the same way and calculate the corresponding $d(i)$ until we reach the end of the record.
4. The steepest pit and the corresponding i_{opt} frame position in the record is selected examining all the $d(i)$ functions for the narrowest pit.
5. In the $k*N$ vicinity of position i_{opt} the frame with the narrowest distance-pit is determined using a gradient search algorithm. This is the lowest point of the function on *Figure 2*.
6. The reference consisting of N_R slices (transformed frames) is extracted from the record beginning with the frame selected in the previous step.
7. This reference is tested for uniqueness using the recognition algorithm. If the reference appears in the record more than once, not only at the correct position, then the next best reference must be selected in the previously described way.
8. The reference is then tried against all the other records, to filter out in-set false alarms. If the reference is found in any other record, step 7 is used for reference reselection.
9. The above steps are applied to all other records.

Figure 5. Percentage of patterns successfully identified by the recognition algorithm

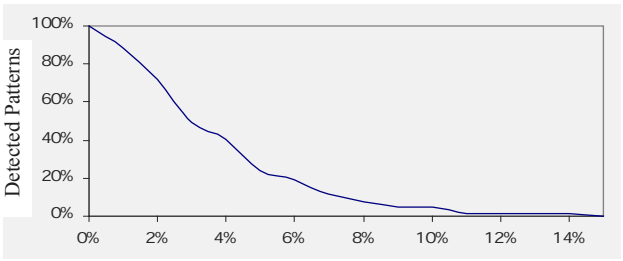

Figure 6. Result of the synchronization test

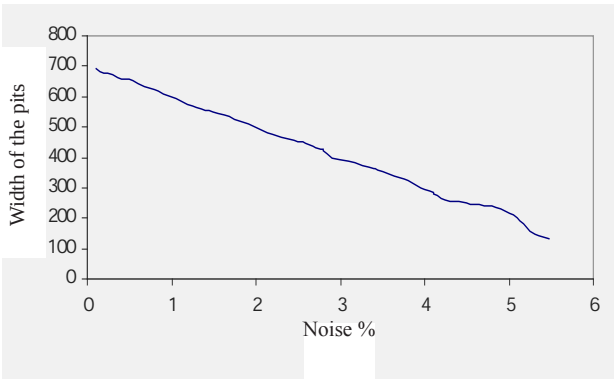

tisements that were broadcast in test Internet stream-media. We added white noise to the input signal to test the robustness of the system. The duration of the test was 48 hours. The recognition results are shown on Figure 5.

We also observed the performance of the system, namely how many references can be handled in real time. The computer used was equipped with a Pentium-II-350 MHz processor and 256 MB of RAM, and the maximum possible number of references was 258. If the record set to be monitored is added to, the reference selection for the added record must be performed, and the new references have to be checked for false alarms. If we detect a possible false alarm due to representative signal similarity the selection must be repeated for the whole set. This takes 525 minutes in case of 69 records. This is a worst-case scenario, and it should be very rare. The average selection time for every new record is 10 minutes.

The second test was a synchronization test. We selected 50 frames from the stream and we observed the dependency of the width of the pit on the level of the noise, and the noise level where the monitoring algorithm cannot synchronize to the frame. The result of this test is shown on Figure 6.

FUTURE TRENDS

Carrying out tests of various pattern recognition methods on live audio broadcasts showed that the success of identification process depends on the proper selection of the representative short segment. The position where this representative segment can be extracted is determined by the recognition algorithm. The selected references must be non-correlated to avoid false alarms.

The proposed method EMESE is an example of the Internet-oriented pattern recognition algorithms, which can be used for content-based search in media streams and files. The performed experiments checked how a monitoring system can synchronize to the stream under various conditions. The measured results proved the efficiency of the method however, more research efforts are necessary to reach a comprehensive content-based search method.

The Bark-spectrum as the base for the audio feature carries the possibility to easily process sampled audio with different sampling properties, since it hides the frequency resolution of the used Fast Fourier transform. However,

this generalization indicates further investigations to define the usable sound-print size and comparison thresholds. The reason for that is the unequal size of feature's frequency bands defined by the sampling frequency.

The system is designed to quickly change the parameters and thresholds for investigating the behavior of longer sound-prints, like a whole record. The idea is the application for automatic identification of even corrupted audio files.

CONCLUSION

The main directions of searching in shared file storages, especially the novel method based on the reference selection has been described. The proposed method was realized for an existing real-time recognition algorithm that was used on live audio streams to identify specific sound signals. The selection algorithm takes the properties of the recognition algorithm into account. The algorithm was tested on Internet media streams with a prerecorded signal set and we reached good results. Further tests should be carried out to determine the exact effect of the input noise level on the width of the distance-pit.

The light-weight pattern recognition methods presented earlier has proved that in Internet-wide environment it is possible to realize a fast recognition method, which does not require extraordinary CPU time or other computing resources. The increasing demand for searching in various media contents involves the popularity of the content-recognition tools. However, there are results, but further researches must be carried out in this field.

KEY TERMS

Application Level Network (ALN): The applications, which are running in the hosts, can create a virtual network from their logical connections. This virtual network is also called ***overlay*** (*see later in the section*). The operations of such software entities are not able to understand without knowing their logical relations. The most cases this ALN software entities use the ***P2P model*** *(see later in the section)*, not the ***client/server*** *(see later in the section))* one for the communication.

Audio Signal Processing: It means the coding, decoding, playing, and content handling of the audio data files and streams.

Bark-Scale: A non-linear frequency scale modeling the resolution of the human hearing system. One Bark distance on the Bark-scale equals to the so-called critical bandwidth that is linearly proportional to the frequency under 500Hz and logarithmically above that. The critical bandwidth can be measured by the simultaneous frequency masking effect of the ear.

Client/Server Model: A communicating way, where one host has more functionality than the other. It differs from the ***P2P model*** (*see later in the section*).

Manhattan-Distance: The L_1 metric for the points of the Euclidean space defined by summing the absolute coordinate differences of the two points (|x2-x1|+|y2-y1|+…). Also known as city block or taxi-cab distance; a car drives this far in a lattice-like street pattern.

Overlay: The applications, which create an ***ALN*** *(see earlier in the section)* work together, and they usually follow the ***P2P communication model*** *(see later in the section)*.

Pattern Recognition: It means the procedure of finding a certain series of signals in a longer data file or signal stream.

Peer-to-Peer (P2P) Model: A communication way where each node has the same authority and communication capability. They create a virtual network, overlaid on the Internet. Its members organize themselves into a topology for data transmission.

Synchronization: It is the name of that procedure, which is carried out for finding the appropriate points in two or more streams for the correct parallel playing out.

Context-Aware Framework for ERP

Farhad Daneshgar
University of New South Wales, Australia

INTRODUCTION

Like many existing ERP models (e.g., Podolsky, 1998; Van Stijn & Wensley, 2001), the OOAB framework is also based on a widely accepted assumption that a corporate-wide information system consists of a set of potentially related subsystems; and as a result, information flows among these subsystems must be identified, and required resources planned, using an appropriate ERP methodology. However, up until now there existed no formalised framework that facilitates sharing of contextual knowledge in ERP processes. A unique attribute of the OOAB framework is that it treats ERP processes as a collaborative processes where various roles/actors collaboratively perform tasks in order to achieve a common overall goal. An object-oriented framework is presented in this article that facilitates sharing the contextual knowledge/resources that exist within ERP processes. Context is represented by a set of relevant collaborative semantic concepts or "objects". These are the objects that are localised/contextualised to specific sub-process within the ERP process.

BACKGROUND

From a purely object orientation perspective, a collaboration is defined as "the structure of instances playing roles in a behavior and their relationships" (OMG, 2001). The behaviour mentioned in this definition refers to an operation, or a use case, or any other behavioural classifier. This article provides an overview of a framework for analysing awareness requirements of the actors in ERP systems using an object-oriented awareness-based approach. A similar study was also conducted for developing a new version of this framework that takes into consideration the specific characteristics of virtual communities (Daneshgar, 2003). The proposed approach specialises the notion of collaboration and extends it to the ERP processes. This has roots in the activity network theory (Kaptilini et al., 1995) and is based on the fact that all ERP processes involve *multiple roles performing various tasks* using appropriate artefacts (e.g., departmental sub-systems, databases, etc.) in order to achieve both their local as well as the overall organization-wide goals. Conceptually speaking, this will justify a frame-based object-oriented approach to analysis and design for ERP processes (Turban & Aaron, 2001). The conceptual model of the proposed framework is made of the following components:

- a set of collaborative semantic concepts including roles, the tasks that these roles play within the process, and the artefacts that these roles use to perform various tasks within the process, and
- relationships among these semantic concepts.

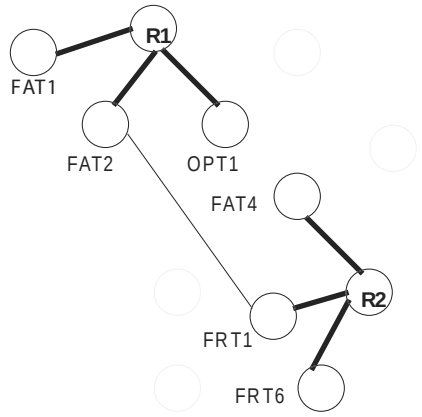
This conceptual model can then be mapped directly to an object model and be used as an analytical tool for identifying awareness requirements of the actors within the ERP process. The fact that ERP is treated as a collaborative process calls for a mechanism for maintaining awareness requirements of the actors involved in this collaboration. Furthermore, due to its object orientation, the framework is capable of encapsulating all complications and dependencies in sub/local processes within individual tasks as well as resources required to perform those tasks, further relieving the ERP management and the associated software.

OOAB FRAMEWORK

A domain-specific conceptual model of a hypothetical ERP process that resembles an object diagram is shown in Figure 1. Use of a domain-specific conceptual model instead of a straight object diagram is justified by the fact that the ontological foundation of the framework prevents growth of the objects and relationships indefinitely, and as a result using an object model may hide such ontology. In Figure 1 there are two roles: R1 and R2; six tasks: FAT1, FAT2, OPT1, FAT4, FRT1 and FRT6 (all shown by circles). It also shows various resources by straight lines connecting tasks and roles. These lines represent rich ontological relationship between a pair of semantic concepts. Each task object requires certain resources for achieving its local/departmental goal or purpose (called *process resource*), as well as certain other resources for achieving the collaborative organization-wide goals of the ERP process (called *collaborative resource*). In Figure 1, a line connecting a role vertex to a task vertex is a process resource, whereas a line connecting two tasks together is a collaborative resource.

According to the framework, effective knowledge and/or resource exchange among actors is closely related to the level of awareness as defined in the awareness model that each

Figure 1. A representation of an ERP collaborative process model



actor possess about the ERP process. These awareness levels are defined in terms of the collaborative semantic concepts used within the ERP conceptual model as shown in Figure 1. Details of the proposed methodology for identifying awareness requirements of actors in ERP process follow:

STEP 1. Develop an ERP Process Model similar to that in Figure 1.
FA: Financial Accounting sub-process/task
OP: Order Processing sub-process/task
CS: Customer Service subprocess/task
FR: Financial Reporting subprocess/task
T1…T6: <appear as postfixes indicating various tasks>

STEP 2. Measure the actual levels of awareness for each role on the process model using the awareness model. In order to measure this level of awareness the actor must be exposed to all the objects on the ERP process model, and be asked to identify those objects that s/he is aware of. Selected pool of objects are then used by an awareness model in order to arrive at a number reflecting the actual level of awareness associated with that role.

STEP 3: The actor's actual level of awareness is then is compared against the required level of awareness; the latter is a parameter, provided by the task that the actor performs within the process. The difference between these two levels of awareness constitutes the collaborative requirement of the actor for that particular task. Factors that affect the required level of awareness of a task include organisational culture, and the nature of task itself. Without possessing such awareness level the actor will not be able to collaborate with others optimally. A comparison between the actual level of awareness of the actor and the required level of awareness of the task will result in one of the following two outcomes:

1. The task's required level of awareness is either equal to, or less than, the role's actual level of awareness. This indicates that the role is qualified, or has sufficient level of awareness for taking up the task, and the OOAB framework cannot enhance collaboration any further.
2. The task's required level of awareness exceeds the role's actual level of awareness. This indicates potential for enhancing collaboration. To do so it will be necessary to put the missing objects within the focus of the actor in a way that s/he can perceive these objects, receive required awareness, and perform that particular task successfully. This will require additional resources in order to enhance the actor's awareness level. These required resources may include one or more of process resources, collaborative resources, and other communication resources, for example resources that provide awareness about other roles and other tasks within the ERP process.

IMPLEMENTATION ISSUES

One method for integration of the OOAB framework with the existing ERP systems is by developing an organisational infrastructure that provides business intelligence to the users of the ERP system by maintaining contextual knowledge that these users/actors require for effective collaboration within the ERP process. The writer is in the process of developing an expert system that provides expert advice for answering the following two specific questions:

(i) In terms of awareness requirements, is an actor capable of performing certain tasks within the ERP process?
(ii) If not, what objects need to be put within his/her focus in order to enable the actor to perform the task properly?

The ERP collaborative process of Figure 1 consists of 15 objects, including two roles, six subprocesses/tasks, six role artefacts and one task artefact. Within each of these objects is encapsulated all relevant contextual knowledge as well as pointers to relevant objects as determined by the process map. Each task possesses a set of attributes and relevant methods; and each method consists of a set of steps that corresponds to codes describing a codified knowledge. These attributes will indicate to which subprocess the task belongs to. This will enable an actor to play various roles within different subprocesses without being permanently linked to a specific subprocess, a factor that can remove some complexities in existing ERP implementations.

FUTURE TRENDS AND CONCLUSION

It was shown that the OOAB methodology can enhance existing ERP systems by formally adhering to a framework that facilitates knowledge sharing among various actors in ERP processes in the following ways: This article introduces a novel concept for measuring collaboration in ERP processes; a concept that is non-existent in current ERP literature. This measure is based on a conceptual model of collaboration that can be directly transformed into an object model. This measure is used to determine required level of awareness of various actors within the ERP process. As far as the author is aware, this is a novel concept that results in treating the organisation-wide ERP process as a single collaborative process that consists of multiple sub-processes, called tasks, that are linked through formal artefacts. These artefacts utilise certain resources in order to carry/deliver contextual collaboration knowledge that is required for effective collaboration. Knowledge sharing occurs through various interaction acts such as exchanging the artefacts, creation of artefacts, and updating artefacts. As a result of its object-orientation and collaborativeness of the ERP process, and contrary to the existing process-based ERP frameworks that assume fixed roles within the ERP process, the OOAB framework enables an actor to assume multiple roles within different ERP subprocesses. This will provide another avenue for sharing contextual knowledge for sub-processes/tasks. The interdependency issue among various subprocesses is also simplified by encapsulating this knowledge within the task objects and relevant artefacts.

By reducing granularity of the collaborative process model, the same model representation can be applied for internal representation of the subprocesses, allowing smooth transition of modelling components from subprocesses to the ERP process, and vice-versa. This in turn will reduce much of the existing complexities in designing ERP systems where the system is permanently responsible to maintain such linkages, rather than delegating such responsibility to various objects within the system.

Work is in progress for incorporating communication and coordination dimensions to the existing collaboration dimesion in order to provide complete analysis of groupware systems that maintain awareness requirements of the actors within the ERP processes (Daneshgar et al., 2004; Sundarraj et al., 2002).

KEY TERMS

Action: A sequence of goal-directed steps.

Actual Level of Awareness: The awareness that a role actually possesses within the ERP process. Actual awareness is represented by an integer number ranging from zero to four, representing various levels of awareness. Actual awareness is a property of an actor who performs one or more roles within the ERP process.

Awareness: A specialised knowledge about the objects that leads an actor to an understanding of various aspects of the ERP collaborative process. It is defined and measured in terms of the semantic concepts (*task, role, process resource,* and *collaborative resource*) used in the map.

Awareness Model: A model that represents various levels of awareness. Level-0 awareness consists of the concepts that lead an actor to knowledge about all the tasks that an actor performs within the process.

Example: In Figure 1, level-0 awareness for the role "R1" is a sub-graph that consists of the tasks "FAT1," "FAT2," and "OPT1," as well as the process resources shown by thick lines connecting "R1" to these tasks. Level-1 awareness is a subgraph that consists of the R1's level-0 awareness subgraph, plus awareness about the concepts that leads an actor to knowledge about other related roles within the process. In Figure 1, level-1 awareness for the role "R1" is the sum of its level-0 awareness subgraph, plus one collaborative resource linking "FAT2" to "FRT1," plus "FRT1" itself, plus the process resources shown by thick lines connecting "FRT1" to "RT2," plus "RT2" itself. A role's level-2 awareness is its level-1 awareness, plus an awareness about all other (or, the rest of) roles within the process. Level-2 awareness is knowledge about the human boundary of the process. In Figure 1, there are no other roles that have not been known to the R1 already, and therefore the R1's level-2 and higher levels of awareness are irrelevant and identical to its level-1 awareness. However, for the sake of completeness, their definitions are presented.

A role's level-3 awareness is its level-2 awareness, plus awareness about all the interactions (represented by the process resources used/shared) that occur between any two roles within the process. And finally, level-4 awareness is the highest level of awareness that a role can have in any ERP process. It is defined as the knowledge about how everything fits together to form the ERP process. In other words, having this level of awareness will bring all the remaining concepts used in the ERP process model of Figure 1 within the focus of the role.

Collaborative Resources: An object representing a resource used/shared/exchanged by a pair of collaborating roles in order to perform certain simple tasks in collaboration with one another.

Process Resource: An object that represents a resource used by a role in order to perform a task in isolation from other tasks.

Required Level of Awareness: A property of a task. It represents the expected awareness from any actor who performs the task. Its value also ranges from 0 to 4.

Role: A set of norms expressed in terms of obligations, privileges, and rights assigned to an actor.

Task: An object with a set of attributes and actions to achieve a specific process goal using certain resource called *process resource.*

Contingency Theory, Agent-Based Systems, and a Virtual Advisor

John R. Durrett
Texas Tech University, USA

Lisa Burnell
Texas Christian University, USA

John W. Priest
University of Texas at Arlington, USA

INTRODUCTION

In this article, we investigate the potential of using a synthesis of organizational research, traditional systems analysis techniques, and agent-based computing in the creation and teaching of a Contingency Theoretic Systems Design (CTSD) model. To facilitate understanding of the new design model, we briefly provide the necessary background of these diverse fields, describe the conceptualization used in the integration process, and give a non-technical overview of an example implementation in a very complex design environment. The example utilized in this article is a Smart Agent Resource for Advising (SARA), an intelligent multi-agent advising system for college students. To test all of the potential of our CTSD model, we created SARA utilizing a distributed instructional model in a multi-university, multi-disciplinary cooperative design process.

Just as a dynamic task environment forces an organization to compress its management structure and to outsource non-core activities in order to become flexible, a dynamic software development environment forces designers to create modular software. Until now, cooperative development paradigms were too complex to facilitate inter-organizational cooperative development efforts. With the increasing popularity of standards-based Web services, the development of pervasive computing technologies, and the advent of more powerful rapid application development languages and IDEs, this limitation has been removed. Our purpose in this research is twofold: first, to test the viability of using Contingency Theory (CT), a sub-discipline of Management Organizational Theory (OT), in an agent-based system; and second, to use these new technologies in creating a distributed instructional model that will allow students to interact with others in diverse educational environments. As an example implementation, we create a virtual advisor that will facilitate student advising in distributed environments.

In the following sections, we outline the background theories involved in the conceptualization of our design model. We start with the shifts in systems design techniques and how CT can be applied to them and to various Multi-Agent Systems (MAS) to allow Contingency Theoretic Systems Design (CTSD). Once the necessary background is in place, we briefly discuss our new eLearning approach to cooperative distributed education. Finally, the structure of the SARA is discussed.

BACKGROUND

Multi-Agent Systems

Agents and communication protocols form the basic components of a multi-agent system. Agents exchange messages according to a protocol of expected messages delivered in a communication language in which the message content and format adhere to a shared standard. Individual agents make decisions, which may include contacting other agents for information, and perform processing to satisfy their goals

An agent is commonly defined as a program or collection of programs that lives for some purpose in a dynamic environment and can make decisions to perform actions to achieve its goals. In other words, agents are goal-based programs that must deal with changing access to resources, yet run continuously. Like the best administrative assistants, agents know and adapt to their master. Individual agents may be conceptualized as having beliefs, desires, and intentions that can communicate with other agents to satisfy their goals. Multi-agent systems are those in which multiple agents (usually) cooperate to perform some task. Agents may be independently developed and allow the decomposition of a complex task into a collection of interacting agents that together solve some problem. It is not necessary that an individual agent "understand" the overall system goals or structure.

Agent communication can be viewed at four distinct levels. The first level is the expected protocol for exchanging sequences of messages, like a script. For example, when negotiating, the parties expect bids to be offered, rejected, and counter-offered. The second level relates to the content or mean-

ing of the messages. To enable inter-agent communication, an ontology is created. Examples of such concepts are things, events, and relationships. At the third level, a representation language defines the syntax for structuring the messages; The Knowledge Interchange Format (KIF) (Gensereth & Fikes, 1992) is one example. At the fourth level, an agent communication language (ACL) such as the Knowledge Query and Manipulation Language (KQML) or the Foundation for Intelligent Physical Agents (FIPA) ACL (Labrou, Finin, & Peng, 1999), defines message formats and message delivery. An example KQML message, in Sandia Lab's Java Expert System Shell (JESS) (Owen, 2004), that shows how an agent registers a service is shown below:

(register :sender student :receiver advisor :reply-with msg1 :language JESS :ontology SARA :content '(MajorCourses: Compliance Check Hours))

Just as human systems created to achieve complex goals are conceived of as organizations, multi-agent systems can be conceptualized as "organizations of agents". Individual components, whether human employees or software agents, need to be managed, guided toward a constructive goal, and coordinated toward the completion of the necessary individual tasks. In "empowered organizations", lower-level employees have the knowledge and authority to perform many tasks without the intervention of superiors. This conceptualization allows us to use well-established research from management organization theory (and Contingency Theory in particular) in creating guidelines for the design of agent-based systems.

ORGANIZATIONAL THEORY (OT)

While much of the background concerning OT is explained in the main chapter below, the following is a brief overview of the relevant research trends. OT examines an organization's structure, constituencies, processes, and operational results in an effort to understand the relationships involved in creating effective and efficient systems. A major division of OT, Contingency Theory (CT), postulates that no organization operates without constraints from environmental, personnel, technological, and informational influences (Andres & Zmud, 2001). This relationship is explained by the information processing theory (IPT) (Galbraith, 1973). IPT postulates that the more heterogeneous, unpredictable, and dependent upon other environmental resources a task is, the greater the information processing that the organization must be able to do in order to successfully accomplish it. As complexity and unpredictability increase, uncertainty increases due to incomplete information. As diversity of processes or outputs increases, inter-process coordination requirements and system complexity increase. As uncertainty increases, information-processing requirements increase. The basic premise of IPT is that the greater the complexity and uncertainty in the tasks in an organizational system, the greater the amount of information that the system must process (Galbraith, Downey, & Kates, 2001). A basic premise of our research is that this relationship is also true for information systems (Avgerou, 2001).

MAIN THRUST OF THE ARTICLE

Multi-Agent System Architectures Using CTSD

Contingency-theoretic system development (CTSD) adapts CT and IPT to the development and maintenance of software systems (Burnell, Durrett, Priest et al., 2002; Durrett, Burnell, & Priest, 2001, 2003). A business can organize employees in a number of different ways, for example by function or by project, and reorganize as the business environment changes. Software systems can benefit from this flexibility as well. The CTSD design approach is focused on design for maintainability, a crucial requirement for complex, dynamic systems.

Agent-based architectures are a means for structuring software systems that adhere to Contingency Theoretic principles. Each agent is viewed as an employee that has specific capabilities, responsibilities, and knowledge within an organization. Agents, like employees, are grouped into departments, as needed, to best satisfy the goals of the organization. Agents can communicate peer-to-peer within and across departments, and manager agents resolve conflicts and make resource allocation decisions.

Tightly interrelated tasks are grouped into one or more agents. Each of these groupings is referred to as a "software team", and parallels a department of employees that perform roughly equivalent jobs. For example, a set of agents that each handle one type of course requirement (e.g., lab, art appreciation) may be grouped into a team, where communication can occur quickly between these agents and with a "manager" agent that can resolve conflicts, exceptions, and course-independent tasks. An example agent in our system is encoded using JESS rules to check that student preferences (e.g., for afternoon courses) and constraints (e.g., no more than 12 hours per semester) are satisfied. Another agent offers heuristic advice as an actual advisor might. For example, a student may be able to enroll in 17 hours of math and science courses, but this may be strongly advised against, depending on the student's GPA and perhaps other factors.

Each agent in a multi-agent architecture has specific tasks to perform and communications requirements. Once an ontology and agent communication language has been specified, agents can be designed independently and integrated into the system to progressively add capabilities. Using CTSD principles, tasks that are dynamic and shared are grouped into support agents to enhance maintainability of the system. The

primary architectural decision is to separate knowledge based on two criteria: the degree of dynamicism and the degree of complexity. Dynamicism is exemplified by how frequently knowledge is expected to change over time, while complexity determines how abstract that knowledge is. A simple example describing the latter is the fact that "a student must be a junior with a GPA greater than 3.0 in all math and science courses". Dynamicism within the SARA domain was determined by advisor interviews, and analysis of degree requirements changes over time at three universities, both large and small and private and public.

Using the above CTSD conceptualizations in previous research (Burnell, Priest, & Durrett, 2002, 2003; Durrett, Burnell, & Priest, 2000), we have developed and tested the following CTSD guidelines for creating MAS:

1. *Describe business activity and identify tasks*: Allow management and developers to refine the overall purpose of the software being designed.
2. *Determine task predictability*: Since a basic premise of CT is that the control structure of a business process must match the environment in which it operates, we must identify the predictability of each task.
3. *Assign tasks to employees*: Once the level of predictability has been estimated for each task, the granularity of the employees being created can be determined and component designs finalized.
4. *Group employees into teams*: As with human organizations, our employees can be grouped along any of several dimensions, including task, workflow, product, manager, or communication requirements, as required by the operating environment.
5. *Identify communications needs:* Once teams are determined, the communication requirements of individual employees, and of teams, can be determined.
6. *Construct management groups*: In software systems operating in a dynamic environment, management is required only when employees are unable to handle events

.

We show the application of these guidelines in a distributed instructional environment in a multi-university, multi-disciplinary cooperative design process.

Multi-Agent System Architectures Using CTSD

Our example implementation of the above CTSD guidelines is SARA, an interactive tool intended to aid in the planning, scheduling, and advising process to complete a college student's degree. SARA, along with the instructional environment in which it was created, is described very briefly next; for more detailed information on SARA or our distributed instructional model please see any of the Burnell, Durrett, or Priest references in the reference section.

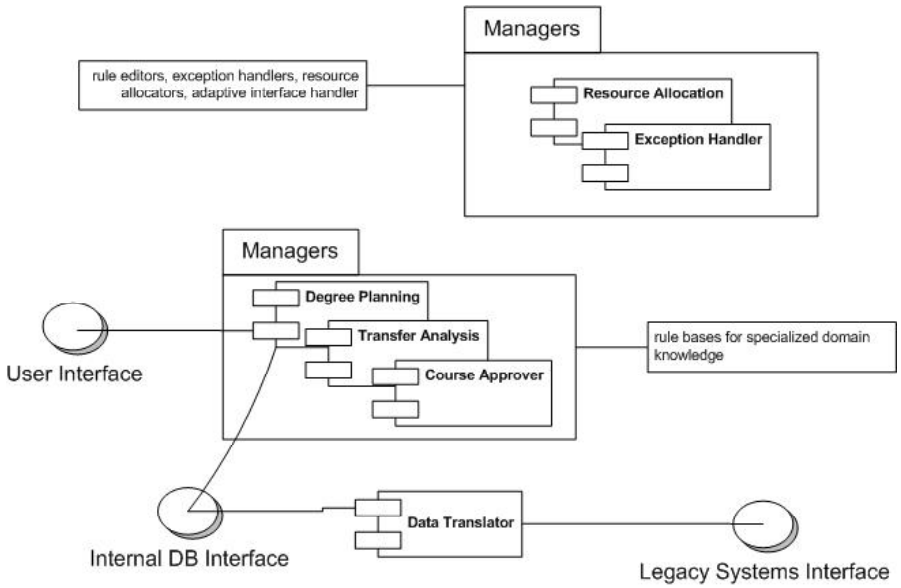
As described previously, CTSD is most effective in complex dynamic environments. To create this environment, SARA was designed in a collaborative education project among three major universities, the University of Texas at Arlington (UTA), Texas Christian University in Fort Worth (TCU), and Texas Tech University in Lubbock (TTU). Teams of students at UTA are in industrial engineering and software design courses. The TCU students are in computer science and have had coursework in artificial intelligence, and the TTU teams are in courses that study application servers and server-based JAVA databases. In creating SARA, responsibilities have been purposefully segregated to create the necessity of interdisciplinary cooperation. Current trends in industry are toward outsourcing in many major Fortune 500 companies (Fox, 2004). In order to do this effectively, the designer and the coders must communicate in an online forum and adapt to rapidly changing conditions. Therefore, we have attempted to emulate this CTSD type environment through our interdependent classes. Also, previous research has shown that a major hurdle to software development is the communication among the programmers, the users, the executives, and the domain experts. A major component of successful software development is overcoming this communication hurdle. We have attempted to emulate these trends in the design of SARA.

Design of SARA

SARA gives students the resources and knowledge to troubleshoot issues with their current degree plan. A profile of student preferences and a transcript of completed courses allow the system to generate customized degree plans. Students can also manually customize degree plans and create schedules course-by-course that are checked for requirements compliance. Errors in plans and schedules are explained so that the student can make corrections. Advisors can review degree plans on the system and send comments back to the students, without their having to physically meet. Thus, some of the most time consuming tasks in advising are eliminated (Priest, Burnell, & Durrett, 2002).

The current prototype of SARA that is depicted in the following diagrams and text is the work of several semesters work at all 3 universities. As a result of these cooperative efforts, a basic system prototype (shown in Figure 1) has been developed, initial system databases have been designed and implemented (shown in Figure 2), and smart user interfaces that utilize MAS (shown in Figure 3) were created. The user interfaces were designed primarily by the TCU teams, the basic CTSD-based analysis and thus overall system requirements were created by the UTA students, and the backend database design and application server support were provided by the TTU students.

Figure 1. Prototype architecture (from Priest et al., 2002)



The architecture depicted previously (in Figure 1) follows the CTSD guidelines discussed. Given the dynamic, complex environment in which the system will operate, we have segregated tasks into individual software teams and empowered the constituent agents with as much decision making ability as possible. Exceptional situations are handled by "manager agents" and by other exception handlers.

The prototype SARA database module depicted next (in Figure 2) was created to provide the flexibility required by the MAS system architecture. Initial implementations are on MySQL, and migration to IBM DB2 to provide for more system automation is planned.

The MAS-based user interfaces (one example of which is depicted in Figure 3) were created using data from TCU's course schedule. They allow students to do most of the routine work in degree planning, freeing up advising time for more meaningful discussions. Once proposed plans are created, they can be evaluated and approved off-line.

FUTURE TRENDS

Our future plans include broadening the scope of the project just described using an open source software development model. Our intent is to research the potential in open source design models for relieving some of the coordination issues inherent in a resource limited project such as ours. We hope that this new model will relieve some of the faculty coordination required and still allow (or force) students to cooperate with each other even though in different disciplines and locations.

CONCLUSION

In the project just described, we have developed a multi-agent system for college advising using the contingency-theoretic system development (CTSD) process. Multi-disciplinary teams of students at three universities were employed to create the system. Once the ontology and agent communication language are defined, individual agents are constructed incrementally. The resulting system is a hierarchy of intelligent agents that together provide support for course scheduling and degree planning and that are adaptable to changing environments. The CTSD process applied to the creation of intelligent multi-agent systems results in maintainable systems operating in complex, dynamic domains. As such domains become increasingly automated, training and support tools for distributed CTSD will be needed. We have created an approach for such training that has been successfully applied to SARA and other projects over the last three years. Support tools will need to be created that capture not only the system design, but provide knowledge-based analysis of designs based on the principles we have defined.

KEY TERMS

Contingency Theoretic Software Development (CTSD): A new model for MAS design using tenets from CT and IPT. The CTSD design approach is focused on design for maintainability, a crucial requirement for complex, dynamic systems.

Contingency Theory (CT): A research branch of organizational theory that suggests that an organization's structure reflects its adaptation to the environment in which it operates. Hierarchical organizations operate best in stable, simple environments while flat, team-based organizations are better adapted to dynamic, complex task environments.

E-Learning: Any form of education or training that utilizes online media and remote connectivity for all or part of its curricula. This model includes both purely online courses and those in brick-and-mortar universities facilitated by email, the Internet, newsgroups, or chat.

Information Processing Theory (IPT): An explanation for the organization structure-environment relationship suggested by CT. IPT suggests that the information processing requirements dictated through interactions with the environment force certain structures in order to be efficient and effective.

Multi-Agent Systems (MAS): Multi-agent systems are those in which multiple agents (usually) cooperate to perform some task.

Ontology: An ontology is a well-defined set of concepts that are ordered in some manner to create an agreed-upon vocabulary for exchanging information.

Smart Agent: A program or collection of programs that lives for some purpose in a dynamic environment and can make decisions to perform actions to achieve its goals. Individual agents may be conceptualized as having beliefs, desires, and intentions that can communicate with other agents to satisfy their goals.

Software Team: Groups of agents which have tasks that are tightly interrelated; these teams roughly parallel a department of employees.

INTRODUCTION

"According to the Standish Group CHAOS Report 2003, each year in the USA there are approximately 175,000 projects in IT application development that spends $250 Billion. Among these, 31.1% of projects will be cancelled, 52.7% of projects will cost 189% of their original estimates, only 52% of required features and functions make it to the released product, and time overruns occur in 82% of the cases. In financial terms $55 billion dollars is wasted in these projects." (Madpat, 2005).

This chapter suggests an innovative platform to analyze software projects in order to overcome the difficulties that are shown through the statistics. The first layer of the platform is based on costing theories in order to handle the cost overruns. At the second layer are the project management tools, and on the third layer is the software engineering. The last two layers give the needed information on the project scope and the development efforts. Connecting those three layers gives a better perspective on the projects, which is the best platform for decision making.

Cost management of a project is defined by the PMBOK (project management body of knowledge) (PMI, 2004) as one of the nine core activities of projects management. This activity is defined as an assembly of processes that include planning, estimating, budgeting, and controlling of project costs so that the process will be executed within the budget framework that has been designated for it. However, although it defines costing as a core activity, it does not provide the methodologies for the application mode of the costing (Kinsella, 2002).

The challenge in project management is described as "the effective allocation of resources within the framework of time, cost and delineation constraints that are balanced against the quality demands and nature of relations with the customer" (Kerzner, 2003. p.5). Hence, cost management should be viewed as part of the project management challenge.

Software projects can be analyzed through software engineering tools, CASE (computer-aided software engineering tools), that assist in the analysis and characterization of the software project and in the evaluation and measurement of the work productivity in the project.

Cooper and Kaplan (1998) analyze the integration between costing systems and operational systems. The integration that Cooper and Kaplan introduce, like the classic costing methods, does not provide a response to the project structure and the features of a software project (such as estimation difficulties, risk management, and lifecycle). This chapter recommends integrating costing systems and operational systems of software projects; the projects management tools and the software engineering tools.

The data presented highlights the significance of costing and the difficulties in costing and estimating software projects. These difficulties derive both from the implementation's limitations of a costing solution in an intricate and changing technological environment (Wouters & Davila, 2004) and from the unique features of projects in general and software projects in particular. The characteristics that obstruct the solving of the costing problem include the project lifecycle that leads to changing work capacities over time (Kerzner, 2003), uncertainty levels and exposure to risk (Rajkumar & Rush, 2000), and a difficulty in defining an evaluation of the project scope.

Given all this, the conclusion that becomes clear is that there is an objective difficulty in establishing an accurate cost framework for the software project, especially prior to its detailed planning. Such planning is executed through software engineering tools. Those tools assist the analysis of the software project and the estimation and measurement of the project's work productivity (Liong & Maciaszek, 2005).

We have seen that cost management within the software project framework requires the combining of software engineering with the involvement of the development team. However, the development team's ability to be fully involved in the cost management process is limited. The develop-

ment team and projects managers function in monitoring the changing technological implementation throughout the project, and in the knowledge management of the project team. Hence, the amount of remaining time for the costing activity is small. Moreover, in order to accurately define the cost structure, there is a need for a costing model that includes, in addition to the direct costs of the project, also overhead costs in the organization. Project managers that work on the engineering and technical aspects of the system struggle with objectively defining and applying such a model (Wouters & Davila, 2004).

Given this, the chapter presents a model that allows the expression of each and every one of the cost's components (direct, indirect, risk, competitiveness), while it links three areas: project management, software engineering, and managerial accounting. The model will enable not only a retrospective analysis of the economic performances of the project/projects portfolio/software house, but also an in-advance evaluation of costs, economic feasibility, and economic risk level of the project/projects portfolio. The model introduces a new approach in the area of software project costing.

THEORETICAL BACKGROUND

This section presents the theoretical and practical foundation for the research model from several aspects. Our objective is to integrate models of software projects with three disciplines: software engineering, project management, and managerial accounting.

The first section reviews the foundation for the integration between the financial systems that serve the classic models of costing and other relevant systems.

The second section reviews the link between software engineering and project management. This section will emphasize the importance of the association between software engineering and project management tools as a managerial and costing necessity in the software project (or projects portfolio). In the third section, costing aspects are introduced and integrated. A basic integrative model for this association will be displayed, and we shall examine the extent of its compatibility with the costing need.

INTEGRATED COST SYSTEMS

In order to make important managerial decisions, detailed costing information is necessary. Detailed costing information is expected to include all types of costs that are required for manufacturing a product or providing a service. These are data that are based on financial systems and contain, in practice, costs that derive from the firms detailed income statement (and backup schedules). These data include the historical execution data and future estimations and forecasts (Needy, 2002).

Otley (2001) proposes an integration of accounting and financial data for obtaining execution and evaluation measures. It is suggested that these measures will be supplemented by information that is not financial. The need of nonfinancial information has evolved in recent decades out of the comprehension that the costing analysis is not sufficient for it being an outcome analysis: this has created the need for performance measurement. Such measurement includes the accounting information and costing logic with the incorporation of figures that are not financial. Various models (such as balanced scorecard) deal with performance measurement (Needy, 2002), and provide an additional layer for the need to execute integration between financial and operational systems.

Williams (2004) supports the integration approach in accordance with the viewpoint that a modern accounting system is supposed to supply a framework for strategic management of the company's resources. In order to realize this conception, Williams proposes a multidimensional construct that clusters information from the company's systems on customers base, activity areas, and more, for the purpose of forming an accounting system that facilitates planning, improvement, and control, analysis and regulation of resources, and enhancement of profitability. Such a system is based on integrative information from a number of systems or from the arrays DWH (data where house)/BI (business intelligence) in five areas: costs, assets, quality/service, time, and outputs.

The pioneers of the combining of financial and operational information are Cooper and Kaplan (1998), who developed the method of activity based costing (ABC) suggest, in light of the technological development of information systems, to define the integration between operational and financial systems for the purpose of building an accurate costing model.

SOFTWARE ENGINEERING AND PROJECT MANAGEMENT

The success of a software project depends on five software engineering areas that are related to each other: the development of the lifecycle of the software, process management, the model's configuration and language, software engineering tools, and project planning (Liong & Maciaszek, 2005. p.3). The combining between the formal tools of the software engineering and project management processes in its different stages has been proved by research as to result

in a positive contribution to the efficacy of the project, and as an improver of the adherence to costs, technical requirements, and the schedules that were allocated to the project (Verma & Barker, 2003). In this study, the researchers argue that following the combination of the areas, it is difficult to separate the contribution of the software engineering from the total contribution. Hence, an initial support may be assumed for the essentiality of the association between the areas. The integration's foundation that was displayed may be extended since it is impossible to separate the costing activity, which deals with financial values, from the total managerial activity, thus, also for the purpose of cost management (cost execution), the combination between software engineering and project management must be considered.

The combining of the areas is described as a comprehensive view of the software development process with the description of the products, resources, schedules, budgets, and the organizational structure that sustains the project. Such a framework provides not only the stages in the planning of the project's monitoring and controlling, but also strategies for managing project's risks (Rajkumar, 2003).

As an anchor for the costing model that will be presented in the study, a model that establishes, in a feasible way, the link between software engineering and the project manager's activities was chosen (Gelbard, Pliskin, & Spiegler 2002). The basis of this study is the mapping between the software engineering, which is implemented by CASE tools and project management tools. The mapping model allows a shift from an engineering description of the realized project, for example, as DFD (data flow diagram), to a description that includes also the project's schedule, which is usually portrayed through Gantt charts. The advantages of such mapping are as follows:

- The evaluation of the effort and costs over time while directly drawing from the engineering basis.
- Extended analysis of costs, time, and resources that also includes engineering parameters, such as complexity and demanded quality.
- Generic fittingness to every type of software project.
- A dynamic controlling of the project's process and evaluations of execution against the planning.
- The ability for "drill down" based both on functionality and intermediate products and on the level of the system's design.
- Integration with the development teams that allows reliable and accurate controlling and estimation.

Despite the model's advantages, it does not encompass project layers, such as an explicit allusion to the project's lifecycle and its risk management (including the cost of the risk). Moreover, the response is given at the single project level and does not reflect effects of project portfolio management, such as indirect costs, transportation of resources between projects, and the like.

On the other hand, the model's application allows an engineering and project insight in terms of time and cost of the project's constituents. Therefore, the gripping on to the model's advantages creates groundwork for the development of a costing model in software projects that will be built on the foundation of integration between the different areas.

COST MODELS AND METHODS

Detailed costing information is expected to include all types of costs that are required for manufacturing a product. Data based on financial systems, which contains costs, derived from the income statement and the estimation of the company's capital and assets, enclosed the historical execution data and future estimations and forecasts (Needy, 2002). Williams (2004) supports the integration approach according to the conception that a modern accounting system is supposed to supply a framework for strategic management of the company's resources. In order to realize this conception, Williams proposes a multidimensional construct that clusters information from the company's systems on customers base, activity areas, and more, for the purpose of forming an accounting system that facilitates planning, improvement and control, analysis and regulation of resources, and enhancement of profitability. Such a system is based on integrative information from a number of systems, or from the arrays DW (data warehouse), BI (business intelligent) in five areas: costs, assets, quality/service, time, and outputs. The pioneers of the combining of financial and operational information are Cooper and Kaplan, who developed the method of activity based costing (ABC) at the end of the eighties. Cooper and Kaplan (1998) suggest, in light of the technological development of information systems, to define the integration between operational and financial systems for the purpose of building an accurate costing model.

In light of this, establishment of integration conception required definition not only of an enterprise costing model, but also definition of interfacing between the different areas and systems; that is, interface between SE aspects-tools, financial aspects-tools, and PM tools.

Cost management is a term that is used for a wide description of short-term and long-term managerial activities that are involved in planning and controlling of costs (Horngren, Dater, & Foster 2000). Table 1 presents variety aspects of costing model in a technological projects environment.

Costs analysis within the framework of technological environment must be carried out with the understanding of

Table 1. Aspects of a costing model in a technological project environment

	Aspect	Description	Difficulties
1.	**Planning**	Costs estimation of the project and for each resource in the projects portfolio	Defining direct and indirect resources and their costs
2.	**Controlling**	Costs analysis for each project and executed task	Attributing in-reality-costs to each project's task
3.	**TimeLine**	Costs analysis over different time periods in planning and execution	Evaluating capacities of resources consumption over specified time periods
4.	**Tasks**	Identification and costing of project's tasks (WBS items)	Matching the costs to each of the project's components
5.	**Overhead Allocation**	A precise allocation of indirect costs	Determining the indirect cost generators in project's tasks
6.	**Risk management**	The inclusion of risk element and its value as part of the costing	Estimating risk on the basis of risk factors in the different tasks
7.	**Scenarios**	The ability to analyze alternative modes of action and costs	Defining assumptions and alternatives to the mode of cost's calculation
8.	**Profitability Analysis**	The understanding of the profit that derives from each of the projects and the whole projects portfolio	The inclusion of all the cost factors in the model

the project lifecycle. Kerzner (2003) portrays the distribution of the project's cost over the project's lifecycle:

- 5% - Conceptualization
- 10% - Feasibility study
- 15% - Preliminary planning
- 20% - Detail Planning
- 40% - Execution
- 10% - Testing and Commissioning

Tasks in each of these stages are described under the work breakdown structure (WBS). The WBS represents the required activities for the project's management in a hierarchical structure. For each component of the WBS, an evaluation of direct and indirect (overhead) costs must be included. Direct costs are divided to work's cost (usually work hours multiple hourly rate) and direct costs that are not work payment, such as travel, materials, and so forth. It is recommended that these costs will include managerial reserve as well (Jurison, 1999).

A reinforcement of the need to include the project's tasks (or the WBS components) in a costing model is intensified in the light of the cost estimations that are founded on work hours' evaluation. It has been argued (Ooi & Soh, 2003) that according to traditional approaches of software costing (time-based estimations), there may be a bending towards time planning without linking it to the specific task and the role player that performs it. Therefore, it is suggested to include the detailing of the tasks (Ooi & Soh, 2003) and/or an elaborate planning of the various project's resources as part of the costing model.

The advantages of the resources' cost analysis throughout activities/tasks: more detailed information for managers, monitoring abilities, analysis of resources' cost and allocation, and a more accurate ability of overhead allocation (Elnathan & Raz, 1999; Jahangir, 2003; Kinsella, 2002; Ooi & Soh, 2003).

Indirect costs (overhead costs) include all types of costs that cannot be attributed directly to a specific task in the project marketing and sales expenses, office supplies, buildings' cost, professional services, information systems, computerization infrastructure, and the like. These costs are only occasionally incorporated in the project planning, but they carry great influence on the profitability of the portfolio and the projects' pricing decisions (Horngren et al., 2000). These costs are described as one of the "major headaches" (Kerzner, 2003). However, in this context, it has been argued that the ability to control costs is largely dependent on the monitoring of these costs.

Table 2 summarizes costing methods according to financial and engineering literature. The table also presents the common evaluation of model compatibility in light of entire costing aspects.

- **Analogy:** Cost estimation based on previous experience, using case based reasoning techniques (CBR).

Table 2. Costing methods according to financial and engineering literature

Legend √ - Good compatibility X - No compatibility P - Partial compatibility * - Adjustments are required			**Planning**	**Controlling**	**Time Line**	**Task Resolution**	**Overhead Allocation**	**Risk Management**	**Scenarios**	**Profitability Analysis**
Software Eng.	Top Down	Analogy	√ *	P*	X	X	P*	X	X	X
		Parametric	√ *	P*	X	X	P*	P*	√	X
	Bottom Up	Function Points	√	X	X	√	P*	√*	√	X
		COCOMO II	√	P	X	√	P*	√	√	X
Costing		Target Costing	√	P	P	P*	P	X	P	√
		Standard Costing	√	P	√*	√*	P	X	√	P
		ABC	√	P	P*	X	√	X	√	√

The accuracy of this method ranges from -10% to +25% (Kerzner, 2003).

- **Parametric:** Cost estimation based on heuristics and thumb's rules (Jahangir, 2003). Similar to the analogy estimation method, a parametrical model is also based on accumulation of historical data of project costs. On the basis of these data, a mathematical model is defined for the prediction of costs (Kinsella, 2002). The level of accuracy of a parametrical model ranges on a wide scope of –25% to +75% (Kerzner, 2003).
- **Function Points:** A method that was first introduced in 1979 by Albrecht. Its objective is to assess the software system's size while using the user's requirements without direct dependence on the technological realization (Hale & Smith, 2001). The function points method is calculated in three steps, using the quantity and complexity of the functional components and the system attributes (Kemerer, 1993).
- **COCOMO** (constructive cost model): The model was first introduced in 1981 and since then, several modifications were made in order to suit fourth-generation languages, decrease in hardware costs, increase in QA levels, advanced and agile development methods. Current version, COCOMO 2.0 (Boehm, Clark, Madachy, Horowitz, Selby, & Westland, 1995), is not based upon line of codes, but on four submodels that match a spiral approach of software system development that are applied according to the stage of the lifecycle (The application-composition model, the early design model, the reuse model, and postarchitecture model).
- **Target costing:** Suits engineering framework in which there are several engineering activities simultaneously, and is utilized as a means for costs strategic management. The idea behind the method is that a product's cost must be based on the sum that can be received for it in the market, and in other words, the development cost should be the basis for the quantity and mode of investment in the development rather then the development's outcome.
- **Standard costing:** ascertains the cost framework while employing the amount of direct cost components and a standard price that was set for this unit. We shall formulate it concisely:

$$TotalCost = \sum_{i-1}^{n} Qty_i * StdP_i .$$

It should be accentuated that the standard price does not solely include the direct price of the component (price per working hour), and is intended to contain the meaning of the cost or the consumption of indirect resources (rent, computerization, etc.). In the calculation of the standard price, it is customary to rely on known performance data from the past (Horngren et al., 2000).

- **Activity based costing (ABC):** Is considered as one of the advanced models for predicting costs while incorporating managerial decisions. The model was developed in the eighties, and its main innovation is in the addition of nonfinancial elements to the cost-

ing model. The model is widely used in a variety of industries, such as agronomy, banking (Kao & Lee, 2001), and medicine. In the projects area, there is not much literature that discusses the application of ABC, however, there are a few studies that help to understand the method. These studies include the description of the method for software developing and assimilation (Ooi & Soh, 2003), the portrayal of the mode in which ABC can be taken on in projects (Elnathan & Raz, 1999), the implementation of ABC in favor of IT cost analysis in the organization, and a recommendation to include this model in PMBOK (Kinsella, 2002).

THE FRAMEWORK

The model proposes an approach to the integration between the financial systems that include the components of the financial reports and the software tools that serve the project management tools and software engineering tools, such as function points.

The model will enable not only an in-retrospect analysis of the economic performances of the project/projects portfolio/software house, but also an in-advance evaluation of costs, economic feasibility, and economic risk level for the project/projects portfolio. The model enables the execution of sensitivity analyses for the purpose of exploring alternatives of planning and organizing (resource utilization, resource transportation between projects, etc.).

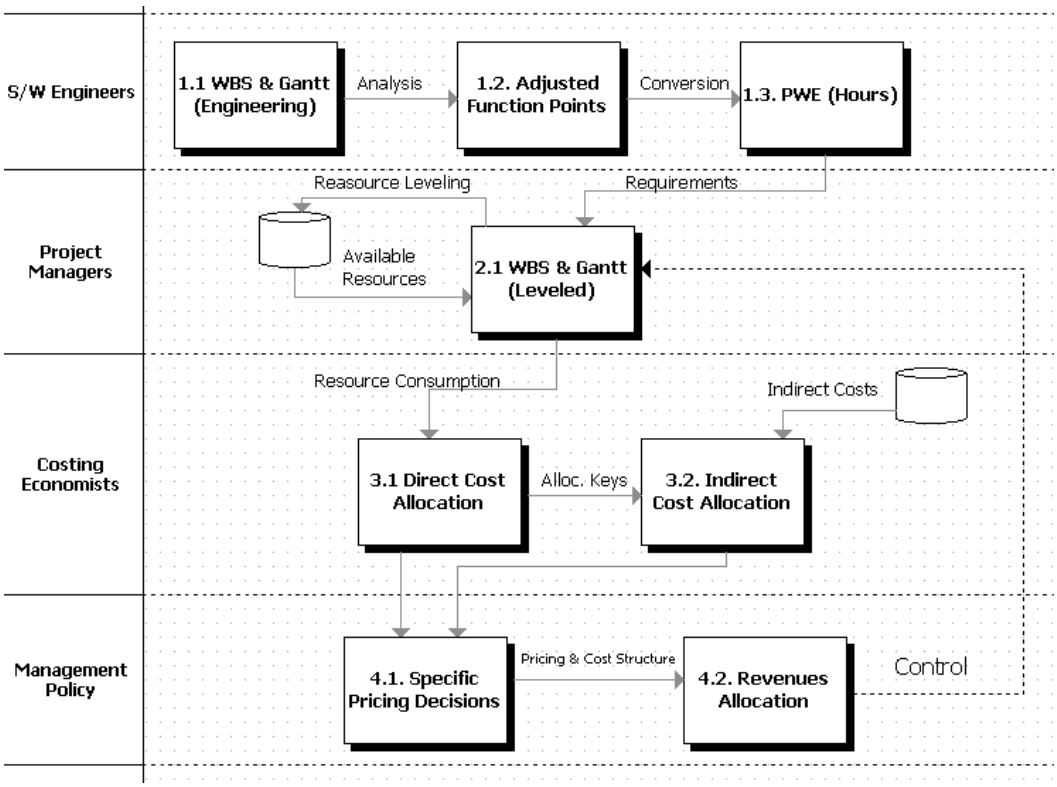
Costing Framework as a Business Process

In order to create a practical framework for costing, we have described the costing framework as a business process. The process combines four types of organization resources: software engineers (stages 1.1-1.3), project managers (stage 2.1), costing economists (stages 3.1-3.2), and managers (stage 4.1-4.2).

Figure 1 illustrates the costing activities and collaboration between the personnel:

The connection between the engineering planning and the project managing is based on the "translation" of the engineering planning terms to working hours, engineering complexity description (AFP – Adjusted Function Points) converted to developing efforts (working hours). In addition, on the top of the engineering planning (developing efforts and tasks composition), there are more constraints

Figure 1. Costing framework as a business process



that derived from the availability of the organization's resources. The project manager is testing the constraints, demands, and costs, and creates the optimal/ultimate GANT project. Those steps connected the managing and planning of the project to the engineering side that takes into account system complexity.

Thereafter, cost elements (that include direct cost calculations) are being introduced and overhead expenses are thereafter, added (indirect costs of the organization). The overhead expenses are based on the loading key that derives from the direct cost. At the end of this stage, we had for each project a "naïve" estimation, namely, a cost that does not depend on political factors (such as require profitability) that find expression at the last stage.

In the final stage, after building the costing structure for the whole project, we have management intervention (with the collaboration of planning factors). Within this framework, management can define the policy for each project according to the project type, the customer, and so on. Political decisions could influence the basics cost structure (costing decisions) and/or determine the profitability level that is necessary for the project (pricing).

This model reflects the integrative framework of the organization, the management, and the project, and raises questions about the effectiveness and applicability level of the model.

CONCLUSIONS

This work presents the costing of software projects as a business process that collaborates between entities in the organization.

Costing models usually have three stages: defining a costing object, cost tracing for direct costs, and cost allocation for indirect cost. Due to the complexity of software projects, these stages are not trivial to comply with. For example, the project life cycle (PLC) and the different tasks in it require the costing object to include several objects (to match the WBS). We have defined the following features for a costing model in order to fulfill its goals. These features are supported by the suggested framework we describe, yet are only partially supported by other known models. They include

- Planning -_understanding and estimating project activities that spread over the lifecycle of the project (project life cycle- PLC)
- Task analysis - The tasks (processes) in each of these stages are described under the work breakdown structure. The WBS represents the required activities for the project's management in a hierarchical structure. For each component of the WBS, an evaluation of direct and indirect (overhead) costs must be included.
- Direct resources_– Derived from engineering requirements, they are the work effort (like programmers) and material (like servers)
- Direct cost - Direct costs are divided into costs of labor (usually work hours multiple by hourly rate) and other direct costs such as materials. It is recommended that these costs will include a managerial reserve. (Jurison, 1999).
- Indirect costs - All types of costs that cannot be attributed directly to a specific task in the project (marketing and sales expenses, office supplies). These costs have a great influence on the profitability of the portfolio and the projects' pricing decisions (Horngren at al., 2000, p.148, 439). Indirect costs are described as one of the "major headaches" (Kerzner, 2003. p. 524). The ability to control costs is largely dependent on the monitoring of these costs.
- Control- An analysis of actual vs. budget and the ability to create forecasts based on planning and partial implementation.
- Timeline – Planning and control activities should take under consideration different types and volumes of activities during the lifecycle. Therefore, the project timeline becomes part of the costing model and its implementation.
- Profitability – Understanding the "bottom line" of the projects. Profitability analysis requires both an allocation of direct and indirect costs as well as revenue allocation.
- Risk analysis - The objective of risk analysis is to predict the value of uncertainty (the risk) that is involved in future project activity (Rajkumar, 2003). The literature shows that one of the challenges of a costing system is to introduce and represent risks as part of the costing process (Rajkumar & Rush, 2000).

The major point raised by these requirements is that the costing model should include a variety of cost information supported by different personnel. The advantage of resource cost analysis throughout the project life cycle is the creation of more detailed information for managers, better monitoring abilities, a more accurate analysis of resources, and better control over overhead allocation (Elnathan & Raz, 1999; Jahangir, 2003; Kinsella, 2002; Ooi & Soh, 2003).

KEY TERMS

Activity Based Costing (ABC): A cost prediction model that has greatly improved the ability to predict a proper allocation of indirect costs among several activities and thereafter, between many products. Before using this model, one has to appreciate and understand the overall business (including its production and marketing). The model is not always applicable: a cost-benefit analysis is necessary before a final decision is made.

CASE/AMD Tools: Software tools (computer aided software engineering), also named AMD tools (analysis modeling and design), to assist the entire system life cycle (SLC). This includes the analysis phase, design phase, testing phase, and even maintenance phase. CASE /AMD tools support the

functional analysis phase using visual modeling notations, which can automatically be converted into code.

Cost Object: Anything for which cost data are desired. A cost object may be a product or a service. Cost object for projects can include a module, milestone, or a specific task. We recommend defining a cost object for a project as a WBS item.

Gantt Chart: A popular type of bar chart that illustrates a project schedule. Gantt charts illustrate the start and finish dates (ES, EF, LS, LF) of entire project elements. Project elements comprise the work breakdown structure (WBS) of the project. Gantt charts also show the dependency (i.e., precedence network) relationships between activities. Gantt charts can be used to show current schedule status using percentage completion shadings and a vertical "today" line.

Project Cost Management: Defined by the PMBOK (project management body of knowledge) as one of nine core activities of project management. This activity is described as the collection of processes including planning, estimating, and budgeting cost control, so that the project will carry out within the intended budgeting framework

Project Management: A wide discipline that includes the knowledge base and techniques for planning, controlling, and implementing projects. The PMI (Project Management Institute) defines it as follows: "Project management is the application of knowledge, skills, tools and techniques to project activities to meet project requirements."

Work Breakdown Structure (WBS): A technique for defining and organizing projects' tasks using a hierarchical tree structure. The first level contains one project outcome, and each level describes outcomes in details. Each level must include 100% of the total work (the sum of the work at the "child" level must equal 100% of the work represented by the "parent," and the WBS should not include any work that falls outside the actual scope of the project)

Creating Order from Chaos: Application of the Intelligence Continuum for Emergency and Disaster Scenarios

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

Rajeev K. Bali
Coventry University, UK

INTRODUCTION

Recently, the world has witnessed several large scale natural disasters: the Tsunami that devastated many of the countries around the rim of the Indian Ocean in December 2004, extensive flooding in many parts of Europe in August 2005, hurricane Katrina in September 2005, the outbreak of Severe Acute Respiratory Syndrome (SARS) in many regions of Asia and Canada in 2003, and the earthquake disaster in Pakistan towards the end of 2005 . These emergency and disaster situations (E&DS) serve to underscore the utter chaos that ensues in the aftermath of such events, the many casualties and loss of life, not to mention the devastation and destruction that is left behind. One recurring theme that is apparent in all these situations is that irrespective of the warnings of the imminent threats, countries have not been prepared and ready to exhibit effective and efficient crisis management. This paper examines the application of the tools, techniques, and processes of the knowledge economy to develop a prescriptive model that will support superior decision making in E&DS and thereby enable effective and efficient crisis management.

BACKGROUND

Changing weather patterns, rapid urbanization, expansion of industry, not to mention development of air and ground transportation networks, population growth and migration, and recently – acts of terrorism , are associated with ever increasing frequency of major disasters involving multiple casualties (von Lubitz, Carrasco, Fausone, Gabbrielli, Kirk, Lary, and Levine, 2005). Emergency Healthcare management is a complex process which has to be tackled on various fronts (Beltrame, Maryni and Orsi, 1998; Kun and Bray, 2002). Such situations require effective crisis management capability, that is, pre-hospital and emergency/trauma, in-hospital medical services, firefighting, disaster-related law enforcement operations, and so forth, and superior decision making capabilities (von Lubitz, et al., 2005; von Lubitz and Wickramasinghe, 2005a; 2005b). Most of these services are governed by different local or national agencies, are subject to different rules and regulations, and develop independent operational plans. This in turn leads to the gathering and storing of data in disparate databases. However, given the interdependent nature of these elements, any decision making based on only one or a few of these data elements will logically provide only a partial picture and, thus, an inferior decision. Hence, it is necessary to collect multi-spectral data, analyze this data in aggregate to develop a complete picture if we are to truly support superior decisions. To do this effectively and efficiently, it is imperative to embrace the tools, techniques and processes of the knowledge economy (Liebowittz, 1999; Maier and Lehner, 2000; Shapiro and Verian, 1999; von Lubitz and Wickramasinghe, 2005b; Wickramasinghe, 2005; Wilcox, 1997; Zack, 1999). Advances in IT, coupled with the advent of Knowledge Management (KM), can facilitate better processes for efficient and effective healthcare (Dwivedi, Bali, James, Naguib, and Johnston; 2002).

MAIN FOCUS

The Intelligence Continuum consists of a collection of key tools, techniques, and processes of the knowledge economy; that is, including data mining, business intelligence/analytics and knowledge management which are applied to a generic system of people, process and technology in a systematic and ordered fashion (Wickramasinghe and Schaffer, 2005). Taken together, they represent a very powerful instrument for refining the data raw material stored in data marts and/or data warehouses and thereby maximizing the value and utility of these data assets. As depicted in Figure 1, the intelligence continuum is applied to the output of the generic information system. Once applied, the results become part of the data set that are reintroduced into the system and combined with the other inputs of people, processes, and technology to develop an improvement continuum. Thus,

the intelligence continuum includes the generation of data, the analysis of these data to provide a "diagnosis," and the reintroduction into the cycle as a "prescriptive" solution. In this way, continuous learning is invoked and the future state always builds on the lessons of the current state.

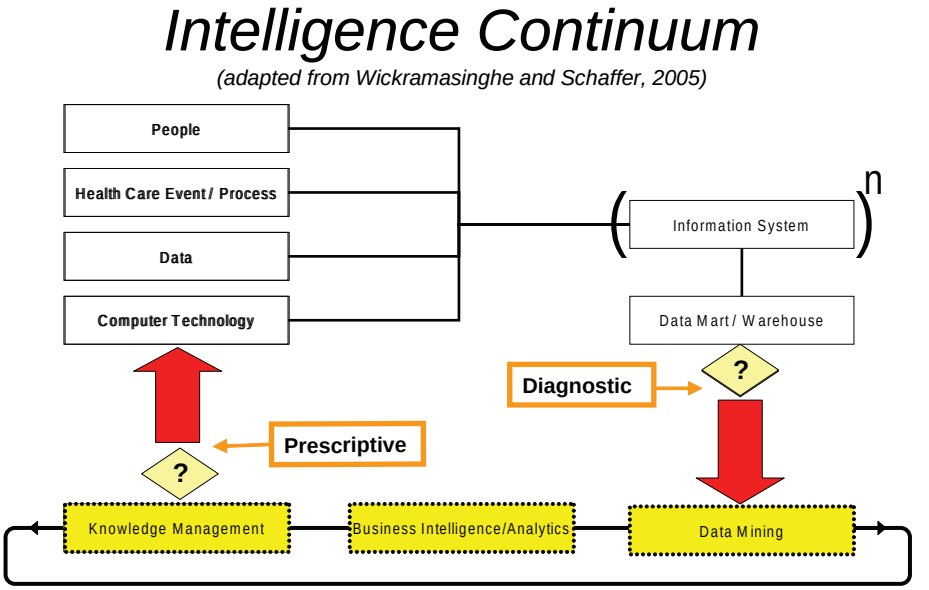
The key capabilities and power of the model are in analyzing large volumes of disparate, multi-spectral data so that superior decision making can ensue. This is achieved through the incorporation of the various intelligence tools and techniques which taken together make it possible to analyze all data elements in aggregate. Currently, most analysis of data is applied to single data sets and uses at most two of these techniques (Newell, Robertson, Scarbrough, and Swan, 2002; Nonaka, 1994; Nonaka and Nishiguchi, 2001; Schultze and Leidner, 2002; von Lubitz and Wickramasinghe, 2005b; Wickramasinghe, 2005; Wickramasinghe and Schaffer, 2005). Thus, there is neither the power nor the capabilities to analyze large volumes of multi-spectral data (ibid.). Moreover, the interaction with domain experts is typically non-existent in current methods. The benefits of applying the capabilities of the intelligence continuum to E&DS scenarios are profound indeed. E&DS scenarios are concomitant with complex, unstable, and unpredictable environments where the unknown or position of information inferiority prevails. Hence, these scenarios are chaotic and sub-optimal decision making typical results. In contrast, the tools and techniques of the intelligence continuum can serve to transform the situation of information inferiority to one of information superiority in real time through the effective and efficient processing of disparate, diverse, and seemingly unrelated data. This enables decision makers to make superior decisions which in turn lessen the chaos and facilitates the restoring of order. In order to appreciate the power of the intelligence continuum in such scenarios, it is necessary to briefly describe its key elements.

Data Mining

Due to the immense size of the data sets, computerized techniques are essential to help decision makers understand relationships and associations between data elements. Data mining is closely associated with databases and shares some common ground with statistics since both strive toward discovering structure in data. However, while statistical analysis starts with some kind of hypothesis about the data, data mining does not. Furthermore, data mining is much more suited to deal with heterogeneous databases, data sets, and data fields, which are typical of data in E&DS that contain numerous types of text and graphical data sets. Data mining also draws heavily from many other disciplines, most notably, machine learning, artificial intelligence, and database technology.

From a micro perspective, data mining is a vital step in the broader context of the knowledge discovery in databases (KDD) that transforms data into knowledge by identifying valid, novel, potentially useful, and ultimately understand-

Figure 1



able patterns in data (Adriaans and Zantinge, 1996; Bendoly, 2003; Cabena, Hadjinian, Stadler, Verhees, and Zanasi, 1998; Fayyad, Piatetsky-Shapiro, Smyth, 1996). KDD plays an important role in data-driven decision support systems that include query tools, report generators, statistical analysis tools, data warehousing, and on-line analytic processing (OLAP). Data mining algorithms are used on data sets for model building, or for finding patterns and relationships in data. How to manage such newly discovered knowledge, as well as other organizational knowledge assets, is the realm of knowledge management.

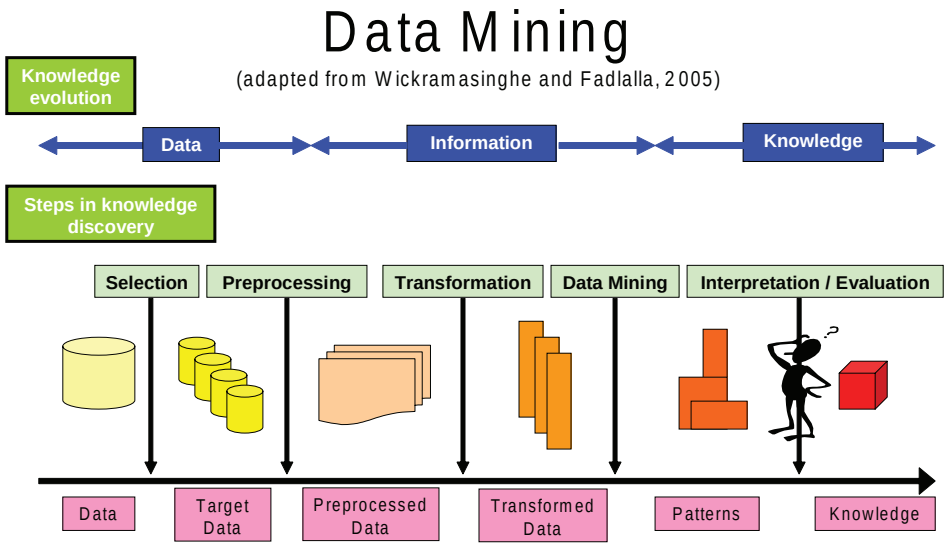
Figure 2 shows an integrated view of the knowledge discovery process, the evolution of knowledge from data to information to knowledge, and the types of data mining (exploratory and predictive) and their interrelationships. In Figure 2, all the major aspects connected with data mining are captured and by so doing the integral role of data mining to knowledge creation is emphasized. This is not normally explicitly articulated in the existing literature although the connection between data, information, and knowledge is often discussed (Becerra-Fernandez and Sabherwal, 2001; Choi and Lee, 2003; Chung and Gray, 1996; Holsapple and Joshi, 2002).

Data mining then, is the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns from data (Fayyad, et al., 1996). It is essential to emphasize here the importance of the interaction with experts who always play a crucial and indispensable role in any knowledge discovery process in facilitating prediction of key patterns and also identification of new patterns and trends.

Business Intelligence/Analytics

Another technology-driven technique, like data mining connected to knowledge creation, is the area of business intelligence and the now newer term of business analytics. The business intelligence (BI) term has become synonymous with an umbrella description for a wide range of decision-support tools, some of which target specific user audiences (Wickramasinghe, 2005; Wickramasinghe and Schaffer, 2005). At the bottom of the BI hierarchy are extraction and formatting tools which are also known as data-extraction tools. These tools collect data from existing databases for inclusion in data warehouses and data marts. Thus, the next level of the BI hierarchy is known as warehouses and marts. Existing healthcare information systems are not generally designed to cater to new (data) needs (Anderson, 1997). Because the data come from so many different, often incompatible systems in various file formats, the next step in the BI hierarchy is formatting tools. These tools and techniques are used to "cleanse" the data and convert it to formats that can easily be understood in the data warehouse or data mart. Next, tools are needed to support the reporting and analytical techniques. These are known as enterprise reporting and analytical tools. On-line analytic process (OLAP) engines and analytical application-development tools are for professionals who analyze data and do, for example, business

Figure 2



forecasting, modeling, and trend analysis. Human intelligence tools form the next level in the hierarchy and involve human expertise, opinions, and observations to be recorded to create a knowledge repository. These tools are at the very top of the BI hierarchy and serve to amalgamate analytical and BI capabilities along with human expertise. Business analytics (BA) is a newer term that tends to be viewed as a sub-set of the broader business intelligence umbrella and concentrates on the analytic aspects within BI by focusing on the simultaneous analysis of patterns and trends in a given context (Wickramasinghe and Schaffer, 2005).

Knowledge Management

Knowledge Management is an emerging management approach that is aimed at solving the current business challenges to increase efficiency and efficacy of core business processes while simultaneously incorporating continuous innovation. Specifically, knowledge management through the use of various tools, processes, and techniques combines germane organizational data, information and knowledge to create business value, and enable an organization to capitalize on its intangible and human assets so that it can effectively achieve its primary business goals as well as maximize its core business competencies (Newell, et al., 2002; Nonaka, 1994; Nonaka and Nishiguchi, 2001; Schultze and Leidner, 2002; von Lubitz and Wickramasinghe, 2005b; Wickramasinghe, 2005; Wickramasinghe and Schaffer, 2005). The importance of knowledge management is confirmed by the increasing attention that the subject has received from both researchers and practitioners (Huang and Newell, 2003).

Broadly speaking, knowledge management involves four key steps of creating/generating knowledge, representing/storing knowledge, accessing/using/re-using knowledge, and disseminating/transferring knowledge (von Lubitz and Wickramasinghe, 2005a; Wickramasinghe, 2005b; Wickramasinghe and Schaffer, 2005).

Knowledge Management (KM) as a discipline is said not to have a commonly accepted or *de facto* definition. However, some common ground has been established which covers the following points. KM is a multi-disciplinary paradigm (Gupta, Iyer & Aronson, 2000) which often uses technology to support the acquisition, generation, codification, and transfer of knowledge in the context of specific organizational processes. Knowledge can either be tacit or explicit (explicit knowledge typically takes the form of company documents and is easily available, whilst tacit knowledge is subjective and cognitive). As tacit knowledge is often stored in the minds of healthcare professionals, the ultimate objective of KM is to transform tacit knowledge into explicit knowledge to allow effective dissemination (Bali, 2005).

KM initiatives should be incorporated in conjunction with the technological revolution that is occurring within healthcare organizations. A balance is required between organizational and technological aspects of the healthcare process (Dwivedi, et al. 2001a).

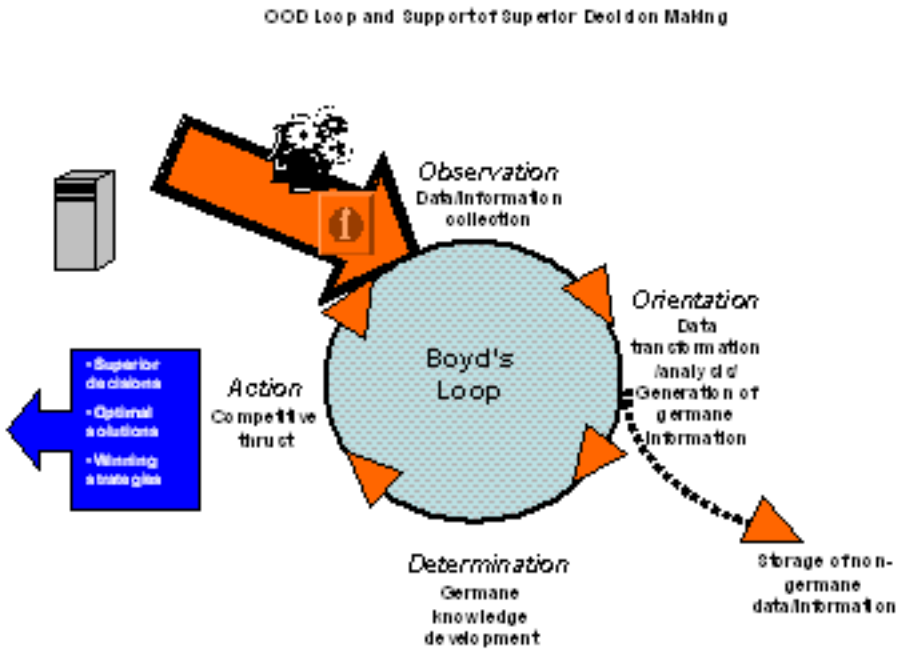
KM can enable the healthcare sector to successfully overcome the information and knowledge explosion by way of appropriate frameworks customized for healthcare institutions (Dwivedi, et al., 2001b, 2002a).

Knowledge Generation In Dynamic And Unpredictable Environments

Hierarchically, gathering of information precedes transformation of information into useable knowledge (Alavi and Leidner, 1999; Massey, Montoya-Weiss, and O'Driscoll, 2002). Hence, the rate of information collection and the quality of the collected information will have a major impact on the quality (usefulness) of the generated knowledge (Chang, et al., 2005). In dynamic and unstable environments, relative to the environment, the decision maker is in a position of tremendous information inferiority. In order to make effective decisions he/she must rapidly process seemingly irrelevant data and information into relevant and useable knowledge (Award and Ghaziri, 2004; Boyd, 1976; Courtney, 2001; Drucker, 1993; Newell, et al., 2002; Schultze and Leidner, 2002; Wickramasinghe, 2005). This necessitates a process perspective to knowledge management (von Lubitz and Wickramasinghe, 2005b; Wickramasinghe and von Lubitz, 2006). The cornerstone of such a perspective is the OODA Loop (Figure 3) which provides formalized analysis of the processes involved in the development of a superior strategy (Boyd, 1976, 1987; von Lubitz and Wickramasinghe, 2006).

The Loop is based on a cycle of four interrelated stages revolving in time and space: Observation, followed by Orientation, then by Determination, and finally Action. At the Observation and Orientation stages, multispectral implicit and explicit inputs are gathered (Observation) and converted into coherent information (Orientation). The latter determines the sequential Determination (knowledge generation) and Action (practical implementation of knowledge) steps. The outcome of the latter affects, in turn, the character of the starting point (Observation) of the next revolution in the forward progression of the rolling loop. The Orientation stage specifies the characteristics and the nature of the "center of thrust" at which the effort is to concentrate during the Determination and Action stages. Hence, the Loop implicitly incorporates the rule of "economy of force," that is, the requirement that only minimum but adequate (containment) effort is applied to insignificant aspects of competitive interaction. The Loop exists as a network of simultaneous and intertwined events that characterize the multidimensional action space (competition space), and both influence and are influenced by the actor (e.g., an organization) at the centre of the network.

Figure 3. (Adapted from von Lubitz and Wickramasinghe, 2005ab)



It is the incorporation of the dynamic aspect of the "action space" that makes the Loop particularly useful to environments that are inherently unstable and unpredictable, that is, medicine, business, war and emergency, and disaster scenarios (von Lubitz and Wickramasinghe, 2005a; 2005b; 2006).

FUTURE TRENDS

The need for more effective, superior crisis management techniques is clearly becoming apparent as we embark upon post crisis analysis for each of the more recent disasters from 9-11, to the Tsunami in December 2004, the floods in Europe, hurricanes Katrina and Rita and the earthquakes in Pakistan. This area is the focus for the emerging discipline of Operations Other than War (OOTW). Commonly considered as military, OOTW now becomes increasingly civilian-driven, and often executed as interventions in potentially unstable environments, or as management activities consequent to destabilizing events. In addition to the most obvious topic of terrorism, where risk assessment and management are prerogative to meaningful counteraction, problems of assessing and managing consequences of natural disasters, epidemic diseases, major industrial or transportation accidents, or humanitarian relief operations, become increasingly relevant. Key issues for OOTW include (Richards, 2004):

- Risk factors and their management
- Preparedness/readiness
- Political factors
- International organizations/national organizations/ NGOs in OOTW
- International cooperation
- Military/civilian interaction
- Law/law enforcement
- Healthcare and medical aspects
  - o telemedical operations
  - o medical logistics
  - o medical information networks in disaster operations
- ICT technology-based tools facilitating assessment and management of risk
  - o data mining/business analytics
  - o simulation/modeling
  - o training in complex synthetic environments
- Field operations and analysis of practical execution

As this nascent field evolves the above areas will form a central research focus for scholars in the near future.

CONCLUSIONS

Sound emergency management requires the ability to (Alexander, 2002, 2004; Marincioni, 2001):

1. Focus on solvable problems;
2. Priorities the elements of a problem in terms of how much progress can be achieved with each element in a small amount of time;
3. Delegate responsibility;
4. Manage the "span of control;"
5. Communicate clearly and rationally;
6. Keep a level head in a crisis; and
7. Make sound decisions.

However, when we analyze the recent natural disasters, a common recurring and unfortunate situation is that countries and regions are never as prepared and ready for the eminent disaster as they perhaps could have been. It is too late once the disaster strikes to have an organized and systematic fashion for contending with the aftermath. What is required is to be able to analyze past crises and develop appropriate lessons to apply to future events. In the advent of a health crisis, knowledge management is in a position to improve information sharing and coordination. The intelligence continuum model coupled with a process perspective of knowledge management appears to fill this void as it can be applied to existing and disparate data elements from past disasters in order to build a predictive model that can facilitate in the development of sound procedures and protocols to facilitate preparedness and readiness a priority so that *ex-ante* operations can, in fact, be more effective and efficient, decision making superior and order replace much of the chaos.

- Preparedness, unless based on broadly-based knowledge is useless. The development of appropriate preparedness is predominantly a strategic task that requires intimate knowledge of several aspects of the environment.
- Readiness, unless based on germane knowledge, is useless. Thus, coping with the sudden and unpredictable event requires the background of germane knowledge that will dictate the nature of the subsequent response. Readiness is, therefore, context dependent.
- Readiness is the most essential tool in response to, and containment of, an unexpected threat. While intuitively obvious, the practical development of readiness is not an easy task. Possession of knowledge is not equivalent to the ability to employ it under the stress of less-than-routine circumstances; that is, E&DS.

Hence in E&DS, what is needed is to be prepared and ready which, in turn, requires not only the possession of pertinent information and germane knowledge, but also the ability to apply it successfully; evoke superior decision making. Efficient flow of information is necessary in managing an outbreak (Kun and Bray, 2002). Hurricane Katrina serves to highlight how vulnerable and insufficient existing crisis management techniques are (CNN 2005a-c) as well as to underscore that developing better techniques through the utilization of critical data sources should be remedied immediately. The Intelligence continuum offers such a possibility.

KEY TERMS

Data Mining and KDD Process: Knowledge discovery in databases (KDD) (and more specifically data mining) approaches knowledge creation from a primarily technology driven perspective. In particular, the KDD process focuses on how data is transformed into knowledge by identifying valid, novel, potentially useful, and ultimately understandable patterns in data (Fayyad, et al., 1996). From an application perspective, data mining and KDD are often used interchangeably.

Explicit Knowledge: Or factual knowledge, that is, "know what", represents knowledge that is well established and documented.

Germane Knowledge: The sum total of all information *plus* the ability to implement it constructively and purposefully in the dynamic and unstable environment.

Knowledge Spiral: The process of transforming the form of knowledge, and, thus, increasing the extant knowledge base as well as the amount and utilization of the knowledge within the organization.

Pertinent Information: Information structured data, grouped into coherent categories that are easily perceptible and understood.

Preparedness: The availability (prepositioning) of all resources, both human and physical, necessary for the management of, or the consequences of, a specific event or event complex .

Readiness: The instantaneous ability to respond to a suddenly arising major crisis (e.g. sudden slow-down in the manufacturing parts supply chain) that is based on the instantaneously and locally available/ un-prepositioned and un-mobilized countermeasure resources.

Tacit Knowledge: Or experiential knowledge, that is, "know how" represents knowledge that is gained through experience and through doing.

Creating Software System Context Glossaries

INTRODUCTION

Requirements engineering (RE) is the area of software engineering responsible for the elicitation and definition of the software system requirements. This task implies joining the knowledge of the services that a software system can and cannot provide with the knowledge of clients' and users' needs (Jackson, 1995; Katasonov & Sakkinen, 2005; Kotonya & Sommerville, 1998; Sommerville & Sawyer, 1997; Sutcliffe, Fickas, & Sohlberg, 2006; Uchitel, Chatley, Kramer, & Magee, 2006). Frequently, this activity is done by people with a software engineering bias. The underlying hypothesis of this choice is that users' needs are easier to understand than the software's possible behaviors. This is not always true; however, this is the metacontext in which most RE heuristics and methodologies have been developed. Understanding clients' and users' needs is far more complex than merely interviewing selected clients and user representatives, compiling all gathered information in one document. Defining how to put into service a complex software system within an organization requires envisioning how the business process of the organization will be in the future from both points of view: software organization and business organization. This is the key of the RE commitment: to imagine how the future business process will be. This RE commitment requires a good knowledge about how the business process actually is. Understanding the software system's preexistent context basically means understanding the clients' and users' culture. In other words, this part of the RE is a learning process.

BACKGROUND

The importance language has in any culture should be noticed. Language is an organized system of speech by which people communicate with each other with mutual comprehension. Also, it is very important to note that by the words it contains and the concepts it can formulate, language is said to determine the attitudes, understandings, and responses in any society. Language, therefore, may be both a cause and a symbol of cultural differentiation (Fishman, 1999; Hall, Hawkey, Kenny, & Storer, 1986). Language reflects environment and technology: Arabic has 80 words for camels, while Japanese has more than 20 words for rice and Inuit has more than 20 words for snow and ice (Nettle & Romaine, 2000). Clients and users have several special words that they use when discussing their activities. The requirements engineer must pick and understand as many of these words as possible as a first step in understanding clients' and users' culture.

Glossaries have been used in software engineering with different purposes, such as data dictionaries in early database books (Codd, 1982) to document entities, attributes, relations, types, and services of databases. Thus, it provides a common understanding of all the system names to the developer team and later to the maintenance team. However, data dictionaries are also an important component of structured analysis, data recording, data storage, and the details of processes (Gane & Sarson, 1982; Senn, 1989), though authors like Gane and Sarson suggest that the real name for them should be *project guide* instead of *data dictionary*. These data dictionaries are created during analysis and also used during system design. They satisfy five objectives: to manage details, communicate common meanings, document system characteristics, help the analysis of details and changes, and locate errors and omissions of the system.

In this article an RE process beginning with the construction of a language-extended lexicon (LEL) as its first activity (Leite, Hadad, Doorn, & Kaplan, 2000) is addressed, and the structure and creation of this LEL is described.

GLOSSARY CREATION

The word *dictionary* was coined by Henry Cockeran in 1623, but the first known dictionaries belong to the seventh century B.C., and they contain the most important data of

the Mesopotamian culture (MSN Microsoft Corporation, 2006). The first dictionaries were catalogues of unusual, difficult, or confusing words and phrases since the common vocabulary was considered to have no need of an explanation or a definition. The oldest glossary comes from the second century A.D. and contains technical Greek words used by Hypocrites. It was in later centuries that a catalogue of all the words of a language was built: for Arabic. So, the origin of glossaries and dictionaries was to give definitions of words and phrases of a particular domain; then, they were extended to an entire language in lexical dictionaries. Nowadays, there are different types of dictionaries covering different necessities, like dictionaries of synonyms and antonyms, dictionaries of idiomatic usage, etymology dictionaries, encyclopedic dictionaries, bilingual dictionaries, glossaries in textbooks, dictionaries of ideologies, slang dictionaries, and dictionaries of neologisms, among many others.

Most relevant or peculiar words or phrases (named LEL symbols) of the universe of discourse (UofD) are included in the LEL. Every symbol is identified by its name (including synonyms) and two descriptions: notion and behavioral response. The notion contains sentences defining the symbol and the behavioral response reflects how it influences the UofD. Figure 1 depicts the model used to represent LEL symbols.

The LEL is created by filling the blanks in the LEL model (see Figure 1) using information obtained from the application domain. Intuition, supported with a good understanding of the LEL model, may be used to create the lexicon. Upon the experience and the skill of the authors, this may or may not lead to a well-conceived document. If so, apparently there is no need for heuristics. On the contrary, heuristics are needed, first to allow everyone to complete the process successfully and second to avoid weaknesses usually present in apparently good-quality LELs. Those weaknesses range from missing relevant symbols to the unnecessary insertion of some others, and the inclusion of excess of details in the symbol descriptions or the lack of them.

The lexicon creation process, depicted in Figure 2 using an SADT[1] model (Ross & Schoman, 1977), consists of five independent activities: (a) plan, (b) collect, (c) describe, (d) verify, and (e) validate.

As seen in Figure 2, the process shows a main stream composed of three tasks: plan, collect, and describe. There is a well-established feedback when the verification and validation activities take place. After verifying the LEL, the process returns to the *describe* activity, where corrections are made based on a DEO list.[2] After the *validate* activity, the process returns to the *collect* activity and/or the *describe* activity, depending on the validation DEO list, in order to make any necessary corrections. For easy reading, the SADT model does not show all the backtracking steps that may occur during the construction process. For instance, while describing a symbol, a wrongly assigned type may be discovered, thus a back step occurs in order to reclassify it (within the *collect* activity). Another example of going backward in the process could appear when a new term is identified while describing another. That is, the strategy is not at all a linear one. It is an iterative process where feedback is a constant mechanism. In addition to this continuous feedback, the main stream does not fully follow a cascade model since in practice its three main tasks may partially overlap. For instance, a symbol may

Figure 1. Language-extended lexicon model

LEL: It is the representation of the symbols in the application domain language.
Syntax: $\{Symbol\}_1^N$

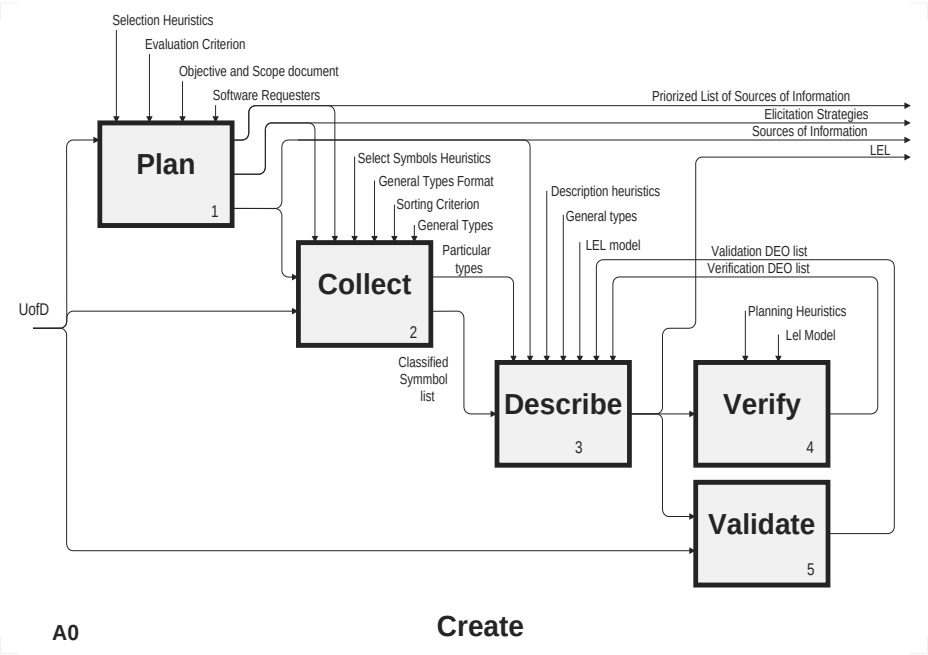
Symbol: It is an entry of the lexicon that has a special meaning in the application domain.
Syntax: $\{Name\}_1^N + \{Notion\}_1^N + \{Behavioral\ Response\}_1^N$

Name: This is the identification of the symbol. Having more than one name represents synonyms.
Syntax: Word | Phrase

Notion: It is the denotation of the symbol.
Syntax: Sentence

Behavioral Response: It is the connotation of the symbol.
Syntax: Sentence

Figure 2. SADT of the LEL creation process



be fully described while new sources of information should be identified to classify or describe others.

Plan. The *plan* activity basically consists of identifying the sources of information, evaluating them, and finally selecting the strategies to elicit symbols. To identify the sources of information, it is necessary to define the context where the RE process will take place. A mandatory source of information is the document of system objectives and scope (if it was written), or the requesters of the software system. The most reliable sources of information are documents and people, but some other relevant sources could be books about related themes, other clients' systems, and other systems available in the market. A source of information could be seen from several perspectives. One of the most salient perspectives is that of effectiveness, which classifies the information as either actual or formal. Formal information is about what should occur, but is not necessary to be put into practice or to be updated; actual information involves current practices or states, that is, what is actually in use. Accessing sources of information biased toward the formal point of view will create the important risk of developing a software system unable to deal with what actually happens in the business. On the other hand, ignoring formal sources of information does not allow the use of the software system as a tool for business process improvement. At this point, balancing the actual and formal points of view is almost impossible, but the requirements engineer must at least understand both.

Collect. The *collect* activity starts creating a candidate symbol list for accessing the sources of information by means of unstructured interviews, reading documents, or eliciting techniques appropriate for each source of information. The most important rules for choosing symbols are as follows.

- Pick exclusively words or phrases belonging to the application domain.
- Select words or phrases frequently used or highly repeated in documents.
- Select words or phrases meaningful in the application domain.
- Exclude too obvious words or phrases.
- Identify the full name no matter how long it is.
- An abbreviation or a partial name may be a synonym of a symbol with a long name.

Once the candidate list of symbols is available, every entry should be assigned to a class. In most cases, the basic classes of subject, verb, object, and state are useful. Subjects are active entities, such as persons, organizations, or software

systems. Objects are passive entities to which actions are applied. Verbs are entries representing actions that happen in the application domain, and states are conditions of a group of subjects, objects, or verbs.

Describe. Describing symbols defines their notions and behavioral responses based on the LEL model and the class to which they belong. In order to describe the symbols, the requirements engineers may use previous elicited knowledge, though often they should go back to the UofD to collect more information. In this case, it is recommended that they conduct structured interviews in order to ask clients and users about the meaning of the symbols. Nevertheless, other sources of information may well be used.

Below, some rules for describing symbols in the lexicon are itemised (description heuristics).

- A symbol must have at least one name, one notion, and one behavioral response.
- Every name of the symbol must be the one used in the application domain.
- Symbols used as synonyms in the application domain must share one entry in the LEL
- Symbols having a regular meaning must contain only the application domain sense.
- Notion and behavioral response must be described using simple and direct sentences.
- Each sentence should express only one idea.
- Each sentence should contain only one verb.
- Each sentence should make it easy to identify the perspective (formal or actual).
- If two symbols share a characteristic, it should be repeated in both entries.
- Every notion and behavioral response must have at least one reference to other symbols.
- References to other symbols should be enhanced (underlining, bolding, or any other way).
- Every symbol must be referenced at least by another symbol.
- A symbol's full name should be used when referenced by other symbols.

Connections among LEL entries should be stressed as much as possible using references to other symbols and reducing the use of vocabulary from outside the LEL.

Verify. Nowadays, inspections have been applied to requirements documents with great success (Leite, Hadad, Doorn, & Kaplan, 2005). Although the verification of the lexicon can be made by several techniques, an inspection variant based on Fagan's (1976) original proposal has been used. This technique provides specific heuristics to detect defects called discrepancies, errors, or omissions (DEOs) (Kaplan, Hadad, Doorn, & Leite, 2000). Each step in the heuristics is based on a defect-oriented form designed for a given type of defect and is accompanied with guides about how to fill the form and how to analyse what it is written in the LEL in order to maximise the finding of the defects.

Validate. While identifying and describing symbols, some degree of validation takes place. Later, a more structured validation activity is carried out allowing the requirements engineer to correct, ratify, or increase the knowledge about the application domain vocabulary. This usually consists of structured interviews or meetings with clients and users at their workplaces. The description of each symbol may be read to the interviewers who confirm, correct, make observations, or add missing information. Sometimes, instead of reading symbol descriptions during the interview, the engineer could give the interviewer a copy of the LEL in advance. Summarizing, the validation activity aims basically to do the following.

- Check notions and behavioral responses of symbols already described
- Ratify the definition of symbols
- Identify new symbols and synonyms

The validation activity generates a DEO list similar to the one produced at verification. It is then sent backward to the *collect* step and/or to the *describe* step to do the necessary corrections. Sometimes the feedback from validation may require identifying new sources of information.

FUTURE TRENDS

Even though the LEL has been used in many studies and practical application by researchers and practitioners, several aspects remain unknown and some questions remain unanswered. For example, there are no stopping rules defined. Different requirements engineers collect different symbols and different numbers of symbols; however, there is no known criterion about how to evaluate such differences.

Almost any LEL contains terms related by hypernym and hyponym relationships (Ureña López, García Vega, & Martínez Santiago, 2001). This symbol hierarchy can be observed among subjects, objects, and verbs. No benefits from this knowledge have been outlined yet.

CONCLUSION

Glossaries may be used in several stages during the software development process; however, their use during the RE phase is very convenient. Their use eases the understanding of the clients' and users' culture and allows creating all RE documents using their vocabulary.

Other documents produced in later phases of the software development process may also take advantage of the use of LEL.

Creating well-conceived system software context glossaries requires a good understanding of the model and following the heuristics and guidelines developed for this purpose.

Verification and validation of the glossary are key practices in the whole process since they will find out most of the existent defects, improving its quality.

KEY TERMS

Elicitation: Elicitation is the activity of acquiring knowledge of a given kind during the requirements engineering process.

Heuristic: It is a set of guidelines to help people to use others' experience to improve performance in a given task.

Language-Extended Lexicon: An LEL is a semiformal model holding the most relevant words or phrases of the language of the application domain carrying special meaning.

Requirements Engineering: It is an area of the software engineering that is responsible for acquiring and defining needs of the software system.

Software Engineering: It is the computer science discipline concerned with creating and maintaining software applications by applying technologies and practices from computer science, project management, engineering, application domains, and other fields.

Sources of Information: These include documents, key people, books, and so forth that can provide useful information about the matter being studied.

Validation: Validation is the activity of contrasting a model with the actual world. It should answer the question "Are we creating the right model?"

Verification: It is the activity of checking for the consistency of different parts of a model or different models among them. It should answer the question "Are we creating the model right?"

ENDNOTES

[1] The following is the notation of SADT: Boxes represent activities, left-pointing arrows represent input required by the activity, down-pointing arrows represent controls, up-pointing arrows represent mechanisms, and right-pointing arrows represent output from the activity.

[2] A DEO list contains the discrepancies, errors, and omissions discovered during the verification or validation activities, where suggestions for corrections are included.

Creating Superior Knowledge Discovery Solutions

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

INTRODUCTION

The information age has made information communication technology (ICT) a necessity for conducting business. This in turn has led to the exponential increase in the electronic capture of data and its storage in vast data warehouses. In order to respond quickly to fast changing markets, organizations must maximize these raw data and information resources. Specifically, they need to transform them into germane knowledge to aid superior decision-making (Wickramasinghe & von Lubitz, 2006). To do this effectively not only involves the analysis of the data and information but also requires the use of sophisticated tools to enable such analyses to occur. Knowledge discovery technologies represent a spectrum of new technologies that facilitate the analysis of data to find relationships from the data to finding reasons behind observable patterns (i.e., transform the data into relevant information and germane knowledge). Such new discoveries can have a profound impact on decision making in general and the designing of business strategies. With the massive increase in data being collected and the demands of a new breed of intelligent applications like customer relationship management, demand planning, and predictive forecasting, these knowledge discovery technologies are becoming competitive necessities for providing a high performance and feature rich intelligent application servers for intelligent enterprises.

Knowledge management (KM) tools and technologies are the systems that integrate various legacy systems, databases, ERP systems, and data warehouse to help facilitate an organization's knowledge discovery process. Integrating all of these with advanced decision support and online real time events enables an organization to understand customers better and devise business strategies accordingly. Creating a competitive edge is the goal of all organizations employing knowledge discovery for decision support (Thorne & Smith, 2000).

The following provides a synopsis of the major tools and critical considerations required to enable an organization to successfully effect appropriate knowledge sharing, knowledge distribution, knowledge creation, as well as knowledge capture and codification processes and hence embrace effective knowledge management (KM) techniques and advanced knowledge discovery.

BACKGROUND

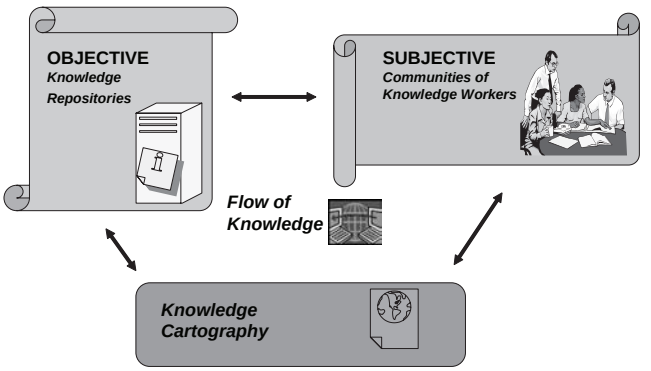
A necessary but not sufficient consideration to facilitate the generation of superior knowledge discovery solutions is the establishment of a sound KM infrastructure (Wickramasinghe et al., 2006). The KM infrastructure, in terms of tools and technologies, (hardware as well as software) should be established so that knowledge can be created from any new event or activity, which in turn will ensure that the extant knowledge base continuously grows (Wickramasinghe, Fadlalla, Geisler, & Schaffer, 2003; Wickramasinghe & Bali, 2006). The entire new know-how or new knowledge can only be created for exchange if the KM infrastructure is established effectively. Critical components of such a KM infrastructure include a repository of knowledge, and networks to distribute the knowledge to the members of organization and a facilitator system for the creation of new knowledge. Such a knowledge-based infrastructure will foster the creation of knowledge, and provide an integrated system to share and diffuse the knowledge in the organization (Srikantaiah & Koenig, 2000).

KNOWLEDGE ARCHITECTURE

Architecture, specifically the information technology architecture is an integrated set of technical choices used to guide an organization in satisfying its business needs (Weil & Broadbent, 1998). Underlying the knowledge architecture (Wickramasinghe, 2003; Wickramasinghe, 2005; refer to Figure 1) is the recognition of the binary nature of knowledge; namely its objective and subjective components. What we realize when we analyze the knowledge architecture closely, is that knowledge is not a clearly defined, easily identifiable phenomenon, rather it has many forms which makes managing it even more challenging (Schultz & Leidner, 2002; Wickramasinghe, 2005).

The knowledge architecture depicted in Figure 1 recognizes the two different, yet key aspects of knowledge; namely, knowledge as an object and a subject. By doing so, it provides the blue prints for an all encompassing knowledge management system (KMS). The pivotal function underlined by the knowledge architecture is the flow of knowledge. The

Figure 1. The knowledge architecture (Adapted from Wickramasinghe & Mills, 2001)



flow of knowledge is fundamentally enabled (or not) by the knowledge management system.

KNOWLEDGE MANAGEMENT SYSTEMS

Given the importance of knowledge, systems are being developed and implemented in organizations that aim to facilitate the sharing and integration of knowledge (i.e., support and facilitate the flow of knowledge). Such systems are called knowledge management systems (KMS) as distinct from transaction processing systems (TPS), management information systems (MIS), decision support systems DSS), and executive information systems (EIS) (Alavi & Leidner, 1999). For example, Cap Gemini Ernst & Young, KPMG, and Acenture all have implemented KMS (Wickramsinghe, 2003). In fact, the large consulting companies were some of the first organizations to realize the benefits of knowledge management and plunge into the knowledge management abyss. These companies treat knowledge management with the same high priority as they do strategy formulation, an illustration of how important knowledge management is viewed in practice (Wickramasinghe, 2003). Essentially, these knowledge management systems use combinations of the following technologies: the Internet, intranets, extranets, browsers, data warehouses, data filters, data mining, client server, multimedia, groupware, and software agents to systematically facilitate and enable the capturing, storing, and dissemination of knowledge across the organization (Alavi et al., 1999; Davenport & Prusak, 1998; Kanter, 1999). Unlike, other types of information systems, knowledge management systems can vary dramatically across organizations. This is appropriate if we consider that each organization's intellectual assets, intangibles, and knowledge should be to a large extent unique and thus systems enabling their management should in fact differ.

KNOWLEDGE MANAGEMENT TOOLS AND TECHNIQUES

KM tools and techniques are defined by their social and community role in the organization in (1) the facilitation of knowledge sharing and socialization of knowledge (production of organizational knowledge); (2) the conversion of information into knowledge through easy access, opportunities of internalization and learning (supported by the right work environment and culture); (3) the conversion of tacit knowledge into "explicit knowledge" or information, for purposes of efficient and systematic storage, retrieval, wider sharing, and application. The most useful KM tools and techniques can be grouped as those that capture and codify knowledge and those that share and distribute knowledge (Duffy, 2000, 2001; Maier, 2001).

Capture and Codify Knowledge

There are various tools that can be used for capture and codify knowledge. These include databases, various types of artificial intelligence systems including expert systems, neural networks, fuzzy logic, genetic algorithms, and intelligent or software agents.

Databases

Databases store structured information and assist in the storing and sharing of knowledge. Knowledge can be acquired from the relationships that exist among different tables in a database. For example, the relationship that might exist between a customer table and a product table could show those products that are producing adequate margins, providing decision-makers with strategic marketing knowledge. Many different relations can exist and are only limited by the human imagination. These relational databases help

users to make knowledgeable decisions, which is a goal of knowledge management. Discrete, structured information still is managed best by a database management system. However, the quest for a universal user interface has led to the requirement for access to existing database information through a Web browser.

Case-Based Reasoning Applications

Case-based reasoning (CBR) applications combine narratives and knowledge codification to assist in problem solving. Descriptions and facts about processes and solutions to problems are recorded and categorized. When a problem is encountered, queries or searches point to the solution. CBR applications store limited knowledge from individuals who have encountered a problem and found the solution and are useful in transferring this knowledge to others.

Expert Systems

Expert systems represent the knowledge of experts and typically query and guide users during a decision making process. They focus on specific processes and typically lead the user, step by step, toward a solution. The level of knowledge required to operate these applications is usually not as high as for CBR applications. Expert systems have not been as successful as CBR in commercial applications but can still be used to teach knowledge management.

Using I-Net Agents: Creating Individual Views from Unstructured Content

The world of human communication and information has long been too voluminous and complex for any one individual to monitor and track. Agents and I-net standards are the building blocks that make individual customization of information possible in the unstructured environment of I-nets. Agents will begin to specialize and become much more than today's general purpose search engines and "push" technologies.

Two complimentary technologies have emerged that allow us to coordinate, communicate, and even organize information without rigid, one-size-fits-all structures. The first is the Internet/Web technologies that are referred as I-net technology and the second is the evolution of software agents. Together, these technologies are the new-age building blocks for robust information architectures, designed to help information consumers find what they are looking for in the way that they want to find it. The Web and software agents make it possible to build sophisticated, well performing information brokers designed to deliver content, from multiple sources, to each individual, in the individual's specific context and under the individual's own control. The software agents supported with I-net infrastructure can be highly effective tools for individualizing the organization and management of distributed information.

Systems to Share and Distribute Knowledge

Computer networks provide an effective medium for the communication and development of knowledge management. The Internet and organizational intranets are used as a basic infrastructure for knowledge management. Intranets are rapidly becoming the primary information infrastructure for enterprises. An intranet is basically a platform based on Internet principles accessible only to members of an organization/community. The intranet can provide the platform for a safe and secured information management system within the organization, help people to collaborate as of virtual teams, crossing boundaries of geography and time. While the Internet is an open-access platform, the intranet, however, is restricted to members of a community/organization through multi-layered security controls. The same platform, can be extended to an outer ring (e.g., dealer networks, registered customers, online members, etc.), with limited accessibility, as an extranet. The extranet can be a meaningful platform for knowledge generation and sharing, in building relationships, and in enhancing the quality and effectiveness of service/support. The systems that are used to share and distribute knowledge could include group collaboration systems, groupware, intranets, extranets, and Internet, office systems, word processing, desktop publishing, or Web publishing.

FUTURE TRENDS

Just implementing a knowledge management system does not make an organization a knowledge based business. For an organization to become a knowledge-based business, several aspects must be considered. An organization that values knowledge must integrate knowledge into its business strategy and sell it as a key part of its products and services. To do this requires a strong commitment to knowledge management directed from the top of the organization. Furthermore, it is necessary for specific people, process, and technology issues to be considered. First, the knowledge architecture should be designed that is suitable given the context of a particular organization in its industry as well as the activities, products or services it may provide. From the knowledge architecture, it is important to focus on the organization's structure and culture and key people issues. Do the structure and culture support a knowledge-sharing environment or perhaps a more team focussed, sharing culture needs to be fostered. In addition, strategies need to be adopted for continuous training and fostering

of knowledge workers. Then, it is necessary to consider the processes of generating, representing, accessing and transferring knowledge throughout the organization. This also requires and evaluation of the technologies required enabling this. Finally, a knowledge based business should also enable organizational learning to take place so that the knowledge that is captured is always updated and current, and the organization is continually improving and refining its product or service as well as enhancing its extant knowledge base.

CONCLUSION

In today's hyper competitive business environment, organizations that can make superior and timely decisions have a greater chance of succeeding. This can only be done effectively and efficiently through the transformation of an organization's data and information assets into germane knowledge and relevant information. By utilizing the spectrum of intelligent technologies as well as embracing the tools and techniques of KM, organizations can successfully effect this required transformation and thereby create appropriate knowledge discovery solutions. Hence, the incorporation of KM and judicious adoption of intelligent technologies becomes a competitive necessity for all organizations.

KEY TERMS

KM Infrastructure: The tools and technologies (the specific tools required to capture and codify organizational knowledge, specific tools required to share and distribute organizational knowledge) that are required to support and facilitate KM in the organization. KM tools and technologies are the systems that integrate various legacy systems, databases, ERP systems, and data warehouse to help organizations to create, and use KM systems in the organization.

Knowledge: Knowledge is more comprehensive than data or information. It is a mix of experience, values, contextual information, expert insights, and grounded intuition that actively enables performance, problem solving decision-making, learning, and teaching.

Knowledge Architecture: The blue prints of subjective and objective knowledge, its flows and cartography of knowledge within the organization.

Knowledge as Object: This is when knowledge is conceptualized in the Lokean/Leibnitzian perspective and used to create efficient and effective solutions.

Knowledge as Subject: This is when knowledge is conceptualized in the Hegelian/Kantian perspective and used to create shared meanings and support sense making.

Knowledge Assets: The knowledge regarding markets, products, technologies, processes, and organizations, that a business owns or needs to own and which enable its business processes to generate profits, add value, etc.

Knowledge-Based Enterprises: Knowledge-based enterprises are those enterprises who derive the most value—from intellectual rather than physical assets. Knowledge-based enterprise is a firm that is fully embracing knowledge management and committed to fostering continuous learning.

Knowledge Management (KM): KM is the process through which organizations generate value from their intellectual and knowledge-based assets. Most often, generating value from such assets involves sharing them among employees, departments and even with other companies in an effort to devise best practices. KM is newly emerging, interdisciplinary business approach that involves utilizing people, processes, and technologies to create, store and transfer knowledge.

INTRODUCTION

The widespread use of databases and the fast increase of the volume of data they store are creating a problem and a new opportunity for credit companies. These companies are realizing the necessity of making an efficient use of the information stored in their databases, extracting useful knowledge to support their decision-making process.

Nowadays, knowledge is the most valuable asset a company or nation may have. Several companies are investing large sums of money in the development of new computational tools able to extract meaningful knowledge from large volumes of data collected over many years. Among such companies, companies working with credit risk analysis have invested heavily in sophisticated computational tools to perform efficient data mining in their databases.

The behavior of the financial market is affected by a large number of political, economic, and psychological factors, which are correlated and interact among themselves in a complex way. The majority of these relations seems to be probabilistic and non-linear. Thus, these relations are hard to express through deterministic rules.

Simon (1960) classifies the financial management decisions in a continuous interval, whose limits are non-structure and highly structured. The highly structured decisions are those where the processes necessary for the achievement of a good solution are known beforehand and several computational tools to support the decisions are available. For non-structured decisions, only the managers' intuition and experience are used. Specialists may support these managers, but the final decisions involve a substantial amount of subjective elements. Highly non-structured problems are not easily adapted to the computer-based conventional analysis methods or decision support systems (Hawley, Johnson, & Raina, 1996).

BACKGROUND

The extraction of useful knowledge from large databases is named *knowledge discovery in databases* (KDD). KDD is a very demanding task and requires the use of sophisticated computing techniques (Brachman & Anand, 1996; Fayyad, Piatetsky-Shapiro, Amith, & Smyth, 1996). The recent advances in hardware and software make possible the development of new computing tools to support such a task. According to Fayyad et al. (1996), KDD comprises a sequence of stages, including:

- Understanding the application domain,
- Selection,
- Pre-processing,
- Transformation,
- Data mining, and
- Interpretation/evaluation.

It is also important to stress the difference between KDD and *data mining* (DM). While KDD denotes the whole process of knowledge discovery, DM is a component of this process. The DM stage is used as the extraction of patterns or models from observed data. KDD can be understood as a process that contains the previous listed steps. At the core of the knowledge discovery process, the DM step usually takes only a small part (estimated at 15-25%) of the overall effort (Brachman & Anand, 1996).

The KDD process begins with the understanding of the application domain, considering aspects such as the objectives of the application and the data sources. Next, a representative sample, selected according to statistical techniques, is removed from the database, preprocessed, and submitted to the methods and tools of the DM stage with the objective of finding patterns/models (knowledge) in the data. This knowledge is then evaluated regarding its quality and/or usefulness, so that it can be used to support a decision-making process.

Frequently, DM tools are applied to unstructured databases, where the data can, for example, be extracted from texts. In these situations, specific pre-processing techniques must be used in order to extract information in the attribute-value format from the original texts.

CREDIT RISK ASSESSMENT

Credit risk assessment is concerned with the evaluation of the profit and guaranty of a credit application. According to Dong (2006), the main approaches proposed in the literature for credit assessment can be divided into two groups: default models and credit scoring models. While default models assess the likelihood of default, credit scoring models assess the credit quality of the credit taker. This text covers credit scoring models.

A typical credit risk assessment database is composed of several thousands of credit applications. These credit applications can be related with either companies or people. Examples of personal credit applications are student loans, personal loans, credit card concessions, and home mortgages. Examples of company credits are loans, stocks, and bonds (Ross, Westerfield, & Jaffe, 1993).

Usually, the higher the value of the credit asked, the more rigorous is the credit risk assessment. Large financial institutions usually have whole departments dedicated to this problem.

The traditional approach employed by bank managers largely depends on their previous experience and does not follow the procedures defined by their institutions. Besides, several deficiencies in the dataset available for credit risk assessment, together with the high volume of data currently available, makes the manual analysis almost impossible. The treatment of these large databases overcomes the human capability of understanding and efficiently dealing with them, creating the need for a new generation of computational tools and techniques to perform automatic and intelligent analysis of large databases.

In 2004, the Basel Committee on Banking Supervision published a new capital measurement system, known as the New Basel Capital Accord, or Basel II, which implements a new credit risk assessment framework that supports the estimation of the minimum regulatory capital that should be allocated for the compensation of possible default loans or obligations (Basel, 2004; Van Gestel et al., 2006). The Basel Committee was created in 1974 by the central-bank of 10 countries. In 1988, the committee introduced a capital measurement system commonly referred to as the Basel Capital Accord. The first accord established general guidelines for credit risk assessment. The new accord, Basel II, stimulates financial institutions to adopt customized rating risk systems based on their credit transaction databases. As a consequence, DM techniques assume a very important role in credit risk assessment. They will allow the replacement of general risk assessment by careful analysis of each loan commitment.

Credit analysis databases usually cover a huge number of transactions performed over several years. The analysis of these data may lead to a better understanding of the customer's profile, thus supporting the offer of new products or services. These data usually hold valuable information, for example, trends and patterns, which can be employed to improve credit assessment. The large amount makes its manual analysis an impossible task. In many cases, several related features need to be simultaneously considered in order to accurately model credit user behavior. This need for automatic extraction of useful knowledge from a large amount of data is widely recognized.

USING DATA MINING FOR CREDIT RISK ASSESSMENT

DM techniques are employed to discover strategic information hidden in large databases. Before they are explored, these databases are cleaned. Next, a representative set of samples is selected. Machine learning techniques are then applied to these selected samples. The use of data mining techniques on a credit risk analysis database allows the extraction of several relevant pieces of information regarding credit card transactions.

The data present in a database must be adequately prepared before data mining techniques can be applied to it. The main steps employed for data preparation are:

- Preprocessing of the data to the format specified by the algorithms to be used;
- Reduction of the number of samples/instances;
- Reduction of the number of features/attributes;
- Features construction, which is the combination of one or more attributes in order to transform irrelevant attributes to more significant attributes; and
- Noise elimination and treatment of missing values.

Once the data have been pre-processed, machine learning (ML) techniques can be employed to discover useful knowledge. The quality of a knowledge extraction technique can be evaluated by different measures, such as accuracy; comprehensibility; and new, useful knowledge.

The application of data mining techniques for credit risk analysis may provide important information that can improve the understanding of the current credit market and support the work of credit analysts (Carvalho, Braga, Rezende, Ludermir, & Martineli, 2002; Eberlein, Breckling, & Kokic, 2000; Horst, Padilha, Rocha, Rezende, & Carvalho, 1998; Lacerda, de Carvalho, Braga, & Ludermir, 2005; Dong, 2006; Huang, Hung, & Jiau, 2006).

Credit analysis can be seen as a pattern classification task that involves the evaluation of the reliability and profitability of a credit application. If the labels associated with the data, characterizing each customer as either a good or a bad customer, are available, customers can be classified into these two classes. This is a binary classification problem. However, a credit scoring system does not need to be restricted to two classes. Financial institutions may have different categories for the customers, according to the provision required, for example. These categories usually form a ranking, with the best customers close to the top. Current economic indexes and changes in the customer profile may change his or her position in the ranking. In this case, a multiclass classification system should be used, preferably one that allows ranking classification.

In credit risk assessment, different misclassifications have different costs. However most of the existing data mining algorithms assume that the goal is to minimize the number of misclassification errors. Whenever different errors have different costs, several authors (Breiman, Freidman, Olshen, & Stone,1984; Turney, 1995) propose to minimize the conditional risk, which is the expected cost of predicting that *x* belongs to $Class_i$. The conditional risk is defined as: $Risk(Class_i / x) = sum_j P(Class_i / x) * C(i,j)$, where C(i,j) is the cost of predicting class i when the true class is j.

Different ML techniques have been used for credit risk assessment datasets. One of the studies found in the literature (Horst et al., 1998) compares the performance of neural networks and decision trees for credit risk assessment. Alternative approaches for the induction of Bayesian classifiers applied to credit scoring are investigated (Baesens, Egmont-Petersen, Castelo, & Vanthienen, 2002). Dong (2006) studies the influence of the metric distance in the performance of a case-based reasoning system used for credit scoring. A model based on support vector machines following the Basel II accord is proposed in Van Gestel et al. (2006). Another work using support vector machines highlights the importance of each input attribute selection (Yu, Lai, & Wang, 2006). The problem of imbalanced distribution of examples into the classes and its influence on different ML techniques is investigated in Huang et al. (2006).

Several of the most recent approaches are based on hybrid intelligent systems (HISs). In Mendes Filho, de Carvalho, and Matias (1997), multi-layer perceptron neural networks are designed by genetic algorithms to credit assessment. Fuzzy and neurofuzzy approaches for credit scoring are compared in Hoffmann, Baesens, Martens, Put, and Vanthienen (2002). Lacerda et al. (2005) show how radial basis function neural networks tuned for credit assessment problems can be evolved by genetic algorithms. Two approaches for learning fuzzy rules for credit scoring by using evolutionary algorithms are investigated in Hoffmann, Baesens, Mues, Van Gestel, and Vanthienen (2007). In another hybrid approach, a classifier based on multi-criteria linear programming is combined with independent analysis (Li, Shi, Zhu, & Dai, 2006).

CRITICAL ISSUES OF CREDIT ANALYSIS IN DATA MINING

There are, of course, a few problems that can arise from the use of data mining techniques for credit risk analysis. The main advantages and problems associated with this technology are briefly presented in Table 1. Current Internet technology may allow the invasion of company databases, which may lead to the access of confidential data. Besides, the stored data may be made available to other companies or used without the knowledge or authorization of the customer. On the other

Table 1. A summary of critical issues of credit risk analysis data mining

Data Mining Extraction of useful information from large Databases	**Privacy & Confidentiality Agreements** Addressing individual right to privacy and the sharing of confidential information
Concept Drifting When statistical properties of the target concept chance over time.	**Training of Employees** Credit analysis should be trained with the new tools available and shown the benefits of the new technologys
Inadequate information Applicants may have supplied incorrect information, intentionally or not	**User Ignorance and Perceptions** Lack of adequate understanding of the Data Mining and it usefulnes
Maintaining and integrity of data Maintaining up-to-date and accurate information on the databases	**Security** Maintaining secure and safe systems and keeping unauthorized user access out

hand, the extraction of useful information from credit risk analysis databases should result in benefits not only to the companies, but also to the customers, with the offering of better and more convenient credit products.

FUTURE TRENDS

A key issue in credit risk assessment is the non-stationary properties of the problem: interests change over time. In this context, methods that take drift into account can improve the generalization capability of the learning algorithms by adaptation of decision models to the most recent data (Gama, Medas, Castillo, & Rodrigues, 2004).

Credit-related data is being produced at growing rates. If the process is not strictly stationary (as in most real-world applications), the target concept could gradually change over time. For example, classes' profiles for good and bad clients may rapidly change. The ability to incorporate this concept drift is a natural extension for future DM systems. In real-time credit assessment, large chunks of data will be collected over time. Future credit assessment DM tools will have to deal with possible modifications in the existing classes. A natural approach for this new situation is the use of adaptive learning algorithms, where incremental learning algorithms take into account such concept drift.

Future work in this area should also take into consideration security issues, support to ubiquitous computing, and a better integration with current databases technology.

CONCLUSION

Several companies perform data mining on personal data stored in their databases. This is particularly true for credit risk analysis databases, where customers' personal data can be employed to improve the quality of credit assessment and support the offer of new credit products. Data mining systems usually employ artificial intelligence and statistical techniques to acquire relevant, interesting, and new knowledge for most applications, including credit risk analysis. Although one cannot avoid the use of these sophisticated techniques to support credit assessment, great care should be taken to guarantee privacy and that personal rights are not violated when working with private information.

A financial problem that shares several similarities with credit risk assessment is bankruptcy prediction. In the movement towards economic blocks, the growing globalization demands robust and reliable systems for banks' bankruptcy forecasting. This demand comes from different sources, like managers, investors, and government organizations. DM has also been successfully used for bankruptcy prediction, as can be seen in Martineli, Diniz, de Carvalho, Rezende, and Matias (1999), Atiya (2001), and Chakraborty and Sharma (2007).

KEY TERMS

Consumer Credit: A loan to an individual to purchase goods and/or services for personal, family, or household use.

Credit: Delivery of a value in exchange of a promise that this value will be paid back in the future.

Credit Scoring: A numerical method of determining an applicant's loan suitability based on various credit factors such as types of established credit, credit ratings, residential and occupational stability, and ability to pay back loan.

Data: The set of samples, facts, or cases in a data repository. As an example of a sample, consider the field values of a particular credit application in a bank database.

Data Mining: The process of extracting meaningful information from very large databases. One of the main steps of the KDD process.

KDD: Process of knowledge discovery in large databases.

Knowledge: Defined according to the domain, considering usefulness, originality, and understanding.

Machine Learning: Sub-area of artificial intelligence that includes techniques able to learn new concepts from a set of samples.

Critical Realism as an Underlying Philosophy for IS Research

Philip J. Dobson
Edith Cowan University, Australia

INTRODUCTION

Many recent articles from within the information systems (IS) arena present an old-fashioned view of realism. For example, Iivari, Hirschheim, and Klein (1998) saw classical realism as seeing "data as describing objective facts, information systems as consisting of technological structures ('hardware'), human beings as subject to causal laws (determinism), and organizations as relatively stable structures" (p. 172). Wilson (1999) saw the realist perspective as relying on "the availability of a set of formal constraints which have the characteristics of abstractness, generality, invariance across contexts."

Fitzgerald and Howcroft (1998) presented a realist ontology as one of the foundational elements of positivism in discussing the polarity between hard and soft approaches in IS. Realism is placed alongside positivist, objectivist, etic epistemologies and quantitative, confirmatory, deductive, laboratory-focussed and nomothetic methodologies. Such a traditional view of realism is perhaps justified within the IS arena, as it reflects the historical focus of its use, however, there now needs to be a greater recognition of the newer forms of realism—forms of realism that specifically address all of the positivist leanings emphasised by Fitzgerald and Howcroft (1998). A particular example of this newer form of realism is critical realism. This modern realist approach is primarily founded on the writings of the social sciences philosopher Bhaskar (1978, 1979, 1986, 1989, 1991). The usefulness of such an approach has recently been recognized in the IS arena by Dobson (2001) and Mingers (2002).

BACKGROUND

Bhaskar's brand of realism (referred to by Searle, 1995, as a form of external realism) argues that there exists a reality totally independent of our representations of it; the reality and the "representation of reality" operating in different domains—roughly a transitive epistemological dimension and an intransitive ontological dimension. For the realist, the most important driver for decisions on methodological approach will always be the intransitive dimension—the target being to unearth the real mechanisms and structures underlying perceived events. Critical realism acknowledges that observation is value laden, as Bhaskar pointed out in a recent interview:

...there is no conflict between seeing our scientific views as being about objectively given real worlds, and understanding our beliefs about them as subject to all kinds of historical and other determinations. (Norris, 1999)

The critical realist agrees that our knowledge of reality is a result of social conditioning and thus cannot be understood independently of the social actors involved in the knowledge derivation process. However, it takes issue with the belief that the reality is a product of this knowledge derivation process. The critical realist asserts that "real objects are subject to value laden observation"; the *reality* and the value-laden *observation of reality* operate in two different dimensions, one intransitive and relatively enduring and the other transitive and changing.

An important aspect of a critical realist approach is that it not only provides direction on the characteristics and behaviour of the underlying objects of enquiry, but it also provides direction as to how to examine these objects. The philosophy is presented as an underlabourer to social enquiry in that it can help with "clearing the ground a little...removing some of the rubbish that lies in the way of knowledge" (Locke, 1894, p. 14). This integral and important role for philosophy in the enquiry process can help to avoid many potentially false pathways and avenues.

For example, Bhaskar (1979) presented fundamental difficulties with the way that prediction and falsification have been used in the open systems evident within the social arena. For the critical realist, a major issue with social investigation is the inability to create closure—the aim of "experiment" in the natural sciences. Bhaskar (1979) argued that this inability implies that theory cannot be used in a predictive manner and can only play an explanatory role in social investigations, because:

…in the absence of spontaneously occurring, and given the impossibility of artificially creating, closed systems , the human sciences must confront the problem of the direct scientific study of phenomena that only manifest themselves in open systems—for which orthodox philosophy of science, with its tacit presupposition of closure, is literally useless. In particular it follows from this condition that criteria for

the rational appraisal and development of theories in the social sciences, which are denied (in principle) decisive test situations, cannot be predictive and so must be exclusively explanatory. (p. 27)

As Mingers (2002) suggested, such an argument has specific ramifications with respect to the use of statistical reasoning to predict future results. Bhaskar (1979) argued that the primary measure of the "goodness" of a theory is in its explanatory power. From Bhaskar's perspective, predictive use of theories is not possible in open social systems, and therefore, predictive power cannot be a measure of goodness. From this point of view, theory acts as primarily an explanatory tool for explaining events in hindsight.

Critical realism uses abductive or retroductive reasoning as its main focus. Positivist approaches are associated more with deductive or inductive reasoning. Deductive reasoning is the fundamental reasoning of mathematics, whereby some statement "*p*" leads to implications "*q*"—a movement from the general to the particular. For example, the general claim that "all crows are black" moves to the particular inference that the next one seen will be black. For the crows example, retroductive or abductive reasoning follows from an observation of numerous black crows to a theory as to a mechanism to explain why crows are disposed to be black. As Mingers (2002) described:

We take some unexplained phenomenon and propose hypothetical mechanisms that, if they existed, would generate or cause that which is to be explained. So, we move from experiences in the empirical domain to possible structures in the real domain. This does not of itself prove that the mechanism exists, and we may have competing explanations, so the next step is to work toward eliminating some explanations and supporting others. (p. 300)

Outhwaite (1987) similarly suggested that the critical realist method involves "the postulation of a possible [structure or] mechanism, the attempt to collect evidence for or against its existence and the elimination of possible alternatives" (p. 58). The realist agrees that we have a good explanation when (a) the postulated mechanism is capable of explaining the phenomenon, (b) we have good reason to believe in its existence, and (c) we cannot think of any equally good alternatives. Such an explanatory target suggests that philosophical considerations must play an important role in the critical realist method, because such an approach often requires transcending, or speculating, perhaps nonobservable mechanisms and structures to explain perceived happenings. Such initial proposition is transcendental or metaphysical in its focus, and as such, any explanation or discovery made is seen to be fallible and extendable as knowledge grows. As Wad (2001) argued:

If we take explanation to be the core purpose of science, critical realism seems to emphasise thinking instead of experiencing, and especially the process of abstraction from the domains of the actual and the empirical world to the transfactual mechanisms of the real world. (p. 2).

This type of thinking is called transcendental by Bhaskar, in that it gives an important role to the crossing of the divide between the empirical and speculative activities of scientific work. As Wad pointed out, this is necessary because often the experienced world of events is not explainable in terms of the empirical facts but only by way of incorporating non-experienced mechanisms incorporated in objects that may be within or outside our domain of investigation.

RESEARCH IMPLICATIONS

Sayer (2000) contended: "Compared to positivism and interpretivism, critical realism endorses or is compatible with a relatively wide range of research methods, but it implies that the particular choices should depend on the nature of the object of study and what one wants to learn about it" (p. 19). As Mingers (2002) suggested, critical realism supports methodological pluralism in that it suggests that an external reality is open to multiple interpretations and understandings.

Yet, critical realism also has important things to say about the objects of enquiry in that it is an ontologically bold philosophy (Outhwaite, 1987, p. 34). It not only encompasses an external realism in its distinction between the world and our experience of it, but it also suggests a stratified ontology and a so-called depth realism in defining the objects that make up such a world. This concept suggests that reality is made up of three ontologically distinct realms: first, the empirical, that is experience; second, the actual, that is events (i.e., the actual objects of experience); and third, the transcendental, nonactual or deep, that is structures, mechanisms, and associated powers. This so-called depth realism proposes that "the world is composed not only of events and our experience or impression of them, but also of (irreducible) structures and mechanisms, powers and tendencies, etc. that, although not directly observable, nevertheless underlie actual events that we experience and govern or produce them" (Lawson, 1997, p. 8). Critical realism, in its use of retroduction, involves a movement from a surface phenomenon to a deeper causal thing; it involves the steady unearthing of deeper levels of structures and mechanisms.

The ontological complexity assumed by critical realism is, however, matched with a conservative epistemology heavily dependent on scientific argument. As Wad (2001) said, critical realism has little to say concerning practical advice:

One may get the feeling that critical realism develops a huge

superstructure of ontological and epistemological insights, but when it comes to practical research we are left with the usual methodological suspects, delivered by inductivists, positivist and empirical-analytical scientists. (p. 12)

As Stones (1996) argued, realist methodologies need to be able to account for the underlying ontological richness they implicitly assume. They also need to reflect the belief that any knowledge gains are typically provisional, fallible, incomplete, and extendable. Realist methodologies and writings, thus, must reflect a continual commitment to caution, scepticism, and reflexivity.

FUTURE TRENDS

Critical realism is becoming influential in a range of disciplines, including geography (Pratt, 1995; Yeung, 1997), economics (Lawson, 1997; Fleetwood, 1999), organization theory (Tsang & Kwan, 1999), accounting (Manicas, 1993), human geography (Sayer, 1985), nursing (Ryan & Porter,1996; Wainwright, 1997), logistics and network theory (Aastrup, 2002), and library science (Spasser, 2002). The application of critical realism within the IS field has been limited to date. Mutch (1995, 1999, 2002) has applied critical realist thinking in the examination of organizational use of information. In so doing, he commented on how difficult it is to apply such a wide-ranging and sweeping philosophical position to day-to-day research issues. Mingers (2001, 2002) examined the implications of a critical realist approach, particularly in its support for pluralist research. Dobson (2001, 2002) argued for a closer integration of philosophical matters within IS research and proposed a critical realist approach. Information systems are social systems, and it makes sense to apply a modern social philosophy such as critical realism to their examination.

CONCLUSION

In researching the social context within which information technology (IT) and IS operate, a modern social philosophy such as critical realism has considerable potential. It can provide useful insight into the type of (retroductive) questions that may be asked and also the means by which an examination can progress. The integrated nature of the philosophy encourages a consistency in research in that it recognizes the tripartite connections between ontology, methodology, and practical theory. As Archer (1995) argued:

The social ontology endorsed does play a powerful regulatory role vis-à-vis the explanatory methodology for the basic reason that it conceptualises social reality in certain terms. Thus identifying what there is to be explained and also ruling out explanations in terms of entities or properties which are deemed non-existent. Conversely, regulation is mutual, for what is held to exist cannot remain immune from what is really, actually or factually found to be the case. Such consistency is a general requirement and it usually requires two-way adjustment. (p. 17)

The required consistency between ontological and epistemological matters has led to the critical realist observation that many of the things that traditionally have been done in researching the social arena are actually inconsistent with the underlying nature of the social objects proposed (see, for example, Lawson, 1997, who presented some of the inconsistencies evident in traditional use of economic theory in the social arena). There are, however, few practical examples of the use of critical realism in the IS field and the obvious potential it has is not yet realized. While, as Wilson (1999) observed, the realist argument has shown a remarkable resilience and resourcefulness in the face of the "rise of relativism," and more practical examples of its application need to be developed. Carlsson (2003) examines IS evaluation from a critical realist perspective.

KEY TERMS

Author's Note: In philosophy, definitions become a basis for debate—they often reflect the area from which the author derives. Perhaps the following reflect realist origins.

Closed and Open Systems: A *closed system* is one restricted in such a way that laws have uniform effects. An *open system* is one that is not closed. Closed systems do not usually occur spontaneously in nature and generally require human intervention, such as in laboratory experiments (from www.raggedclaws.com/criticalrealism).

Critical Realism: The careful or critical application of the scientific approach to the social sciences.

Epistemology: The study of knowledge or how we come to know.

Ontology: The study of what exists.

Philosophy: "The critical examination of the grounds for fundamental beliefs and an analysis of the basic concepts employed in the expression of such beliefs" (*Encyclopaedia Britannica*, p. 388, *Micropedia*, Vol. 9, 1985) or the "rational, methodical, and systematic consideration of those topics that are of greatest concern to man" (*Macropedia*, Vol. 25, p. 742, 1985 edition).

Realism: The belief that there is a reality independent of our perceptions of it.

Transitive and Intransitive Dimensions: The *intransitive dimension* in the philosophy of science corresponds roughly to ontology, and the *transitive dimension* corresponds roughly to epistemology. Intransitive objects exist and act independently of our knowledge of them (except when we use our knowledge to intervene (see www.raggedclaws.com/criticalrealism).

Critical Realist Information Systems Research

Sven A. Carlsson
Lund University, Sweden

INTRODUCTION

The information systems (IS) field is dominated by positivistic research approaches and theories (Chen & Hirschheim, 2004). IS scholars have pointed out weaknesses in these approaches and theories and in response different strands of post-modern theories and constructivism have gained popularity—see, Lee, Liebenau, and DeGross (1997) and Trauth (2001). The approaches argued for include ethnography, constructivism, grounded theory, and theories like Giddens' structuration theory and Latour's actor-network theory. (We refer to these different research approaches and theories as "post-approaches" and "post-theories" when distinction is not required).

BACKGROUND

Although post-approaches and post-theories overcome some of the problems noted with positivistic approaches and theories, they have at least three major weaknesses and limitations. First, their fascination with the voices of those studied leads to IS research as mere reportages and local narratives which can lead to any narrative/reportage being as good as another narrative/reportage. Second, their focus on agency leads to ignoring the structural dimension—the agency/structure dimension is collapsed, leading to a flat treatment of the dimension. Third, their rejection of objectivist elements leads to problems when researching ICT-artifacts and ICT-based IS. For elaborate critique of post-approaches and post-theories, see Archer, Bhaskar, Collier, Lawson, and Norrie (1998).

An alternative to traditional positivistic models of social science as well as an alternative to post-approaches and post-theories is critical realism (CR). CR argues that social reality is not simply composed of agents' meanings, but that there exist structural factors influencing agents' lived experiences. CR starts from an ontology which identifies structures and mechanisms through which events and discourses are generated as being fundamental to the constitution of our natural and social reality. This article briefly presents CR and exemplifies how it can be used in IS research.

CRITICAL REALISM IN IS RESEARCH

CR has primarily been developed by Roy Bhaskar (1978, 1998) and can be seen as a specific form of realism. Good summaries of CR are available in Sayer (2000) and Archer *et al*. (1998) and key concepts and main developments are presented in Hartwig (2007). CR's manifesto is to recognize the reality of the natural order and the events and discourses of the social world. It holds that:

> *… we will only be able to understand—and so change—the social world if we identify the structures at work that generate those events and discourses … These structures are not spontaneously apparent in the observable pattern of events; they can only be identified through the practical and theoretical work of the social sciences.* (Bhaskar, 1989, p. 2)

Bhaskar (1978) outlines what he calls three domains: the *real*, the *actual*, and the *empirical*. The real domain consists of underlying structures and mechanisms, and relations; events and behavior; and experiences. The generative mechanisms, residing in the real domain, exist independently of but capable of producing patterns of events. Relations generate behaviors in the social world. The domain of the actual consists of these events and behaviors. Hence, the actual domain is the domain in which observed events or observed patterns of events occur. The domain of the empirical consists of what we experience; hence, it is the domain of experienced events. Bhaskar argues that:

> *…real structures exist independently of and are often out of phase with the actual patterns of events. Indeed it is only because of the latter we need to perform experiments and only because of the former that we can make sense of our performances of them. Similarly it can be shown to be a condition of the intelligibility of perception that events occur independently of experiences. And experiences are often (epistemically speaking) 'out of phase' with events—e.g. when they are misidentified. It is partly because of this possibility that the scientist needs a scientific education or training. Thus I [Bhaskar] will argue that what I call the domains of the real, the actual and the empirical are distinct.* (Bhaskar, 1978, p. 13)

CR also argues that the real world is ontologically stratified and differentiated. The real world consists of a plurality of structures and mechanisms that generate the events that occur.

CR has primarily been occupied with philosophical issues and fairly abstract discussions. In recent years attention has been paid to how to actually carry out research with CR as a philosophical underpinning—see Layder (1998), Robson (2002), Kazi (2003), and Pawson (2006). Gregor (2006) argues that five interrelated types of IS theory can be distinguished: (1) theory for analyzing, (2) theory for explaining, (3) theory for predicting, (4) theory for explaining and predicting, and (5) theory for design and action. The five types can be clustered into two main types: "traditional" natural/social research (first four types) and design science research (fifth type). This section briefly presents how CR can be used in the first four types of IS research and the next section addresses IS design science research based on CR.

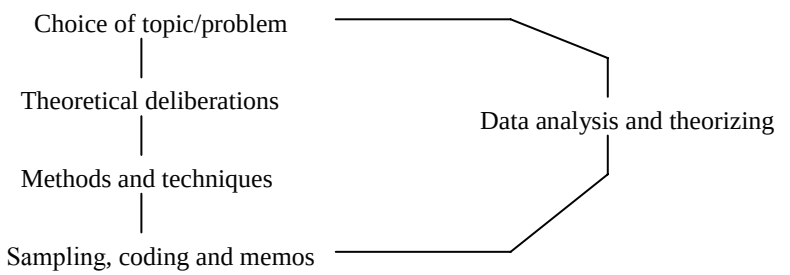
Bhaskar says that explanations (theories) are accomplished by the RRRE model of explanation comprising a four-phase process: (1) *Resolution* of a complex event into its components (causal analysis); (2) *Redescription* of component causes; (3) *Retrodiction* to possible (antecedent) causes of components via independently validated normic statements; and (4) *Elimination* of alternative possible causes of components." (Bhaskar, 1998). This is a rather abstract description of explanation (theory) development. Here we will instead use Layder's (1998) less abstract "adaptive theory." It is an approach for generating theory in conjunction with empirical research. It attempts to combine the use of pre-existing theory and theory generated from empirical data. Figure 1 depicts the different elements of the research process. There is not some necessary or fixed temporal sequence. Layder stresses that theorizing should be a continuous process accompanying the research at all stages. Concerning research design and methods, CR is supportive of: (1) the use of both quantitative and qualitative methods, (2) the use of extensive and intensive research design, and (3) the use of fixed and flexible research design.

To exemplify how CR and Layder's adaptive theory can be used in IS research addressing Gregor´s (2006) four first IS theory types, we will use a project on the use of executive information systems (EIS). The project was done together with Dorothy Leidner.[1] Here a new discussion of the research is carried out.

Layder's adaptive theory approach has eight overall parameters. One parameter says that adaptive theory "uses both inductive and deductive procedures for developing and elaborating theory." (Layder, 1998). The adaptive theory suggests the use of both forms of theory-generation within the same frame of reference and particularly within the same research project. We, based on previous EIS theories and Huber's (1990) propositions on the effects of advanced IT on organizational design, intelligence, and decision making, generated a number of hypotheses (a deductive procedure). These were empirically tested. From a CR perspective the purpose of this was to find patterns in the data that would be addressed in the intensive part of the study. We also used an inductive procedure. Although previous theories as well as the results from the extensive part of the project were fed into the intensive part, we primarily used an inductive approach to generate tentative explanations (theories) of EIS development and use from the data. The central mode of inference (explanation) in CR research is retroduction. It enables a researcher, using induction and deduction, to investigate the potential causal mechanisms and the conditions under which certain outcomes will or will not be realised. The inductive and deductive procedures led as to formulate explanations in terms of what mechanisms and contexts could lead (or not lead) to certain outcomes—outcomes being types of EIS use with their specific effects.

Another parameter says that adaptive theory "embraces both objectivism and subjectivism in terms of its ontological presuppositions" (Layder, 1998). The adaptive theory conceives the social world as including both subjective and objective aspects and mixtures of the two. In our study, one objective aspect was the ICT used in the different EIS and one subjective aspect was perceived effects of EIS use.

Figure 1. Elements of the research process (Layder, 1998, p. 29)



Two other parameters say that adaptive theory "assumes that the social world is complex, multi-faceted (layered) and densely compacted" and "focuses on the multifarious interconnections between human agency, social activities and social organization (structures and systems)" (Layder, 1998). In our study we focused the 'interconnections' between agency and structure. We addressed *self* (e.g., perceptions of EIS), *situated activity* (e.g., use of EIS in day-to-day work), *setting* (e.g. organizational structure and culture), and *context* (e.g., national culture and economic situation). Based on our data we hypothesized that national culture can affect (generate) how EIS are developed and used and how they are perceived. We also hypothesized that organizational 'strategy' and 'structure' as well as 'economic situation' can affect (generate) how EIS are developed and used and how they are perceived.

Our study and the results (theory) were influenced by, e.g. Huber's propositions, the 'theory' saying that EIS are systems for providing top-managers with critical information, and Quinns' competing values approach (Quinn et al., 2004). The latter theory was brought in to theorize around the data from the intensive (inductive) part of the study. Adaptive theorizing was ever present in the research process. In line with CR, we tried to go beneath the empirical to explain *why* we found what we found through hypothesizing the mechanisms that shape the actual and the events. Our study led to our argument that it is a misconception to think of EIS as systems that just provide top-managers with information. EIS are systems that support managerial cognition and behavior—providing information is only one of several means—as well as it can be one important means in organizational change. Based on our study, we "hypothesize" that "tentative" mechanisms are, for example, national culture, economic development, and organizational strategy and culture. We also hypothesized how the mechanisms together with different actors' decisions and actions, based on their desires, beliefs, and opportunities, lead to the development and use of different types of EIS. For example: (1) EIS use for personal productivity enhancement respectively EIS use for organizational change, and (2) EIS use for organizational change respectively EIS use for control and stability.

FUTURE TRENDS

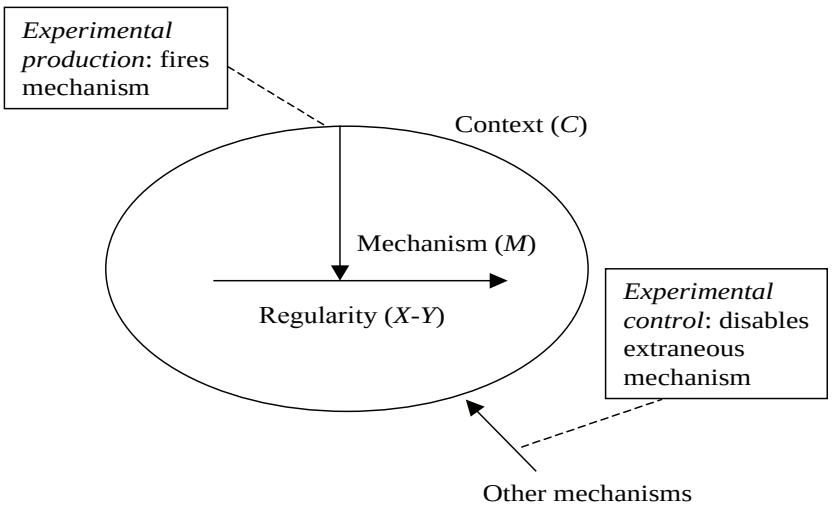
This section presents how CR can be used in IS design science research. The primary constituent community for the output of IS design science research is IS-professionals (Walls et al., 1992). This means primarily professionals who plan, manage and govern, design, build, implement, operate, maintain and evaluate different types of IS initiative and IS.

Using van Aken's (2004) classification we can distinguish three different types of designs an IS professional makes when designing and implementing an IS-initiative: 1) an *object-design*, which is the design of the IS intervention (initiative), 2) a *realization-design*, which is the plan for the implementation of the IS intervention (initiative), and 3) a *process-design*, which is the professional's own plan for the problem solving cycle and includes the methods and techniques to be used to design the solution (the IS intervention) to the problem. IS design science research should produce knowledge that can be used by the professionals in the three types of designs. Van Aken defines a technological rule as "…an instruction to perform a finite number of acts in a given order and with a given aim"; and a technological rule is "*a chunk of general knowledge, linking an intervention or artefact with a desired outcome or performance in a certain field of application*" (van Aken, 2004, p. 228). A technological rule is general, which for IS design knowledge means that a rule is a general prescription for a class of IS problems. Since a technological rule should be used by practitioners it should be applicable and actionable. Generally, the form of the technological rules is like "if you want to achieve A (outcome) in situation B (problem) and context C, then something like action/intervention D can help because E (reason)." "Something like action/intervention D" means that the rule is to be used as a design exemplar. A field-tested and grounded technological rule has been tested empirically and is grounded in science. Field-tested and grounded technological rules will in most cases be in the form of heuristics. This is consistent with CR's view on causality and means that the indeterminate nature of a heuristic technological rule makes it impossible to prove its effects conclusively, but it can be tested in context, which in turn can lead to sufficient supporting evidence (Groff, 2004).

Van Aken (2004) suggests that management design science research has much in common with CR-based evaluation research of social programs (Pawson & Tilley, 1997; Kazi, 2003). In line with CR-based evaluation research, the intention of IS design science research is to produce ever more detailed answers to the question of *why* and *how* an IS initiative works, *for whom*, and *in what circumstances*. This means that a researcher attends to how and why an IS initiative has the potential to cause the (desired) change. In this perspective, an IS design science (ISDS) researcher works as an experimental scientist, but not according to the logics of the traditional experimental evaluation research. Bhaskar states: "The experimental scientist must perform two essential functions in an experiment. First, he must trigger the mechanism under study to ensure that it is active; and secondly, he must prevent any interference with the operation of the mechanism. These activities could be designated as 'experimental production' and 'experimental control'." (Bhaskar, 1998). Figure 2 depicts the realist experiment.

ISDS researchers do not perceive that IS initiatives "work." It is the actions of different stakeholders and participants that make them work, and the causal potential of an IS initiative takes the form of providing the reasons and

Figure 2. The realist experiment (Pawson & Tilley, 1997)



resources to enable different stakeholders and participants to "make" changes. This means that an ISDS researcher seeks to understand why and how an IS initiative, for example, the implementation of an enterprise system works through understanding the action mechanisms. It also means that an ISDS researcher seeks to understand for whom and in what circumstances (contexts) an IS initiative works through the study of contextual conditioning.

ISDS researchers orient their thinking to context, mechanism, outcome pattern configurations (CMOCs). This leads to the development of transferable and cumulative lessons from ISDS research. A CMOC is a proposition stating what it is about an IS-initiative which works for whom in what circumstances. A refined CMOC is the finding of an evaluation of an IS initiative. Outcome patterns are examined from a "theory-testing" perspective. This means that an ISDS researcher tries to understand what the outcomes of an IS initiative are and how the outcomes are produced. Hence, the researcher does not just inspect outcomes in order to see if an IS initiative works, but analyzes the outcomes to discover if the conjectured mechanism/context theories are confirmed.

In terms of generalization, an ISDS researcher through a process of CMOC abstraction creates "middle-range" theories. These theories provide analytical frameworks for interpreting differences and similarities between classes and sub-classes of IS-initiatives. Given that the goal is to develop design theories and knowledge—to construct and test CMOCs explanations—for practitioners ISDS researchers need to engage in a learning relationship with IS practitioners.

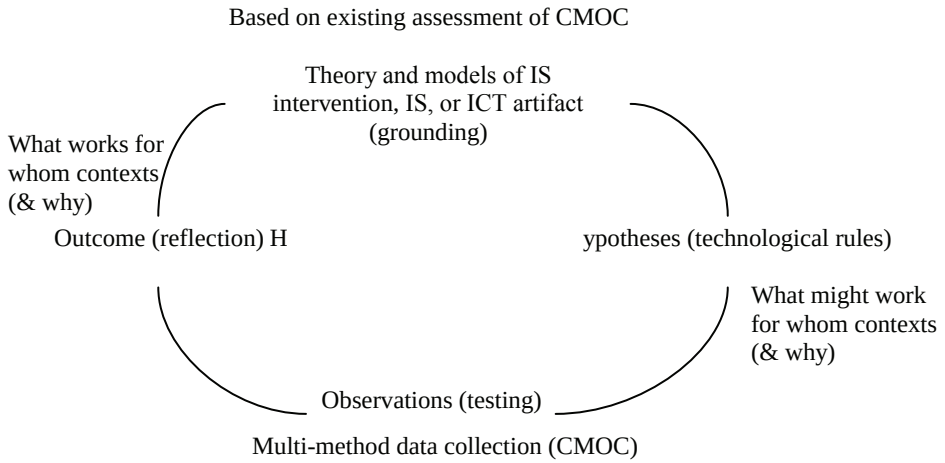
ISDS research based on the above can be carried out through an IS design science research cycle (Figure 3).

The starting point is theory and problems or issues. The research is driven by problems or issues. Problems or symptoms can be identified by practitioners or by researchers. For example, an organization can have the problem that their "ERP-projects are not leading to desired outcomes." The problems can also be identified through quantitative studies carried out by a researcher. For example, the researcher can analyze a data base containing use data for an IS and is looking for unwanted patterns. The theory includes propositions on how the mechanisms introduced by an IS intervention into a pre-existing context can generate (desired) outcomes. This entails theoretical analysis of mechanisms, contexts, and expected outcomes. This is the first step in developing technological rules and means that one tries to generate technological rules using our current knowledge, that is, grounding in theory. In general, the IS-researchers have been far from good in systematic reviews of research results. Pawson (2006) shows, from a critical realist perspective, how to do systematic reviews and make sense of a heterogeneous body of literature. Using Pawson's approach it should be possible to test and refine IS interventions. For example, it is possible to move away from the many one-off studies in the IS-field and instead learn from fields like medicine and policy studies on how to develop evidence-based IS design knowledge. Such a systematic review can be part of the starting point.

The second step consists of generating more specific "hypotheses." Typically the following questions would be addressed in the hypotheses: 1) what changes or outcomes will be brought about by an IS intervention (initiative), 2) what contexts impinge on this, and 3) what mechanisms (social, cultural, and others) would enable these changes, and which one may disable the intervention. In this step the technological rules are refined.

The third step is the empirical test. It is done through intervention and guided by theory and technological rules.

Figure 3. The information systems design science research cycle (based on Pawson & Tilley, 1997, and Kazi, 2003)



The step includes also the selection of appropriate data collection methods. ISDS research employs no standard research design formula. The base strategy is to develop a clear theory of IS initiative mechanisms, contexts and outcomes. Given the base strategy, an ISDS researcher has to design appropriate empirical methods, measures, and comparisons. In this step it might be possible to generate support of the IS intervention's ability to "change" reality. Based on the result from the third step, we may return to the IS intervention to make it more specific as an intervention of practice. Next, but not finally, we return to theory. The theory may be developed, the hypotheses and the technological rules refined, the data collection methods enhanced, etc. To develop the technological rules means that the cycle will be repeated. As said above most of the technological rules will be heuristic. Through multiple case-studies one can accumulate supporting evidence which can continue until "theoretical saturation" has been obtained. The researcher can be more or less active in the implementation (use) of the technological rules. The researcher can be very active and work like an action researcher, but can also be quite passive and work like an observer.

CONCLUSION

Although CR has influenced a number of social science fields, it is almost invisible in the IS field. CR's potential for IS research has been argued by, for example, Carlsson (2003, 2004, 2006), Dobson (2001), Mingers (2004), Mutch (2002), and Longshore Smith (2006). This article argued that CR can be used in IS research—behavioral and design science—to overcome problems associated with positivism, constructivism, and postmodernism.

KEY TERMS

Constructivism (or Social Constructivism): Asserts that (social) actors socially construct reality.

Context-Mechanism-Outcome Pattern: Realist evaluation researchers orient their thinking to context-mechanism-outcome (CMO) pattern configurations. A CMO configuration is a proposition stating what it is about an IS initiative which works for whom in what circumstances. A refined CMO configuration is the finding of IS evaluation research.

Critical Realism: Asserts that the study of the social world should be concerned with the identification of the structures and mechanisms through which events and discourses are generated.

Empiricism: Asserts that only knowledge gained through experience and senses is acceptable in studies of reality.

Positivism: Asserts that reality is the sum of sense impression. In large, equating social sciences with natural sciences. Primarily using deductive logic and quantitative research methods.

Postmodernism: A position critical of realism and rejects the view of social sciences as a search for over-arching explanations of the social world. Has a preference for qualitative methods.

Realism: A position acknowledging a reality independent of actors' (incl. researchers') thoughts and beliefs.

Realist IS Evaluation: Evaluation (research) based on critical realism aiming at producing ever more detailed answers to the question of *why* an IS initiative works (better) for *whom* and in *what* circumstances (contexts).

Retroduction: The central mode of inference (explanation) in critical realism research. Enables a researcher to investigate the potential causal mechanisms and the conditions under which certain outcomes will or will not be realised.

Critical Success Factors for Distance Education Programs

Ben Martz
University of Colorado at Colorado Springs, USA

Venkat Reddy
University of Colorado at Colorado Springs, USA

INTRODUCTION

Distance education is playing an ever-growing role in the education industry. As such, it is prudent to explore and understand driving conditions that underlie this growth. Understanding these drivers and their corresponding concerns (Table 1) can help educators in the distance education field better prepare for the industry.

BACKGROUND

Distance education's primary driver is that it is the major growth segment in the education industry. In 1999, nearly 80% of the public, four-year institutions and over 60% of the public, two-year institutions offered distance education courses. Over 1.6 million students are enrolled in distance courses today. Over 90% of all colleges are expected to offer some online courses by 2004 (Institute of Higher Education Policy, 2000). Corporations envision online training warehouses saving large amounts of training dollars. Combined, the virtual education market and its sister market, corporate learning, are predicted to grow to over $21 billion by the end of 2003 (Svetcov, 2000).

A second major driver is employer expectations. Fundamental job market expectations are changing. Today, employees are not expected to stay in the same job for long periods of time; 20-plus year careers are not expected. The current modes of careers include multiple careers, combinations of part-time work in multiple jobs, telecommuting, leaving and re-entering into the full-time work force, switching jobs, and so forth, and today's employee easily accepts the need to maintain a level of knowledge current with the career demands (Boyatzis & Kram, 1999). To complement these changes in employer expectations, employees have begun to accept the need for life-long learning.

A third driver is the profit potential. Cost savings may be obtained and if significant enough may drive up demand and costs may be lowered. For example, elective classes that do not have enough students enrolled in them on-campus may pick up enough distance students to make teaching the course more feasible (Creahan & Hoge, 1998). A final driver is the institution's mission. Most educational institutions serve a geographical region, either by charter or mission, and a distance-learning program may be a practical method to help satisfy this strategic mission (Creahan & Hoge, 1998).

However, the "commercialization" of education raises its own concerns about the basic process of learning (Noble, 1999). For example, are there any problems fundamental to the distance environment because of limited social interaction?

Retention may be one such problem. Carr (2000) reports a 50% drop-out rate for online courses. Tinto (1975) compared the learning retention of distance groups with traditional groups and found that the social integration was a key factor in successful retention of traditional groups. Haythornthwaite et al. (2000) think they found another one. They looked at how social cues such as text without voice,

Table 1. Influences on the distance education industry

Table 1. Influences on the distance education industry	
Drivers	Concerns
Growth segment in education industry	Retention
Job market expectations	Fading Back
Life-long learning as an education paradigm	Less social learning
Profit center for educational institutions	Trust & isolation
Possible strategic competence	Impact of technology

voice without body language, class attendance without seating arrangements, and students signing in without attending Internet class impacted students "fading back." They found that the likelihood of students "fading back" is greater in distance-learning classes than in face-to-face classes. From the United Kingdom, Hogan and Kwiatkowski (1998) argue that the emotional aspects of this teaching method have been ignored. Similar concerns are raised from Australia, where technology has been supporting distance- teaching for many years, as Hearn and Scott (1998) suggest that before adopting technology for distance teaching, education must acknowledge the social context of learning. Finally, two other factors, trust and isolation, have been researched by Kirkman et al. (2002), whereby communication helped improve the measures of trust in students using the virtual environment.

By definition, the paradigm of distance education changes the traditional education environment by expanding it to cover geographically dispersed learning. In turn, this means that students will probably respond differently to this environment than they do to the traditional classroom. In addition, academic researchers have always been interested in explaining how people react to the introduction of technology. This body of work can be useful to the distance education environment.

Poole and DeSanctis (1990) suggested a model called adaptive structuration theory (AST). The fundamental premise of the model is that the technology under study is the limiting factor or the constraint for communication. It further proposes that the users of the technology, the senders and the receivers, figure out alternative ways to send information over the channel (technology). A good example here is how a sender of e-mail may use combinations of keyboard characters or emoticons (i.e., :) – sarcastic smile, ;) – wink, :o – exclamation of surprise) to communicate more about their emotion on a subject to the receiver.

Ultimately, the key to realizing the potential of distance education is trading off the benefits and the concerns to produce a quality product. In the new Malcolm Baldridge evaluation criteria, companies are asked to better show a program's effectiveness through customer satisfaction. In turn, Gustafsson et al. (2000) show customer satisfaction linked significantly to quality at Volvo Car Corporation. Finally, in their more broad analysis of well-run companies, Peters and Waterman (1982) deemed customer satisfaction as a key factor contributing to the companies' performance.

With these perspectives in mind, we suggest that these areas interact to identify satisfaction as one important measure of quality for distance education programs. Therefore, one of the key factors to a program's success will be the

Table 2. Questions that correlate significantly to satisfaction

ID	Question Statement	Correlation	
		Coef.	Sign.
16	I was satisfied with the content of the course	.605	.000
17	The tests were fair assessments of my knowledge	.473	.000
18	I would take another distance course with this professor	.755	.000
19	I would take another distance course	.398	.000
20	The course workload was fair	.467	.000
21	The amount of interaction with the professor and other students was what I expected.	.710	.000
22	The course used groups to help with learning	.495	.000
23	I would like to have had more interaction with the professor.	-.508	.000
26	The course content was valuable to me personally	.439	.000
28	Grading was fair	.735	.000
30	Often I felt "lost" in the distance class	-.394	.000
31	The class instructions were explicit	.452	.000
33	Feedback from the instructor was timely	.592	.000
34	I received personalized feedback from the instructor	.499	.000
36	I would have learned more if I had taken this class on-campus (as opposed to online)	-.400	.000
37	This course made me think critically about the issues covered.	.423	.000
38	I think technology (email, web, discussion forums) was utilized effectively in this class	.559	.000
39	I felt that I could customize my learning more in the distance format	.254	.001
42	The course content was valuable to me professionally	.442	.000
43	I missed the interaction of a "live," traditional classroom	-.341	.002
46	Overall, the program is a good value (quality/cost)	.258(1)	.017
LOHITECH	Aggregate of Yes votes in Q6 through Q15	.270(1)	.012
(1) While significant, the low correlation coefficient below .300 should be noted			

satisfaction of one of its key stakeholders – its students. If one can identify what helps satisfies students in a distance education environment, one has a better chance to develop a successful program.

THE RESEARCH STUDY

The distance program used in this study is one of the largest, online, AACSB-accredited MBA programs in the world (US News and World Report, 2001). The methodology used a questionnaire with a battery of 49 questions to gather the data. The questions were developed using the concepts and ideas from literature discussed earlier as a guide.

Once the subject identified his or her reference course, that subject's grade was obtained from administrative records and recorded. In addition, four other demographic questions gathered information on gender, number of courses taken, student status, amount of time expected to spend in the reference course, and the amount of time actually spent in the reference course (Martz et al., 2004).

Two sets of questions were used. The first set asked about the student's use of different technologies (i.e., chat, e-mail, streaming video, etc.) in the class and if used, how effective (five-point Likert: 1 = LO …. 5 = HIGH) did they believe the technology to be in helping them with the class. We created a new variable, LOHITECH, for analysis purposes. Using LOHITECH, respondents can be placed in one of two groups: one group that reported using three or less technologies, while the second group reported using four or more technologies in their reference class. The second set of questions asked students to rate (five-point Likert: 1 = Strongly Agree …. 5 = Strongly Disagree) their experience with the reference distance course against statements concerning potential influences for satisfaction. These questions associated a five-point rating scale to statements about the issues identified earlier. The order of the questions was randomly determined and the questionnaire was reviewed for biased or misleading questions by non-authors.

The questionnaire was sent to 341 students enrolled in the distance MBA program. In Fall 2002, the program served 206 students from 39 states and 12 countries. The majority of these students are employed full-time. The program used in this study has been running since Fall 1996 and has over 179 graduates. It offers an AACSB accredited MBA and its curriculum parallels the on-campus curriculum. Close to 33% of the enrolled students are female. The oldest student enrolled is 60 years old and the youngest is 22. The average age of all students enrolled is 35. Over 25 PhD qualified instructors participate in developing and delivering the distance program annually. Recently, the news magazine *US News and World Report* (2001) classified the program as one of the top 26 distance education programs.

There were 131 useable questionnaires returned. The students' final grade for their reference course was obtained and added to the questionnaire record as a variable. These were separated into two groups: 30 that had not yet taken a course and 101 that had completed at least one course. This second group, those students who had completed at least one course, provided the focus for this study.

RESEARCH RESULTS

Question 24, "Overall, I was satisfied with the course," was used as the subject's level of general satisfaction. The data set was loaded into SPSS for analysis. Table 2 shows that 23 variables, including LOHITECH, proved significantly correlated to satisfaction (Q24).

The large number of significant variables leads to the need for a more detailed analysis on how to group them (StatSoft, 2002). Kerlinger (1986, p. 590) suggests the use of factor analysis in this case "to explore variable areas in order to identify the factors presumably underlying the variables". An SPSS factor analysis was performed with a Varimax Extraction on those questions that had proven significantly correlated to satisfaction. All reliability coefficients (Cronbach Alpha) are above .7000 and all Eigenvalues are above 1.00, indicating an acceptable level for a viable factor (Kline, 1993; Nunnally, 1978). Finally, the five components explain 66.932% of the variance.

In summary, 22 variables from the questionnaire proved significantly correlated to satisfaction. A factor analysis of those 22 variables extracted five possible constructs. These

Table 3. Correlation of final constructs to satisfaction

Construct (Component: Loading)	Correlation	Significance
Professor Interaction (Q18: .576, Q21: .643, Q33: .794, Q34: .849)	.771	.000
Fairness (Q17: .722, Q20: .738, Q28: .626, Q31: .512)	.695	.000
Course Content (Q16: .596, Q26: .850, Q39: .689, Q42: .825)	.588	.000
Classroom Interaction (Q23: -.354, Q30: -.514, Q36: -.809, Q43: -.770)	-.515	.000
Technology Use & Value (LOHITECH: .508, Q19: .596, Q22: .542, Q37: .494, Q38: .478, Q46: .700)	.624	.000

constructs were labeled: Interaction with the Professor; Fairness; Content of the Course; Classroom Interaction; and Value, Technology & Learning, based upon the key characteristics of the underlying questions. Table 3 shows the results of combining the ratings for the questions in each construct and correlating each of them to satisfaction. As can be seen from the table, the constructs hold up well as five indicators of satisfaction.

FUTURE TRENDS

As mentioned earlier, the organization, the school in this case, is a key stakeholder in the success of a distance education program. The future success of distance programs depends largely on satisfying these critical success factors. Distance education courses and programs are not only used for providing an alternative delivery method for students but also to generate revenues for the offering unit/college/university. As the number of distance courses and programs increase at an exponential rate, the necessity to enhance quality and revenues also takes prominence. We conclude with a set of operational recommendations that can impact online program success (Table 4).

The data in this study indicate that a timely and personalized feedback by professors results in a higher level of satisfaction by students. The administrators therefore have to work closely with their faculty and offer them ways to enrich the teacher-student relationships. Paradoxically, a faculty member needs to use technologies to add a personal touch to the virtual classroom. For example, faculty should be encouraged to increase the usage of discussion forums, respond to e-mail within 24 to 48 hours, and keep students up-to-date with the latest happenings related to the course.

The data also indicate that good course content and explicit instructions increase student satisfaction in the virtual classroom. It may well be that this basically sets and manages the expectations for the distance student. This result suggests that faculty should have complete Web sites with syllabi and detailed instructions. In turn, this suggests that distance education administrators should focus their attention on providing faculty with support such as good Web site design, instructional designer support, test design, user interaction techniques, and so forth, appropriate for distance learning.

Since distance students' notion of value intertwines learning and technology, it is imperative that distance administrators offer, and faculty use, the available technology in the distance program. Technology in this case not only refers to the actual software and hardware features of the platform but also how well technology is adapted to the best practices of teaching. The results imply that if technology is available but not used, it lowers satisfaction. So, technology options that are not being used in a course should not appear available. For the program administrator, this would suggest adoption of distance platforms that are customizable at the course level with respect to displaying technological options.

CONCLUSION

This study attempts to identify potential indicators for satisfaction with distance education. A body of possible indicators was derived from the literature surrounding the traditional versus virtual classroom debate. A 49-question questionnaire was developed from the indicators and was administered to MBA students in an established distance education program. One hundred and one questionnaires from students with one or more distance classes were analyzed with the result that 22 variables correlated significantly to satisfaction. A factor analysis of the questionnaire data extracted five basic constructs: Professor Interaction, Fairness, Course Content, Classroom Interaction and Technology Use & Value. Several recommendations for implementing and

Table 4. Recommendations to increase online program success

1	Have instructors use a 24-48-hour turnaround for e-mail.
2	Have instructors use a 1-week turnaround for graded assignments.
3	Provide weekly "keeping in touch" communications.
4	Provide clear expectation of workload.
5	Provide explicit grading policies.
6	Explicitly separate technical and pedagogical issues.
7	Have policies in place that deal effectively with technical problems.
8	Provide detailed unambiguous instructions for coursework submission.
9	Provide faculty with instructional design support.
10	Do not force student interaction without good pedagogical rationale.
11	Do not force technological interaction without good pedagogical purpose.
12	Collect regular student and faculty feedback for continuous improvement.

managing a distance program were extracted from these constructs and discussed.

KEY TERMS

Classroom Interaction: The interaction that can only be achieved face-to- face in a classroom. For example, the real-time feedback of facial expressions is not (yet) available in a distance course and so would be considered "classroom interaction".

Concerns of "Commercialization": The negative factors that the implantation and use of distance education may create.

Course Content: The main themes covered in a course.

Critical Success Factors: The few key areas in which activities must "go right" so that a project of program succeeds (Rockart, 1979).

Exploratory Factor Analysis: A process used to identify statistically significant constructs underlying a set of data.

Fairness: A subjective term defining the level to which a student feels he or she was treated fairly by the professor with respect to the class, including but not limited to test questions, grading, schedule flexibility, and so forth.

Market Drivers for Distance Education: The key elements that seem to be driving the diffusion and usage of distance education in the marketplace.

Professor Interaction: The amount of communication (e-mail, phone calls, video, chat rooms, etc.) that occurs between a student and the professor.

Satisfaction Constructs for Distance Education: Five constructs identified that seem to help identify satisfaction in distance education programs.

Technology Use: The usage of a technology whether it be e-mail, chat rooms, automated tests, software, and so forth.

Technology Value: The user's benefits (perceived and actual) over the costs (perceived and actual) created by the use of technology.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 622-627, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Critical Success Factors for E-Health

Nilmini Wickramasinghe
Illinois Institute of Technology, USA

Jonathan L. Schaffer
The Cleveland Clinic, USA

INTRODUCTION

Within the umbrella of e-commerce, one area, e-health, has yet to reach its full potential in many developed countries, let alone developing countries. Each country is positioned differently and has varying potential and preparedness regarding embracing e-commerce technologies generally and e-health in particular. Given the macrolevel nature of many issues pertaining to the development of e-health (Alvarez, 2002), in order to be more effective in their e-health initiatives, it is important for countries to assess their potential, identify their relative strengths and weaknesses, and thereby develop strategies and policies to address these issues to effectively formulate and implement appropriate e-health initiatives. To do this effectively, it is valuable to have an integrative framework that enables the assessment of a country's e-health preparedness. This article serves to develop such a framework that can be applied to various countries throughout the globe, and from this generate an e-health preparedness grid. In so doing, we hope to facilitate better understanding of e-health initiatives and thus maximize their power.

BACKGROUND

Reducing health care expenditure as well as offering quality health care treatment is becoming a priority globally. Technology and automation have the potential to reduce these costs (Institute of Medicine, 2001; Wickramasinghe, 2000); thus, e-health, which essentially involves the adoption and adaptation of e-commerce technologies throughout the health care industry (Eysenbach, 2001; Wickramasinghe, Misra, Jenkins, & Vogel, 2006), appears to be a powerful force of change for the health care industry worldwide.

Health care has been shaped by each nation's own set of cultures, traditions, payment mechanisms, and patient expectations. Therefore, when looking at health systems throughout the world, it is useful to position them on a continuum ranging from high government involvement (i.e., a public health care system) at one extreme to little government involvement (i.e., a private health care system) at the other extreme, with many variations of a mix of private and public in between. However, given the common problem of exponentially increasing costs facing health care globally, irrespective of the particular health system one examines, the future of the health care industry will be partially shaped by commonalties such as the universal issue of escalating costs and the common forces of change including (a) empowered consumers, (b) e-health adoption and adaptability, and (c) a shift to focus on the practice of preventative- vs. cure-driven medicine. Additionally, there will be four key implications, namely, (a) health insurance changes, (b) workforce changes and changes in the roles of stakeholders within the health system, (c) organizational changes and standardization, and (d) the need for health care providers and administrators to make difficult yet necessary choices regarding practice management.

THE GOALS OF E-HEALTH

In order to develop a robust framework, it is imperative to understand the many goals of e-health. These goals, taken together, perhaps best characterize what e-health is all about (or what it should be about; *Journal of Medical Internet Research* [JMIR], 2003). Specifically, significant goals of e-health include the following.

Efficiency: One of the promises of e-health is to increase efficiency in health care, thereby decreasing costs. One possible way of decreasing costs would be by avoiding duplicative or unnecessary diagnostic or therapeutic interventions, through enhanced communication possibilities between health care establishments, and through patient involvement (Health Technology Center, 2000). The Internet will naturally serve as an enabler for achieving this goal in e-health.

Quality of care: Increasing efficiency involves not only reducing costs, and thus is not an end in and of itself, but rather should be considered in conjunction with improving quality, one of the ultimate goals of e-health. More educated consumers (as a result of the informational aspects of e-health) would then communicate more effectively with their primary care providers, which will, in turn, lead to better understanding and improved quality of care.

Evidence: E-health interventions should be evidence based in the sense that their effectiveness and efficiency should not be assumed but proven by rigorous scientific

evaluation and support from case histories. Web-accessible case repositories facilitate the timely accessibility of such evidence and thus help in achieving the necessary support of a diagnosis or treatment decision. The evidence-based medicine goal of e-health is currently one of the most active e-health research domains, yet much work still needs to be done in this area.

Empowerment of consumers and patients: By making the knowledge bases of medicine and personal electronic records accessible to consumers over the Internet, e-health opens new avenues for patient-centered medicine, enables patient education, and thus increases the likelihood of informed and more satisfactory patient choices (Umhoff & Winn, 1999).

Education of physicians and consumers: Online sources (continuing medical education for physicians, and health education and tailored preventive information for consumers) make it easier for physicians as well as consumers to keep up to date with the latest developments in the medical areas of their respective interests. This, in turn, is likely to have a positive impact on the quality of care vis-à-vis the use of the latest medical treatments and preventive protocols.

Extension of health care: Extending the scope of health care beyond its conventional boundaries, in both a geographical sense as well as in a conceptual sense, leads to enabling such techniques as telemedicine and virtual operating rooms, both of which are invaluable in providing health care services to places where it may otherwise be difficult or impossible to do.

Ethics: E-health involves new forms of patient-physician interaction and poses new challenges and threats to ethical issues such as online professional practice, informed consent, privacy, and security issues (Healthcare Advisory Board, 2002). However, this is not an intrinsic feature of e-health but rather a feature of the Internet technology, which is the foundation for all e-business initiatives; therefore, e-health along with e-government, e-insurance, e-banking, e-finance, and e-retailing must all contend with these ethical issues. Given the nature of health care, these issues could be more magnified.

Equity: To make health care more equitable is one of the aims of quality identified by the American Institute of Medicine (2001) generally and is one of the goals of e-health. However, at the same time there is a considerable threat that e-health, if improperly implemented and used, may deepen the gap between the "haves" and the "have-nots," hence the need for a robust framework to ensure the proper implementation of e-health initiatives. In particular, some of the key issues for equity revolve around broad access and familiarity with the technology.

PREREQUISITES FOR E-HEALTH

In order to actualize and thereby support the key goals of e-health presented above, it is necessary to have four critical prerequisites for any successful e-health initiative, namely, ICT architecture and infrastructure; standardized policies, protocols, and procedures; user access and accessibility policies and infrastructure; and finally government regulation and control. These will now be briefly discussed in turn.

ICT Architecture and Infrastructure

The ICT infrastructure typically includes phone lines, fiber trunks, submarine cables, T1, T3, OC-xx, ISDN (integrated services digital network), DSL (digital subscriber line), and other high-speed services used by businesses, as well as satellites, earth stations, and teleports. A sound technical infrastructure is an essential ingredient to the undertaking of e-health initiatives by any nation. Such infrastructures should also include telecommunications, electricity, access to computers, Internet hosts, ISPs (Internet service providers), and available bandwidth and broadband access. To offer good multimedia content and thus provide a rich e-health experience, one would require high bandwidth. ICT considerations are undoubtedly one of the most fundamental infrastructure requirements.

Networks are now a critical component of the business strategies for organizations to compete globally. Having a fast microprocessor-based computer at home has no meaning unless you have high-bandwidth-based communication infrastructure available to connect computers with the ISP. With the explosion of the Internet and the advent of e-commerce, global networks need to be accessible, reliable, and fast to participate effectively in the global business environment. Telecommunications is a vital infrastructure for Internet access and hence for e-commerce. One of the pioneering countries in establishing a complete and robust e-health infrastructure is Singapore, which is in the process of wiring every home, office, and factory to a broadband cable network that will cover 98% of Singaporean homes and offices (Wickramasinghe, 2007a).

Standardization Policies, Protocols, and Procedures

E-health by definition spans many parties and geographic dimensions. To enable such far-reaching coverage, significant amounts of document exchange and information flow must be accommodated. Standardization is the key for this. Once a country decides to undertake e-health initiatives, standardization polices, protocols, and procedures must

be developed at the outset to ensure the full realization of the goals of e-health. Fortunately, the main infrastructure of e-health is the Internet, which imposes the most widely and universally accepted standard protocols such as TCP/IP (transmission-control protocol/Internet protocol) and HTTP (hypertext transfer protocol). It is the existence of these standard protocols that has led to the widespread adoption of the Internet for e-commerce applications.

The shift to e-health by any country cannot be successfully attained without the deliberate establishment of standardization policies, protocols, and procedures that play a significant role in the adoption of e-health and the reduction of many structural impediments (Samiee, 1998).

User Access and Accessibility Policies and Infrastructure

Access to e-commerce is defined by the WTO (World Trade Organization) as consisting of two critical components: (a) access to Internet services and (b) access to e-services (Panagariya, 2000); the former deals with the user infrastructure, while the latter pertains to specific commitments to electronically accessible services. The user infrastructure includes the number of Internet hosts and number of Web sites, the number of Web users as a percent of the population as well as ISP availability and costs for consumers, the PC penetration level, and so forth. Integral to the user infrastructure is the diffusion rate of PCs and Internet usage. The United States and the United Kingdom have experienced the greatest penetration of home computers (Samiee, 1998). For developing countries such as India and China, there is, however, very low PC penetration and teledensity. In such a setting, it is a considerable challenge then to offer e-health since a large part of the population is not able to afford to join the e-commerce bandwagon. Countries thus have to balance local call charges, rentals, subscription charges, and so on; otherwise, the majority of citizens will find these costs a disincentive. This is particularly significant for developing and emerging nations where access prices tend to be out of reach for most of the population. Upcoming new technologies hold the promise to increase connectivity as well as the affordability level, and developing countries will need to seriously consider these technologies. In addition to access to PCs and the Internet, computer literacy is important; users must be familiar not only with the use of computers and pertinent software products, but also with the benefits and potential uses of the Internet and World Wide Web (Samiee).

Governmental Regulation and Control

The key challenges regarding e-health use include (a) cost effectiveness, that is, e-health must be less costly than traditional health care delivery, (b) functionality and ease of use, meaning it should enable and facilitate many uses for physicians and other health care users by combining various types and forms of data as well as be easy to use, and (c) e-health must be secure. One of the most significant legislative regulations in the United States is the Health Insurance Portability and Accountability Act (HIPAA; Protegrity, 2001).

Given the nature of health care and the sensitivity of health care data and information, it is incumbent on governments not only to mandate regulations that will facilitate the exchange of health care documents between the various health care stakeholders, but also to provide protection of privacy and the rights of patients. Some countries, such as China and Singapore, even control access to certain sites for moral, social, and political reasons while elsewhere, transnational data flows are hindered by a plethora of regulations aimed at protecting domestic technology and related human resource markets (Gupta, 1992; Samiee, 1998; Wickramasinghe, 2007a). Irrespective of the type of health care system, that is, whether it is 100% government driven, 100% private, or a combination thereof, it is clear that some governmental role is required to facilitate successful e-health initiatives.

KEY IMPACT OF E-HEALTH

The significance of the preceding four prerequisites for e-health initiatives will be modified by the impacts of IT education, morbidity, cultural and social dimensions, and the world economic standing as elaborated upon below.

Impact of IT Education

A sophisticated, well-educated population boosts competition and hastens innovation. According to Michael Porter (1990), one of the key factors to a country's strength in an industry is strong customer support. Thus, a strong domestic market leads to the growth of competition, which leads to innovation and the adoption of technology-enabled solutions to provide more effective and efficient services such as e-health and telemedicine. As identified earlier, the health consumer is the key driving force in pushing e-health initiatives. We conjecture that a more IT-educated health care consumer would then provide stronger impetus for e-health adoption.

Impact of Morbidity Rate

There is a direct relationship between health education and awareness and the overall health standing of a country. Therefore, a more health-conscious society, which tends to coincide with a society that has a lower morbidity rate, is more likely to embrace e-health initiatives. Furthermore, higher morbidity

rates tend to indicate the existence of more basic health needs (World Health Organization [WHO], 2003). Hence, treatment is more urgent than the practice of preventative medicine and thus e-health could be considered an unrealistic luxury; in some instances, such as when a significant percentage of a population is suffering from malnutrition-related diseases, e-health is even likely to be irrelevant at least in the short term. Thus, we conjecture that the modifying impact of the morbidity rate prioritizes the level of spending on e-health vs. other basic health care needs.

Impact of Cultural and Social Dimensions

Health care has been shaped by each nation's own set of cultures, traditions, payment mechanisms, and patient expectations. While the adoption of e-health, to a great extent, dilutes this cultural impact, social and cultural dimensions will still be a moderating influence on any countries' e-health initiatives. Another aspect of the cultural and social dimension relates to the presentation language of the content of the e-health repositories. The entire world does not speak English, so the e-health solutions have to be offered in many other languages. The e-health supporting content in Web servers and sites must be offered in local languages, supported by pictures and universal icons. This becomes a particularly important consideration when we look at the adoption and diffusion of evidence-based medicine as it will mean that much of the available evidence and case-study data will not be easily accessible globally due to language barriers.

Therefore, for successful e-health initiatives, it is important to consider cultural dimensions. For instance, an international e-commerce study by International Data Corp. indicates that Web surfing and buying habits differ substantially from country to country (Wilson, 1999), and this would then have a direct impact on people's comfort in using e-commerce generally and e-health in particular, especially as e-health addresses a more fundamental need. Hence, the adoption of e-health is directly related to one's comfort with using the technology and this in turn is influenced in a major way by cultural dimensions. Also connected to cultural aspects is the relative entrepreneurial spirit of a country. For example, Hofstede (1980) indicates that in a cultural context, Indians score high on "uncertainty-avoidance" criteria when compared to their Western counterparts. As a result, Indian nationals, for example, do not accept change very easily and are hostile toward innovation. This then would potentially pose a challenge to the start-up of e-health initiatives, whose success depends on widespread adoption for their technological innovations. Thus, we conjecture that fear of risk and absence of an entrepreneurial mind-set as well as other cultural and social dimensions can impact the success of e-health initiatives in a given country.

Impact of World Economic Standing

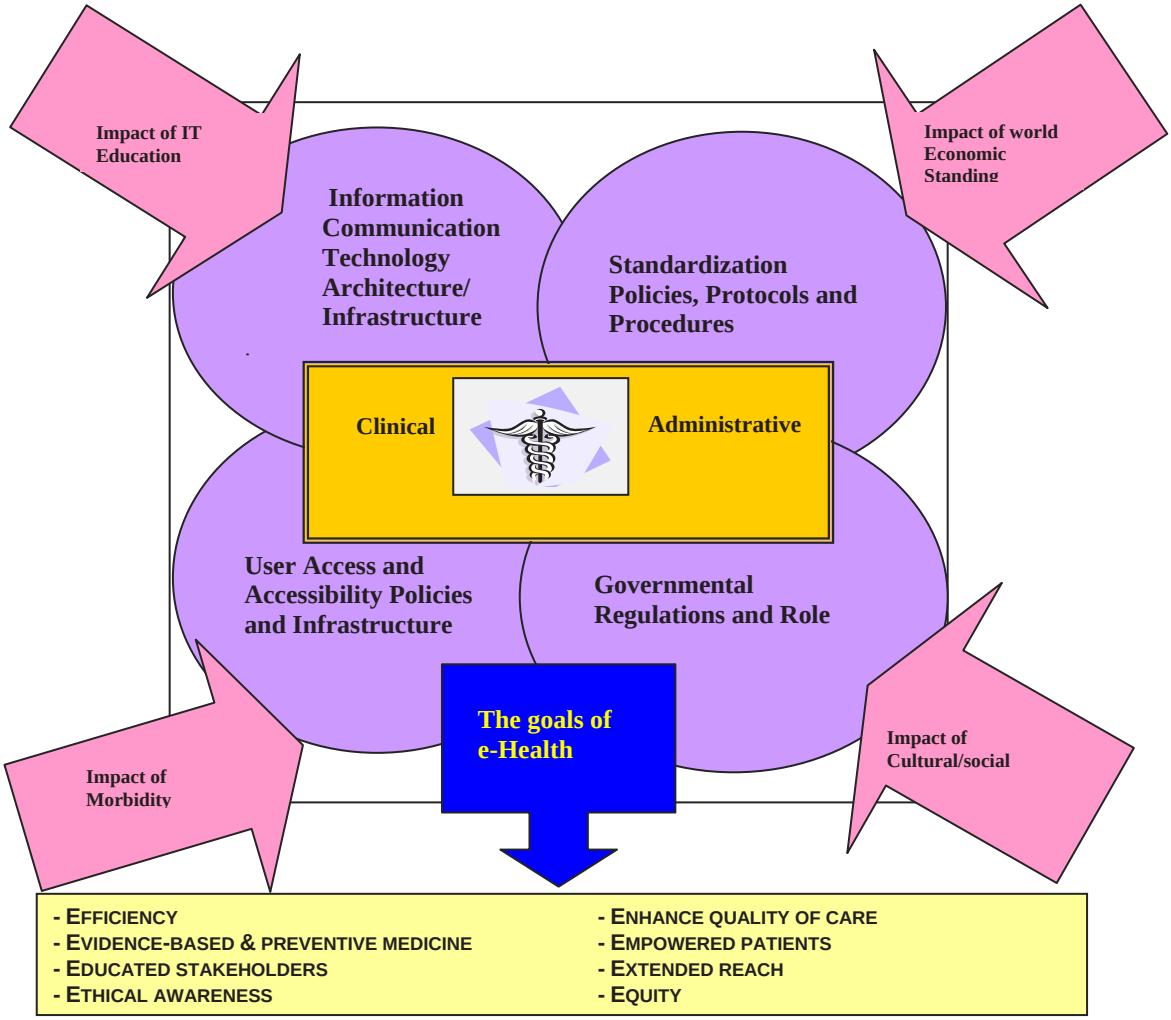
Economies of the future will be built around the Internet. All governments are very aware of the importance and critical role that the Internet will play on a country's economy. This makes it critical that appropriate funding levels and budgetary allocations become a key component of governmental fiscal policies so that such initiatives will form the bridge between a traditional health care present and a promising e-health future. Thus, the result of these initiatives would determine the success of effective e-health implementations and consequently have the potential to enhance a country's economy and future growth.

The World Economic Forum's global competitiveness ranking measures the relative global competitiveness of a country. This ranking takes into account factors such as physical infrastructure, bureaucracy, and corruption. Thus, we conjecture that when weak physical infrastructure is combined with high levels of bureaucracy and corruption, this will lead to significant impediments to the establishment of successful e-health initiatives.

A FRAMEWORK FOR ASSESSING E-HEALTH POTENTIAL

In order to understand numerous critical considerations to facilitate prudent decision making concerning any e-health initiative, it is most useful to have one integrative framework that not only brings together the eight goals of e-health but also the prerequisites and key impact aspects. We propose the framework shown in Figure 1 as such an integrative framework to assess the e-health potential and preparedness of countries as well as potential barriers for any particular e-health initiative. Health care polices are generally developed to a large extent at a macro, country level and thus we believe it is also necessary when looking at e-health to first take a macro perspective and analyze the level of the country in terms of embracing e-health. The framework highlights the key elements that are required for successful e-health initiatives and therefore provides a tool that allows analysis beyond the quantifiable data into a systematic synthesis of the major impacts and prerequisites. The framework contains four main prerequisites, four main impacts, and the implications of these prerequisites and impacts to the goals of e-health. By examining both the prerequisites and the impacts, it is now possible to assess the potential of a country and its preparedness for e-health as well as its ability to maximize the goals of e-health in a systematic and careful manner.

Figure 1. A framework for assessing a country's or region's e-health potential



FUTURE TRENDS

In developing an e-health initiative, a good first step for any country is to assess its standing with respect to the four prerequisites and four impacts discussed above. In this way it will be possible to evaluate its preparedness with respect to these parameters and consequently devise appropriate policies and strategies for an effective and successful e-health initiative. As e-health initiatives become more prevalent and mature, it will also become necessary to continually update and refine many aspects, most especially the knowledge and data content (Puentes, Bali, Wickramasinghe, & Naguib, 2007; Wickramasinghe, 2007b). To do this in a systematic fashion so that at all times it is possible to leverage the extant knowledge base, we anticipate that the application of the tools and techniques of knowledge management will begin to play a growing role in the future developments of all e-health initiatives, and we urge for more research in this area.

CONCLUSION

E-commerce, as noted by the United Nations secretary general's address, is an important aspect of business in the 21st century. No longer then is it a luxury for nations, but rather it is a strategic necessity in order for countries to achieve economic and business prosperity as well as social viability. One of the major areas within e-commerce that

has yet to reach its full potential is e-health. This is due to the fact that health care generally has been slow in adopting information technologies. Furthermore, there is a shortage of robust frameworks that may be used as guidelines for assessing countries' e-health preparedness and identifying the key areas and deficiencies that need to be addressed in order for successful e-heath initiatives to ensue. In addition, e-health is more than a technological initiative; rather, it also requires a major paradigm shift in health care delivery, practice, and thinking. We have attempted to address this gap by developing a framework that identifies the major factors involved in assessing the e-health preparedness of countries, thereby facilitating them in focusing their efforts on the relevant issues that must be addressed in order for successful e-health initiatives to follow (the goals of e-health are realized). An outcome from our analysis indicates that the relative health care system (i.e., whether government driven, public, or two tier) would appear to have less significance in establishing successful e-health initiatives. The first step in the development of any viable e-health strategy is to make an assessment of the current state of e-health preparedness and then to move to a state of higher preparedness. Finally, we note that with respect to our framework, other parameters also exist and could also be considered important, perhaps even as important as the ones we used. However, we believe that the framework will still function the same way (i.e., provide a useful tool for any country trying to determine and develop a successful e-health initiative) irrespective of the number of parameters; in this regard, we preferred simplicity over complexity.

KEY TERMS

Efficiency: One of the promises of e-health is to increase efficiency in health care, thereby decreasing costs.

E-Health: It is health care delivery supported and enabled through the use of information systems and information technology, especially Web-based technologies.

Equity: This refers to making health care more equitable. In particular, some of the key issues for equity revolve around broad access and familiarity with the technology.

Evidence Based: E-health interventions should be evidence based in the sense that their effectiveness and efficiency should not be assumed but proven by rigorous scientific evaluation and support from case histories.

Framework: It is the conceptual structure used to solve a complex issue.

IT Infrastructure: It is the combination of hardware, software, networking, and telecommunications that forms the foundation for supporting IT capabilities in place.

Morbidity: This refers to either the incidence rate or to the prevalence rate of a disease.

Telemedicine: Telemedicine is the use of information systems and information technology to provide or facilitate the delivery of clinical-care evidence-based medicine. It also involves the application of uniform standards of evidence gained from previous cases to facilitate superior medical-practice outcomes.

C

Critical Trends, Tools, and Issues in Telecommunications

John H. Nugent
University of Dallas, USA

David Gordon
University of Dallas, USA

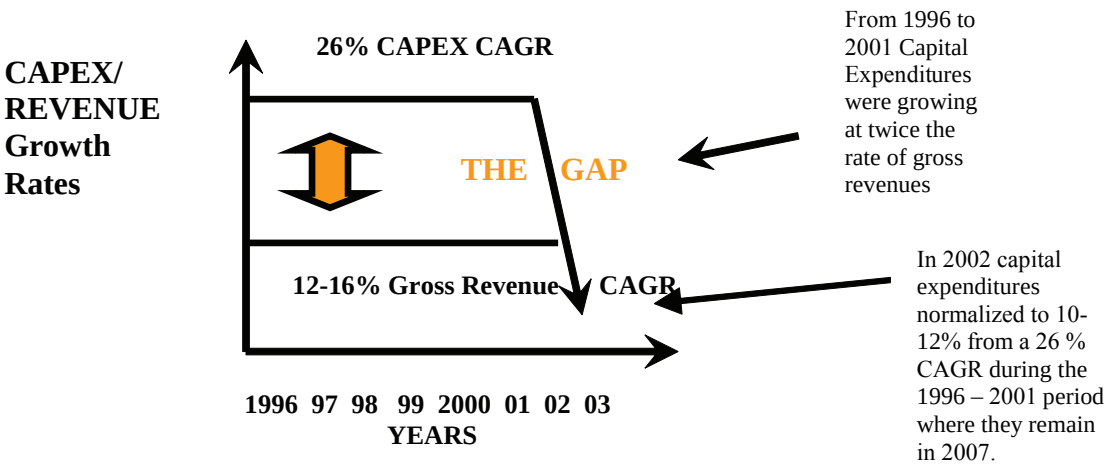
INTRODUCTION

As in all industries, in order to win in a market and set an appropriate strategy, it is important to know as much as possible about that market and have at one's disposal tools that will provide insight and competitive advantage when properly, collectively, consistently, and timely applied. This paper presents a series of powerful, but easy to use and understand, analytical and operational tools that deliver insight and competitive advantage to the telecommunications professional. Moreover, it should be stated that as with all good tools, the tools and models as presented herein transition across industry lines and are not limited to the telecommunications industry alone.

BACKGROUND

Starting in the 1990s, the telecommunications market appeared to experience unprecedented and unbounded growth with the advent of The Telecommunications Act of 1996. This growth was paralleled by a growth in capital equipment purchases (CAPEX) by network operators (see Figure 1). However, by the early 2000s, we saw a major market correction and the collapse of many firms that caught many industry professionals, bankers, and investors by surprise. The economic dislocations caused by the failure of so many telecommunications network providers were enormous. Hence, an examination was undertaken to see if tools and models existed that could provide significant insight into

Figure 1. The revenue capital expenditure growth rate comparisons



Source: Hilliard Consulting Group, Inc., 2007

changing market conditions. By examining these market dynamics and the fundamentals at play in the telecommunications space, it becomes apparent there are models and tools that provide insight as to the market's stage, and where it is likely to go next. Such a view is important to the investor, creditor, and operator alike in order to have a vision of the current and future market states so appropriate and timely decisions can be reached.

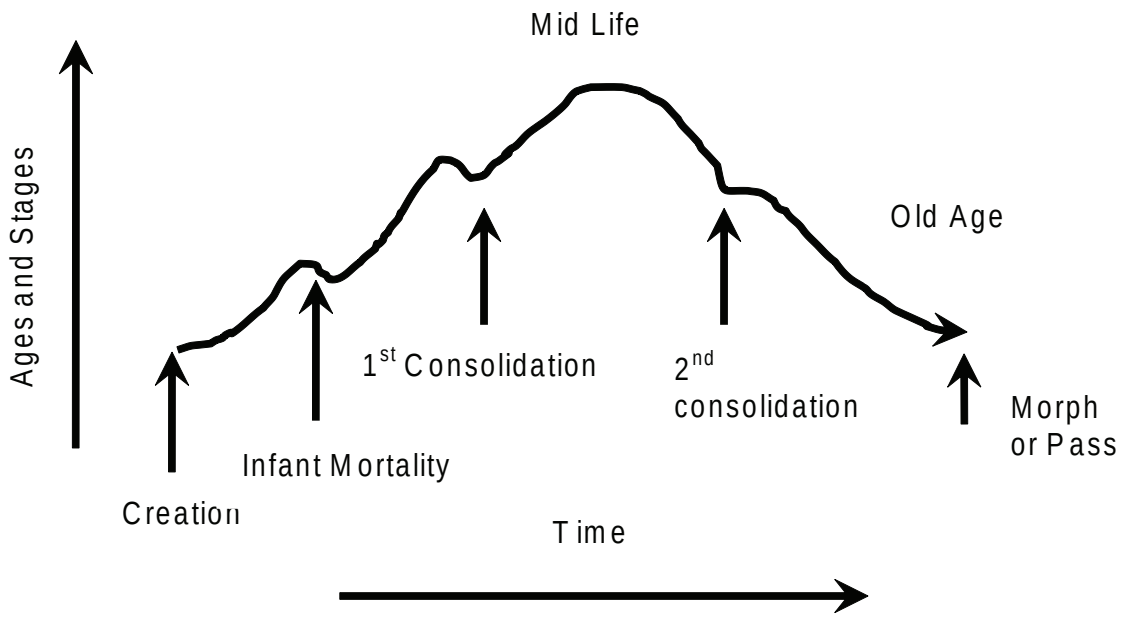
ANALYTICAL TOOLS AND MODELS

Because of the turmoil experienced in the telecommunications industry over the past decade, it is useful to view tools that can assist the telecommunications professional with understanding the market(s) and the trends at play. Looking at the telecommunications market from 1996 to 2007, it can be seen that the market exploded in the first half of this period with a 26% cumulative annual capital expenditure growth rate (CAPEX CAGR), collapsing in the latter part of this period (Hilliard, 2007; Lehman Brothers, 2000).

When capital expenditures so far outstrip the gross revenue growth rate, one knows this situation cannot continue unabated, and a return to a more normal state must take place. In order to discern approximately when a return to a more normal state will come about, one may examine the underlying market drivers (Nugent, 2001, 2003). Market drivers will often signal the size, breadth, and depth of a market.

Market Drivers: During the period of 1996-2003 several large drivers were evident. The first was identified as the Y2K driver. Here many firms determined it to be better, easier, and less costly and risky to replace versus remediate infrastructure equipment. But here it was known this driver would be satiated by 2000. A second major driver was The Telecommunications Act of 1996 (www.fcc.gov). This Act brought about the creation of many new telecom competitors that raised billions of dollars in the equity and debt markets that went on a spending spree. However, most of these firms had flawed business plans, and through competitive thrusts by the incumbents in the form of administrative delay, regulatory appeal, and litigation, these new entrants were literally bled dry via the consumption of cash in non-revenue producing activities such as regulatory appeals and litigation, and doomed to failure (Nugent, 2001, 2003). Understanding how significant incumbents fight and how they use the most strategic weapons of all – cash position and cash flow – the demise of these new incumbents could be foreseen.

Figure 2. The life cycle curve



Source: Hilliard Consulting Group, 2006

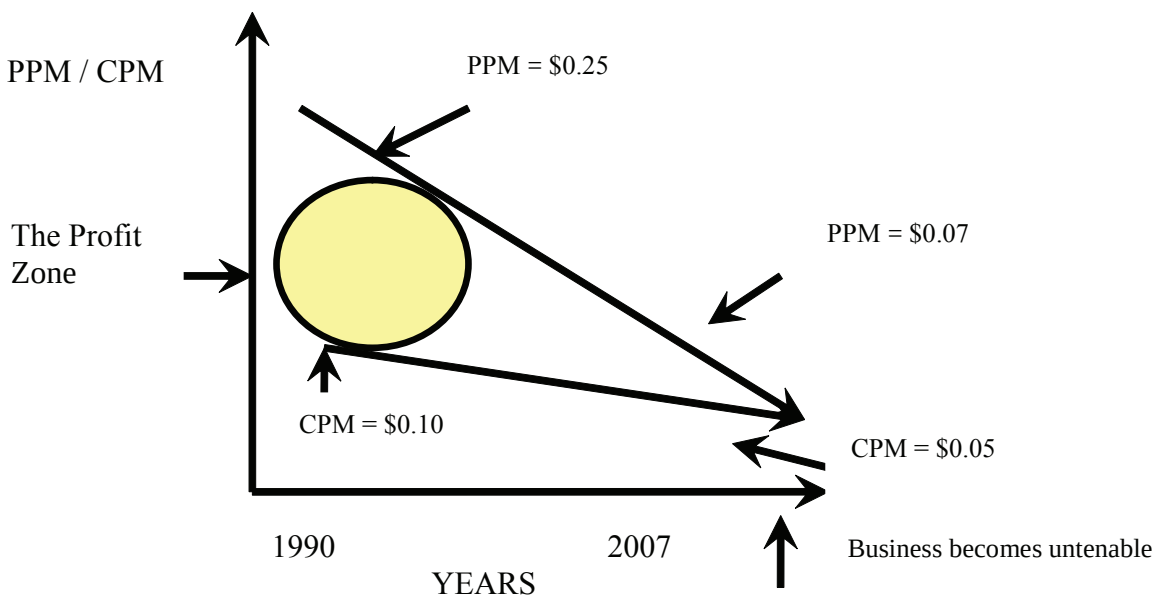
Another significant driver was the explosion in the number of wireless customers brought about by the "Digital One Rate" plan initiated by AT&T. Here wireless growth exploded from approximately 50 million subscribers to over 120 million in just several years. However, there are models that indicate this type of market satiates at approximately 50% of the overall population or 70% of the adult population (Nugent, 2003). In the United States, this satiation point is approximately 145 million narrowband voice subscribers – approximately where we are today. So this spending spurt on narrowband voice wireless Customer Premise Equipment (CPE) and infrastructure equipment could have also been estimated to end as the market approached satiation.

Hence, the telecommunications market downturn should not have been a surprise to anyone, as an understanding of the principal market drivers would have permitted an estimate of the market's size, breadth, depth, and duration.

Life Cycle Curve: Another important strategic understanding is the Life Cycle Curve. This Gaussian Curve (Bell Curve) is representative of all things, whether they are individuals, enterprises, nations, states, or civilizations. That is, each is created, grows rapidly, matures and passes. All such bodies, other than individuals, have the ability to change and adapt versus pass, but this almost never happens. Two companies that lasted longer than most, Stora Kopparbergs Bergslags AB, a Swedish trading company tracing its origins to the Middle Ages was acquired in 2002, and Kongo Gumi, in continuous operation since 560 AD, got into operating trouble in 2006 and was also acquired in November of that year. In fact, most of the leading companies last 40 years on average or less before the pass. This may be seen by looking back at any of the leading business lists of 40 years ago and seeing how many are still on the leading lists of today. Typically 80% of the entities on the first list will not appear on the second. Hence, an understanding of where one stands in its respective life cycle, as well as where its primary competitors, customers, and suppliers stand, is also important because leverage is changing all the time amongst this set. Moreover, to gain and sustain competitive advantage, one needs to constantly discern how and where to reallocate its assets. And the Life Cycle helps determine relative position.

The fundamentals of this model are that approximately 85+% of enterprises fail in the first five years of life, the Infant Mortality stage. The next two contractions represent major market consolidations (mergers and acquisitions). The first such consolidation takes place at approximately 50% market satiation; and the second consolidation at approximately 90+% market satiation. This understanding is important because it permits a right sizing of entity investments and business activity when the first market consolidation takes place, and provides clarity when one should exit its market

Figure 3. The minute margin squeeze model for the interexchange carrier (IXC) market



Key: PPM = Price Per Minute; CPM = Cost Per Minute Source: Hilliard Consulting Group, Inc. ©2007

if it cannot change the market. Moreover, it also hints that at and after the second consolidation point, an entity should only buy like kind assets at steep discounts versus large premiums. This is because in competitive markets at this point in time, dynamic growth and margins are gone.

Most recently we have seen several large 2nd Consolidation Stage purchases in the telecom arena where the industry is at the 90+% satiation point: AT&T's acquisition of Bell South and Cingular's acquisition of AT&T Wireless. In each case a large premium was paid for like kind assets late in the life cycle. This strategy is almost always costly in truly competitive markets, unless the enterprise can create a *de facto* duopoly where the two primary competitors no longer compete on price. The issue involves unit prices and unit costs, and the typical relationship between these functions. That is, as a function of time and competitive pressures, in competitive markets, unit prices decline faster than unit costs. A generic model of long distance unit prices and costs appears below:

This Unit Price Unit Cost Model above indicates that enterprise value, growth, and margins are greatest when the gap between unit prices and unit costs is greatest, The Profit Zone, and least when these functions (slopes) converge.

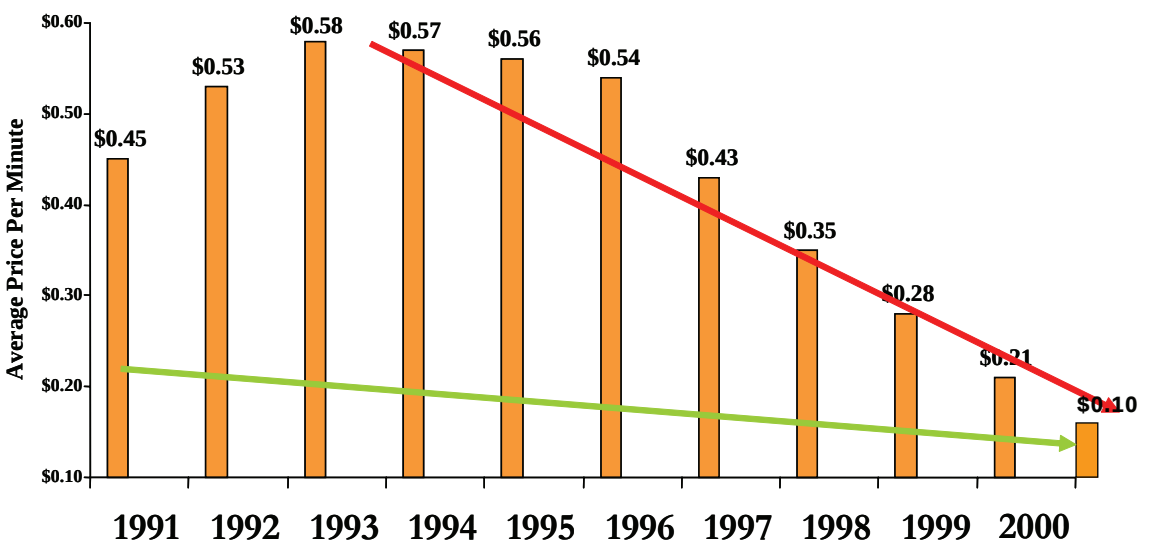
We see this same relationship in the United States narrowband wireless voice arena. Here, too, margin and growth are gone as the unit price/unit cost squeeze is on. Yet, we saw Cingular pay a large premium for AT&T Wireless late in life when margin and growth have abated. This will almost always create stress unless a *de facto* duopoly is created where the unit price degradation slope can be perverted as the two primary competitors no longer compete on price.

At a high level it is also important to understand where a market is today, and where it is going to be tomorrow. To help understand these conditions, a State, Gap, and Trend (SG&T) Analysis tool provides helpful insight (Hilliard, 2003; Wolford-Ulrich, 2004).

The development of a SG&T tool calls for a "one for one" transition (a "this to that" scenario over a period of time – there can be no ambiguities). Hence, a current and future state can be determined with some clarity.

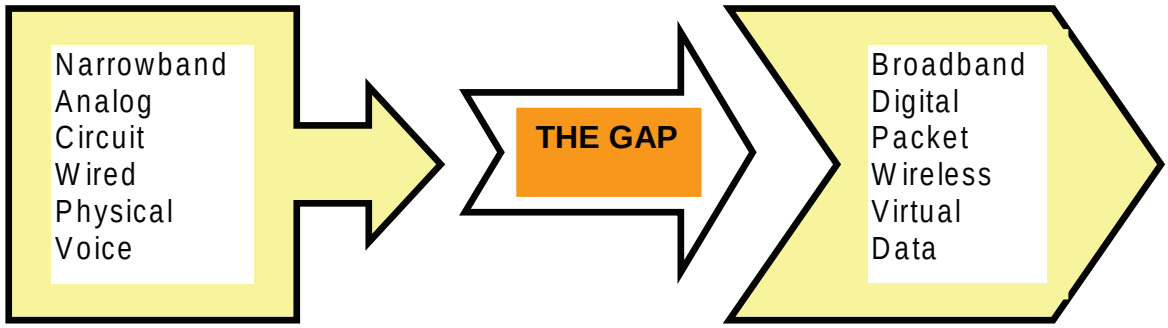
An examination of this SG&T tool presented in Figure 5 indicates that the telecommunications world is moving from a fixed, tethered, narrowband, analog, circuit-based world, to one principally comprised of mobile, wireless, broadband, digital, packet-based communications. This transition portends significant issues for land-based carriers whose assets principally are in big physical plant (central offices, switching facilities, tethered trunks and circuits, etc.). Yet in the two large telecom acquisitions mentioned above, we saw premiums being paid for yesterday's technology where markets are already satiated. This model further indicates that land-based carriers' assets are probably depreciating significantly faster than their balance sheets indicate. Supporting this premise is the decline in the number of residential landlines from approximately 168 million lines in 2001 to approximately 140 million residential landlines today (www.fcc.gov).

Figure 4. Wireless minute unit prices and costs



Source: FCC Annual Report on Wireless Industry, June 2001

Figure 5. State gap and trend analysis: Technology transition

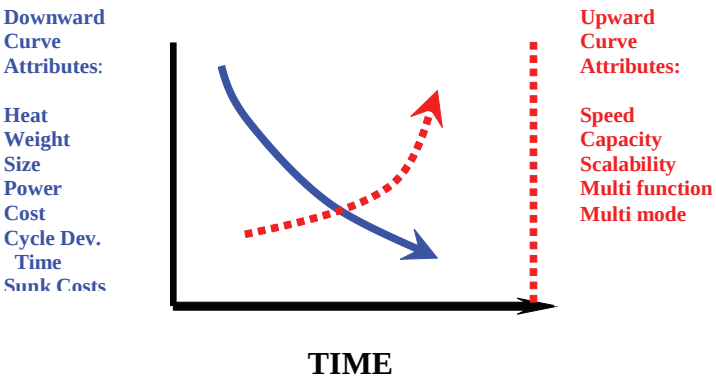


Source: Hilliard Consulting Group, Inc. © 2007

The issue of yesterday's assets and liabilities and the value shown in the financial statements will become apparent in the first quarter of 2008 when most SEC reporting companies must start reporting under FAS 157, Fair Value Accounting. Under this requirement, enterprises must disclose the difference in value from the value indicated on the balance sheet and their current value. For instance, Verizon carries on its books its wireless licenses at approximately $48 billion. In November, 2006 the FCC licensed approximately twice as much spectrum as Verizon holds for approximately $14 billion. This would indicate, under a market value approach, that Verizon's wireless licenses are worth significantly less than their carrying value by perhaps as much as $41 billion.

Moving from a macro model of market trends (SG&T) analysis in Figure 5, it can also be seen on a micro (tactical) level (Product Curve) what attributes successive telecommunications products must follow to win in future markets (Hilliard, 2006). Here, a Product Curve model is most helpful.

Figure 6. Product curve



Source: Hilliard Consulting Group, 2006

The Product Curve demonstrates that devices (network and CPE) need to become smaller, consume less power, weigh less, give off less heat, cost less, be developed in faster and faster cycle times, and have less in sunk development costs, while at the same time do more. They need to operate at faster speeds and higher capacities while performing more functions to win in future markets. The Product Curve also portends troubles for land-line carriers as it can be seen in not too many years, the central office of today will be displaced by a laptop wireless broadband tool of tomorrow. The SG&T Analysis and the Product Curve shown in Figures 5 and 6, respectively, only highlight some important attributes. There other numerous others that may, and should be added for a fuller comprehension of the industry.

To see the Product Curve in action, a comparison of the original Motorola "Brick" cell phone may be made with the sleek small wireless communication devices we use today. Here, we can see that the devices have become smaller, weigh less, consume less power, cost less, give off less heat, but do more. This model would have also clearly shown that Iridium and ICO had to fail because they each fought the attributes of the Product Curve: long cycle development times, high costs and prices, large bulky equipment, consumed a lot of power, gave off a lot of heat, etc. And, because the development cycle times were so long, alternate market winning technologies were developed that did follow the Product Curve attributes – GSM wireless solutions in the main.

Mix Shift Analyses are another way to discern important market changes (Hilliard, 2006). Here, many consulting firms forecast where we are today and likely will be tomorrow.

MIX SHIFTS

These Mix Shift analyses indicate that the telecommunications industry will move from a tethered to a wireless world in the relatively near future, while at the same time the mix of telecommunications traffic will shift from principally voice to principally data. This mix shift does not mean that voice traffic will decline; rather it indicates that data traffic will grow dramatically compared to voice over the period indicated. It is presently estimated that data is growing at 2+ exabytes a year (2 X 10 to the 18th power). Moreover, voice will largely become data as Voice over the Internet Protocol (VoIP) becomes more the norm. This trend is highlighted in the SG&A analysis above where we see a shift from circuit to packet, and narrowband to broadband communications. Hence, when we again look at the recent acquisitions mentioned herein, where yesterday's technology was principally acquired at a large premium, it is likely that the enterprise will be challenged to deal with this situation going forward.

OPERATIONAL TOOLS AND MODELS

Slope Analysis is the Converging/Diverging Gross Margin Analysis. Here, actual data from the Income Statement is plotted for several periods. Converging Gross Margins indicate increasing operational efficiency while diverging gross margins signify decreasing operational efficiency.

Table 1. Transport shift

Transport \ Year	2003	2008	2015
Landline	80%	50%	10%
Wireless	20%	50%	90%

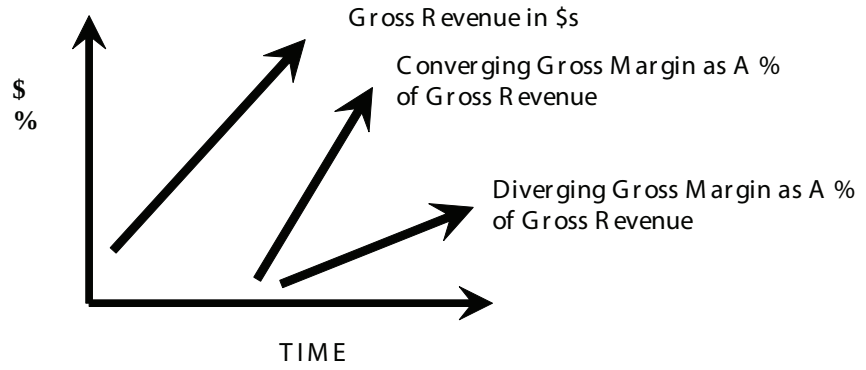
Source: Hilliard Consulting Group, Inc. 2006

Table 2. Mode shift

Service \ Year	1995	2020
Voice	90%	10%
Data	10%	90%

Source: Hilliard Consulting Group, Inc. 2006

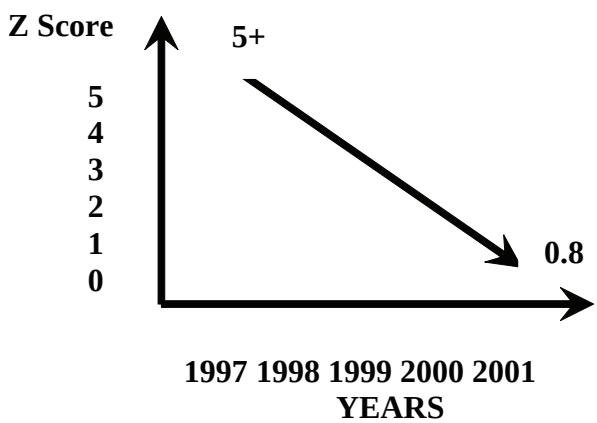
Figure 7. Converging/diverging gross margin analysis



Source: Hilliard Consulting Group, Inc. 2003

Examining AT&T's Initial Public Offering (IPO) for its wireless unit demonstrates the importance of this tool. The IPO for AT&T's wireless unit was well received and the stock price climbed immediately. However, a reading of the offering document would have shown that the Gross Margin decreased (diverged) by over 50% in the preceding annual period. This indicated significant operational troubles. By discerning this diverging gross margin and drilling down to determine the reasons, one would have discerned that AT&T's successful "Digital One Rate Offering" caught the company short, far short, of network capacity to support demand. Hence, AT&T had to go off-net and pay other carriers high fees to originate or terminate its traffic. This understanding would have highlighted additional issues facing AT&T Wireless: either take on more debt or dilute current shareholders further by issuing more stock in order to build more infrastructure.

Figure 8. AT&T Modified Z Score 1997 - 2001



Year	Score
1997	5+
1998	3.91
1999	1.87
2000	1.1
2001	.8

Source: Hilliard Consulting Group, Inc. 2006

One final operational tool is the Discriminant Function Algorithm (DFA) used to discern changes in corporate health on a prospective basis – Inflection Points. (Amdocs Corp., 2003; Slywotzky. Morrison, Moser, Mundt, & Quella 1999) This model uses Altman's Z Score algorithm for determining bankruptcy on a prospective basis (Altman, 1983). However, unlike Altman where he uses absolute scores, the DFA model only cares about changes in score - either positive or negative (Nugent, 2003). Moreover, the scale is changed in the DFA model from Altman's Bankruptcy Prediction model. As an example of what this tools yields on a prospective basis, AT&T is again viewed.

As can be seen, AT&T's Modified Z Score declined from over 5 in 1997 to under 1 by 2001. This is a dramatic negative decline. Yet, during much of this period, Wall Street was in love with this stock. Had one begun plotting this Z score in 1997, one could have discerned by 1999 that things were heading south long before others foresaw this decline. For instance, if Ericsson had been using this model in 1997 and beyond, it would have provided Ericsson early warning that it needed to re-address its marketing and sales strategy as its largest customer, AT&T, had a degrading corporate health.

FUTURE TRENDS

From our examination of the past and the tools that may be employed to glean a view of the future, it is apparent that major transitions are underway at the strategic level; namely, voice to data, circuit to packet, narrowband to broadband, wired to wireless, and physical to virtual. Such transitions will require new networks to support these changes. Moreover, at the product or tactical level, we see that new solutions will be required to be smaller, lighter, less costly, consume less power, give off less heat, weigh less, and be developed in shorter time cycles if they are to be successful in subsequent markets.

CONCLUSION

High level analytical and operational tools and models can assist the telecommunications professional in understanding the telecommunications market's characteristics, life cycles, trends, directions, limits, drivers, duration, and likely prospective performance. These tools demonstrate that wireless communications will follow the same life cycle characteristics as wired communications. Proper utilization of such tools collectively, consistently, and continually can lead to important and timely insights hopefully leading to competitive advantage based upon an early detection of changes in marketplace dynamics.

KEY TERMS

CAGR: Cumulative Annual Growth Rate – The percent of growth from one annual period to the next.

CAPEX: Capital Equipment Expenditures usually measured as a percent of gross revenue.

Converging/Diverging Gross Margin Analysis: A Slope Analysis Tool used to plot actual sales and gross margin data for several periods in order to discern trends and likely outcomes. Measure operational efficiency or inefficiency.

CPE: Customer Premise Equipment (end-user equipment).

Discriminant Function Algorithm: A term developed for Edward Altman in describing his Z Score analytical tool in determining the likelihood of an enterprise going into bankruptcy on a prospective basis. Used as a method for determining inflection points – changes in corporate health versus for bankruptcy prediction.

Inflection Points: Significant changes in corporate performance.

IXC: Interexchange Carriers (long distance companies that transport inter Local Access Transport Area (LATA) traffic).

LATA: Local Access Transport Area – a geographic area defined by the FCC.

Minute Margin Squeeze: Also known as Unit Price/Unit Cost Model – see below.

Mix Shifts: Shifts in the market between major components usually requiring different technology or solutions.

Product Curve: This tool takes a micro view of transitioning requirements or attributes successive solutions it must adhere to in order to win in the future market place.

Slope Analysis: The plotting and visualization of certain operating functions in order to discern trends, often before others see them, thereby permitting alteration of strategies in order to gain competitive advantage.

State Gap & Trend Analysis: A tool used to present in a structured format current market or technology states as well as future states. This analysis requires a "one for one" transition – a "this to that" view. This model calls for no ambiguities. The perilous part of this tool is determining how to transition the Gap – where one has to be by when, with what.

Unit Price/Unit Cost Model: A Slope Analysis Tool used to plot actual unit prices and unit costs for several periods in order to discern future trends and likely outcomes.

Cross-Cultural Challenges for Information Resources Management

Wai K. Law
University of Guam, Guam

INTRODUCTION

Western organizations have led the globalization of business operations, especially in the deployment of multi-domestic strategy. The decentralized organizational control and customized operations support the fast penetration of huge global markets. Western management theory considers information the lifeblood of organization. The sharing of information lubricates the interlocking divisions within the organization, promoting the effective achievement of organizational goals with external business partners. However, in many regions of the world, information represents power, and managers often try to accumulate as much of it as they can while denying access to others (Oz, 2002). For others, the disclosure of information is considered a threat to the span of management control (Rocheleau, 1999). In some cases, administrators could be more interested in the scale of the information system and its associated budget, than the capability and functionality of the system (Kalpic & Boyd, 2000). These are examples of conflicting cultural values in a cross-cultural environment. The introduction of Western management approaches conflicts with regional administrative styles, diminishing the effectiveness of information systems (Raman & Watson, 1997; Shea & Lewis, 1996). Sensitivity to cultural differences has been recognized as an important factor in the successful global deployment of information systems. Minor information management issues potentially resolvable through improved communication in the west often manifest as major challenges in a cross-cultural environment.

BACKGROUND

The literature provided thorough coverage on designs, development, and implementation of computer-based information systems (CBIS). Numerous studies examined various systems-solutions for organization needs (McLeod, 1998; O'Brien, 2002). However, the projected value of information technology has been formulated based on a rough assessment of the possibilities without full appreciation of the limitations due to resistance to organizational and social changes (Osterman, 1991). Increasingly, management realized that massive deployment of information systems on a global basis, even with prudent management of the systems, has not been producing the desirable outcomes of value generation. Recent studies revealed the significant influence of cultures toward the success of transferring information technology beyond the Western world. National culture, organization culture, and MIS culture induced influence over the successful development and management of information resources (Hofstede, 1980; Raman & Watson, 1997). Shea and Lewis (1996) suggested the desirability of placing close attention to user absorptive rate in the transfer of new technology into a different cultural environment. It became apparent that adaptation of information system designs to new cultural environments was insufficient to guarantee successful implementation. User selection of technological features, driven by cultural preferences, could be a key factor for designing information systems in multi-cultural environments. Other studies reported the numerous obstacles of developing CBIS under various cultural settings, even with highly motivated leaders to support the deployment of information systems (Al-Abdul-Gader, 1999; Raman & Watson, 1997).

The information system function must enhance user effectiveness and efficiency in utilizing the information to improve value delivery for the organization. New challenges emerged as non-technical issues clouded the measurement of information system performance. A typical information system would be designed to provide information to users with common needs. Good data reports should contain all the required information with accurate representation of events. The reports needed to be generated in a timely fashion and in a format usable by the users (McLeod, 1998). However, individual users tended to value information systems for providing custom reports to meet individual needs in specific circumstances (Heeks, 1999). Inconsistent expectations in a cross-cultural environment crippled the effective management of information resources. Cultures carried different interpretations for timeliness, completeness, and relevancy of information.

Makeshift management decision generated new dynamics in several ways. In the spirit of promoting free information exchange, the department that owned the information system became obligated to provide information to others (Oz, 2002). However, the new responsibility seldom came with additional resources. The information owners became reluctant to supply information; doing so would take away

resource from other regular tasks (Davenport, 1997). Some managers shifted the data reporting responsibilities to other divisions, creating a bureaucratic nightmare for the users. Some ignored data requests, and others manipulated the data flows with respect to organizational politics (Oz, 2002; Rocheleau, 1999). Those working in the public sector faced the challenge of maintaining a delicate balance as they attempted to fulfill their responsibilities for both confidentiality and access to data (Duncan, 1999; Osterman, 1991). The problems would be more severe under a relationship-based culture where favors could not be declined.

Cultural backgrounds shaped the preferential information system model. In some cultures, managers would be intuitive, and feelings based, and have vague expectation for the performance of the information system. There would be more emphasis on group harmony and saving face than actual problem solving (Bjerke, 1999). Others would be more interested in meeting obligations, ignoring the source and validity of the reports. The controlling manager seeked a complex and broad information system providing qualitative data (Kluckhohn & Strodtbeck, 1961; Lane & DiStefano, 1992; Shea & Lewis, 1996). All these personality extremes co-exist in a cross-cultural setting, making it more challenging to design systems than a single culture environment. The perceived value of information resources became less predictable in cross-cultural environments.

CROSS-CULTURAL IRM CHALLENGES

The rapid expansion of Western influence on a global basis created an environment under the crosscurrents of Western corporate culture and regional cultures. In recent years, Western organizations have invested heavily in information technology (IT), turning it into an important tool, especially for the rapid expansion of business operations to global locations. Many organizations were surprised by the turbulence associated with the global deployment of information technology.

Management encountered new challenges as national workers joined the global team in serving customers from diversified cultural backgrounds. The national workers tended to hold on to their traditions, diluting the penetration of Western influence in the workplaces. The predominating regional workforce challenged Western corporate culture through their deep-rooted traditions and work habits. For example, a massive absenteeism could be expected on festival days, even without approved leaves or holidays. Timely arrival at a meeting could be accepted as up to several hours after the scheduled time. Mandated reports could be excused without penalty, and the uttermost concern to preserve group harmony over efficiency. Sometimes, this meant ignoring facts to restore stability and group harmony. Periodic acquisition of technology would be celebrated even without the appropriate infrastructure support, preventing the proper usage of the technology. Cross-cultural IRM issues emerged as significant challenges in cross-cultural environments.

Challenge 1: Information Resources Perception Challenges

Even as IT is transforming the world, a majority of the world's population still has limited understanding of information as a resource. The concepts of information resources escape the mind of even seasoned managers in the Western world. Potential cultural myopia requires great efforts to communicate the principles of information resources management.

Perception Challenge 1: Cultural Acceptance of IRM Practices

In a cultural environment that lacks appreciation for information resources, management must champion data planning and skillfully align the information support needs throughout the organization.

In cultures where gesture is more important than details, systematic failure to collect information would be accepted and forgiven. Information systems applications are often limited to payroll and accounting (Kalpic & Boyd, 2000). In some cases, the lack of adequate information is the key to assure continuing financial support, and the scale of the information system acquisition could be more important than the functionality. Organizations are unprepared to collect and store data to support meaningful decision support applications. A common pitfall is the underutilization of expensive information systems.

Perception Challenge 2: Information Resources Considered as Capital Expenditure

Funding is a necessary but insufficient condition for information resource development. The lack of proper organizational infrastructure dooms information system projects.

Deficiency in organizational data is often related to the lack of capital spending in IT resources. This perception underestimates the requirements for system analysis, data architecture development, data security and distribution, maintenance, technical support, and user training. Lack of organizational readiness stalls the deployment of information systems. Inflated expectation and uncoordinated usage of data services nullifies the value of the information systems. Erratic funding pattern destroys development projects, making it extremely difficult to retain technical personnel. Poor maintenance damages equipment and threatens data

integrity. Cultural managers eager to modernize without fully understanding the implications of information resources management eventually abandon their support for information resources.

Perception Challenge 3: Information Resources Development by Delegation

Information resources development without central coordination creates confusion and depresses the perceived value of information resources.

Management seeking an easy fix to the organizational data problem mandates data compilation by the functional divisions. Besides undermining information resources as a critical organizational asset, divisional managers tend to avoid the unfamiliar tasks by deferring to workers with little technical background. Unmotivated managers neglect data quality and resist data distribution. Administrator turnovers cause discontinuity in data resources development.

Perception Challenge 4: Information as a Freely Available Resource

The true value of information emerges from its effective distribution to end users. Information distribution is an expensive service.

Information resources can be compared to utility services such as water, the value of which relies on reliable and effective distribution with assured quality and sufficient supply. Often neglected is the accountability of the value contribution of information system, beyond periodic technical improvements. There is a need for benchmark studies to identify cost performance, as well as the critical roles of information resources within the organization.

Challenge 2: IT Transfer Challenges

The design objectives of information systems must expand from efficiency orientation to adaptive accommodation of cultural habits. It becomes desirable to allow and track dynamic modification of data processing procedures according to shifting organizational and cultural influences.

While a primary design objective of information systems is to facilitate efficient transaction processing, often the affected human system is slow to accept the implicit MIS culture embedded in the system design. Western cultures emphasize timeliness and accuracy, which are less important to other cultures (Kaufman-Scarborough & Lindquist, 1999; Straub, Loch, & Hill, 2001). For example, it often takes months to update databases from paper documents. Some users rely on the information system for information, while others insist on paper documents only. Hence circulation of multiple versions of reports is common depending on the sources of the reports. Parallel operations to accommodate parallel cultures generate organizational conflicts. Influential users and administrative interventions threaten the integrity of information systems. The full potential of information systems is suppressed in preference for cultural norms, and only system features that do not threaten cultural practices would be allowed to remain. Some local cultures put more emphasis on protecting family members than performance appraisal. The value of information is not as much for improving decision making, but to endorse group position, to preserve relationship, and to avoid embarrassment.

Challenge 3: Data Resources Management Challenges

Western culture encourages innovation, creativity, and the sharing of ideas and information. The same may not hold true under many cultures that adopt a historical perspective and value social stability to changes. Information resources could be jealously guarded in these cultures, and data distribution restricted.

Practical Challenge 1

There is a need for the clear definitions of data ownership and responsibilities for data acquisition, data quality control, and data distribution. This is especially challenging in cultural environments where the political attributes of information interfere with the communicative value of information.

In many Eastern cultures, credible information is deferred to leaders and elders with power and status. Political relationships dictate the availability of information and the accessibility to organizational data. This is in contrary to the basic assumptions of CBIS that promote the free exchange of information (Osterman, 1991; Oz, 2002; Rocheleau, 1999). The bureaucratic procedures for the approval of data usage defeat the designed roles of the information system. Fully developed database supports very limited applications. The lack of explicit system objectives coupled with the practice of delegating data management responsibility to the lowest level unskilled workers creates data integrity problems. For example, withholding information to gain and maintain power is acceptable among many Asian cultures. Openness would be considered a sign of weakness. It would be critical to formally establish the credibility, relevancy, and accessibility of data resources.

Practical Challenge 2

Management must meticulously plan data acquisition, data preparation, data distribution, and data usage, and fully understand the required organizational incentive and associated costs for maintaining information flow within the organization. This is especially important in cultural environments where data-driven decision-making is a new practice.

An uncoordinated approach to information resources management creates fragmented entities to process information for narrow applications. The fad of data-driven decision-making created a mad race for data reports using every available political connection. The result would be a great assortment of data reports with massive details. Inconsistency occurred among data reports depending on the data processing methods and storage formats. For example, a report from an off-line, static database in a remote office could be given equal credibility as a report generated from a current database from the data center. In a cross-cultural environment, influential individuals would compete to justify the merit of their reports from their cultural perspectives. The heated debates along with discrepancies among the reports frustrate the end users and lead to distrust toward the information systems for the inability to produce usable information reports. Regretfully, the information systems are seldom seriously designed for decision support.

Practical Challenge 3

Management must take leadership in establishing precise, formal data definitions, and communicate them to all potential data users, and those assigned roles in data distribution. This is especially important where mastery of languages, cultural predisposition, level of information literacy, and social attitude could strongly influence the group dynamic of data usage.

Technology evolution increasingly places information systems under the direct control of end users. However, end users often lack the technical expertise, and few are committed to the development of information resources. Events and samples are confused with statistics. Relaxed practices in standards and data definitions create issues in data validity and data quality. Potential information is lost when processed data replaces the raw data, while ignoring the time sensitivity of dynamic data. Time series data are deleted to preserve storage space. The information system is often blamed for the unfortunate chaos. For instance, technology facilitates individual users to maintain multiple copies of a database. Top management, unwilling to escalate cultural tension, ignored the potential seriousness of the data integrity issue. Improper database management practices yield different outcomes for identical requests for information from the different versions of the database. The absence of a single standard triggers disputes on the interpretation of data definitions according to the language understanding of the end users, while the actual data definition used by the data center to maintain the database is being rejected!

Challenge 4: Knowledge Sharing Challenges

Different cultures adopt different views toward knowledge, even among Western societies. Some cultures treat knowledge as an individual asset, a tradable resource. Intellectual property and usage rights become the main concern in knowledge sharing. Other cultures claim ownership of knowledge by the society and deny individual ownership of knowledge. A major concern would be censorship and control of information flow. Some cultures consider access to knowledge a privilege, given to individuals with the proper social ranks, while other cultures desire the widest distribution of knowledge to every member of the society. Information systems can be a threat to one society while high valued in another. Some cultures support openness, and others are conservative. Thus the emphasis could be on communication support in one society, while on preservation of traditions in another (Forstenlechner, 2005). Potential value clashes emerge in a cross-cultural setting when an individual raised in one social environment manages knowledge under a different social expectation. Knowledge sharing challenges are also expected with partnerships between organizations from different cultural background (Ford & Chan, 2003).

Challenge 5: Information Resources Accountability Challenges

As information resources emerge from a supportive role to become strategic assets, their management must also mature from the simple control measures for supplies. A greater challenge is to safeguard certain information resources as critical assets to be accessible only by trusted individuals.

Accountability Challenge 1

The increased complexity and frequency of usage of information reports is in reality a severe drain in budgetary resources, and management needs to develop a mechanism to track data usage and adjust resources appropriately. This could be more challenging under cultural environments that lack sophistication in information processing.

Modern management practices seeked opportunities to replace physical resources with information. When management failed to adjust budgets to support the in-

formation services, those affected would try every means to discontinue information services. On the other hand, uncontrolled access encouraged abuse, wasting valuable resources. Ethics, disciplined usage, and an understanding of information value supported the information practices in Western society. The problems would be crippling in cultures with different appreciation for information under different ethical standards. A local culture of generosity would insist on the free distribution of fully colored documents. Another practice has been the circulation of printed copies of e-mail to avoid offending anyone. These practices quickly deplete the budget for supplies.

Accountability Challenge 2

Management must take an active role in controlling the flow of organizational data, both within the organization and to the external environment. Management should consider endorsement of an official organizational data set to ensure consistency rather than leaving official data reports to random actions. This is especially important in cultural settings where it is impractical to correct public statements of social leaders regardless of facts.

In cultures where subordinates would not question the positions of leaders, information systems must implicitly support the decisions and public statements of the leaders (Gannon, 2001). In one example, officials of a local organization proposed an expensive marketing campaign pointing to decline in demand in the primary market. However, published data actually attributed the demand decline to the collapse of an emerging market. It would be an embarrassment to point out the omission, and the wrath of the society could be on those who allowed the facts to be publicized.

Accountability Challenge 3

Management must carefully orchestrate the deployment of information resources, with expected outcomes and supports. Strategic deployment rather than equal access should improve the value contribution of information resources.

While is it culturally sensitive to provide equal access to information resources, it is much more challenging to expect performance improvement with the availability of information resources. Management needs to carefully link value contribution to the deployment of information resources.

FUTURE TRENDS

The historical development of information systems has followed the model of a rational manager, with emphasis on openness, clear structure, innovative practices, and logical thinking. In regions where traditions and relationships resisted changes, information system designers must consider the needs of emotional decision-makers, with heavy emphasis on the concern to maintain social and cultural stability. Some cultures demand tight control of information flow, while other cultures are very casual about the absolute data quality. Some organizations integrate information systems as organizational backbone; others preferred to separate information in isolated pockets. Some prefer a simple information system, while others invest in a sophisticated intelligence system. Information systems for cross-cultural environments must deliver value to users with diversified backgrounds. Comparative study on information system features valued across cultural settings should improve the value delivery of the information system function.

CONCLUSION

Despite rapid technological development, information resource management is still a relatively new concept. Data reports preparation is often a laborious activity, and accepted practices and administrative preferences still drive decision-making. Organizations that anticipate increasing exposure to multi-cultural environments should allow longer time for organizational adjustment to technical development. Information systems originally developed as productivity tools for data processing, and report generation must undergo radical design evaluation to meet the diversified user expectations and information skills. Information resource managers must also carefully consider data ownership and data distribution issues. Cultural preferences and information values should be carefully considered in the justification of information services. Information system objectives should be clearly distinguished from information system capabilities, especially with different cultural interpretation of information value. Top management should play an active role in defining organizational data flow, with implementation of appropriate incentives. Special attention should be given to precise data definition, especially with a workforce with a different training background under different cultural and language settings. Lastly, it is critical to emphasize strict standards for data quality, due to differences in expectations for the information system performance.

KEY TERMS

Cross-Cultural IRM: The special information resources management practices needed with the coexistence of more than one cultural influence in different segments of a society, or the simultaneous adoption of different cultural practices at work, social event, and family life.

Cultural Habit: Accepted behaviors within a group of people, sharing some common backgrounds, such as language, family heritage, education, living, and socializing environment.

Data Definition: An elaborate statement of the representation of each piece of data, its source, storage method, and intended usage.

Data Resources Management: The acquisition, organization, protection, maintenance, and selective distribution of organizational data.

Data-Planning: The projection of expected future need for data, with specifications on data sources, data collection

and storage, data processing and presentation, data distribution, and data security.

Information Resources: Resources required to produce information, including hardware, software, technical support, users, facilities, data systems, and data.

Information Resources Accountability: The activities related to tracking information resources usages, evaluation of information resources value contribution, and the monitoring of access to critical information resources.

IT Transfer: The introduction of an information communication technology to a new region of the world.

Cross-Cultural Research in MIS

Mark Srite
University of Wisconsin-Milwaukee, USA

INTRODUCTION AND BACKGROUND

"Globalization of business highlights the need to understand the management of organizations that span different nations and cultures" (Srite et al., 2003, p. 31). In these multinational and transcultural organizations, there is a growing call for utilizing information technology (IT) to achieve efficiencies, coordination, and communication. However, cultural differences between countries may have an impact on the effectiveness and efficiency of IT deployment. Despite its importance, the effect of cultural factors has received limited attention from information systems' (IS) researchers. In a review of cross-cultural research specifically focused on the MIS area (Evaristo, Karahanna, & Srite, 2000), a very limited number of studies were found that could be classified as cross-cultural. Additionally, even though many of the studies found provided useful insights, raised interesting questions, and generally contributed toward the advancement of the state of the art in its field, with few exceptions, no study specifically addressed equivalency issues central to measurement in cross-cultural research. It is this methodological issue of equivalency that is the focus of this article.

METHODOLOGICAL ISSUES

Methodological considerations are of the utmost importance to cross-cultural studies, because valid comparisons require cross-culturally equivalent research instruments, data collection procedures, research sites, and respondents. Ensuring equivalency is an essential element of cross-cultural studies and is necessary to avoid confounds and contaminating effects of various extraneous elements.

Cross-cultural research has some unique methodological idiosyncrasies that are not pertinent to intracultural research. One characteristic that typifies cross-cultural studies is their comparative nature, i.e., they involve a comparison across two or more separate cultures on a focal phenomenon. Any observed differences across cultures give rise to many alternative explanations. Particularly when results are different than expected (e.g., no statistical significance, factor analysis items do not load as expected, or reliability assessment is low), researchers may question whether results are true differences due to culture or merely measurement artifacts (Mullen, 1995).

Methodological considerations in carrying out cross-cultural research attempt to rule out alternative explanations for these differences and enhance the interpretability of results (van de Vijver & Leung, 1997). Clearly, the choice and appropriateness of the methodology can make a difference in any research endeavor. In cross-cultural research, however, one could go to the extreme of classifying this as one of the most critical decisions. In this section, we briefly review such cross-cultural methodological considerations. Specifically, this section will address equivalence (Hui & Triandis, 1985; Poortinga, 1989; Mullen, 1995) and bias (Poortinga & van de Vijver, 1987; van de Vijver & Leung, 1997; van de Vijver & Poortinga, 1997) as key methodological concerns inherent in cross-cultural research. Then, sampling, wording, and translation are discussed as important means of overcoming some identified biases.

Equivalence

Achieving cross-cultural equivalence is an essential prerequisite in ensuring valid cross-cultural comparisons. Equivalence cannot be assumed a priori. Each cross-cultural study needs to establish cross-cultural equivalence. As such, equivalence has been extensively discussed in cross-cultural research, albeit using different terms to describe the phenomenon (Mullen, 1995; Poortinga, 1989).

To alleviate confusion created by the multiplicity of concepts and terms used to describe different but somewhat overlapping aspects of equivalence, Hui and Triandis (1985) integrated prior research into a summary framework that consists of four levels of equivalence: conceptual/functional equivalence, equivalence in construct operationalization, item equivalence, and scalar equivalence. Even though each level of equivalence is a prerequisite for the subsequent levels, in practice, the distinction between adjacent levels

of equivalence often becomes blurry. Nonetheless, the objective in cross-cultural research is to achieve all four types of equivalence. Hui and Triandis' (1985) four levels of equivalence are discussed as follows:

1. *Conceptual/functional equivalence* is the first requirement for cross-cultural comparisons and refers to whether a given construct has similar meaning across cultures. Furthermore, to be functionally equivalent, the construct should be embedded in the same nomological network of antecedents, consequents, and correlates across cultures. For instance, workers from different cultures may rate "supervisor is considerate" as a very important characteristic; however, the meaning of "considerate" may vary considerably across cultures (Hoecklin, 1994).
2. *Equivalence in construct operationalization* refers to whether a construct is manifested and operationalized the same way across cultures. Not only should the construct be operationalized using the same procedure across cultures, but the operationalization should also be equally meaningful.
3. *Item equivalence* refers to whether identical instruments are used to measure the constructs across cultures. This is necessary if the cultures are to be numerically compared.
4. *Scalar equivalence* (or full score comparability; see van de Vijver and Leung, 1997) occurs if the instrument has achieved all prior levels of equivalence, and the construct is measured on the same metric. This implies that "a numerical value on the scale refers to same degree, intensity, or magnitude of the construct regardless of the population of which the respondent is a member" (Hui & Triandis, 1985, p. 135).

Bias: Sources, Detection, and Prevention

To achieve equivalence, one has to first identify and understand factors that may introduce biases in cross-cultural comparisons. Van de Vijner and Poortinga (1997) described three different types of biases: construct bias, method bias, and item bias:

1. *Construct bias* occurs when a construct measured is not equivalent across cultures both at a conceptual level and at an operational level. This can result from different definitions of the construct across cultures, lack of overlap in the behaviors associated with a construct [e.g., behaviors associated with being a good son or daughter (filial piety) vary across cultures], poor sampling of relevant behaviors to be represented by items on instruments, and incomplete coverage of the construct (van de Vijver & Leung, 1997). Construct bias can lead to lack of conceptual/functional equivalence and lack of equivalence in construct operationalization.
2. *Method bias* refers to bias in the scores on an instrument that can arise from characteristics of an instrument or its administration (van de Vijver & Leung, 1997), which results in subjects across cultures not responding to measurement scales in the same manner (Mullen, 1995). Method bias gives rise to concerns about the internal validity of the study. One source of method bias is sample inequivalency in terms of demographics, educational experience, organizational position, etc. Other method bias concerns relate to differential social desirability of responses (Ross & Mirowsky, 1984) and inconsistent scoring across populations (termed "selection-instrumentation effects" by Cook and Campbell, 1979, p. 53). For instance, on Likert scales, Koreans tend to avoid extremes and prefer to respond using the midpoints on the scales (Lee & Green, 1991), while Hispanics tend to choose extremes (Hui & Triandis, 1985). Differential scoring methods may also arise if respondents from a particular culture or country are not familiar with the type of instrument being used.
3. *Item bias* refers to measurement artifacts. These can arise from poor item translation, complex wording of items, or items inappropriate for a cultural context. Consequently, item bias is best prevented through careful attention to these issues. Like method bias, item bias can influence conceptual/functional equivalence, equivalence of operationalization, and item equivalence.

Table 1 presents a summary of how the three types of bias can be prevented or detected. The next section discusses three important methods of bias prevention: sampling, wording, and translation. This article concludes by presenting a set of cross-cultural methodological guidelines derived by a committee of international scholars.

Sampling

Sampling decisions in cross-cultural studies involve two distinct levels: sampling of cultures and sampling of subjects (van de Vijver & Leung, 1997). Sampling of cultures involves decisions associated with selecting the cultures to be compared in the study. Many studies involve a convenience sample of cultures, typically ones where the researcher has preestablished contacts. Even though this strategy reduces the considerable costs of conducting cross-cultural research, it may hinder interpretability of results, particularly when no differences are observed across cultures (van de Vijver & Leung, 1997). Systematic sampling of cultures, on the other hand, identifies cultures based on theoretical considerations.

Table 1. Types of bias, prevention, and detection

	Detection	Prevention
Construct bias (focus: constructs)	• Informants describe construct and associated behaviors • Factor analysis • Multidimensional scaling • Simultaneous confirmatory factor analysis in several populations • Comparison of correlation matrices • Nomological network	• Informants describe construct and associated behaviors in each culture
Method bias (focus: administration procedures)	• Repeated administration of instrument • Method triangulation • Monomethod-multitrait matrix	• Sampling (matching, statistical controls) • Identical physical conditions of administering the instrument • Unambiguous communication between interviewer and interviewee • Ensured familiarity with the stimuli used in the study
Item bias (focus: operationalization)	• Analysis of variance • Item response theory • Delta plots • Standardized *p*-difference • Mantel–Haenszel procedure • Alternating least squares optimal scaling • Multiple group LISREL	• Wording • Translation

Typically, this involves selecting cultures that are at different points along a theoretical continuum, such as a cultural dimension. Random sampling of cultures involves selection of a large number of cultures randomly and allows for wider generalizability of results.

Most cross-cultural studies discussing sampling considerations, however, refer to sampling of subjects. Ensuring sample equivalency is an important methodological consideration in cross-cultural research, and it refers to the inclusion of subjects that are similar on demographic, educational, and socioeconomic characteristics. Sample equivalency can be achieved by either matching subjects across groups based on these background variables or statistically controlling for the differences by including such demographic variables as covariates in the cross-cultural comparisons (van de Vijver & Leung, 1997).

Wording and Translation

This is one of the key problems in cross-cultural methods, because in most cases, different cultures also have different languages. Even in cases when subjects from different countries are conversant with English, they may miss the nuances of the intended meanings in questionnaire items (e.g., British, Canadian, and American English all have unique terms). Researchers should ensure that measurement instruments keep the same meanings after translation. Moreover, a given latent construct should be measured by the same questionnaire items in different populations. In fact, researchers such as Irvine and Carrol (1980) made a convincing case for using factor-matching procedures to test for invariance of factor structures across groups before any quantitative analysis is performed.

To translate correctly, there is a need to translate to the target language. This needs to be performed by a native speaker of the target language. Then, the text must be back-translated to the original language, this time by a different native speaker of the original language. Brislin (1986) provided fairly complete guidelines for this process.

IMPLICATIONS

Judging by the issues described above, achieving cross-cultural equivalence is straightforward. However, it is also clear that many precautions can be taken to prevent construct, method, and item bias and thus increase the level of equivalence. These range from sampling, wording, and translation, to careful attention to administration procedures across cultures. A number of guidelines for cross-cultural research have been put forth by an international committee of scholars (Hambleton, 1994; van de Vijver & Hambleton, 1996). Even though the primary focus of these is on research on psychological and educational issues, these guidelines easily generalize to MIS research.

In addition to prevention, various statistical tools can assist in the detection of the various types of biases. In summary, similar patterns of functional relationships among variables need to be shown (Triandis, 1976). Moreover, multimethod measurement can help us to avoid the confound between the interaction of the method and groups studied and is unlikely to share the same statistical underlying assumptions, or even require strong conceptualization ability (Hui & Triandis, 1985). This idea is similar to the notions of multiple operationism and conceptual replication (Campbell & Fiske 1959). Hui and Triandis (1985) claimed that this may not be as difficult as one may think, as long as there is prior planning of research. As an example, Hui and Triandis (1985) mentioned that an instrument may be improved by proper translation techniques, and:

…then establish conceptual/functional equivalence as well as instrument equivalence by the nomological network method and by examination of internal structure congruence. After that, the response pattern method and regressional methods can be used to test item equivalence and scalar equivalence. (p. 149)

The major implication of methodological problems is complications in making valid inferences from cross-cultural data. Clearly, there are many problems with correctly inferring from data in a cross-cultural research project and attributing results to true cross-cultural differences. To do so, alternative explanations need to be ruled out. Establishing (and not merely assuming) the four levels of cross-cultural equivalence previously discussed in this article is a major step in this direction.

FUTURE DIRECTIONS AND CONCLUSION

Initial attempts at reviews of cross-cultural research in MIS (Evaristo, Karahanna, & Srite, 2000) show that, for the most part, MIS studies have refrained from testing theories across cultures, and when comparisons are made, they are often post hoc comparisons utilizing data from prior published studies in other countries. Clearly, this provides some insights into differences across cultures but suffers from a number of methodological shortcomings. In fact, the conclusions of Evaristo, Karahanna, and Srite (2000) were as follows:

In summary, we suggest that there are mainly three points where the MIS cross-cultural research is lacking: lack of theory base (testing or building); inclusion of culture as antecedents of constructs, and general improvement in methodologies used.

All three points are related, although to different extents, to methodological issues. The conclusion is that one critical issue that cross-cultural research in MIS needs to address before reaching the same level of sophistication and quality already attained by mainstream MIS research is to attend to methodological concerns. The current article is a step ahead in this direction and sets the stage for future research.

KEY TERMS

Conceptual/Functional Equivalence: Refers to whether a given construct has similar meaning across cultures.

Construct Bias: Occurs when a construct measured is not equivalent across cultures both at a conceptual level and at an operational level.

Equivalence in Construct Operationalization: Refers to whether a construct is manifested and operationalized the same way across cultures.

Item Bias: Refers to measurement artifacts.

Item Equivalence: Refers to whether identical instruments are used to measure the constructs across cultures.

Method Bias: Refers to when subjects across cultures do not respond to measurement scales in the same manner. Bias in the scores on an instrument can arise due to characteristics of the instrument or its administration.

Multinational Corporation: A firm that has operations in multiple countries.

Scalar Equivalence: Refers to whether the construct is measured on the same metric across cultures. This occurs if the instrument has achieved all prior levels of equivalence, and the construct is measured on the same metric.

Transcultural Organization: A firm that operates across multiple cultures.

Cultural Diversity in Collaborative Learning Systems

Yingqin Zhong
National University of Singapore, Singapore

John Lim
National University of Singapore, Singapore

INTRODUCTION

Globalization makes cultural diversity a pertinent factor in e-learning, as distributed learning teams with mixed cultural backgrounds become commonplace in most e-learning programs, which can be study-based (schools and universities) or work-based (training units) (Zhang & Zhou, 2003). In these programs, collaborative learning is supported via computer-mediated communication technologies and instructional technologies. The primary goal of enhancing learning with technology aids, aligning with the goal of education at all levels, is to engage students in meaningful learning activities, which require learners to construct knowledge by actively interpreting, acquiring, and analyzing their experience (Alavi, Marakas, & Yoo, 2002). In accordance, meaningful learning requires knowledge to be constructed by the learners but not by the teachers. In this regard, collaborative learning, an activity where two or more people work together to create meaning, explore a topic, or improve skills, is considered superior to other individualistic instructional methods (Lerouge, Blanton, & Kittner, 2004). The basic premise underlying this is the socio-learning theory, which advocates that learning and development occur during cooperative socialization among peers and emerge through shared understandings (Leidner & Jarvenpaa, 1995). This highlights the criticality of the communication and collaboration pertaining to an individual's learning process. Since culture reflects the way one learns (Hofstede, 1997; Vygotsky, 1978), group members' cultural backgrounds play a significant role in affecting the collaborative learning process (Chang & Lim, 2005). Language, cognitive style, and learning style are some aspects of culture that concern collaborative learning in the short term.

Groups which have members of different cultural backgrounds are expected to be availed a wider variety of skills, information, and experiences that could potentially improve the quality of collaborative learning (Rich, 1997). In contrast, a group comprising members of similar backgrounds is vulnerable to the "groupthink" syndrome; when the syndrome operates, members could ignore alternatives, resulting in a deterioration of efficiency in making a group decision (Janis, 1982). Accordingly, it is conceivable that groups formed by members of different cultural backgrounds are inherently less prone to the "groupthink" syndrome. However, the advantages of cultural diversity in achieving meaningful collaborative learning are not easily realized, as the basic modes of communication may vary among different cultures and, in consequence, communication distortion often occurs (Chidambaram, 1992). Collaborative learning systems (CLS) are being increasingly researched owing to their potential capabilities and the associated new opportunities in supporting collaborative learning, in particular for distributed groups involving members of different cultural backgrounds (Alavi & Leidner, 2001). Collaborative learning systems provide the necessary medium to support interaction among learners, and therefore modify the nature and the efficiency of the collaborative learning activities (Mandryk, Inkepn, Bilezikjian, Klemmer, & Landay, 2001). The current article looks into how collaborative learning systems may better accommodate cultural diversity in e-learning groups. In addition, this article discusses pertinent issues regarding the role of a leader in building the common ground among learners in order to maximize the potential of collaborative learning systems when cultural diversity is present.

BACKGROUND

Collaborative learning is superior to individualistic instruction in terms of increase in individual achievement, positive changes in social attitudes, and general enhancement of motivation to learn, among other positive outcomes (Slavin, 1990). Learners tend to generate higher-level reasoning strategies, a greater diversity of ideas and procedures, more critical thinking, more creative responses, and better long-term retention when they are actively learning in collaborative learning groups than when they are learning individually or competitively (Schlechter, 1990). Growing interest in supporting the needs of collaborative learning, boosted by concurrent improvements in both computer mediated communication (CMC) and group support systems (GSS), has led to the emergence of the instructional technology known as collaborative learning systems. These are systems

implemented to provide computer-supported environments which facilitate collaborative learning. The importance of these systems lies fundamentally in their being a medium through which learners can cooperate with others.

Technology shapes the communication among users in terms of five media characteristics: symbol variety, parallelism, rehearsability, reprocessability, and immediacy of feedback (Dennis & Valacich, 1999). Symbol variety refers to the bandwidth that information can be communicated; parallelism is the number of concurrent conversations that a medium can support; rehearsability is the capability enabling users to modify a message before sending; reprocessability refers to the extent to which messages sent can be reprocessed during the communication; immediacy of feedback indicates whether a medium supports spontaneous feedback. In comparing collaborative learning systems and face-to-face setting in terms of three media characteristics—parallelism, rehearsability and reprocessability—the former outperforms the latter by embedding anonymity, text recording, and multiple access features; in terms of the other two media characteristics, symbol variety and immediacy of feedback, the situation is reversed (Dennis & Valacich, 1999).

Feather (1999) suggests that individuals will prefer learning in the virtual environment if they require more time to think about a question before answering, find it hard to speak out in a traditional class albeit possessing contributions, or like some degree of anonymity. Empirical evidence demonstrates that computer-mediated cooperative learning tended to have positive impacts on learners' performance and autonomy in controlling their learning pace (Salovaara, 2005; Yu, 2001).

MAIN THRUST OF THE ARTICLE

Potential of Collaborative Learning System in Accommodating Cultural Diversity

Culture is defined as the collective programming of the mind which makes the inhabitants of one country distinguishable from another (Hofstede, 1997). A heterogeneous group is one whose members are of different (national) cultural backgrounds while a homogeneous group has members of the same (national) cultural background. Hofstede (1997) has suggested four main cultural dimensions: individualism-collectivism, power distance, uncertainty avoidance, and masculinity-femininity. Hofstede's theory entails major cultural dimensions and seeks to explain the underlying causes of dissimilar behaviors in communication; indeed, different group behaviors are noted between heterogeneous and homogeneous groups (Stephan & Stephan, 2001). Members in an individualistic culture generally prefer loose ties with other peers during the collaboration process. In contrast, members in a collectivistic culture are typically more concerned with the common goal of the group and tend to prefer to work together.

A potential benefit of the collaborative learning systems is the support of diverse learning styles (Wang, Hinn, & Kanfer, 2001). Functions embedded in collaborative learning systems can enable more effective collaborative learning activities in heterogeneous groups by smoothing the communication process. In the face-to-face setting without technology aid, learners may feel the need to wait for others to express their ideas, by which time they may have either forgotten their own ideas or become less confident with these ideas; this phenomenon is called production blocking. Through embedding concurrent inputs by multiple users, collaborative learning systems offer a unique opportunity to eliminate production blocking, particularly as group size increases (Valacich, Jessup, Dennis, & Nunamaker, 1992). Moreover, text-based communication in these systems offers important features for communication that are radically different from the face-to-face setting. Group members' comments are recorded as text and they can be revisited repeatedly; such a feature is expected to enhance learning effectiveness as compared to oral communication, especially for non-native speakers, since no speaking has to take place (Herring, 1999). The communication support in collaborative learning systems has been suggested to be an effective tool in dealing with the lack of peer interaction in the classroom (Li, 2002). The underlying reason is that participation becomes more evenly distributed among members with computer-mediated interaction, while status and hierarchical structures become less important (Laughlin, Chandler, Shupe, Magley, & Hulbert, 1995).

Besides the communication difficulty mentioned previously, learners' uncertainty and anxiety form another challenge posted by cultural diversity in the face-to-face setting. In the absence of technological aid, when team members interact in the course of collaboration, uncertainty and anxiety of being in a heterogeneous group are likely to affect learners' communication with one another (Gudykunst, 1995), thus decreasing their performance. However, owing to the differences in communication process (as compared to face-to-face interaction), the rehearsability and the relatively lower degree of social presence embedded in collaborative learning systems are able to help the communication process in heterogeneous groups by lowering members' uncertainty and anxiety (Young, 2003). Therefore, the negative effects of cultural differences are reduced if not altogether eliminated by computer-aided systems, as learners of different cultures gain more accurate understanding of one another. Notwithstanding this, the diversity in terms of cultural values and experiences, earlier argued to be a strength, is not eroded. Also, the systems do not take the heterogeneous groups back to the "groupthink" situation which is more commonly present

in homogeneous groups. Thus, with the aid of collaborative learning systems, the potential strengths of heterogeneity can be optimized and cause the learners in heterogeneous groups to outperform those in homogenous groups. Yet, as far as satisfaction with the process is concerned, the heterogeneous groups and the homogeneous groups are not likely to differ; this is attributable to the overwhelming effect of collaborative learning systems which pervades the communication process, as well as minimizes the prominence of cultural diversity (Lim & Zhong, 2004).

Furthermore, learners in heterogeneous groups will conceivably have a more positive attitude toward collaborative learning systems usage as the systems make it easier for them to communicate with members of different cultural backgrounds—in comparison with their previous experience in face-to-face settings. The underlying reason is that learners in heterogeneous groups are more likely to be apprehensive toward oral communication; correspondingly, they perceive the text-based collaborative learning systems to be a more comfortable communication medium, an alternative to oral communication (Brown, Fuller, & Vician, 2004). Since members of homogeneous groups would not suffer communication barriers even in a face-to-face setting, they would not appreciate the benefits of collaborative learning systems to the extent their counterparts in heterogeneous groups would, relatively speaking.

Building Common Ground in Collaborative Learning Systems through Leadership

Collaborative learning systems have the potential to deal with the challenges introduced by cultural diversity; however, a mere focus on technology alone cannot guarantee an enhanced learning experience. Effective communication in collaborative learning systems hinges on establishing a common ground among members of a learning group (Cramton, 2002); common ground refers to the mutual understanding of the knowledge constructed during the learning process. Such mutual understanding is composed of not only the specific pieces of information but also the awareness that other members know the information. When common ground is achieved in a group, collaborative learning is more likely to be effective.

However, heterogeneous groups are inherently poor in establishing and maintaining such common ground; group members tend not to be able to understand or remember contextual information of others, and this may result in inaccurate understandings. Still worse, users from different cultural backgrounds may deem a certain technology (or a specific function) better suited for a given task. In general, collectivistic cultures, which prefer high-context communication (e.g., Asia), tend to perceive collaborative technologies to be a better fit for conveyance process in communication (e.g., composing messages, providing explanations, and carrying out convergence-oriented communications); on the other hand, individualistic cultures, which are leaning toward low-context communication (e.g., U.S.), tend to perceive collaborative technologies as a more appropriate tool for convergence process (e.g., making a group decision) (Massey, Montoya-Weiss, Hung, & Ramesh, 2001). This is also applicable to the context of collaborative learning systems, as the two primary processes in communication, conveyance and convergence, are inherently relevant in the collaborative learning activities. Conveyance process in collaborative learning refers to the exchange of information among learners; convergence process is the construction of shared meaning for information. In consequence, electronic means of communication embedded in collaborative learning systems may make it difficult to discover and resolve misunderstandings (e.g., uneven distribution of information among members) (Cramton, 2002).

We posit that leadership may facilitate the development and maintenance of common ground in collaborative learning systems. The leader of a learning group takes the responsibility for organizing a group, delegating assignments, coordinating information, and supporting the contributions of others (Hostager, Lester, Ready, & Bergmann, 2003). A leader facilitates group process by allowing varied views to be heard, providing information, probing for more information, and summarizing the progress the group is making toward its goals. The leader has to quickly recognize when a group wanders off and bring the participants back to the issue at hand.

The leaders should gain an adequate appreciation of the different reactions that technologies have evoked among members with different cultural backgrounds. Thereafter, he would be in a position to help facilitate in developing the group norms or guidelines concerning communications in a heterogeneous team. In formulating these rules or guidelines, the leader must recognize the influential role of cultural differences on users' perception. For example, learners of collectivistic cultural backgrounds should utilize features of the asynchronous discussion forum for their collaborative learning activities; these learners may prefer asynchronous groupware which allows more time to compose messages and express themselves. In particular, these rules or guidelines should define how, when, and which technologies should be used, and how the team will deal with conflict and make decisions based on members' perceptions and preferences. By doing so, the fit between the task and technologies used can be achieved, and eventually, this fit would enhance the common ground building among members in collaborative learning systems. All these activities carried out by a leader contribute toward forming a common ground and, in turn, lead to the achievement of meaningful learning.

FUTURE TRENDS

The current research has defined cultural diversity exclusively in terms of nationality being either heterogeneous or homogeneous. This approach can be used as a benchmark (or a foundation) for future studies, so as to develop greater conceptual understanding, or even a substantive theoretical model, of cultural diversity. Undoubtedly, there are other aspects that also deserve research attention to study the notion of degree of heterogeneity in groups.

Two examples are time and the type of cultural differences. First, cultural diversity may be affected by the time factor. Although cultural background of a person is mainly inherited from the society where he originates, it can change with time when he moves to a new society. Next, the concept of cultural diversity can be more precisely calibrated in terms of the extent of variety of cultures embedded in a given team. A heterogeneous group consisting of American and European members is in a sense less heterogeneous than one that comprises Japanese and Americans. Consequently, to utilize the potential benefit, collaborative learning systems should be incorporated into the learning process while taking into consideration the degree of heterogeneity.

Additionally, the effect of collaborative learning systems cannot be adequately discussed without considering other pertinent contextual factors that would help realize the potential of these systems in addressing cultural diversity in the context of e-learning. In this connection, leadership, common ground, conveyance process, and convergence process are the contextual factors identified in this article. They deserve to be further researched both in terms of breadth and depth.

CONCLUSION

Globalization and the paradigmatic shifts toward collaborative learning make cultural diversity a pertinent factor in e-learning. To provide meaningful collaborative learning experience to learners, collaborative learning systems facilitate heterogeneous groups by smoothing the communication process; they are, therefore, expected to play an important role in e-learning. This article addresses the conceptual and practical issues in invoking collaborative learning systems to support cultural diversity. By synthesizing the theoretical perspectives regarding cultural issues, the current article identifies the corresponding collaborative learning systems functions in overcoming the challenges alongside the conceptual expositions. In addition, it expounds on the role of leadership in building common ground among learners to utilize the potential of heterogeneous groups in e-learning.

KEY TERMS

Collaborative Learning Systems (CLS): Systems implemented to provide computer-supported environments which facilitate collaborative learning. Primarily, these systems serve as a medium through which learners can cooperate with others.

Common Ground in Collaborative Learning Group: The mutual understanding of the knowledge constructed during the learning process. Such mutual understanding is composed of not only the specific pieces of information but also the awareness that other members know the information.

Convergence Process in Collaborative Learning: The construction of shared meaning for information in collaborative learning activities.

Conveyance Process in Collaborative Learning: The exchange of information among learners in collaborative learning activities.

Cultural Diversity: The composition of members' (national) cultural backgrounds in a group. It is defined exclusively in terms of nationality, being either heterogeneous or homogeneous.

Heterogeneous Group: A group whose members are of different (national) cultural backgrounds.

Homogeneous Group: A group whose members are of the same (national) cultural background.

Cultural Issues in the Globalisation of Distance Education

Lucas Walsh
Deakin University, Australia

INTRODUCTION

This article discusses ongoing cultural challenges faced by distance education providers seeking to deliver programs of study transnationally. Focusing on a key period of distance education during the late twentieth century, this discussion begins by tracing the impact of global economic and technological developments, such as the growth of mega-university enrolments, privately owned education providers and the Internet. The 1990s saw intense interest in the use of Internet-based applications for distance learning and the subsequent arrival of important new actors in this marketplace, such as Blackboard and WebCT.

The author then examines some of the key cultural challenges arising from this convergence of economic, educational and technological dimensions of globalisation, such as the problematic use of models of independent learning in distance delivery.

Turning to future trends, three recent developments in the Internet pose significant challenges to these markets and approaches: open courseware and other initiatives seeking to provide open access to educational resources; the diffusion of user-generated applications, tools and environments; and the fragmentation of online information sources. These trends invite education providers to reflect on the cultural dimensions of distance education. It is argued that while new approaches to e-learning present new opportunities to enhance distance learning, certain key lessons from the 1990s should continue to inform the contemporary development of distance education.

BACKGROUND

The 1990s was a period of tremendous growth internationally in distance education, evident in the expansion of mega-universities, virtual campuses and Open University courses throughout the world. Distance education involves "the provision of programs of study which provide both content and support services to students who rarely, if ever, attend for face-to-face teaching or for on-campus access to educational facilities" (Cunningham et al., 1998, p. 23). Designed to appeal to students seeking greater choice in relation to the time and place of study, and to the mode and pace of learning, these programs tend to be taken by students who find on-campus attendance impractical due to factors such as geography, work and family commitments (Ryan, 1998). Open learning frameworks further allow students to enrol in off campus programs of study irrespective of their previous credentials (Cunningham et al., 1998).

Mega-universities were established throughout Asia in response to the new commercial realities of globalisation. At the time, a mega-university such as Sukhothai Thammathirat Open University of Thailand attracted around 250,000 students, while Indonesia's Universitas Terbuka had more than 350,000 enrolments. Other mega-universities in India, Korea and China had equally massive enrolments (International Centre for Distance Learning, 1995).

By the mid 90s, more than 2 million students from the Asia-Pacific region were enrolled in informal and formal distance education programs (Commonwealth of Learning, 1994; Latchem, 1997). Public universities across South East Asia were encouraged to develop distance education programs as a low-cost basis for mass education. Universiti Sains Malaysia and Hanoi Open University expanded their distance education programs, targeting potential students among working adults and those residing in more remote regions (Ziguras, 2000). Privately owned education providers within Asia also responded to the market potential of distance learning. Malaysia's first virtual university, Universiti Tun Abdul Razak (UNITAR), opened in 1999 and used technologies such as the Internet to teach students exclusively by distance mode (Ziguras, 2001).

UNITAR was one of a number of virtual universities seeking to exploit changing markets in distance learning. Institutions such as The University of Phoenix and Western Governors University were already providing distance education in North America. The first Web-based university courses emerged around 1995 (Bates, 2005). Like UNITAR, Western Governors University operates without a conventional home campus (Gilbert, 1996). While The University of Phoenix developed a flexible distance program for working adults, Western Governors University–a nonprofit online provider–sought to "expand the marketplace for instructional materials, courseware, and programs utilising advanced technology," as well as "identify and remove barriers to the free

functioning of these markets" (Noble, 1998, p. 361). With the growth in distance education in regions such as Asia, many Western education institutions saw an opportunity to capture potentially lucrative global education markets. Growth in the number courses offered via distance mode during this decade was significant. In 1997, 1,000 institutions throughout the world offered roughly 33,000 distance education courses and programs, a tenfold increase since 1991 (Latchem, 1997).

The latter 1990s was a watershed period of technological diffusion; namely, of the Internet. Important new actors, such as Blackboard and WebCT, entered the global education marketplace late in the decade and soon dominated the market for global provision of learning management services and systems. By 2001, WebCT had sold over 1 million student licences across 80 countries (Bates, 2005). During this period of uneven development, many transnational distance education providers struggled to effectively deliver educational courses and content within this confluence of market growth and changing technology.

CULTURAL CHALLENGES OF DISTANCE EDUCATION

Demand for distance education provided a powerful incentive for higher education, professional development and training providers to collaborate with commercial software developers to create Learning Management Systems (LMS) capable of efficient, low-cost delivery of course content and educational resources. Much of the early e-learning software was developed through these collaborations and then sold to other universities. LMS, such as WebCT, were developed during the latter 1990s to enable easier access to course materials, teaching tools and learning objects via Web-browsers. Designed to standardise online course development and simplify technological training and support at the deliverer's end, these systems came to dominate online provision in this education sector.

One of the major appeals of e-learning is the capacity of the Internet to enable geographically dispersed students to engage with their "virtual" classmates as part of an online community of independent learners. An important motivation for distance learning was the strategic interest of educational providers in using new technologies to grow student numbers and facilitate greater economies of scale in course-delivery. Reliant on Western content, many online providers failed to take into consideration the cultural dimensions of transnational delivery (Ziguras, 2000; 2001). The "one-size fits all" model underpinning transnational delivery presumed that Western standards, content and modes of delivery were "universally relevant and universally welcome" across different cultural settings (Patrick, 1997, p. 2).

During the 1990s, influential e-learning frameworks and software were developed in the English language (mainly in North America), and adopted Western models of learning. These were then used in other cultural settings without sufficient consideration of their appropriateness to the pedagogical and learning needs within those settings. To make distance courses simpler to use and more marketable for transnational delivery, distance courses were globalised to remove any cultural specificity of content. Seeking to provide curriculum and materials which "transcend local cultural and language barriers" and that are "relevant to learners wherever they happen to reside," many online courses were offered internationally but not modified to suit local sites of delivery (Bates & de los Santos, 1997, p. 49).

When delivering distance courses across different cultural settings, the models of independent learning underpinning distance education were in some instances problematic and in others, disastrous. During the 1980s, for example, Indonesia's Universitas Terbuka adopted a model of distance education based on the UK Open University. The Western approach to independent, self-directed learning that underpinned this model was unfamiliar to students and teachers from heteronymous Indonesian cultural backgrounds. Courses used text-based resources, which in an orally-based society characterised by low levels of reading and writing further contributed to the failure of this model (Dunbar, 1991).

The University of the South Pacific (USP) experienced similar problems when it adopted a distance education program. The program delivered resources to over 5,000 students spread across numerous islands, languages and cultures. The cultural backgrounds of this diverse group of learners were not taken into sufficient consideration in the course design. Like Universitas Terbuka, the program's emphasis on independent learning and use of the English language was unsuitable to Pacific peoples accustomed to learning from one another through physical interaction, observation and imitation, and through intimate relationships with their teachers (Thaman, 1997).

These examples highlight the kinds of cultural challenges associated with the globalisation of distance education; particularly the need to understand how the pedagogical and learning assumptions of a given distance framework impact upon different cultural settings. Courses via distance mode typically assume that students are self-motivated, self-directed learners (Cunningham et al., 1998), which may not be favourable to students (or teachers) from diverse cultural and educational backgrounds.

The cultural problems of the USP and Indonesian examples described above can, in part, be attributed to the dangers of a "quick fix" approach. Due to the somewhat *ad hoc* approach adopted by providers, implementation of technologically-assisted open and distance learning during the 1980s and 1990s was marred by a lack of coordination

or pooling of educational experience (Walker, 1997). While understanding of the pedagogical and cultural dimensions of e-learning in distance education improved significantly during the 1990s—particularly in areas that directly mediate learning, such as instructional design (Alexander & Blight, 1996; Henderson, 1994) and transnational delivery (Ziguras & Rizvi, 2001)—education providers, governments, telecommunications providers and industry struggled to collaboratively develop a common vision and understanding of the economic, social and cultural national and global benefits of distance learning during this time of often explosive and uneven development (Latchem, 1997).

FUTURE TRENDS

The market in distance learning continues to grow, both financially and in terms of global reach. It has been estimated that by 2015, the global online higher education market will be worth more than $69 billion (Hezel Associates, 2005). As a large proportion of this growth will consist of some form of distance education, not only will providers and educators face the kinds of issues described above; the market itself may be challenged by three developments in Internet-based learning: (1) the emergence of electronic publishing and open courseware initiatives seeking to provide open access to these educational resources; (2) the development of user-generated applications, tools and environments; and (3) the fragmentation of information sources and information units used for informal and institutionalised modes of learning.

During the last several years, a number of initiatives have developed that offer free access to course materials from all over the world. The Massachusetts Institute of Technology's (MIT) *OpenCourseWare* project enables open access to educational materials from over 1,400 MIT courses, including syllabi, lecture notes, exams, reading lists and video lectures. The idea of providing educators, students and self-learners with free access is part of MIT's efforts to reposition itself in a changing and competitive distance environment (Massachusetts Institute of Technology [MIT], 2006). Similarly, the Open University's *OpenLearn* project is also making educational resources freely available via the Internet in response to digital divide problems of availability and cost (BBC, 2006). Echoing other initiatives in the U.S. and Japan, *OpenLearn* reflects a shift away from the proprietary, "top-down" delivery models prevalent in the 1990s.

The growing development of open source and subsequent availability of free software packages, such as *Moodle*, further challenge proprietary, suite-based frameworks. In recent years, there have been signs of a shift from the centralised provision of content toward applications and services that enable users to take more control over how they access and share information. The rapid adoption and diffusion of user-generated Web sites such as wikis and Web logs reflect a broader shift in Internet-usage toward open-ended, user-driven, participatory online platforms to share, organise and repurpose different kinds of content for publication, subscription and linking across networks (Spivack, 2003; O'Reilly, 2005; Davis, 2005). A blog, for example, is in its most basic sense a personal journal consisting of "a hierarchy of text, images, media objects and data, arranged chronologically, that can be viewed in an HTML browser" so that it can be shared via the Web (Winer, 2003). By enabling users to develop, repurpose and customise their online educational resources and environments, these resources and platforms present opportunities for learning collaborations, knowledge construction and the localisation of culturally appropriate e-learning.

Tools such as wikis and blogs are designed for collaborative participation in the knowledge construction process, facilitating forms of personal knowledge mapping (Langreiter & Bolka, 2005). Wikipedia, for example, is a widely-used reference tool that enables documents to be written collaboratively using a simple Web-browser, and then continually revised, corrected and expanded by users. Issues of scholarship, authenticity and reliability aside, users of wikis can contribute to knowledge construction as consumers, creators and sharers of content. These applications and approaches broaden the scope for interaction and dialogue, inviting new opportunities for student participation that "is very different from traditionally assigned learning content. It is much less formal. It is written from a personal point of view, in a personal voice… what happens when students blog, and read reach others' blogs, is that a network of interactions forms - much like a social network" (Downes, 2005).

This movement away from the 1990s LMS paradigm favouring passive models of "content-consumption" and object-centred approaches is loosely referred to as "E-learning 2.0." Seeking to move beyond e-learning as a mode of delivery, this approach focuses more on learning actions, the use of interoperable *collections* of software applications. It also emphasises user-centred design and the nurturing of collaborative learning online (Mowbray, 2007). By interweaving approaches, online resources and applications, E-learning 2.0 suggests a movement in online education toward interoperating applications that enable creative learner-centred and potentially collaborative environments. Moving away from established top-down delivery frameworks which narrowly understand e-learning "as being a type of content, produced by publishers, organised and structured into courses, and consumed by students," this shift in e-learning seeks to avoid dependency on "an institutional or corporate application" in favour of "a personal learning center, where content is reused and remixed according to the student's own needs and interests" (Downes, 2005).

These approaches and tools for e-learning are not without certain familiar challenges. For example, the cultural frame of MIT courses is predominantly North American and, at the very least, requires varying degrees of contextualisation (e.g., by a local teacher) to be effective. English is arguably the *de facto* language of the international open source community. (Even though *Moodle's* online discussions take place in dozens of languages, the English-language nevertheless predominates.)

Much of the current enthusiasm for E-learning 2.0 needs to avoid the dangerous assumption that providing the technological tools for self-expression and creation will lead to empowerment and improved learning and teaching. Changing the emphasis from the design of learning content to the way it is used is a positive step; however, certain cultural and pedagogical issues need to be kept in mind. Langreiter and Bolka (2005) rightly caution that while content can be aggregated and tailored to the needs of individual learners, the task of consolidating and organising disaggregated content is shifted toward the learner. Using *Moodle* as its central platform, the *OpenLearn* project encourages learners "to become self-reliant, but also to use online communities to support their learning" (Lane, cited in BBC, 2006). Nevertheless, user-centred approaches require greater responsibility for content creation and maintenance. Not all teachers and learners will have the skills, technological literacy or resources to undertake these learner-centred responsibilities. While many of tomorrow's distance students will indeed be "digital natives" familiar to (if not proficient in) the use of the applications underpinning these environments, one could safely assume that they will continue to have a diverse range of skills, abilities and cultural backgrounds.

The emergent learning environments described above have their own structural biases and values that favour certain learning styles. It may well be that some students prefer to work independently and may not feel comfortable engaging in this kind of participatory process. However, implicitly privileging certain styles of independent learning will not be appropriate for all cultural learning styles.

Spurred by the spontaneous generation and dissemination of content by Web users, a diversification and expansion of information sources and educational resources is challenging conventional processes of information-gathering, research and access to content. The development of online learning may be characterised by a diversification of the types of educational resources available to learners in both informal and institutional settings. Where learners have traditionally consulted a single body of authoritative work (such as a printed book, journal article or teacher) students increasingly draw from a plethora of Web-based resources, such as online encyclopaedias, teaching materials, discussion forums, and RRS posts (Langreiter & Bolka, 2005).

While this process of fragmentation may be associated with problems such as the questionable use of unauthoritative sources and plagiarism, it is also stimulating educators to develop more diverse approaches to e-learning. Langreiter and Bolka highlight one benefit of fragmentation: information chunks created using a blogging application or a wiki are much easier to produce and maintain than larger networks. "Furthermore," they suggest, "disaggregated content - theoretically - can be re-aggregated to optimally suit an individual learner's preferences (instead of the needs of an idealised common denominator)" (2005, p. 80). Whereas conventional e-learning management systems tend to locate learners as relatively passive receivers of course-materials within a standardised framework, these tools offer new opportunities for distance education to become more responsive and culturally attuned to the different ways that students learn, and through which teachers have the potential to use technology more effectively according to their particular pedagogical strategies.

CONCLUSION

Cultural differences of learners (and teachers) have often been unacknowledged or treated as unproblematic in the design of software and content for online distance learning and delivery. Improved awareness of cultural issues in distance learning is informing the development and adaptation of learning programs and materials for cross-cultural delivery by acknowledging differences in communication and education cultures and incorporating this awareness into programs, resources and modes of delivery (Banks, 2006; Collis, 1996; Zaltsman, 2006). Effective, culturally sensitive and pedagogically appropriate distance learning requires understanding how the basic structure of courses, such as time allocation, assessment practices and pedagogy, and impact upon learners from different backgrounds by privileging certain values over others. In addition, education providers and developers of online distance learning programs, resources and software must be aware of how cultural biases may be built into the design of Websites and software, be it a digital repository, collaborative virtual learning environment, user-driven application or conventional LMS.

According to Sharma and Mishra (2006, p.1), "e-learning is the fastest growing sub-sector of a $2.3 trillion global education market." With this continued growth, there continues to be a danger that online distance learning will be driven by financial rather than culturally sensitive educational imperatives.

Following the unsteady and often culturally problematic growth of the global distance education marketplace during the 1980s and 1990s, recent online developments, such as user-generated software applications, open tools, free content and collaborative approaches present new opportunities and challenges. Nevertheless, the case studies from Indonesia and USP described above illustrate the importance of incor-

porating understandings of culture into any distance learning program, particularly when delivery is transnational. The mode of delivery may affect learners differently depending on the cultural styles of teaching and learning to which they are accustomed. For example, the collaborative and user-generated learning technologies discussed in the previous section will invariably be imbued with structural properties that may privilege some learners while excluding others previously schooled in different cultural milieus.

And while approaches such as E-learning 2.0 offer scope for flexibility in how learners negotiate distance learning and each other, the effectiveness of any technology in distance learning will continue to depend on how it is used rather than any particular feature of the medium itself (Bates, 2005; Inglis, Ling & Joosten, 2002).

KEY TERMS

Distance Education: Provides programs of study and support services to students who do not wish to regularly attend face-to-face teaching or who find on-campus study impractical due to factors such as geographical constraints, family or work commitments.

E-Learning 2.0: Promotes online learning as a platform for personal learning through interoperable tools that enable reusable content to be authored, repurposed, mixed and shared according to students' particular needs and interests.

Globalisation: Globalisation is a process by which the impact of geographical constraints on cultural and social formations is diminished. Economic globalisation, which has arisen due to factors such as changing patterns of world trade and international mobility, is linked to the emergence of a seemingly universal ideology emphasising the need for flexible responsiveness to global markets.

Learning Management System (LMS): Educational software that enables the delivery and management of learning content and resources to students.

Moodle: An open-source online course management system (the name is derived from the acronym *Modular Object-oriented Dynamic Learning Environment*).

Web Log (Blog): A form of personal journal shared over the Web.

Wiki: Enables content to be written collaboratively using a simple Web browser that can be continually revised, corrected and expanded by its users.

Cultural Motives in Information Systems Acceptance and Use

INTRODUCTION

Understanding the moderating factors that influence user technology acceptance and adoption in different contexts continues to be a focal interest in information systems (hereafter, IS) research. Moderating factors may account for both the limited explanatory power and the inconsistencies between studies (Sun & Zhang, 2006). Accordingly, based on a careful literature review, we believe that culture, defined as mental concepts influencing the relationships with other people, the environment and the concept of time (see Hofstede, 1991; Hall, 1989; Trompenaar, 1995), is an important moderating-factor; that is, culture constitutes "the broadest influence on many dimensions of human behaviour" (Soares, Farhangmehr, & Shoham, 2007).

Particularly, culture is a factor that has been shown to be significant but underresearched in recent studies of information-accessing behaviour. Nevertheless, there is increasing interest in the IS research literature in the impact of cultural differences on the development and use of information technologies (hereafter, IT) and IS. For example, the following authors identified cultural values as one of the influential factors on adoption of information and communication technology (hereafter, ICT): Bagchi, Cerveny, Hart, and Peterson (2003), Johns, Smith, and Strand (2003), Maitland and Bauer (2001) and Sørnes, Stephens, Saetre, and Browning (2004). Straub (1994) has used the uncertainty avoidance dimension to explain why the diffusion of information technologies differed in the USA and Japan. Watson, Ho, and Raman (1994) have also used the individualism-collectivism dimension to account for differences in the way Group Support Systems (GSS) affected group decisions in the USA and Singapore. Findings from Chau et al. (2002) illustrate how users from different countries differ in their perception of the purpose of Internet and, consequently, exhibit differences in their behaviours and general attitudes toward the Internet. Marcus and Gould (2000) examine a number of cultural dimensions and their possible impact on user-interface design (see also Barber & Badre, 2001; Del Galdo & Nielsen, 1996). Other authors, for example, explore cultural influences on technology development and innovation (Herbig, 1994), cultural influences on technology adoption (Straub, 1994), and culture as a factor in the diffusion of the Internet (Cronin, 1996; Goodman, Press, Ruth, & Rutkowski, 1994; Maitland, 1999). Finally, Veiga, Floyd, and Dechant (2001) suggest that perceptions of a technology's ease-of-use and usefulness are connected to an individual's broader system of belief, including culturally-sensitive beliefs.

Therefore, because of an anticipated large number of IS users from multiple cultures, research may systematically examine the acceptance and usage models and other models related to cross-cultural motives and beliefs. As Sun and Zhang (2006) suggest, these models have traditionally presented two limitations: (1) the relatively low explanatory power; and (2) inconsistent influences of the cross-study factors. Research may (1) focus on identifying the major cultural dimensions and their corresponding relationships with IS acceptance; and (2) examine the potential moderating effects that may overcome these limitations.

To sum up, culture's role within acceptance and usage model has been only recently investigated. Little research has systematically examined IS preferences of users related to cross-cultural design characteristics. Some researchers have done work in the area of culture and design, but results have been either inconclusive or unrelated to developing loyal users. In this sense, we deem it necessary to highlight several main starting questions. This would add to the few studies that take into account the individual and contextual factors in technology acceptance; specifically, a better understanding of how cultural differences could affect users' evaluations of IS can uncover ways of localising a global interface. While user-interfaces targeted to different cultures may not need to be completely different from each other, there might be some features that allow the targeted audience to feel *at home*.

BACKGROUND

In view of academic and theoretical perspective, the effects of culture on IS acceptance have been studied by researchers mostly based on Hofstede's (1980) cultural construct. It has also been shown to be stable and useful for numerous studies across many disciplines. First, Hofstede's dimensions assume culture falls along national boundaries and that the cultures are viewed as static over time. Second, Hofstede (1980) asserts that central tendencies in a nation are replicated in their institutions through the behaviour or practices of individuals. And, third, Hofstede's framework explicitly links national cultural values to communication practices; i.e., communication practices using ICT are central to our study (see Merchant, 2002; Samovar, Porter, & Jain, 1981; Stohl, 2001). Furthermore, Hofstede's model was important because it (a) organised cultural differences into overarching patterns, and (b) conducted the most comprehensive study of how values in the workplace are influenced by culture, which (c) facilitated comparative research and launched a rapidly-expanding body of cultural and cross-cultural research in the ensuing 20 years. Hofstede's (1980) cultural dimensions serve as the most influential culture theory among social science research, and has received strong empirical support. Hofstede, therefore, contributed the influential work in cross-cultural research.

Hofstede (1984, p. 51) defines culture as "the collective programming of the mind which distinguishes the members of one group from another"; and (b) proposes a series of four dimensions (a fifth was added later; that is, Confucian dynamism) that distinguishes between work-related values. The cultural dimensions are individualism-collectivism, power distance, uncertainty avoidance, and masculinity-femininity. Hofstede and Bond (1988) found an additional dimension, which is particularly relevant to Asian culture, Confucian dynamism (i.e., often referred to as long/short term orientation). These value dimensions, which distinguish national value systems, also affect individuals and organizations.

The present study, however, does not intend to examine the whole range of cultural dimensions influencing IS adoption. This article aims to restrict its focus on individualism and uncertainty avoidance. First, according to Hofstede's model, of the four dimensions, individualism vs. collectivism is the most common dimension used by researchers to understand the differences between two or more given cultures (see also Cohen & Avrahami, 2006). Furthermore, Hofstede's proposition confirms that an individualistic culture is also likely to be a low power-distance culture. Individualism is inversely related to the power distance dimension, which is -0.64 in Hofstede's original study, and -0.70 in the sample of teachers and -0.75 in that of students used in Schwartz's cross-cultural study (Schwartz, 1994; see also Gouveia & Ros, 2000). Power distance shows a pattern of correlations almost opposite to Hofstede's individualism (Hofstede, 1984). At least at a cultural level, individualism is the opposite of the acceptance of hierarchy and of ascribed social inequality. Therefore, we propose power distance index is dropped from explicit consideration here.

Second, with regard to the topic of this study, cultures have a different attitude toward uncertain or unknown matters (specifically, IS acceptance and usage by users from diverse cultures). The tolerance for ambiguity and uncertainty is expressed through the extent to which a culture resorts to written or unwritten rules to maintain predictability; for instance, the absence of physical contact with online partners emphasizes the role of perceived risk. Users in countries with a high score on uncertainty avoidance will thus be more risk-adverse and will not like making changes. For instance, Yeniyurt and Townsend (2003) found the uncertainty avoidance dimension, among other dimensions, to be negatively correlated with the adoption of ICT-based services such as Internet and PCs. In fact, uncertainty avoidance has the most direct bearing on preference for and use of communications media

Third, Bagchi et al. (2003) argued that «IT promote more cooperation at work, better quality of life and these values are espoused in nations with low MF (i.e., masculinity/femininity) index». However, as comment, «it could be argued equally well that in a country with high masculinity there would also be a positive attitude toward implementing ICT if these technologies improve performance, increase the chance of success and support competition, which are all key factors of a masculine culture». In this sense, Johns et al. (2003) included the individualism/collectivism and uncertainty avoidance dimensions only; these authors felt that achievement orientation (masculinity/femininity dimension) has a mixed impact on the use of technology. The masculinity/femininity dimension could thus have at least at the conceptual level a mixed impact on the ICT (see Kovacic, 2005). In this research, we also propose that masculinity/femininity dimensions are also dropped from explicit consideration.

INDIVIDUALISM AND UNCERTAINTY AVOIDANCE DIMENSIONS

Individualism/Collectivism

Individualism/collectivism focuses on the degree the society reinforces individual or collective achievement and interpersonal relationships. Hofstede (1980) argued that cultures high on individualism tend to promote individual decision-making over group consensus. Research has shown that individualistic users support individual identity, and they think that they should be self-sufficient; that is, they resist influence

attempts by higher-status individuals. In other words, status influence is likely to be low. Thus, the task and objectives is more important for them than the relationship.

In contrast, in societies emphasizing collectivism, the group becomes the primary source of an individual's identity and individuals seek approval, status and support through group affiliation. Collectivistic users are more group-oriented, and support the group identity over the individual identity (Chau, 1996). The relationships for the collectivistic users are more essential than the task to be completed. Concerns with respect to group welfare are emphasised, as aggregate interests tend to prevail over autonomous, individualistic ones (Hofstede & Bond, 1988).

Given these shortcomings, several studies have thus found that individualistic users show a greater degree of instrumental motivational orientation in comparison to collectivistic users. Individualism implies that social behaviour is established by personal goals and does not overlie the goals of the collective, while in collectivism the group is more important than the individual and the people in the group are ready to cooperate. Individualistic users (a) are motivated by achievement needs and (b) tend to exhibit more of certain values such as assertiveness, competitiveness and rationality. The core element of individualism is the assumption that individuals are independent of one another. In an individualistic culture, people therefore seem to be more innovative and trusting in exchange relationships with external parties (Veiga, Yanouzas, & Buchholz, 1993). On the contrary, the core element of collectivism is the assumption that groups bind and mutually obligate individuals.

Therefore, individualistic users could view the different IS as tools for performing tasks, whereas collectivistic users could view them as tools for socialization. In highly-individualistic societies, perceptions about the usefulness of the IS are likely to be based on beliefs about how they affect the individual's job performance. Because they believe in personal control and individual achievement, users in individualistic cultures accept task accomplishment as their personal responsibility. Beliefs about the usefulness are thus made based on the extent to which the IS are seen to enhance the task performance of individuals.

Individualistic users will try the different IS, even if they do not have a positive attitude toward using them, because they may provide productivity enhancement (i.e., usefulness). Consequently, individualistic users need to perceive them as being useful or they will not attempt to use it. It is expected that individualistic users' IS perceived usefulness may exert a more intense influence on determining the intention to use the Web. On the contrary, collectivistic users (related to lower instrumental usage) would tend to underestimate the perceived usefulness of the IS. Collectivistic users, as opposed to individualistic users, would not perceive them as being relatively useful.

Finally, when individualistic users engage in instrumental behaviour, they are motivated to perform their activities in an efficient, focused and timely manner, and with a minimum of irritation (adapted from Babin, William, & Griffinn, 1994). Accordingly, individualistic users do not want to be distracted from their tasks. IS that are easy to understand and use can thus be associated with being able to save effort and irritation. As we commented above, perceived ease-of-use influences individual attitudes through two mechanisms: self-efficacy and instrumentality. IS that save effort are correlated with increasing utility. Over time—that is, increasing self-efficacy as a basic determinant of perceived ease-of-use—the indirect effect of perceived ease-of-use (through perceived usefulness) becomes stronger (Watson et al., 1994). Therefore, perceived ease-of-use—as a factor facilitating task-performance and utility—will likely be weighted more strongly by individualistic and weak uncertainty avoidance users.

Uncertainty Avoidance

Hofstede (1991, p. 113) defines Uncertainty Avoidance Index (UAI) as "the extent to which the members of a culture feel threatened by uncertain or unknown situations." UAI focuses on the level of tolerance for uncertainty and ambiguity within the society, that is, unstructured situations. In a culture high on uncertainty avoidance, individuals are more likely to avoid acceptance and use new technologies because of the uncertainty and ambiguity involved. Moreover, IT may be considered inherently risky (Herbig, 1994). Individuals from high uncertainty avoidance societies attempt to reduce personal risk. For instance, empirical research in 11 European countries by Steenkamp, Ter Hofstede, and Dulton (1999) revealed that uncertainty avoidance scores, among other dimensions, is a strong cultural influence on user's innovativeness in general. It has been found that cultural uncertainty avoidance has a negative impact on users' innovativeness. Specifically, with regard to the topic of this study, cultures have a different attitude towards uncertain or unknown matters. The tolerance for ambiguity is expressed through the extent to which a culture resorts to written or unwritten rules to maintain predictability.

In strong uncertainty-avoidance societies, their members are encouraged to anticipate the future, create institutions establishing and reinforcing security and stability, and avoid or manage risk. Those members tend to "take time" for action until they acquire enough knowledge and information to reduce and resolve unclear and unstructured situations. Organizational members in strong uncertainty avoidance countries have a feeling of anxiety when encountering unfamiliar risks, deviant ideas, or conflicts in their work place. Moreover, in a culture high on uncertainty avoidance, individuals could be "comprehensive processors" who attempt to assimilate all available information before rendering judgment, while in a culture low on uncertainty

avoidance individuals could be "selective processors" who often rely on a subset of highly available and salient cues in place of detailed message elaboration (see also Meyers-Levy & Maheswaran, 1991; Meyers-Levy & Sternthal, 1991; Morris & Venkatesh, 2000). In contrast, in a weak uncertainty-avoidance society, members are encouraged to tolerate uncertainty, take risks, *take each day* as it comes; perhaps have low expectations and a fatalistic outlook. Members in weak uncertainty-avoidance countries tend to feel less uncomfortable in unclear and unstructured circumstances and are more likely to take risks in unfamiliar situations where encountering deviant and innovative ideas and behaviour with no rules. Achievement functions as a great motivational factor and it encourages those members to take actions in either familiar or unfamiliar situations.

Uncertainty avoidance societies could thus (a) hold lower perceptions of self-efficacy; (b) show more concern about the risks associated with technologies; and (c) experience higher levels of anxiety and more negative feelings; that is, the average risk propensity of an entire population of people tends to be higher for low uncertainty-avoidance cultures and lower for high uncertainty-avoidance cultures. *The uncertainty inherent in life is felt as a continuous threat which must be fought*. Hence, given the lower levels of perceived self-efficacy among uncertainty avoidance societies, users (a) could perceive greater risks, so (b) they will be more IS-usage averse. As Keil, Beranek, and Konsynski (2000) comment, decision makers tend to exhibit risk-averse behaviour when risk perception is high and risk-seeking behaviour when risk perception is low (Steenkamp et al., 1999) (e.g., Staw, Sandelands, & Dutton, 1981).

Hofstede (1980) argued that uncertainty avoidance is related to anxiety that could be the feeling-output when confronted with problems or challenges. The extent to which this occurs might negatively influence willingness to IS usage. That is to say, these societies–more risk averse and with a lower self-confidence–(a) will not engage in behaviours without previously adjusting their attitudes, and (b) will take more time to decide to try the different IS. Expanding the previous reasoning, attitude toward using IS will, therefore, be a relevant mediator between perceptions and intention to use them among uncertainty avoidance cultures.

Also, in general, once collectivist societies establish a positive attitude toward something, they tend to internalise it and take it into their in-group circle (Rice & Love, 1987; Pavlou & Chai, 2002). Thus, we would expect that members of a collectivist culture would want to maintain harmonious "IS<->user" relationships.

Furthermore, the high perceived risk associated with the IS-usage significantly reduces the weak uncertainty-avoidance societies' perception about (a) their self-efficacy in using it, (b) its perceived usefulness, and (c) its ease-of-use. These low evaluations of perceptions among weak uncertainty-avoidance societies can cause an increase in the salience of them in determining attitudes toward using the IS (adapted from Venkatesh & Morris 2000). Weak uncertainty-avoidance cultures may not be willing to accept a difficult and annoying interface.

To sum up, individuals from high uncertainty avoidance societies attempt to reduce personal risk, while being more likely to resist innovative ideas and conform to the rules. On the other hand, these individuals seek to avoid ambiguity and thus create rules for most possible situations. Members of a low uncertainty avoidance culture might be more broad-minded, without a lot of need for social approval, more prone to risk taking, with tolerance toward deviant behaviour and acceptance of innovative ideas.

FUTURE TRENDS

This study has future implications both in practice and in theory. It shows that cultural variables are relevant to IS acceptance and usage. Individualistic and weak uncertainty-avoidance scripts should thus focus on the following user-interface and design elements. On the one hand, work tasks, roles, and mastery, with quick results for limited tasks (aspects traditionally related to goal-directed activities); and, on the other hand, navigation-oriented to control and attention gained through games and competitions.

Likewise, in an attempt to develop positive attitudes among collectivistic and high uncertainty-avoidance cultures toward the IS, researchers and professionals might suggest and introduce courses and programs to gain more experience and self-efficacy and, in turn, higher optimal experiences; also, the creation of technical support programs which combine user service with precise, simple, understandable technical information, avoiding the use of jargon (i.e., clarity and courtesy). These policies (a) strengthen the user's perception of trustworthiness based on IS design, and (b) promote the progressive reduction of risk and technological anxiety, showing a determined willingness to understand and comprehend user's needs. The theoretical background provides evidence for culturally differentiated IS acceptance and usage.

Therefore, the study has an implication for diffusion theory, or adoption of IS; that is, findings may be taken as an operational basis for more intensive cultural adaptations of the IS. Our proposals justify the inclusion of moderating cultural-variables. These suggestions range from changes in pedagogy and perspective to making the computer a tool of collaboration between pairs or groups of users rather than individuals (adapted from Bryson & de Castell 1995; Littleton & Bannert 1999); and to giving collectivistic cultures a context in the IS-based experience. Therefore, while it seems that

these differences are perhaps more enduring than expected, they could certainly be controlled and rendered reasonable by the appropriate use of training-sessions.

CONCLUSION

Information systems offer unprecedented opportunities for world-wide access to information resources. Accordingly, the theoretical proposals presented in this article analyse the moderating effect of national culture (specifically, individualism and uncertainty avoidance dimensions) on the use of the IS. Differences among cultures in the ways in which they approach and interact with the IS are highly relevant to understanding how users use them in all settings.

Culture is one of the most relevant aspects of a user's personal and social context. Findings suggest that attitude formation is influenced by the objective characteristics of the IS, the extent of use, and individual and social users' differences. Studies continuously report that users are not always rational in selecting and using media and technologies, but attitudes toward and use of media and technologies are influenced by culture, norms, social contexts, or salient others (adapted from Fulk, Schmitz, & Schwartz, 1992; Rice & Love, 1987). Cultural differences (1) would be thus potentially critical to our understanding of IS acceptance and use; and (2) would play an important moderating role in determining how individuals make their decisions about adopting and using IS.

Cultural aspects need to be taken into account when developing IS that are especially to be used by a global audience. For instance, as Hermeking (2005) suggests, "a culturally well designed Web site may be defined as communicating the right information at the right place with the right layout in the right manner and in the right time according to the culture of each of its users."

Like any research, our study also has certain limitations. On the one hand, findings represent only preliminary tendencies. One of the main reasons for this is the high complexity and contingency of influences on IS design beyond cultural values and communication styles. On the other hand, Hofstede's method could thus be a significantly useful framework used in IS design. However, critics question the applicability of the dimensions to all cultures, emphasizing that "one can conjuncture that other types of samples might yield different dimensions and order of nations" (see Schwartz, 1994; Erez & Early, 1993; Soares et al., 2007). Most frequently, researchers question Hofstede's methodology and sample (e.g., Myers & Tan, 2002). Beyond age-based critiques, researchers also criticise Hofstede's dimensions for being data driven and not having a strong enough base in theory (e.g., Smith & Schwartz, 1997). Lastly, as Baack and Singh (2007, p. 182) summarise, "scholars point out that Hofstede's survey is specific to work values and may not apply to marketing research." Straub et al. (2002) argued that individuals may or may not identify with the national culture and they can show different cultural orientation even though they are in the same country. The social identity theory enables IS researchers to have a theoretical framework for studying at an individual level with a complimentary research perspective.

KEY TERMS

Culture: Refers to the collective programming of the mind which distinguishes the members of one group from another.

Individualism (IDV): The degree to which individuals are integrated into groups. On the individualist side we find societies in which the ties between individuals are loose: everyone is expected to look after him/herself and his/her immediate family. On the collectivist side, we find societies in which people from birth onward are integrated into strong, cohesive in-groups, often extended families (with uncles, aunts and grandparents) which continue protecting them in exchange for unquestioning loyalty.

Masculinity (MAS): Refers to the distribution of roles between the genders which is another fundamental issue for any society to which a range of solutions are found.

Perceived Ease-of-Use (PEOU): Defined as the degree to which a person believes that using a particular IS would be free of effort.

Perceived Usefulness (PU): Defined as the degree to which a person believes that a singular IS would enhance his/her job performance.

Power Distance Index (PDI): The extent to which the less powerful members of organizations and institutions (like the family) accept and expect that power is distributed unequally.

Uncertainty Avoidance Index (UAI): Deals with a society's tolerance for uncertainty and ambiguity; it ultimately refers to man's search for Truth. It indicates to what extent a culture programs its members to feel either uncomfortable or comfortable in unstructured situations.

Culture and Anonymity in GSS Meetings

Moez Limayem

Adel Hendaoui
University of Lausanne, Switzerland

INTRODUCTION

Managers spend a considerable part of their work time in meetings participating in group decision making. Group support systems (GSSs) are adopted in a variety of group settings—from within-organization team to multi-organization collaboration teams (Ackermann, Franco, Gallupe, & Parent, 2005)—to aid the decision-making process (Briggs, Nunamaker, & Sprague, 1998). A key characteristic of GSSs is anonymity, which improves various aspects of group performance, including improving group participation and communication, objectively evaluating ideas, and enhancing group productivity and the decision-making process (Nunamaker, Dennis, Valacich, Vogel, & George, 1991; Pinsonneault & Heppel, 1997; Postmes & Lea, 2000). Anonymity, as a distinct aspect of GSSs, was expected to increase productivity by reducing the level of social or production blocking, increasing the number of interpersonal exchanges, and reducing the probability of any one member dominating the meeting (Newby, Soutar, & Watson, 2003). For example, Barreto and Ellemers (2002) manipulated two aspects of anonymity separately: visibility of respondents (i.e., participants could or could not see who the other group members were) and visibility of responses (participants could or could not see the responses given by other group members). Results show that when group identification is low, anonymity manipulations affect group members' effort. Similarly, in their experiment, Reinig and Mejias (2004) found that anonymous groups produced more critical comments than identified groups did at the group level of analysis.

Numerous empirical findings have suggested that the use of anonymity and process structure in electronic brainstorming (EBS) generally promotes a positive effect on the number of ideas generated (Jessup, Connolly, & Galegher, 1990; Gallupe, Bastianutti, & Cooper, 1991) and quality of ideas achieved in decision making (Zigurs & Buckland, 1998). However, the anonymity function inherent in multi-workstation GSSs has been found to heighten conflict as members tend to communicate more aggressively because they tend to be more critical (Connolly, Jessup, & Valacich, 1990; Jessup, Connolly, & Tansik, 1990; Valacich, Jessup, Dennis, & Nunamaker, 1992), to have no effects on inhibition (Valacich, Dennis, & Connoly, 1994; Valacich et al., 1992), to increase group polarization (Sia, Tan, & Wei, 2002), and to have no effects on group performance (Valacich et al., 1994). Other studies show that, in terms of effectiveness, nominal brainstorming may be equal to (Gallupe et al., 1991; Cooper, Gallupe, Pollard, & Cadsby, 1998; Barki & Pinsonneault, 2001) or sometimes less than (Valacich et al., 1994; Dennis & Valacich, 1993) electronic brainstorming, indicating that at least as far as laboratory studies are concerned, empirical investigations have been inconclusive.

BACKGROUND

Ferraro (1998) provides a succinct definition of culture as follows: "Culture is everything that people have, think, and do as members of their society." Culture has been defined as the collective programming of the mind, which distinguishes the members of one group or category of people from another (Hofstede 1991; Tan, Watson, & Wei, 1995). Culture involves the beliefs, value system, and norms of a given organization or society, and can exist at national, regional, and corporate levels. In fact, even information systems theories and research are heavily influenced by the culture in which they were developed, and a theory grounded in one culture may not be applicable in other countries (Tan et al., 1995; Triandis, 1987). The theories explaining the effects of GSSs have come mainly from a North American perspective and may need adjustment for appropriate explanation of the same phenomenon in different contexts. Therefore, in order to incorporate a global dimension, theories and models that attempt to explain the effectiveness of technology will need to take into account the cultural background of the group being examined.

Hofstede (1991) identifies five dimensions of national culture based on his IBM study in 72 different countries:

- *Power distance* focuses on the degree of equality, or inequality, between people in a society. A high power distance ranking indicates that inequalities of power and wealth have been allowed to grow within that society. Similar societies—with high power distance—are more likely to follow a caste system that does not allow significant upward mobility of its citizens. A low power

distance ranking indicates that a society deemphasizes the differences between citizens' power and wealth. In these types of societies, equality and opportunity for everyone is stressed. Individuals in societies with low power distance cultures (e.g., the United States) may be more inclined to adopt technologies that reduce power distance (Reinig & Mejias, 2003). However, power distance effects can be helpful for some phases of group decision making but harmful for others (Tan, Watson, Wei, Raman, & Kerola, 1993).

- *Individualism* focuses on the degree in which a society reinforces individual or collective achievement and interpersonal relationships. This is opposed to *collectivism,* which implies a preference for a tightly knit social framework in which individuals can expect their relatives and clan to protect them in exchange for loyalty. A high individualism ranking indicates that individuality and individual rights are paramount within the society. Individuals in these societies may tend to form a larger number of looser relationships. A low individualism ranking typifies societies of a more collectivist nature with close ties between individuals. These cultures reinforce extended families and collectives where everyone takes responsibility for fellow members of their group. The people of collectivistic-culture societies (e.g., Hong Kong) tend to sustain group harmony and agreement, which exhibits less critical comments than those of individualistic-culture societies (e.g., the United States) in using group support systems (Reinig & Mejias, 2004). Likewise, Chinese participants, whose culture leans strongly toward collectivism, are more prone to follow the view of the majority, while Americans, whose culture leans strongly toward individualism, is less prone to follow the view of the majority (Zhang, Lowry, & Fu, 2006).
- *Masculinity* focuses on the degree in which the society reinforces, or does not reinforce, the traditional masculine work role model of male achievement, control, and power. On the contrary, *femininity* implies a preference for relationships, modesty, caring for the weak, and quality of life. A high masculinity ranking indicates that the country experiences a high degree of gender differentiation. In these cultures, males dominate a significant portion of the society and power structure, with females being controlled by male domination. A low masculinity ranking indicates the country has a low level of differentiation and discrimination between genders. In these cultures, females are treated equally to males in all aspects of the society.
- *Uncertainty avoidance* focuses on the level of tolerance for uncertainty and ambiguity within the society, that is, unstructured situations. A high uncertainty avoidance ranking indicates the country has a low tolerance for uncertainty and ambiguity. This creates a rule-oriented society that institutes laws, rules, regulations, and controls in order to reduce the amount of uncertainty. A low uncertainty avoidance ranking indicates the country has less concern about ambiguity and uncertainty, and more tolerance for a variety of opinions. This is reflected in a society that is less rule oriented, more readily accepts change, and takes more and greater risks.
- *Long-term orientation* focuses on the degree the society embraces, or does not embrace, long-term devotion to traditional, forward-thinking values. High long-term orientation ranking indicates the country prescribes to the values of long-term commitments and respect for tradition. This is thought to support a strong work ethic where long-term rewards are expected as a result of today's hard work. However, business may take longer to develop in this society, particularly for an "outsider." A low long-term orientation ranking indicates the country does not reinforce the concept of long-term, traditional orientation. In this culture, change can occur more rapidly, as long-term traditions and commitments do not become impediments to change.

It is interesting to note that power distance and individualism are found to be inversely related (Hofstede, 1991; Kim, Triandis, Kagitcibasi, Choi, & Yoon, 1994; Triandis, 1995). Many Western countries such as the United States, Great Britain, and Australia have been described as individualistic, low power distance cultures, while many Asian countries such as Hong Kong, Singapore, and China have been described as collectivistic, high power distance cultures (Hofstede, 1991).

More recently, Srite and Karahanna (2006) examined the influence of national culture on individual behavior and extended the Technology Acceptance Model by incorporating espoused national cultural values (masculinity/femininity, individualism/collectivism, power distance, and uncertainty avoidance) into the model. With respect to the impact of individualism/collectivism value on behavior for example, and because of the growing "virtualness" of collaborative teams, these authors call for further research investigating the acceptance of technologies used by teams composed of individuals from different national cultures.

CULTURE AND ANONYMITY IN GSS STUDIES

Although a GSS is a socio-technical system that involves not only computer and communication technologies but also a group of participants, culture was not specifically considered as an important dimension in the early studies of GSSs.

However, with globalization it is becoming increasingly important to adapt this tool to the cultural background of the organization or group that intends to use it effectively. These dimensions have been investigated in cross-culture GSS studies (such as Robichaux & Cooper, 1998; Tan, Wei, Watson, Clapper, & McLean, 1998; Tung & Quaddus, 2002; Watson, Ho, & Raman, 1994). Among the five dimensions, power distance and individualism have been shown to have impacts on group behavior and group outcomes (Tan et al., 1998; Watson et al., 1994). This is because the anonymity and simultaneous input features of GSSs support low power distance and individualistic cultural norms of desirable group behavior (Watson et al., 1994).

Watson et al. (1994) later provided empirical support for the inclusion of culture as a dimension of GSSs to add to DeSanctis and Gallupe's (1987) dimensions of group size, member proximity, and task type. Their study examined American and Singaporean cultures using GSSs, and the findings suggested that Singaporean groups tended to have a higher pre-meeting consensus and less change in consensus than the U.S. group. This may be explained with reference to the collectivist nature of Singaporean culture, as collectivists have a tendency towards group consensus (Mejias, Shepherd, Vogel, & Lasaneo, 1997).

Tan et al. (1995) suggested ways that different cultures can be studied with other important variables such as task type and group size. The study focused on finding a way to examine the robustness of previous and current GSS research across different cultures and to add a cultural perspective to existing GSS knowledge. Hofstede's dimension of power distance was examined in relation to GSSs, and the possible impacts of a GSS intervention in both high and low power distance countries were explored.

In studies examining only Singaporean groups (Tan et al., 1995), the use of a GSS resulted in a decreased impact of status and normative influences on decision making. These findings showed that change in consensus was greater in American groups than it was in than Singaporean groups, and influence was more equal in Singaporean groups than it was in American groups. The higher power distance of Singaporean groups may explain the differences between these two meeting outcomes, and the study supports the proposition that a GSS can overcome the effect of high power distance on group meetings.

A study comparing North American and Mexican groups participating in GSS sessions showed differences in terms of perception of consensus and satisfaction levels of group members (Mejias et al., 1997). American and Mexican groups were also studied for GSS effects on participation equity, with Mexican groups reporting higher participation equity levels than American GSS groups (Mejias et al., 1997). It was suggested that high power distance cultures benefit from GSSs, and that these findings indicate that culture has a significant bearing on crucial aspects of GSS meeting outcomes.

When members interact at different locations and at different times, GSS teams are considered virtual teams. Globalization implies that virtual collaborative teams are often made up of participants with different backgrounds (national culture, spoken language, and value system). Carte and Chidambaram (2004) suggested that GSS features can reduce the negative effects of cultural diversity (i.e., communication difficulties, misunderstandings, decreased cohesion, and increased conflict) early in the life of a culturally diverse team. Based on these findings, Staples and Zhao (2006) provided evidence that cultural diversity effects are different depending on the communication mode used between members (e.g., face-to-face vs. virtual-electronic) and specifically that the performance of heterogeneous teams using electronic channels of communication was higher than heterogeneous teams using face-to-face communication. The findings could have implications for the design and use of anonymity features in GSS-supported meetings.

Based on Hofstede (1991), Shin and Higa (2005) investigated the attitude of people with a particular cultural background toward different scheduling approaches. They found that face-to-face coordination led to higher group satisfaction than automated approaches did. Extending the implications of their study, their findings suggest that organizational cultures that show strong collectivism and social interactivity may hinder adoption and use of virtual technologies such as GSSs.

The feature of anonymity in GSSs facilitates group processes by moderating those participants who dominate group discussions, by hiding the identities of the participants to eliminate the influence of authority, and by removing the reliance on nonverbal cues in communication between group members. Some researchers have hypothesized that anonymity enhances group member participation by reducing inhibitions. For example, Wilson and Jessup (1995) found that groups interacting under anonymity generate more total comments and unique ideas, more ideas of higher rarity, and more critical comments than groups interacting without anonymity.

In his study of the effect of individuals' personality characteristics on their participation in a decision-making meeting, Hartmann (2001) investigated also the moderating effect by anonymity. It is found that anonymity allows the disagreeable persons (i.e., those who are less willing to help others) to participate more and provide more on-task comments with a high level of anonymity than they would with a low level of anonymity in a GSS-supported meeting. However, groups with agreeable individuals will perform better, but anonymity will allow the disagreeable individuals to participate more and therefore create more conflict, resulting in poor performance from the group.

Limayem, Khalifa, and Coombes (2003) conducted a study to explain the different effects of anonymity on the behavior of Hong Kong and Canadian groups during GSS

sessions. In the Hong Kong Chinese culture, group interactions tend to emphasize harmony, conformance, and reciprocal respect rather than openness and spontaneity. However, the Canadian group's culture, which frequently exhibits openness and spontaneity, will usually allow individuals to deviate from the norm. Anonymity was found to have more significant positive effects for Hong Kong groups. With anonymity, the performance of the Hong Kong group improved significantly in terms of number of contributions, quality of contributions, and perceived level of participation. No significant differences in the performance were found for the Canadian groups, except for the quality of contributions, which deteriorated with anonymity. A qualitative analysis of this negative effect revealed social loafing and lack of accountability as possible causes. This finding is consistent with the previous study that anonymity induces social loafing and flaming, reduces accountability, and ultimately may decrease participation (Er & Ng, 1995; Pinsonneault & Kraemer, 1990).

In a study exploring the usefulness of electronic brainstorming (a component of GSS), Dennis and Reinicke (2004) note that reinforcing the group culture is considerably more difficult, especially when brainstorming is anonymous. According to theses authors, adoption of such technologies depends on the relative importance of existing culture and power structures to key group members, because of the difficulty to identify and sanction those members who challenge current structures. Moreover, they suggest that if anonymity may improve performance, removing it may increase overall usefulness. They finally called for further research to predict adoption of GSS technologies with more refined versions of the Technology Acceptance Model.

In sum, studies investigating the use of GSS by people from different cultures have indicated that culture has a significant impact on GSS usage, and that cultural dimensions, such as those proposed by Hofstede (1991), have some relevance in explaining these differences. However, there is still uncertainty as to the specific impacts of culture on the performance of groups in anonymous GSS sessions, and therefore more must be done to clearly understand how different cultures respond to anonymity.

FUTURE TRENDS

Migrating to the era of virtual organization, it is more and more common that cross-organization project teams rely on GSSs to accomplish their daily tasks. Since team members are often from different cultural backgrounds, the optimal performance of the GSS relies on the cultural context in which it operates. Hence, the practical implications of cultural studies in GSS research are of significant value not only to facilitators of GSS, but also to users of groupware applications, as well as many other inter-organizational electronic communication systems.

In the same vain, anonymity in GSSs per se involves no value judgment at all. One cannot simply judge that it is a favorable or an unfavorable feature, especially when participants with different cultural backgrounds are involved. The use of anonymity should depend on the cultural context in which it is applied. For example, the use of anonymity in GSSs is likely to result in better meeting performance in groups that do not emphasize status hierarchies, conformance, mutual obligation, and reciprocity than in groups that emphasize on these qualities. In the former situation, anonymity could even lead to negative outcomes such as social loafing due to the reduction in motivation and effort that occurs when individuals work in anonymous groups. Conversely, it may be beneficial to use anonymity for GSS-supported groups with cultures that normally exhibit higher levels of conformance pressure and evaluation apprehension.

In a broader sense, GSS and groupware designers and developers should pay special attention to the implementation of anonymity features. For example, they could make it easier for users to turn these features on and off to accommodate the culture of the groups using the systems. Finally, facilitators should remember that studies suggest that culture influences participation in the GSS environment (Tung & Quaddus, 2002). Therefore, facilitators should study the culture of the group using the technology before blindly using anonymity to generate or evaluate ideas.

CONCLUSION

Culture is obviously an important factor affecting a group's response to anonymity in the GSS context. Cultural effect on group structure and evaluation apprehension is also an important consideration for designers, facilitators, and users of GSSs. Considering the rather rare number of studies investigating the impact of culture on GSSs, further research in this area is warranted. An interesting line of research in GSSs for the future would be to isolate the relative impact of anonymity in the context of different cultures engaged in different tasks and situations. The knowledge gained from this and other continuing studies will assist in the effective application of GSSs in increasingly diverse and global contexts.

KEY TERMS

Anonymity in GSS: The situation when participants' names are not made public in a GSS environment.

Culture: The collective programming of the mind, which distinguishes the members of one group or category of people from another.

Group Support System (GSS): Any combination of hardware and software that enhances groupwork.

Individualism: A preference for a loose-knit social framework in a society in which individuals are only supposed to take care of themselves and their immediate families. This is opposed to collectivism, which implies a preference for a tightly knit social framework in which individuals can expect their relatives and clan to protect them in exchange for loyalty.

Long-Term Orientation: The fostering of virtues oriented towards future rewards, in particular perseverance and thrift. Its opposite pole, short-term orientation, stands for the fostering of virtues related to the past and present, in particular, respect for tradition, preservation of 'face', and fulfilling social obligations.

Masculinity: A preference for achievement, heroism, assertiveness, and material success; as opposed to femininity, which implies a preference for relationships, modesty, caring for the weak, and quality of life.

Power Distance: The extent to which a society accepts the fact that power in institutions and organizations is unevenly distributed.

Uncertainty Avoidance: The degree to which a society feels threatened by uncertain and ambiguous situations, which leads its members to support beliefs promising certainty and to maintain institutions protecting conformity.

Current Network Security Technology

INTRODUCTION

Network security is defined as "a set of procedures, practices and technologies for protecting network servers, network users and their surrounding organizations" (Oppliger, 2000, Preface). The need for network security is caused by the introduction of distributed systems, networks, and facilities for data communication. Improved network security is required because of the rapid development of communication networks. Network security is achieved by using software- and hardware-based solutions and tools.

BACKGROUND

This article gives a topical overview of network security technologies, that is, the topics are not covered in detail, and most topics are briefly introduced and left for further study. The main objective is to present "state-of-the-art" network security technologies and to stimulate discussion about related skills and education needed by network users, IT professionals, and network security specialists.

PROTECTION AGAINST MALICIOUS PROGRAMS

Malicious software exploits vulnerabilities in computing systems. Malicious program categories are (Bowles & Pelaez, 1992):

- **Host Program Needed:** Trap door, logic bomb, Trojan horse, and virus.
- **Self-Contained Malicious Program:** Bacteria and worm.
- **Malicious Software Used by an Intruder after Gaining Access to a Computer System:** Rootkit.

Threats commonly known as adware and spyware have proliferated over the last few years. Such programs utilize advanced virus technologies for the reason to gather marketing information or display advertisements in order to generate revenue (Chien, 2005).

Modern malicious programs (including adaware and spyware) employ anti-removal and stealth techniques as well as rootkits to hide and to prevent detection. Rootkits conceal running processes, files, or system data. This helps an intruder to maintain system access in a way, which can be extremely difficult to detect with known security administration methods and tools. Rootkits are known to exist for a variety of operating systems such as Linux, Solaris, and versions of Microsoft Windows. A computer with a rootkit on it is called a rooted computer (Hoglund & Butler, 2005; Levine, Grizzard, & Owen, 2006).

The ideal protection is prevention, which still must be combined with detection, identification, and removal of such malicious programs for which prevention fails. Protection software is usually called antivirus software, which is characterized by generations (Stephenson, 1993):

- **First Generation:** Simple scanners searching files for known virus "signatures" and checking executable files for length changes.
- **Second Generation:** Scanners using heuristic rules and integrity checking to find virus infection.
- **Third Generation**. Memory resident "activity traps" identifying virus actions like opening executable files in write mode, file system scanning, and so forth.
- **Fourth Generation:** Software packages using many different antivirus techniques in conjunction.

Anti-adware/spyware modules are usually integrated in these software packages.

Protection levels of modern antivirus software are:

- **Gateway Level Protection:** Consists of mail server and firewall protection. Viruses are detected and removed before files and scripts reach a local network.
- **File-Server-Level Protection:** Consists of server software. Viruses are detected and removed even before network users access their files/scripts.

- **End-User-Level Protection:** Consists of workstation software. Viruses undetected in outer defense lines are detected and removed. However, this level is the only antivirus protection level for data communication, which is end user encrypted.

All levels should be combined to achieve depth in antivirus defense. Virus definition databases should be automatically and/or manually updated.

Examples of antivirus and anti-spyware software are Ad-Aware, F-Secure Internet Security, and Norton AntiVirus.

FIREWALL TECHNOLOGY

Firewalls protect computers and computer networks from external security threats. Firewalls fall into four broad categories (Stallings, 2006):

- **Packet-Filtering Router:** Applies a software and/or hardware implemented filtering rule set to each incoming/outgoing IP packet and then forwards or discards the packet. Most TCP/IP routers support basic user defined filtering rules. A packet-filtering firewall can also be a stand-alone network link device, for example, a computer with two network cards.
- **Application-Level Gateway (Proxy Server):** Acts as an application level traffic relay, that is, traffic is filtered based on specified application rules. A typical application level gateway is a protocol oriented proxy server on a network link, for example, an HTTP proxy, a SMTP proxy, a FTP proxy, and so forth.
- **Circuit-Level Gateway:** Typically relays TCP packets from one connection to another without examining the contents. Traffic is filtered based on specified session rules such as when a session is initiated by a recognized computer.
- **Stateful Multilayer Inspection Firewall:** Traffic is filtered at three levels, based on a wide range of specified application, session, and packet filtering rules.

CRYPTOGRAPHIC TECHNOLOGY

Cryptographic network security technology consists of network security applications, network security system software, and cryptographic hardware.

Secure-Network-Level Data Communication

Secure-network-level data communication is based on the Internet protocol security (IPSec) protocol. Two computers in the same TCP/IP network implement end-to-end security through the network, when IPSec software is installed and properly configured in both computers. IPSec provides two operation modes:

- **Transport Mode:** Original IP headers are used.
- **Tunnel Mode:** New IP headers are created and used to represent the IP tunnel endpoint addresses.

IPSec is usually embedded in virtual private network (VPN) software. VPN provides secure LAN functionality in geographically distributed network segments and for Internet connected computers. Fundamental VPN types are:

- **Access VPN:** Secure connection to a LAN through a public TCP/IP Network.
- **Connection VPN:** Secure remote connection between two logical LAN segments through a public TCP/IP network.

IPSec and VPN functionality is included in Windows 2000/XP. Commercial VPN software products are F-Secure VPN+™, Nokia VPN, Cisco Security VPN Software, and so forth. Open source IPSec and VPN software is also available (Openswan Portal, 2006).

Middleware

Middleware is a software layer between the network and the applications for providing services like identification, authentication, authorization, directories, and security (Internet2 Middleware Initiative [I2-MI] Portal, 2006). Shibboleth is an example of open source authentication and authorization middleware (Shibboleth Project Portal, 2006). Commercial security middleware based on the SHH protocol is SSH Tectia Solution (2006).

Secure-Transport-Level Data Communication

Many network applications are based on the IETF transport layer security (TLS) standard (Dierks & Rescora, 2006). The TLS/SSL protocol is based on an established client-server TCP connection. Then both computers execute the SSL handshake protocol to agree on the cryptographic algorithms and keys for use in the actual data communication. TLS/SSL versions of common application level TCP/IP protocols are available (see Table 1).

VPN solutions can also be implemented using the TLS/SSL protocol and executed on the transport level. This technology, called SSL-VPN, provides VPN functionality to geographically distributed network segments and for Internet connected computers using a standard Web browser.

Table1. Secure application level protocols based on TLS/SSL (Oppliger, 2000, p. 135)

Secure protocol	Port	Description
HTTPS	443	TLS/SSL protected HTTP
POP3S	995	TLS/SSL protected POP3
IMAPS	993	TLS/SSL protected IMAP4
SMTPS	465	TLS/SSL protected SMTP
NNTPS	563	TLS/SSL protected NNTP
LDAPS	636	TLS/SSL protected LDAP

Open source SSL-VPN software can be downloaded from OpenVPN Portal (2005).

Web Security

Basic Web security features are access level security and transaction level security. Access level security is provided with firewalls, which guard against intrusion and unauthorized use. Transaction level security requires protocols for protecting the communication between a Web browser and a Web server. Proposed protocols are HTTPS, S-HTTP, and PCT (Pulkkis, Grahn, & Åström, 2003). HTTPS was originally introduced by Netscape for the Navigator browser. Presently HTTPS is an accepted standard supported by practically all Web browsers, while S-HTTP and PCT are seldom used.

E-Mail Security

E-mail traffic between e-mail servers is protected using the SMTPS protocol. Sessions between e-mail client programs and e-mail servers can be protected

- By using the mailbox access protocols POP3S and IMAPS.
- By embedding an e-mail client program in a HTTPS Web page.

E-mail content security requires solutions for signing and/or encrypting outgoing messages as well as for decryption and/or signature verification of incoming messages. These solutions can be adapted on

- Client level, by e-mail client program security extensions.
- Server level, by gateway security extension solutions.

The most widely used e-mail security extensions are PGP and S/MIME (see Stallings, 2006, Chap. 15). A commercial e-mail security extension solution is Utimaco Safeware's SecuE-Mail Gateway supporting OpenPGP (Open PGP) Alliance Portal, 2006) and S/MIME.

A current problem with e-mail is spam e-mail sent by some unknown party to a large number of recipients. Usually this spam e-mail has some commercial contents. Spam e-mail is also used to spread spyware and viruses. Server level solutions detect spam e-mail before they reach the e-mail server and client solutions, embedded in modern client level security suites, detect spam e-mail when e-mail reaches the e-mail client.

E-Commerce Security

There are three main e-commerce transaction categories:

- **Consumer-to-Business (C2B) Transactions:** Occur between a consumer and an electronic marketplace or a bank over public networks, usually over the Internet.
- **Business-to-Business (B2B) Transactions:** Called market link transactions. Here, businesses, governments, and other organizations conduct business using different electronic communication technologies.
- **Intraorganizational Transactions:** Also called market driven transactions for internal strategies by collecting outside information and by customer monitoring (Kalakota & Whinston, 1999).

Secure Electronic Transaction (SET), introduced by MasterCard and Visa, is a standard protocol for securing credit card transactions over insecure networks such as the Internet (Stallings, 2000). SET provides secure communication, trust based on X.509v3 digital certificates, and privacy based on strictly controlled access to sensitive information. The SET protocol was published in the late 1990s but has still only a small market share in existing implementations of C2B transactions.

HTTPS is presently a standard protocol for securing C2B transactions on the Internet. When a customer browses to an e-commerce Web page, then authentication of this Web page with a trusted X.509v3 certificate is required before any transactions occur. A typical transaction is then a SSL/TLS protected authorization of the customer to the e-commerce Web page to charge the cost of a purchase from the credit card account of the customer. For online transactions with bank accounts, customers have private HTTPS protected Web pages. When a customer browses to his/her private Web page, then mutual authentication of the customer and the customer's bank is required before any transactions occur. In this authentication the bank uses a trusted X.509v3 certificate, and the customer uses either a trusted X.509v3 certificate or a one-time password according to the requirements of the bank. In this case a typical transaction is an SSL/TLS protected authorization signed by the customer to transfer a specified amount of money from the customer's account to some other account. The signature is created with a trusted X.509v3 certificate or with a randomly chosen signature code according to the requirements of the bank.

For B2B transactions, the main technologies are RosettaNet XML, Electronic Data Interchange (EDI), and EDI over the Internet (EDIoI).

RosettaNet is a consortium of major information technology (IT), electronic components (EC), and semiconductor manufacturing (SM) vendors dedicated to the development and deployment of open e-commerce standards for B2B transactions in high tech supply chains. *RosettaNet Implementation Framework* (RosettaNet Implementation Framework: Core Specification, 2001) is an open common networked application framework defining a XML format for exchange of B2B documents. This framework includes S/MIME v2 for secure authentication, authorization, and confidentiality of B2B transacting.

The latest version of the international EDI standard can be downloaded from UN/EDIFACT Portal (2006). For B2B transacting via EDI, the trading partners must agree on

- what information is to be exchanged,
- which message standards are used, and
- the means of transportation (EDI network).

An EDI network consists of direct modem-to-modem data links between involved companies or is implemented by a third-party value-added network (VAN) service. The security of VANs is high, since they are private networks physically out of the reach for outsiders. Examples of present EDI VAN service providers are AT&T, British Telecom, IBM network, and General Electric Information Services (Kalakota & Whinston, 1999; Whiteley, 2000).

B2B transacting via EDIoI means EDI network implementation by the Internet. EDI transactions are implemented by Web browsing operations, which can be mutually authenticated and protected by the HTTPS protocol. To support the use of EDIoI, IETF has standardized the Electronic Data Interchange Applicability Statement 2 protocol (AS2), which uses S/MIME messaging for authentication and data confidentiality (Moberg & Drummond, 2005).

Secure Shell (SSH)

The secure shell (SSH), a secure remote connectivity protocol in TCP/IP networks, is a de-facto standard being further developed by one of the IETF Security Area Working Groups. Two SSH versions have hitherto been developed: SSH1 and SSH2. Commercial as well as open source SSH implementations are available (OpenSSH Portal, 2006; SSH Tectia Solution, 2006).

Wireless Security Software

A radio interface is by nature easy to access. Security threats are either passive or active attacks. Active attacks involve altering data streams. Passive attacks, on the other hand, include snooping on transmission. The most important security features are authentication, authorization, confidentiality, integrity, and availability. The corresponding software is included in the network.

WLAN security is built up around the security protocol 802.11i/WPA2 (Wi-Fi Protected Access). WPA2 was created to address problems with the security protocols WEP (wired equivalent privacy) and WPA. For authentication, IEEE 802.1X is used in current systems (Wi-Fi Protected Access, 2003).

WiMAX (WiMAX Forum, 2006) has adopted the DOCSIS BPI+ (Data Over Cable Service Interface Specification – Baseline Privacy Interface Plus) protocol. Authentication relies on PKM-EAP (privacy key management-extensible authentication protocol) and TLS (transport layer security). The CCMP (counter mode with cipher block chaining message authentication code protocol) protocol and the AES (Advanced Encryption Standard) algorithm are used for encryption.

In Bluetooth, there are three security modes handled by the security manager (Grahn, Pulkkis, & Guillard, 2002). A bonding process including pairing and authentication, and encryption based on the SAFER+ algorithm are implemented. Also a concept of trusted devices is applied.

ZigBee (ZigBee Alliance, 2006) uses basic security elements in IEEE 802.15.4. The AES is used to protect data. Any two devices must share a key for encryption and decryption. The public key encryption algorithm is based on ECC (elliptic curve cryptography).

The security features in a GSM network can be divided into three subparts: subscriber identity authentication, user and signaling data confidentiality, and subscriber identity confidentiality. In 3G systems security is based on what was

implemented in GSM. The encryption algorithm is stronger; the application of authentication algorithms is stricter, and subscriber confidentiality is tighter. The security principles are all incorporated into the authentication and key agreement (AKA) procedure (Grahn et al., 2002).

Secure Network Management

A protocol for secure network management, SNMPv3, was introduced in 1998 by IETF to address the lack of security in earlier SNMP versions. SNMPv3 incorporates authentication and encryption features to SNMP managers and access control features to SNMP agents (Stallings, 2000).

Secure DNS (DNSSEC)

The absence of trust in DNS host name resolution is a security hazard in all TCP/IP applications. To address this problem IETF formed a Working Group to develop the DNSSEC standard. The objective is to provide both authentication and integrity to DNS information. DNSSEC uses public key cryptography to sign DNS information (DNSSEC, 2006).

Secure Routing Software

Routing protocols and their hardware/software implementations in computer networks are usually open and functionally unprotected. A manifestation of an emerging recognition of routing security in the Internet community is the recently formed IETF Routing Area Working Group "Routing Protocol Security Requirements (rpsec)," which in October 2004 published an Internet Draft "Generic Threats to Routing Protocols" (Barbir, Murphy, & Yang, 2004).

Cryptographic Hardware

Cryptographic hardware is needed for data protection and also computational acceleration purposes. A piece of cryptographic hardware is usually used for both purposes, and it is called:

- a hardware security module (HSM Module), when the goal is to achieve data security
- a crypto co-processor or cryptographic accelerator chip, when the goal is improved computational efficiency

HSM Modules are used for:

- protection of sensitive cryptographic data structures like symmetric and private cryptographic keys
- secure generation and use of sensitive cryptographic data structures, such as:
  - one-time passwords with short validity time
  - cryptographic keys
  - irreproducible random numbers needed in key generation and for nonce generation in authentication protocols to prevent replay
- execution of key agreement protocols
- execution of encryption and decryption operations using symmetric and private keys

The cryptographic keys in HSM Modules are protected by pin codes or biometrically by digital fingerprint comparison and/or by digital voice recognition.

Examples of cryptographic hardware are:

- Smartcard chips. Smartcard types are:
  - Electronic Identity Cards (PKI Cards)
  - SIM, PKI SIM, USIM, and SWIM cards in mobile phones
- USB HSM tokens
- PC Card HSM Modules with PCMCIA or PCMCIA Express interface
- PCI card HSM Modules
- SecurID (Nystrom, 2000) and Digipass (Vasco Product Range, 2006) HSM Modules for generation and use of one-time passwords with short validity time
- TRNG (True Random Number Generator) devices for extraction of natural physical randomness for generation of irreproducible random numbers. TRNG devices are implemented by:
  - radiation counters
  - radio noise monitors
  - audio noise monitors
  - monitors of thermal noise in diodes, leaky capacitors, mercury discharge tubes, and so forth
- cryptographic processors/acceleration chips for execution of
  - symmetric encryption/decryption operations with DES, 3DES, AES, and so forth
  - RSA encryption/decryption operations in public key cryptography
  - arithmetics with discrete points on elliptic curves in elliptic curve cryptography
  - SHA-1 hashing

With smartcards, the most widely used cryptographic hardware, a smartcard reader is needed. With other cryptographic hardware no separate reader is needed. For true pin code security a smartcard reader with a dedicated keypad is necessary. Software required for accessing cryptographic tokens on smartcards is

- Device driver for communication with the smartcard through the used smartcard reader.

- PC/SC, a specification set released by an international consortium (PC/SC Workgroup, 2006) for integration with the operating system. In PC/SC a device manager keeps track of the cards and card readers connected to a computer.
- An Application Programming Interface (API) like PKCS#11, also called CrypTokI, or Microsoft Crypto API.

Public Key Infrastructure (PKI)

Network server authentication is usually based on the use of certified public key cryptographic key pairs. In network access software, such as SSH and VPN, a network user authentication option is based on the use of certified key pairs. The server or the network is authenticated by proving the ownership of the private key in a certified key pair. The Internet standard for key pair certification is presently X.509v3 (Public-Key Infrastructure [X.509] Working Group [pkix], 2006). An X.509v3 certificate is a public digitally signed data structure consisting of:

- the public key of a key pair
- the subject (=owner) of the key pair
- validity time of the certificate
- usage of the key pair
- issuer of the certificate

Also digital signatures are created and verified with certified key pairs in the X.509v3 standard. An X.509v3 certificate is signed by the private key in the key pair of the issuer. The public key in an X.509v3 certificate is trusted, if the issuer is trusted Certification Authority (CA). A PKI is hardware, software, people, policies, and procedures needed to issue, manage, store, distribute, use, and revoke X.509v3 certificates.

SECURITY ADMINISTRATION

Security administration uses intrusion detection software, vulnerability checking software, and software for security software management.

An intrusion detection system (IDS) monitors traffic in a network and/or user behavior in a host computer to identify possible intruders and/or anomalous behavior and/or misuse (Stallings, 2006). A distributed intrusion detection system coordinates and brings cooperation among several intrusion detection systems across a whole network. Standards to support such distributed intrusion detection systems are defined by the IETF Intrusion Detection Working Group (Stallings, 2000).

Major vulnerabilities are too short, easily guessed, or cracked passwords. A potential intruder could run a password cracker on the encrypted passwords stored in a network. System administrators can use cracking to disable usage of bad passwords.

Intrusion prevention requires regular scans for unnecessary open ports and other vulnerabilities like missing security patches.

Data encryption software protects data stored in networks using encryption. Encryption per user or per group of data stored in files and databases protects data contents from unauthorized access. Data encryption software examples are:

- Microsoft's Encrypting File System (EFS) technology for file and folder encryption on user level.
- Utimaco Safeware's SafeGuard LAN Crypt software for file and folder encryption on both user and group level. SafeGuard LAN Crypt supports encrypted network traffic for the encrypted data.

Network security software in host computers and in other network nodes like routers is often software managed. A management software example is F-Secure® Policy Manager™ for management of "not only antivirus solutions, but all critical network security solutions on all tiers of the network" (F-Secure Policy Manager, 2006).

DEVELOPMENT OF SECURITY SOLUTIONS

Antivirus protection programming skills require knowledge about self-modifying programs/scripts and about virus sensitive operating system features.

Firewall software programming skills are based on detailed knowledge of TCP/IP protocol stack implementation software.

The open source toolkit OpenSSL is available for TLS/SSL application design (The OpenSSL Project, 2005). OpenSSL is installed as a C function library. Also commercial development tools are available, for example (Certicom Security Builder SSL, 2006).

S/MIME e-mail extensions can with special toolkits be added to existing network software and be embedded in network software being developed. Freeware S/MIME v3 toolkits are (S/MIME Freeware Library, 2006) and the Mozilla S/MIME Toolkit. Phaos S/MIME Toolkit is a Java package (Phaos S/MIME, 2004) for secure messaging in Java applications.

IPSec software development is usually VPN software development. IPSec can be integrated in the networking software and/or hardware of a router/a computer node. Commercial IPSec developer toolkits are available, for example Certicom Security Builder IPSec (2006).

Program libraries for SSH protocol integration during network software design are also available; see, for example, Ganymed SSH-2 for Java (2005).

In smartcard application development usually some development kit is used. Microsoft offers a Smartcard Toolkit to be used together with visual programming tools.

DESIGN OF SECURE NETWORK SOFTWARE

Network security software implements security features. Other network software implements functionality and other features like usability, efficiency, simplicity, safety, dependability, reliability, and so forth. Security requirements for any network software include:

- absence of vulnerabilities and security holes
- secure interfaces

Security should be integrated in the network software life cycle starting from the specifications. The need to assess vulnerability and to react on security incidents should be proactively minimized before network software is used. A recent handbook for secure software design is available (Viega & McGraw, 2002).

FUTURE TRENDS

IPSec is integrated in the new version of the IP protocol, IPv6 (IP version 6, 2006). Thus IPSec is automatically included in the IP software in all nodes in future TCP/IP networks. Also DNSSEC and secure routing protocols will be included in the system software of future TCP/IP networks.

New wireless network protocols emerging are among others Wireless USB (WUSB) (Kolic, 2004) and ZigBee (ZigBee Alliance, 2006). WUSB will offer the same functionality as standard wired USB devices. ZigBee is a low-power, short-range, wireless technology. Both technologies will be used in networking solutions for home/industrial automation.

Wi-Fi Protected Access version 2 (WPA2) includes full 802.11i support in a WLAN (Wi-Fi Protected Access, 2003). WPA2 will replace RC4 with AES. It will also include the CCM protocol. The new standard implementation is hardware accelerated and will require replacement of most access points and some NICs (Network Interface Cards).

Session key agreements in future wired network, will be based on absolutely secure quantum cryptography protocols (Bennett, 1984), which are physically implemented by transmission of randomly polarized laser pulses in optical fibers (Stucki, Gisin, Guinnard, Ribordy, & Zbinden, 2002). Absolutely secure means that verified reception of a session key is also a proof that the same key has not been eavesdropped. Commercial Quantum key distribution technology is already available (id Quantique Portal, 2006).

CONCLUSION

Software and hardware solutions and tools are network security cornerstones. Today, network security technology is a large and complex rapidly expanding area. Network security software skills are needed by every computer and computer network user. This has profound implications on all education, since use of computer networks is inevitable.

Education for professional network security software skills should include:

- installation, configuration, and test use of all categories of available network security software/hardware solutions and products,
- source code inspection exercises of open source network security software solutions, and
- programming exercises and projects with TLS/SSL application development environments and cryptographic toolkits.

Network security software development skills are important in upper level network security education.

KEY TERMS

E-Mail Protocols: Simple mail transport protocol (SMTP) is a set of commands for transport of ASCII encoded e-mail messages. Post office protocol (POP3) retrieves new messages from a mailbox to a remote e-mail client. A remote e-mail client can simultaneously access several mailboxes on different mail servers with the Internet message access protocol (IMAP).

Internet Engineering Task Force (IETF): An open international community engaged in Internet architecture evolution (IETF, 2006). Working Groups in several topical areas develop technical drafts and Internet standards.

Internet Protocol Security (IPSec): The IPSec protocol suite is developed by an IETF Security Area Working Group. IPSec introduces a new TCP/IP protocol stack layer below IP. IPSec adds authentication and optionally encryption to transmitted data packets. Authentication ensures that packets are from the right sender and have not been altered. Encryption prevents unauthorized reading of packet contents.

Pretty Good Privacy (PGP): An e-mail extension used to encrypt/decrypt and cryptographically sign e-mail, as well as to verify e-mail signatures. Verification of a signature is a proof of sender identity and message authenticity.

Secure Multipurpose Internet Mail Extensions (S/MIME): A secure e-mail standard based on MIME. S/MIME, being further developed by an IETF Security Area Working Group, accomplishes privacy and authentication by using encryption/decryption, digital signatures, and X.509 certificates.

Simple Network Management Protocol (SNMP): An application layer TCP/IP protocol for management information exchange between network devices. SNMP includes two main software entity types: managers and agents.

Virus: Malicious code added to an executable file loaded to a computer and executed without the user's knowledge and consent. Computer viruses often copy and spread themselves to other computers in the same network.

Current Practices in Electroencephalogram-Based Brain-Computer Interfaces

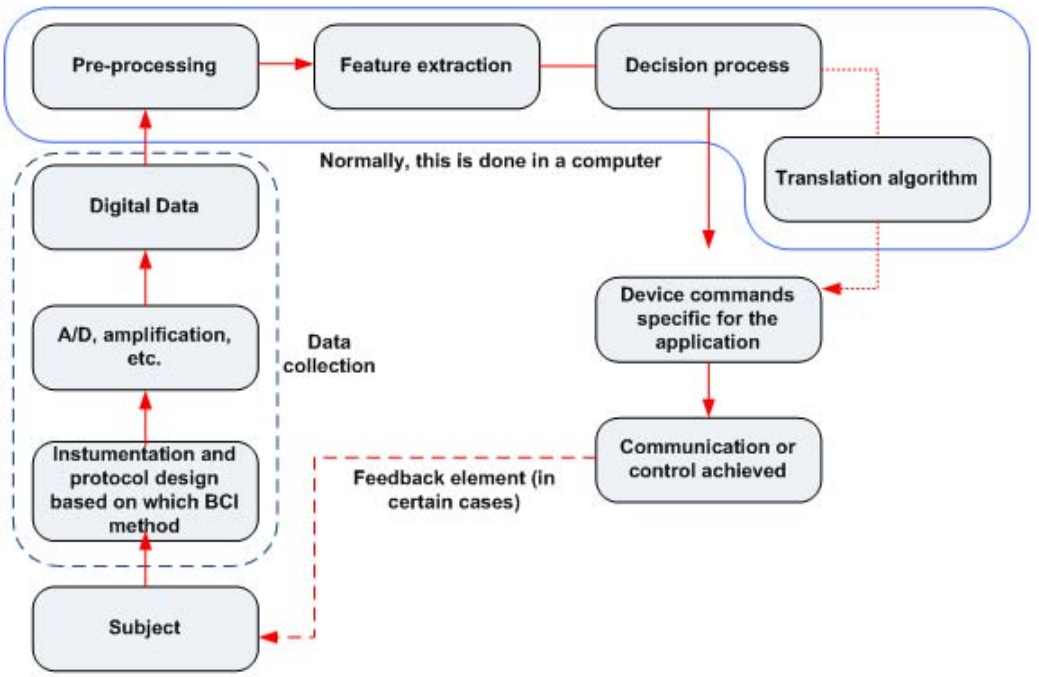
INTRODUCTION

Electroencephalogram (EEG) is the electrical activity of the brain recorded by electrodes placed on the scalp. EEG signals are generally investigated for the diagnosis of mental conditions such as epilepsy, memory impairments, and sleep disorders. In recent years there has been another application using EEG: for brain-computer interface (BCI) designs (Vaughan & Wolpaw, 2006).

EEG-based BCI designs are very useful for hands-off device control and communication as they use the electrical activity of the brain to interface with the external environment, therefore circumventing the use of peripheral muscles and limbs. Some current applications of BCIs in communication systems are for paralyzed individuals to communicate with their surroundings through character/menu selection and in device control such as wheelchair movement, prosthetics control, and flight and rehabilitative (assistive) technologies. For the general public, some of the possible applications are hands-off menu selection, flight/space control, and virtual reality (entertainment). BCI has also been applied in biometrics (Palaniappan & Mandic, 2007).

Figure 1. Main elements of general BCI system



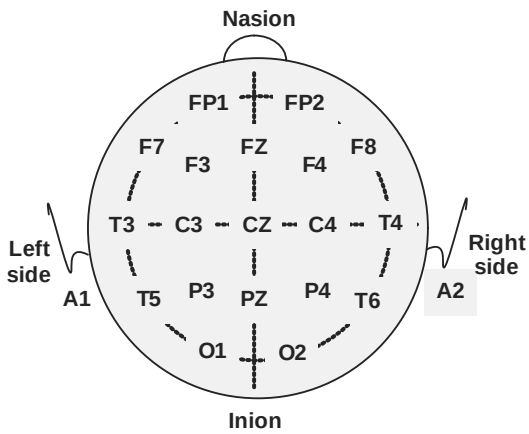
This research area is extremely exciting, and in recent times, there has been an explosive growth of interest in this revolutionary new area of science which would enable computers (and therefore any other reactive device) to be controlled by thought alone—the benefits for the severely disabled would be truly astonishing. For example, in 1990, there were less than 10 groups (mostly in the U.S.) with research interests in BCI; but this has grew to more than 130 groups worldwide in 2004 (Vaughan & Wolpaw, 2006). It is a multidisciplinary field comprising areas such as computer and information sciences, engineering (electrical, mechanical, and biomedical), neuroscience, and psychology. State-of-the-art BCI designs are still very primitive, but because of their potential to assist the disabled, there is an increasing amount of investment in their development.

This article will give an overview of the general elements in a BCI system and existing BCI methodologies, state the current applications of BCI devices in communication system and device control, and describe the current challenges and future trends in BCI technology.

BACKGROUND

In general, a BCI system comprises five stages: data collection, pre-processing, feature extraction, decision making (which includes translation algorithm[1]), and device command. Normally, the pre-processing, feature extraction, and decision-making stages are done using a computer, though a dedicated hardware could be designed for this purpose. Sometimes, these five stages can be simplified to just three: sensor, decoder, and actuator (Hochberg & Donoghue, 2006).

Figure 2. 10-20 electrode placement system



Data Collection Through Electrodes

Subjects will generate brain activity through an experimental paradigm that would depend on the particular BCI approach. The protocol to be followed by the subjects could be thinking about making imaginary movements, focusing on flashing characters on a screen, and so forth. This brain activity will be picked by electrodes (normally Ag/AgCl) placed on the scalp. The placement of electrodes commonly follows the 10-20 system (19 electrodes) or extensions of this system (32, 64, 128, or 256 electrodes). The recordings are normally referenced to the left and/or right mastoids. An example of the 10-20 electrode placement system is shown in Figure 2.

As the recorded signals are in the range of microVolts, amplifiers will be needed to amplify the multi-channel signals. These signals will then be sampled at a suitable frequency (a typical sampling frequency is 256 Hz) using an analogue-to-digital conversion device (nowadays with precision of 16-24 bits per channel). Currently, there are electrodes available that do the first-stage amplification in the electrode itself (which minimizes preparation time). In general, a single portable EEG signal acquisition unit is capable of amplification, sampling, and data transfer to the computer. Figure 3 shows an example of a subject using a BCI device.

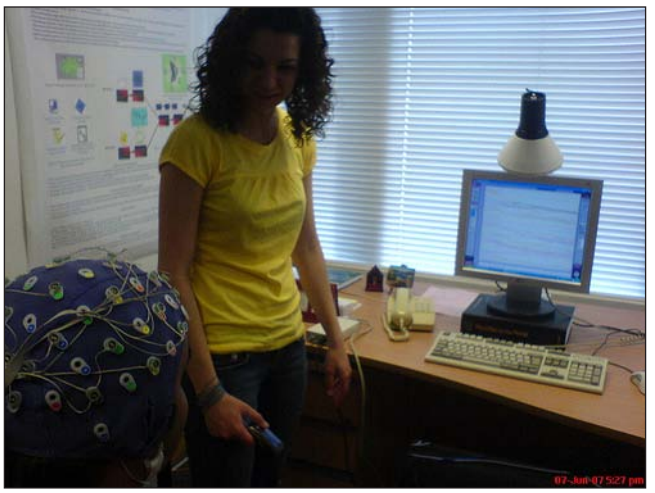
Pre-Processing

These digital EEG data normally contain a lot of noise (artifacts). Some examples of noise sources are 50/60 Hz power line interference, fluorescent lighting, baseline drift (low frequency noise), electrocardiogram (ECG), electromyogram (EMG), and random noise. Simple frequency-specific filtering is normally sufficient to reduce the narrow band noises such as the power line interference, baseline drift, and fluorescent lighting. However, more sophisticated methods such as principal component analysis (PCA) and independent component analysis (ICA) are popular to reduce ECG and EMG noises that have overlapping spectral information with EEG. Another common artifact that corrupts EEG signals is eye blinks; many techniques have been proposed to solve this problem (Thulasidas et al., 2004).

Feature Extraction

Though the raw EEG signal could be used by the next decision-making stage, very often features are extracted from these EEG signals. Depending on the EEG approach used in the BCI, the feature extraction approach would vary. For example, for the mental-activity-based BCI, autoregressive (AR) features have been used (Anderson, Stolz, & Shamsunder, 1998), where Burg's method (Shiavi, 1999) is the common procedure used to estimate the AR coefficients with

Figure 3. Example of a subject using a BCI device



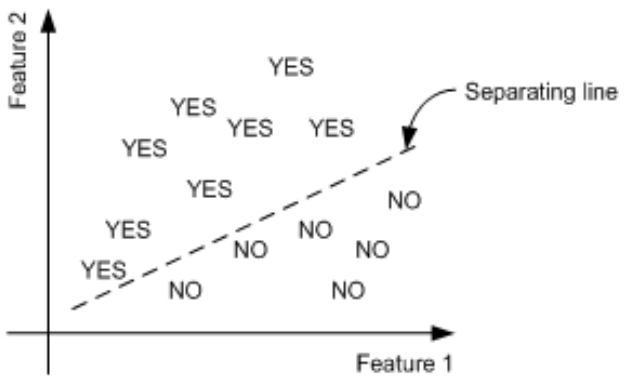
the model order chosen by Akaike Information Criterion (AIC) (Akaike, 1974). When there are inter-hemispheric differences, asymmetry ratio (Keirn & Aunon, 1990) provides to be a good feature extraction method. Some of the other common feature extraction methods are spectral analyses, voltage amplitude measurements, spatial filtering, and single neuron-separation (Wolpaw, Birbaumer, McFarland, Pfurtscheller, & Vaughan, 2002). The features could be in the time domain, such as the P300-evoked potential amplitude (Farwell & Donchin, 1988), or they could be in the frequency domain, using classical or modern spectral analyses—for example, mu or beta rhythm amplitudes (Pfurtscheller & Da Silva, 1999). Joint time-frequency features could also be used (Schalk, Wolpaw, McFarland, & Pfurtscheller, 2000).

Decision Making

This stage normally classifies the features from the previous stage into different categories based on the required device output. For example, for the P300 speller matrix paradigm (Donchin, Spencer, & Wijesinghe, 2000), this stage would classify the features into one of the categories representing the alphanumeric characters. There are several popular classification methodologies that have been explored in BCI: linear classifiers, non-linear classifiers, and Bayesian classifiers.

The most popular linear classifier in BCI design is the linear discriminant analysis (LDA), sometimes known as Fisher's LDA. This classifier uses hyperplanes to separate the

Figure 4. Simple linear separation of two classes: YES and NO



features into different classes (Duda, Hart, & Stork, 2001). For a two-class problem with two features, the boundary is simply a straight line (as shown in Figure 4). It should be noted that a simple binary switch ('YES', 'NO') such as the one shown is capable of generating more complex responses through, say, nested menu icon selection or by using some translation algorithm (such as Morse code).

For classifying several classes, the general strategy is multi-levels of 'one vs. the rest' classification, though one level of multi-class classification is also possible with the generation of several hyperplanes.

LDA is simple to use and in general gives acceptable levels of performance (Lotte, Congedo, Lecuyer, Lamarche, & Arnaldi, 2007), though EEG data is generally non-linear, but its low complexity makes it particularly suitable for online BCI systems. It has been used successfully in motor imagery-based BCI (Pfurtscheller & da Silva, 1999; Tsui, Vuckovic, Palaniappan, Sepulveda, & Gan, 2006), P300 speller matrix (Donchin et al., 2000), mental activity BCI (Huan & Palaniappan, 2004), and asynchronous BCI (Leeb et al., 2007).

The artificial neural network (ANN), typically the multilayer perceptron (MLP) architecture, is one of the most common non-linear classifiers employed in BCI designs (Garret et al., 2003). With enough neurons in the single hidden layer, MLP could approximate any continuous function, thereby being suitable for BCI designs. Typically, the back propagation and its modern variants have been used to train the MLP ANN (Palaniappan, 2004). Some of the other ANNs that have been used in BCI studies are Fuzzy ARTMAP (Palaniappan, Raveendran, Nishida, & Saiwaki, 2002) and learning vector quantization (Pfurtscheller, Flotzinger, & Kalcher, 1993).

A support vector machine (SVM) could be either a linear or non-linear classifier depending on which kernel function is used. SVMs have also been used successfully in several BCI designs: linear SVMs use linear decision boundaries (Rakotomamonjy, Guigue, Mallet, & Alvarado, 2005), while the non-linear ones use Gaussian or radial basis function kernels (Garret et al., 2003).

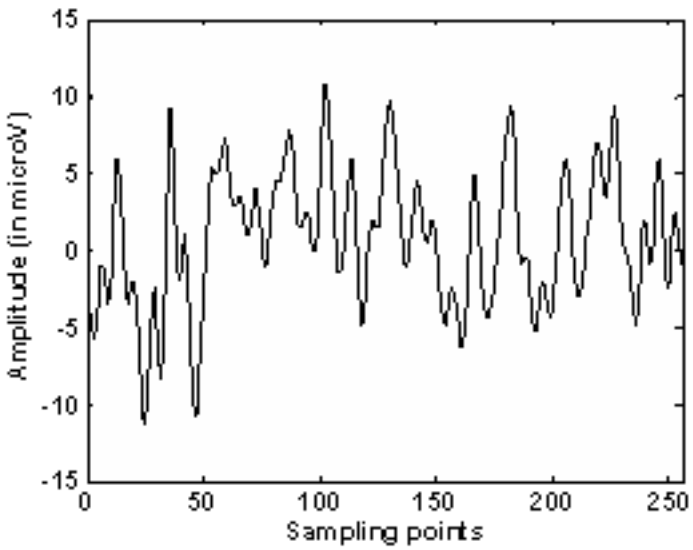
The nearest neighbor classifier is one of the simplest classifiers, but due to its computational complexity (as the distance of every test data from every training data must be computed), it has not seen much use in BCI except in a few studies (Palaniappan & Danilo, 2007; Ravi & Palaniappan, 2005).

Similarly, Bayesian classifiers are also not popular, though they were used successfully in motor imagery (Lemm, Schafer, & Curio, 2004) and mental activity BCI (Keirn & Aunon, 1990). Bayesian classifiers (typically the naïve version that assumes independence of features) use the prior class probability and conditional probability of the training data to estimate the maximum posterior hypothesis (i.e. class) of the test data.

Translation Algorithms

The translation algorithm translates the output of the classifier into meaningful information or command controls. For example, a sequence of mental activity denotes a particular command to move a wheelchair or some code to translate a sequence of imagined movements into English alphabets.

Figure 5. Example of a recorded EEG signal



However, this element is not present nor required for all BCI designs.

Sometimes, there is feedback from the device output to the subject. This will allow the subject to enhance its EEG output to increase the accuracy; this sort of feedback is common during the design of some BCIs like those using slow cortical potential (SCP).

OVERVIEW OF NON-INVASIVE BCI METHODOLOGIES

Basically, the BCI approaches could be either invasive or non-invasive. The non-invasive BCI methods using EEG, magnetoencephalogram (MEG), positron emission topography (PET), functional magnetic resonance imaging (fMRI), and optimal imaging (near-infrared spectroscopy (NIRS)) are more popular than the invasive one based on electrocorticogram (ECoG), though effective due to health hazards posed by the latter (as the electrodes are surgically implanted).

EEG-Based BCI

EEG is the brain's electrical activity recorded using electrodes attached to the scalp; it is the cumulative effect of thousands or more neurons (in the cortex) that are activated during mental processes. It is in the microVolts range due to high attenuation by skull and scalp (so for proper analysis, they have to be amplified). Figure 5 shows an example of a recorded EEG signal.

There are several methodologies for implementing EEG-based BCI: evoked potentials (typically from visual stimulus, though not always), better known as visual evoked potential (VEP) (Donchin et al., 2000; Wang, Wang, Gao, Hong, & Gao, 2006), mental activity (Palaniappan, 2006b), motor imagery (Wolpaw et al., 2002), and SCP (Mensh, Werfel, & Seung, 2002). The VEP approach could be further divided into P300-based VEP (Donchin et al., 2000) and steady state VEP (SSVEP) (Wang et al., 2006).

P300-Based VEP

VEP is a component in EEG that is evoked in response to an external visual stimulus like visualizing a picture or flash of light. The recorded signal consists of spontaneous EEG and VEP, where the spontaneous EEG is many times higher in amplitude as compared to VEP. Hence, measures like averaging from many trials are needed to obtain a reliable enough VEP. In recent years, principal component analysis (Palaniappan & Ravi, 2006) and independent component analysis (Palaniappan, 2006a) have been suggested for separating VEP from EEG in single trials.

P300 (or P3) is the third positive component in VEP (see Figure 6), and it is maximal in midline (like locations Cz, Pz, Fz, etc). It is evoked in a variety of decision-making tasks and, in particular, when a target stimulus is recognized. It is evoked around 300 ms after stimulus onset, and in general, P300 components encountered for BCI purposes are limited to 8 Hz.

Typically, the oddball paradigm is used to evoke P300 (Polich, 1991). In this paradigm, a target stimulus that oc-

Figure 6. Commonly encountered VEP components

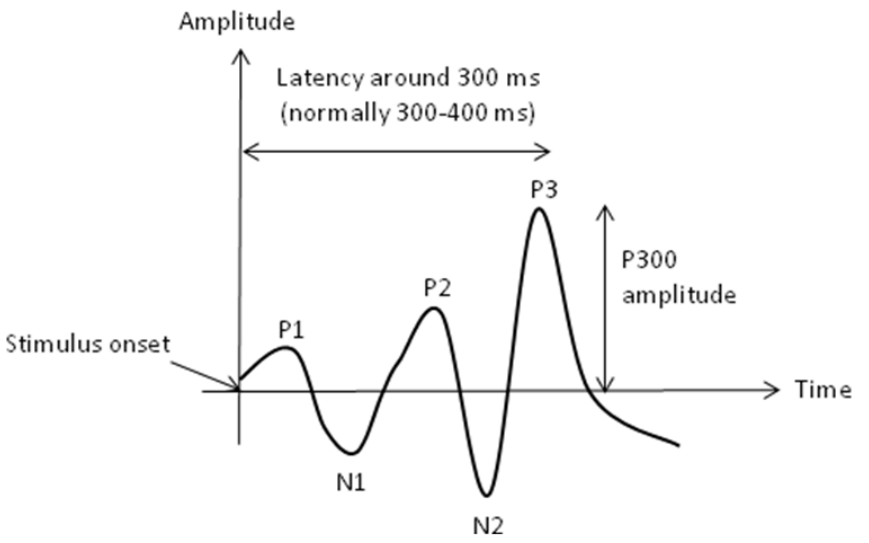


Figure 7. Onscreen display for speller matrix paradigm (Donchin et al., 2000)

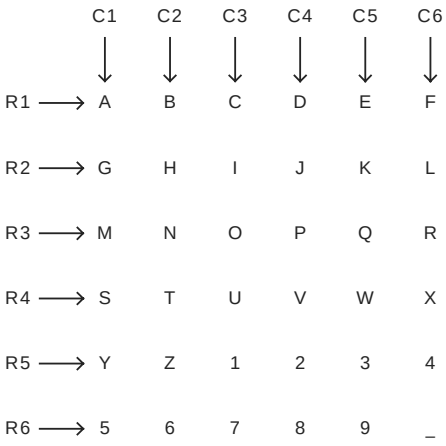

curs infrequently compared to a non-target stimulus will evoke P300. In P300-VEP BCI designs (Donchin et al., 2000), a variation of this paradigm is used: spelling matrix or Donchin paradigm. In this paradigm, the screen consists of alphanumeric characters. Spontaneous EEG plus VEP is recorded when rows and columns flash, where each trial consists of 12 flashes and trials are repeated, typically 15, 20, or 40 times. Averaging from trials is performed to reduce unrelated spontaneous EEG from VEP. Normally, a low-pass filter (LPF) with cut-off at 8 Hz is used, and P300 peak detected around 300-400 ms (sometimes, other ranges like 300-500 or 400-600 ms are also used) and amplitude of P300 peak stored for analysis. The row and column containing the target (focused) character will have a higher P300 amplitude compared to the row or column that does not contain the target character. Figure 7 shows the onscreen display in this paradigm, while Figure 8 shows an example of real averaged VEP signals from 12 flashes obtained from a subject, where the focused target character is N (row 3, column 2). The abscissa is the amplitude of the VEP (in microVolts) and ordinate is the time (in seconds) after stimulus onset.

Mental-Activity-Based BCI

In this BCI design (Keirn & Aunon, 1990; Palaniappan et al., 2002; Palaniappan, 2006b), EEG signals are recorded when users think of different mental tasks covering a wide range of cognitive abilities (without any vocalizing or physical movements). Some examples of used mental tasks include:

- *Baseline*—Subjects relax and think of nothing in particular.
- *Letter Composing*—Subjects mentally compose a letter to someone.
- *Math*—Subjects do nontrivial multiplication problems, such as *42 x 18*.
- *Visual Counting*—Subjects visually imagined sequential numbers being written on a blackboard with the previous number being erased before the next number is written.
- *Geometric Figure Rotation*—Subjects imagine a figure being rotated around an axis.

These four active mental tasks (i.e., excluding baseline tasks) exhibit inter-hemispheric differences. For example: math tasks utilize more processes in the left hemisphere as compared to visual tasks that utilize more processes in the right hemisphere.

One useful measure to detect the activated hemisphere is through asymmetry ratio (AS) (Keirn & Aunon, 1990):

Figure 8. An example of real averaged VEP signals from 12 flashes (the focused target character is from row 3, column 2: N)

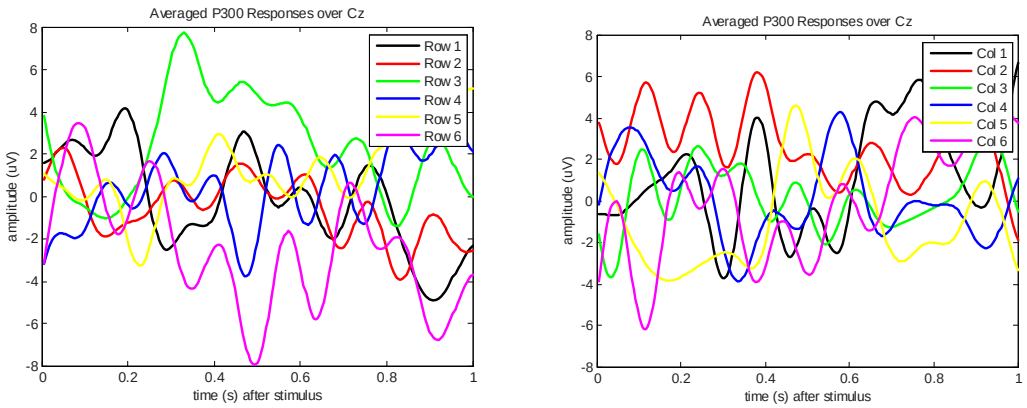

Figure 9. Some example of mental tasks

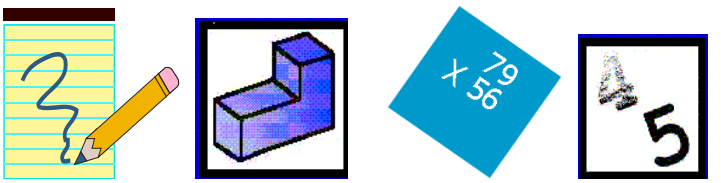
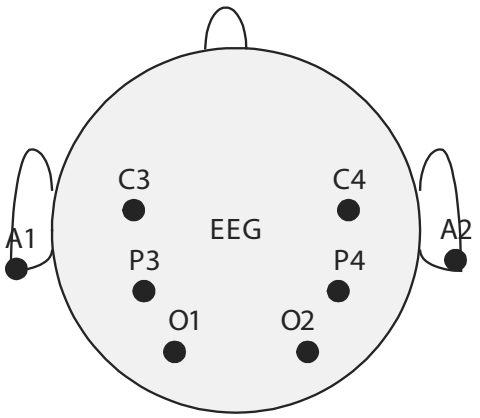


$$AS = \left[\frac{E_1 - E_2}{E_1 + E_2} \right], \quad (1)$$

where E_1 is the energy in one EEG channel in the left hemisphere and E_2 is the energy of EEG in another channel but in the right hemisphere. For example, for the electrodes shown in Figure 10, AS using channels (electrodes) O1 and O2 will be positive for maths activity as compared to object rotation (visual) activity. AS for baseline tasks will be near zero. So we can use baseline (B) and two tasks—maths (M) and object rotation (O)—to construct a communication method using a translation algorithm.

Here, translation algorithm translates the sequence of detected mental tasks into a command/output. For example, for wheelchair movement: task sequence MBO could denote 'turn left', while task sequence OBM could denote 'turn right'. For communication purposes, Morse code could be used to translate the sequence of mental tasks into alphabets. For example, letter I in Morse code is 'dot dot', so the sequence of mental tasks: OBOB or (MBMB) could denote letter I, where the baseline denotes the end and start of a new mental task (except for the first mental task). Figures 11 and 12 illustrate the use of this translation algorithm.

Figure 10. Electrode locations to illustrate AS



SSVEP BCI

SSVEP is the response due to a visual stimulus modulated at a frequency higher than 6 Hz. It is maximum in the visual cortex, specifically in the occipital region. In this design, each onscreen target flickers with a specific frequency, and a photic driving response in the brain causes the frequency (and its harmonics) to appear in SSVEP. In other words, the onscreen "flickers" drive a photic response (with corresponding frequencies) in the optical regions of the brain. So, determination of SSVEP frequency (through spectral analysis like Fourier methods) is enough to decide on the focused target. An example of the onscreen display for dialing telephone numbers is shown in Figure 13.

The flicker frequency selection can be up to 45 Hz; in general the higher frequency is better as this causes less strain on the eyes of the user (Wang et al., 2006). For example, for the onscreen telephone keypad as in Figure 13, the flicker frequencies could be in 1 Hz intervals: 1 (9 Hz), 2 (10 Hz), 3 (11 Hz), ……0 (16 Hz), # (17 Hz). In the work by Wang et al (2006), normalized fast Fourier transform (FFT) magnitude is computed from four seconds of SSVEP. Peak detection (above a certain threshold) is used to determine the frequency. Once detected, the number appears onscreen and the subject moves on to look at another number.

Generally, harmonics should be avoided (e.g., if 9 Hz is used for a block, integer multiples of this such as 18, 27, 36, or 45 Hz should not be used). However, recently Muller-Putz, Scherer, Brauneis, and Pfurtscheller (2005) showed that using harmonics could improve the detection of the focused target.

Motor Imagery BCI

In this approach, BCI is designed using imaginary movements, that is, when the subject imagines moving a limb (could be arm, leg, tongue, etc). An actual voluntary movement is composed of three phases: planning, execution, and recovery. But it is known that even during imaginary movement (motor imagery), there is the planning stage.

During planning, event-related desynchronization (ERD) and event-related synchronization (ERS) occur in μmeter[2] (alpha, 10-12 Hz) and beta (12-14 Hz) frequency ranges. ERD is the attenuation in EEG in primary and secondary

Figure 11. The requirement of space in addition to dot to construct the letter I (Palaniappan et al., 2002)

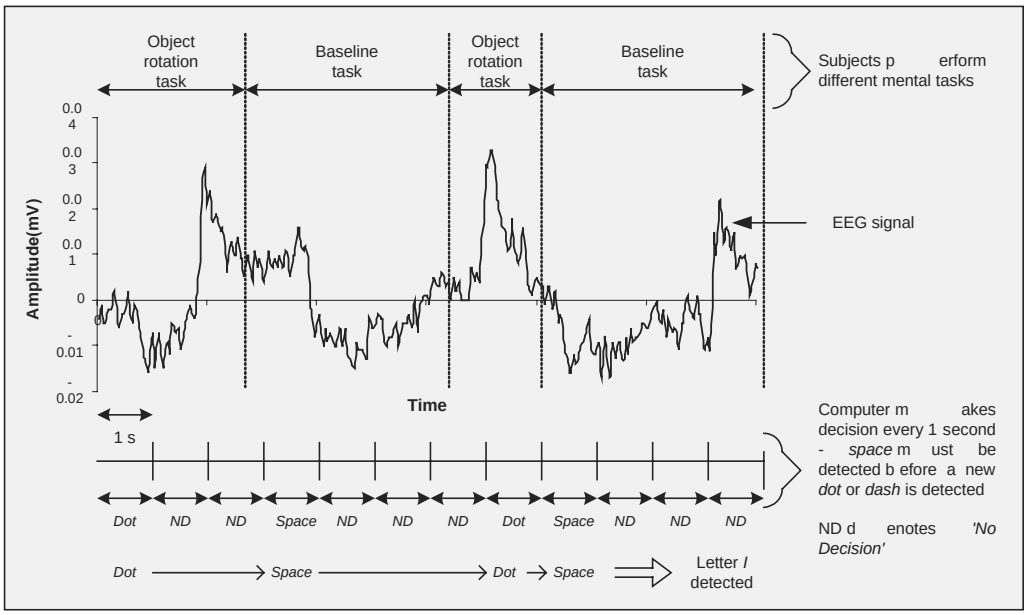


Figure 12. Schematic examples of the word 'EAT' constructed using tri-state Morse code scheme (Palaniappan et al., 2002)

Letter	Morse Code	Corresponding Mental Tasks

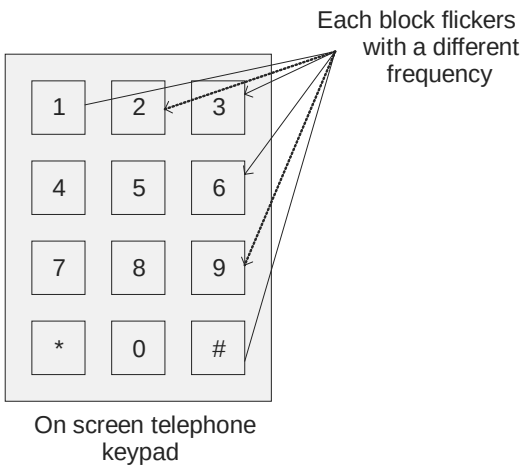
A	● —	Letter, baseline, count, baseline
T	—	Count, baseline

Figure 13. Onscreen display using SSVEP BCI design to dial telephone numbers



motor cortices during the preparatory stage which peaks at movement onset in contralateral hemisphere (e.g., left-hand motor imagery, ERD in the right side of the brain), while ERS is the corresponding EEG amplification but in an ipsilateral hemisphere. The ERD/ERS can be computed using power values by squaring the samples in the frequency ranges or using some power spectral density (PSD) measure (Pfurtscheller & Da Silva, 1999). In addition to these changes in alpha and beta frequency ranges, there is also the gamma burst, which is a sharp increase in EEG in the gamma (36-40 Hz) frequency range. Figure 15 shows an example of these ERD/ERS and gamma bursts.

One simple method to implement this paradigm is shown in Figure 16. Here, the subject imagines moving his or her left or right hand. Discrimination of these imagined movements can be used for a BCI design. This could be done by computing the PSD of EEG in C3, C4, and CZ. Next, the sum of PSD (SPSD) is computed. If $C3_{SPSD}$-CZ_{SPSD} > $C4S_{SPSD}$-CZ_{SPSD}, then it is a left-hand motor imagery; if $C4_{SPSD}$-CZ_{SPSD}

Figure 14. Normalized amplitude spectra corresponding to different data lengths. The 'number' focused here is '#', as there is a clearly defined peak at 17 Hz (Wang et al., 2006).

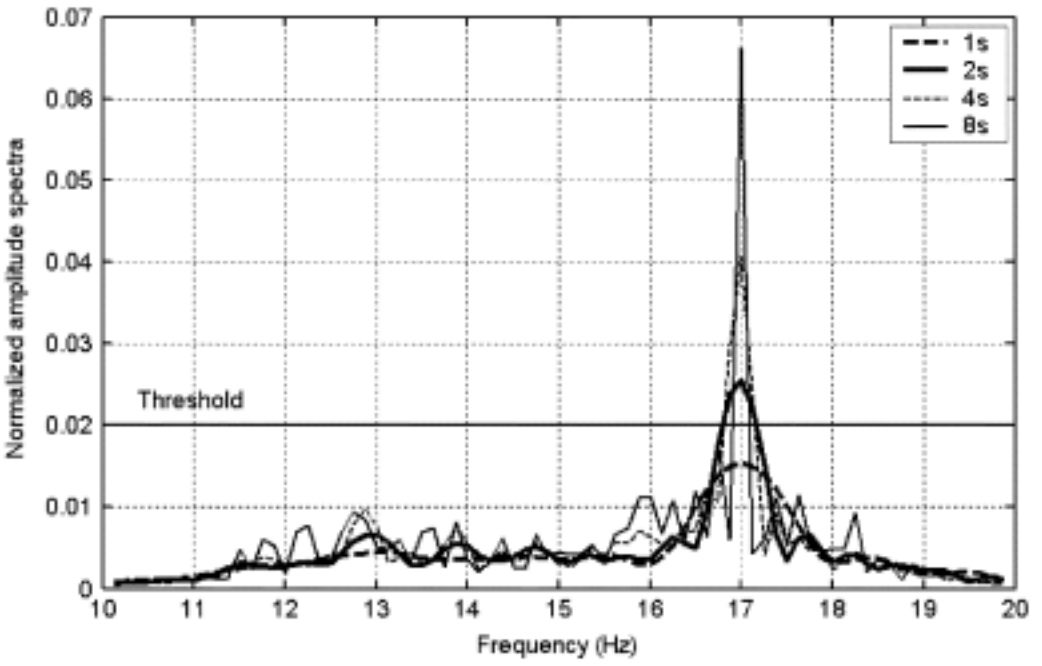


Figure 15. ERD/ERS and gamma bursts (Durka, Ircha, Neuper, & Pfurtscheller, 2001)

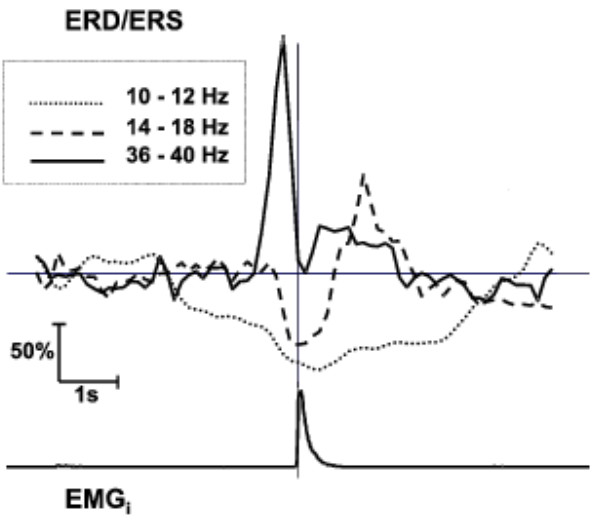

> $C3_{SPSD}$-CZ_{SPSD}, it is a right-hand motor imagery, and if $C4_{SPSD}$-$CZ_{SPSD} \approx C3_{SPSD}$-$CZ_{SPSD}$, then it denotes that no motor imagery has been detected.

SCP BCI

SCP is the potential shift in EEG (around 1-2 Hz) which can last several seconds. Humans can control SCP using feedback and a positive reinforcement mechanism, where the negativity SCP can be generated with tasks such as readiness to move or mobilization of resources for cognitive tasks, and the positivity SCP can be generated during execution of cognitive tasks or simply in inactive states. Self-regulation of SCP can be used to generate a binary signal or even menu/letter selection on screen for use in BCI designs. But the main problem with this approach is that it requires extensive training, typically a few months (Hinterberger et al., 2004).

Other Non-Invasive BCIs

Though the focus of this article is not on non-EEG-based BCIs, a short discussion on other current non-invasive BCIs would be useful and is given here.

PET-based BCI is where a tracer medium (radioactive isotope with short half life) is injected in blood. This tracer

Figure 16. ERD/ERS from left/right-hand motor imagery

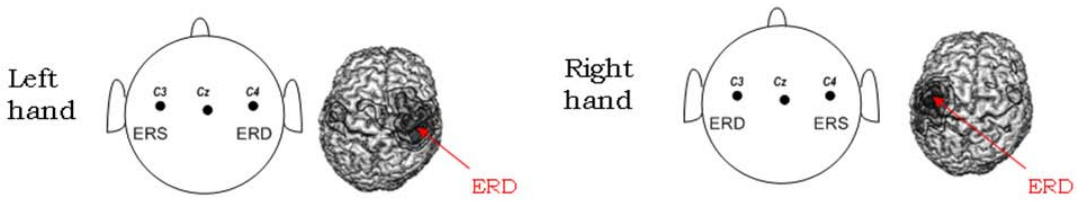

Figure 17. Negativity and positivity from SCP EEGs (Hinterberger et al., 2004)

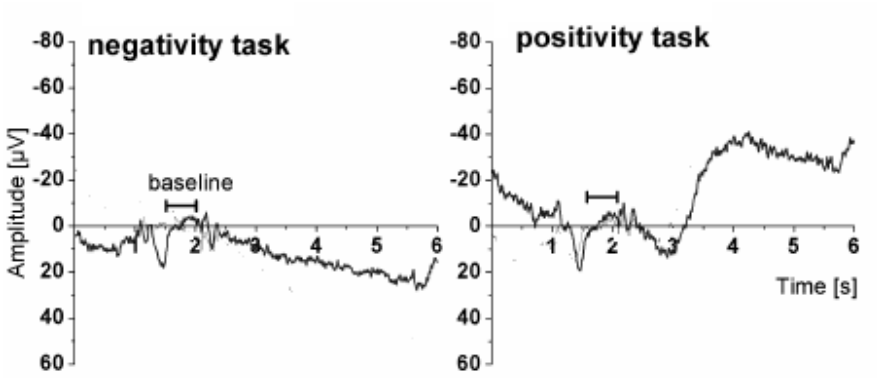

medium moves in blood and decays by emitting a positron, and gamma photons are generated when the positron annihilates with an electron. A special scanner measures these gamma photons. So, changes in blood flow due to specific brain activity could be detected. For example, in a subject thinking of moving his or her right hand, brain activity will be detected in the left hemisphere, and vice versa. This detected brain activity could be translated for BCI applications. It is not popular as the equipment is too expensive and bulky where a cyclotron is needed for generation of tracer medium. It is also partially invasive (as it requires radioactive injection), though no surgery is involved. Furthermore, the waiting period is typically an hour before the system can be used and not suitable for continuous usage.

fMRI-based BCI detects oxygen-level changes in blood hemoglobin which generates magnetic resonance. The resulting image intensity variations show the brain activation areas, and this could be translated for BCI application. This is also not popular as it requires a bulky scanner (hence no mobility for subjects) and the vascular response is too slow—local response to this oxygen utilization occurs after a delay of approximately 1-5 seconds, with peaks at 4-5 seconds; in addition there is the possible detrimental effects due to prolonged exposure.

NIR-based BCI is a relatively new method that uses the near infra-red region of the electromagnetic spectrum (from about 800 nm to 2500 nm). The penetration is deeper into the skull as it uses NIR; NIR light is emitted and the reflection from the blood cells (specifically, oxygen level in hemoglobin) is used as a measure of blood flow. This blood flow denotes activation of brain areas (activation deduced from images with higher reflectance intensity). This procedure is sometimes known as an optical method, as NIR produces intensity images. Mobility is not limited (unlike fMRI) as the sensor-detector can be fixed on the skull, but its main hindrance is the slow vascular response (on the order of a few seconds). Also, though most NIR energy is reflected, a small portion of NIR energy might be absorbed by the brain cells and potentially be damaging in the long run.

MEG-based BCI is similar to EEG but uses measurements of magnetic fields rather than electric fields. The magnetic field generated by the brain is measured outside the scalp. The temporal resolution is better than EEG, but not popular due to high cost and difficulty in obtaining proper MEG readings as ultra-sensitive magnetic field detectors are needed. Mobility is also restricted, and shielding from other magnetic sources is also necessary which inhibits usage outside the lab environment.

BCI APPLICATIONS

One of the most important BCI applications is restoring control functions to those with motor impairments caused by progressive disorders such as amyotrophic lateral disorder (ALS), muscular dystrophy, and multiple sclerosis, and non-progressive disorders such as brainstem stroke, traumatic brain injury, spinal cord injury, and numerous orders that impair the neural pathways preventing proper muscle control. But BCI devices can also be developed for everyday use by the healthy population, though this is not its main use.

Individuals with Motor Disabilities

Severely affected individuals may lose all forms of voluntary muscle control. However, these individuals are able to survive with modern life technology support, but are completely 'locked-in' without any ability to communicate at all. The use of EEG-based BCI technologies can offer these individuals an alternative mode of communication. A typical example of a communication BCI system would be brain-controlled word processing software.

These technologies could also aid the disabled in restoring mobility (controlling wheelchair movement); environmental control (controlling TV, power beds, thermostats, etc); prosthetics control (motor control replacement, controlling artificial limbs); and rehabilitative (assistive) control—to restore motor control (strengthen or improve weak muscles).

Other Applications

The general population might also benefit from BCI devices. A simple example is environmental control (hands-off control), for example, control of external devices without using the external limbs (hand/legs). Other examples are in areas such as virtual reality (entertainment), for example, computer games like Mind Pacman (Krepki, Blankertz, Curio, & Müller, 2007). Recently, BCI has also been studied for use by astronauts in space, for example when they become temporarily paralyzed or to control devices in severely restricted extra terrestrial environments (Menon et al., 2007).

Biometrics is yet another recent application of BCI where BCI devices are used to identify an individual (Palaniappan, 2004) or authenticate an individual using thoughts alone (Palaniappan & Danilo, 2007). It is very useful for high-security individual identification applications, as EEG-based biometrics is more fraud resistant compared to other biometrics like fingerprints, iris scans, retina, ear shape, odor, and so forth (since thoughts cannot be forged!). EEG-based biometric verification is also more secure than personal identification numbers (PINs) and passwords, which can be easily compromised through shoulder surfing or other means. For example, the BCI device used to spell alphabets (Donchin et al., 2000) can actually be adapted to generate passwords that are based on thoughts alone.

CURRENT CHALLENGES

There are numerous current challenges for BCI designs. The following descriptions are not exhaustive but serve to illustrate some of the issues facing this research field that is still very much in its infancy.

It is not clear how the BCI designs will require adaptation for real users (like disabled people) and in real noisy environments. Most of the BCI research studies are conducted in laboratory environments where the condition is ideal. For example, the BCI experiments at the University of Essex are conducted in the BCI laboratory where there is special lighting with an electromagnetic radiation shield and under noise-free conditions. However, it should be remembered that the main BCI users will be disabled individuals, who will use the devices in a not ideal environment. So, it is important to realize that the high performances obtained in the laboratory are unlikely to be repeated in the real world. Another similar issue is that a large number of BCI studies are tested using healthy subjects (typically university students), and BCI systems may not perform up to expectation when used by disabled individuals and will require special adaptations.

A BCI system cannot be 'on' all the time. So we will need to separate algorithms to turn on or off the devices. In recent years, studies that combine the required BCI output and this on/off state recognition have been explored. These systems are known as asynchronous or self-paced BCI.

The current maximum information transfer rate for BCI systems is about 25 bits per second (Wolpaw et al., 2002), and even this—'still slow' for practical performance—is normally achieved only after extensive training or fine tuning. Improved systems are needed so that they are more accurate and give faster response. It may not be possible to train a disabled individual, and so systems that do not require any prior training and ease of use will be needed as well.

In general, most of the BCI systems are fine tuned for specific subjects. This results in individual BCI and not universal BCI, which is a problem as it may not be possible for fine tuning in disabled individuals. Therefore, universal BCIs should be explored more extensively.

Since BCI research is relatively new, it is not evident on the long-term effects of these systems on the user's health and if the performance would be stable across time.

Ethics is especially an issue of using (or testing) BCI with those already paralyzed. For example, it is difficult to decide if the permission from a responsible nearest relative of a completely disabled subject is sufficient or even appropriate to conduct experiments with the disabled subject.

FUTURE TRENDS

The solutions for all the issues discussed in the previous section will need to be explored—of course, some of these are already under consideration. For example, the use of active electrodes[3] simplifies the set-up and minimizes the preparation time. Also, dry electrodes (which do not require any wet gel to achieve the necessary impedance) are being investigated, as this will allow 24/7 use by subjects (especially the disabled).

Advancement in BCI algorithms related to signal preprocessing, feature extraction, and classification will need to be explored to maximize the accuracy while achieving a quicker response. Further, other more suitable paradigms should be explored for BCI designs.

CONCLUSION

Of the non-invasive BCI methods, EEG-based ones are the most common due to low cost and portability. Furthermore, only EEG has relatively short time constants (for rapid responses) compared to others like PET, fMRI, and NIRS (Wolpaw et al., 2002).

Each EEG-based BCI approach method has its own advantages and disadvantages. For example, some methods do not require prior user training like P300-VEP, but this method requires many trials, so has a slower response. Motor imagery BCI has faster response, but performance is not satisfactory without prior user training. Methods based on SSVEP have been shown to be successful using only one active channel (Wang et al., 2006), but require users to gaze at flashing blocks, which is only practical for short time use (typically a few minutes). Mental activity BCI tasks have fast response and do not require any visual interface, but performance is not stable over time. SCP-based BCI requires extensive training, but once mastered, performance is relatively stable.

Overall, EEG-based BCI is the most practical, portable, and cheap enough approach. A multidisciplinary approach involving clinicians (neurologists, physiatrists, psychologists), engineers, computer scientists, neuroscientists, and so forth is required to successfully design complete working BCI systems, which is probably realizable in a decade or so. With adequate engagements from the experts in these areas, BCI systems could be developed to provide an important mode of communication and control for those with severe disabilities, and in addition, to those without any disability for use in special environments.

KEY TERMS

Biometrics: Identification or authentication of the individuality of a person using the behavioral or physiological characteristics of the person.

Brain-Computer Interface/Brain-Machine Interface (BCI/BMI): Devices that use electroencephalogram signals to perform a communication or control action.

Electrodes (channels): Sensors normally made of Ag/AgCl that are used to record electroencephalogram.

Electroencephalogram (EEG): Brain activity obtained as recorded signals from the scalp using electrodes.

Mental Activity/Task: Any task that generates EEG for use in BCI designs.

Motor Imagery: Used in BCI designs where subjects imagine moving a limb.

P300 Component: The third positive component in visual evoked potential; normally evoked around 300 ms after stimulus onset.

Slow Cortical Potentials: The potential shifts in EEG (around 1-2 Hz), which can last several seconds.

Steady State VEP: A type of VEP caused by photic response (frequency following effect).

Visual Evoked Potential (VEP): An EEG component that is in response (i.e., evoked) by a visual stimulus modality.

ENDNOTES

1 This algorithm translates the decision system output into usable information or action.

2 A frequency range that is similar to alpha but occurs during actual movement/motor imagery.

3 Active electrodes have miniscule chips that are able to reduce noise caused by poor skin contact, thereby circumventing the necessity to clean the scalp prior to electrode attachment.

Customer Relationship Management and Knowledge Discovery in Database

INTRODUCTION

Customer relationships are increasingly central to business success (Kotler, 1997; Reichheld & Sasser, 1990). Acquiring new customers is five to seven times costlier than retaining existing customers (Kotler, 1997). Simply by reducing customer defections by 5%, a company can improve profits by 25% to 85% (Reichheld & Sasser, 1990). Relationship marketing—getting to know customers intimately by understanding their preferences—has emerged as a key business strategy for customer retention (Dyche, 2002).

Internet and related technologies offer amazing possibilities for creating and sustaining ideal customer relationships (Goodhue, Wixom, & Watson, 2002; Ives, 1990; Moorman, Zaltman, & Deshpande, 1992). Internet is not only an important and convenient new channel for promotion, transactions, and business process coordination; it is also a source of customer data (Shaw, Subramaniam, Tan, & Welge, 2001). Huge customer data warehouses are being created using advanced database technologies (Fayyad, Piatetsky-Shapiro, & Smyth, 1996).

Customer data warehouses by themselves offer no competitive advantages: insightful customer knowledge must be extracted from such data (Kim, Kim, & Lee, 2002). Valuable marketing insights about customer characteristics and their purchase patterns, however, are often hidden and untapped (Shaw et al., 2001). Data mining and knowledge discovery in databases (KDD) facilitate extraction of valuable knowledge from rapidly growing volumes of data (Mackinnon, 1999; Fayyad et al., 1996).

This article provides a brief review of customer relationship issues. The article focuses on: (1) customer relationship management (CRM) technologies, (2) KDD techniques, and (3) Key CRM-KDD linkages in terms of relationship marketing. The article concludes with the observations about the state-of-the-art and future directions.

BACKGROUND

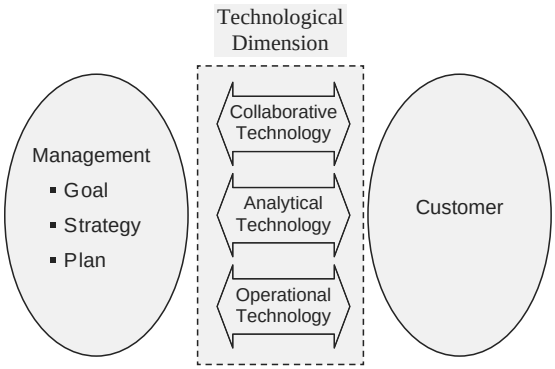
CRM Technologies

CRM is interpreted in a variety of ways (Goodhue et al., 2002; Winer, 2001; Wright, 2002). In some cases, CRM simply entails direct e-mails or database marketing. In other cases, CRM refers to CICs (customer interaction centers) and OLAP (online analytical processing), which is referred to as various types of online query-driven analyses for examining stored data. Overall, CRM can be seen as a core business strategy to interact with, create, and deliver value to targeted customers to improve customer satisfaction and customer retention at a profit. It is grounded in high quality customer data and enabled by information technology (Ang & Buttle, 2002).

Three core dimensions characterize buyer-focused CRM systems: customers, management, and technologies. *Customer* service and related issues must be included in the design, implementation, and operation of any CRM system. Organizations benefit from CRM only when such systems benefit their customers—using CRM merely as a sales or customer service solution is a recipe for failure (Davids, 1999). *Management's* articulation and tracking of customer relationship goals, plans, and metrics is an essential CRM component (Ang & Buttle, 2002; Greenberg, 2002). Successful CRM implementations rely on management goals, strategies, and plans that reflect customer commitment and promote a customer-responsive corporate culture at all levels of the organization (Ang & Buttle, 2002; Smith, 2001). *Technologies* for facilitating collaborative, operational, and analytical CRM activities are the manifest aspects of CRM (Goodhue et al., 2002).

Collaborative CRM systems refer to any CRM function that provides a point of interaction between the customer and the marketing channel (Greenberg, 2002). Web-based

Figure 1. Alignment of three dimensions of CRM



Internet, and in some cases mobile commerce systems, offer multiple "touch points" for reaching the customers. In employing the Web and mobile technologies, it is important to ensure that such technologies enhance older, preexisting channels (Johnson, 2002). *Operational CRM* systems refer to technologies that span the ordering-delivery cycle (Goodhue et al., 2002). Operational CRM is concerned with automating the customer-facing parts of the enterprise (Ang & Buttle, 2002). Since the sales process depends on the cooperation of multiple departments performing different functions, integration of all such functions is critical for operational CRM systems (Earl, 2003; Greenberg, 2002). *Analytical CRM* systems analyze customer data warehouses so that the firm can detect valuable patterns of customers' purchasing behavior. Off-line data mining of customer data warehouses as well as online analytical processing (OLAP) can aid in applications such as campaign management, churn analysis, propensity scoring, and customer profitability analysis (Goodhue et al., 2002). It is this component of CRM that has a clear linkage to KDD methods.

KDD Techniques

Since multiple data formats and distributed nature of knowledge on the Web make it a challenge to collect, discover, organize, and manage CRM-related customer data (Shaw et al., 2001), KDD methods are receiving attention in relationship marketing contexts (Fayyad et al., 1996; Mackinnon, 1999). Massive databases are commonplace, and they are ever growing, dynamic, and heterogeneous (Mackinnon & Glick, 1999). Systematic combining of data mining and knowledge management techniques can be the basis for advantageous customer relationships (Shaw et al., 2001).

KDD is defined as the process of data selection, sampling, pre-processing, cleaning, transformation, dimension reduction, analysis, visualization, and evaluation (Mackinnon, 1999). As a component of KDD (Fayyad et al., 1996), data mining can be defined as the process of searching and analyzing data in order to find latent but potentially valuable information (Shaw et al., 2001).

KDD constitutes the overall process of extracting useful knowledge from databases. It is a multidisciplinary activity with the following stages (Brachman, Khabaza, Kloesgen, Piatetsky-Shapiro, & Simoudis, 1996; Bruha, Kralik, & Berka, 2000; Fayyad et al., 1996):

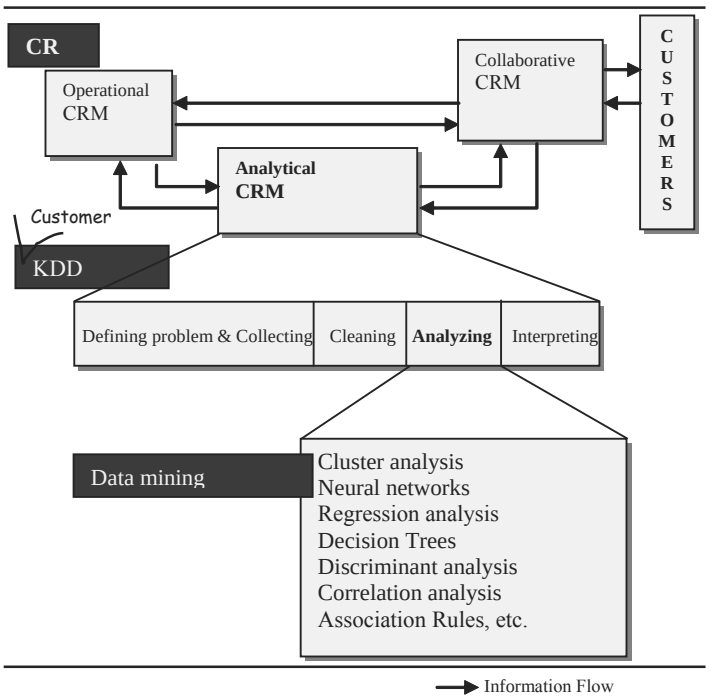
- Selecting the problem area and choosing a tool for representing the goal to be achieved
- Collecting the data and choosing tools for representing objects (observations) of the dataset
- Preprocessing of the data: integrating and cleaning data
- Data mining: extracting pieces of knowledge
- Post-processing of the knowledge derived: testing and verifying, interpreting, and applying the knowledge to the problem area at hand

In Web-based relationship marketing, three distinct categories of data mining have emerged: Web content mining, Web structure mining, and Web usage mining (Jackson, 2002). Web usage mining is also referred to as clickstream analysis (Edelstein, 2001). Valuable information hidden in the clickstream data of many e-commerce sites can provide sharp diagnostics and accurate forecasts, allowing e-commerce sites to profitably target and reach key customers (Moe & Fader, 2001). Therefore, many detailed studies have been conducted on Web usage mining. For example, Web access pattern tree (WAP-tree) mining is one of the sequential pattern mining techniques for Web log access sequences (Ezeife & Lu, 2005).

Such Web-based CRM systems require large, integrated data repositories and advanced analytical capability. Even though there are many success stories, Web-based CRM projects continue to be expensive and risky undertakings. OLAP refers to the various types of query-driven analysis for analyzing stored data (Berry & Linoff, 1997). Data mining and OLAP can be seen as complementary tools (Jackson, 2002). Both Web-based CRM systems and OLAP, in general, involve vast volumes of both structured and unstructured data. One common challenge with managing this data is to incorporate unstructured data into a data warehouse. Traditional database systems are not designed for unstructured data.

Research in KDD in general is intended to develop methods and techniques to process a large volume of unstructured data in order to retrieve valuable knowledge (which is "hidden" in these databases) that would be compact and abstract, yet understandable and useful for managerial applications (Bruha et al., 2000).

Figure 2. CRM and KDD process connection



STRENGTHENING CRM-KDD LINKAGES

Figure 2 explains the CRM-KDD linkage from a process point of view. As explained previously, the importance of gaining knowledge has been well recognized. In line with this notion, CRM starts with understanding customers and gaining in-depth knowledge about customers. Therefore, the intersection between KDD and CRM can be seen as the analytical CRM part of CRM systems and customer knowledge discovery in database process of overall KDD process as shown in Figure 2. Collaborative CRM systems help collect accurate information from customers, while operational CRM can capitalize on the result of the analyses. The problem definition stage of KDD process can be done also in the management dimension of CRM. Following the definition of KDD and data mining, techniques for data mining are included under the analysis stage of KDD.

Turning to the relationship marketing issues, with help of CRM and KDD technologies, database marketing and one-to-one marketing methods have come to the fore. Direct and database marketing methods can be regarded as powerful instruments to achieve CRM goals even though CRM is not a sub-task of direct and database marketers (Wehmeyer, 2005). The strategic goal of database marketing is to use collected information to identify customers and prospects as individuals and build continuing personalized relationships with them, leading to greater benefits for the individuals and greater profits for the corporation (Kahan, 1998). Database marketing anticipates customer behavior over time and reacts to changes in the customer's behavior. Database marketing identifies unique segments in the database reacting to specific stimuli such as promotions (McKim, 2002).

One-to-one marketing represents the ultimate expression of target marketing—market segments with just one member each—or at least one at a time (Pitta, 1998). It relies on a two-way communication between a company and its customers to enhance a true relationship and allows customers to truly express the desires that the company can help fulfill (Dyche, 2002). A promising solution to implementing one-to-one marketing is the application of data mining techniques aided by information technology. Data mining allows organizations to find patterns within their internal customer data. Whatever patterns are uncovered can lead to target segmentations. Armed with such information, organizations can refine their targets and develop their technology to achieve true one-to-one marketing (Pitta, 1998).

As an extension of one-to-one marketing, the concept of permission marketing is focused on seeking customers' consent about desired marketing methods. Customers not only need to be communicated with as individuals, but they themselves should also be able to stipulate how and when they wish to be approached (Newell, 2003). One-to-one and permission marketing rely heavily on information technology to track individual customers, understand their differences, and acknowledge their interaction preferences (Dyche, 2002).

Table 1. Customer relationship related data analysis and data mining tools

	CUSTOMER RELATIONSHIP MARKETING ISSUES		
	Database Marketing	One-to-One Marketing	Permission Marketing
Issue	Understanding customers with the database on customer behavior over time including reactions to changes	Communicating with customers as individuals Developing custom products and tailored messages based on customers' unspoken needs	Seeking customers' agreement about desired marketing methods
Challenge	Identifies unique segments in the database	Find patterns within the internal customer data. Track individual customers Understand their differences	Track individual customers Understand their differences Acknowledge their interaction preferences Stimulate the customer's response
Possible analysis	Segmentation	Classification Prediction	Classification Dependency Analysis
Data mining technique most likely used	Descriptive and visualization Cluster analysis Neural networks	Regression analysis Neural networks Decision Trees Discriminant Analysis	Descriptive and visualization Neural networks Regression analysis Correlation analysis Decision Trees Discrimination analysis Case-based reasoning Association Rules

Data mining methods allow marketers to sift through growing volumes of data and to understand their customers better. Shaw et al. (2001) introduced three major areas of application of data mining for knowledge-based marketing: (1) customer profiling, (2) deviation analysis, and (3) trend analysis. Also, Jackson (2002) noted that data mining can be used as a vehicle to increase profits by reducing costs and/or raising revenue. Some of the common ways to use data mining in customer relationship contexts include:

- Eliminating expensive mailings to customers who are unlikely to respond to an offer during a marketing campaign.
- Facilitating one-to-one marketing and mass customization opportunities in CRM.

In sum, many organizations use data mining to help manage all phases of the customer lifecycle, and CRM systems can benefit from well-managed data analysis based on data mining. Table 1 summarizes the relationship marketing issues, and includes the possible customer analyses and relevant data mining techniques.

Though data mining can be very useful in finding hidden patterns, there are important notions to keep in mind.

First, it is important to note that KDD and data mining involve continuous human-computer interactions (Firestone, 2005). Data mining is not like a simple easy button. It is the skills and background knowledge of humans that will make a difference in the performance of data mining and KDD. For example, Firestone (2005) argued that the quality of information in the data warehouse is critical. Records and information management managers can enhance the performance of KDD process with the ability to create information that can lead to new knowledge by interpreting and evaluating.

Second, a fit between information technology (IT) in an organization and organizational strategy and marketing requirement is required (Wehmeyer, 2005). Relationship marketing and CRM have been mainly discussed at a strategic level (Wehmeyer, 2005). Therefore, rather than separated marketing support technologies functioning only for itself, there should be a fit (Venkatraman, 1989) between IT support and marketing requirements at the operational as well as at the strategic level to design successful IT-enhanced marketing processes (Wehmeyer, 2005).

FUTURE TRENDS

Due to the advance of information technology, there are more opportunities to collect the data about customers. The Internet provides and promotes interactive communications

between the business and the customers, and it leads to increasing volume of rich data about customers. Based on the rich data collected, it is possible to successfully identify new prospective customers by using customer lifetime value to evaluate the current customers and match their profiles with those of new prospects (Wilson, 2006).

However, in interactive marketing contexts, customers are also able to "block out" the intrusive marketing actions, and therefore, appropriate depth and width of "permissions" should be obtained (Godin, 1999; Krishnamurthy, 2001). Therefore, understanding customers will become more critical as new information technology is being developed.

Furthermore, companies and customers can have opportunities to co-create products, pricing, and distributions. Information technology provides this opportunities by allowing companies to assess each customer individually and then to determine whether to serve that customer directly or via a third party, and whether to create an offering that customizes the product or standardizes the offering (Sheth, Sisodia, & Sharma, 2000). All the decisions to make should be based on thorough analyses of customer data and accurate knowledge generation about customers.

In the similar vein, it is projected that knowledge generation—business intelligence—and data mining technologies are integrated because of importance of business performance management (BPM), which is focused on metrics development and data gathering to measure performance (Firestone, 2005).

Not only knowledge generation, but also knowledge sharing and dissemination through the organization should be considered. Shaw et al. (2001) argued that ownership and access to the marketing knowledge, standards of knowledge interchange, and sharing of applications become critical. Ho and Chuang (2006) argued that it is important to establish a knowledge management and CRM mechanism that has a system, a plan, a classification feature, objectives, and an evaluation management mechanism to satisfy customers.

In various organizational environments, both managing KDD processes to generate customer knowledge and managing customer relationship based on the knowledge generated and shared through organization are challenges for the future.

CONCLUSIONS

This article offered a brief review of customer relationship issues. CRM systems consist of management, technology, and customer dimensions. CRM technologies are divided into three categories: analytical, operational, and collaborative CRM. As the importance of knowledge increases, KDD techniques are receiving attention as systematic processes to generate knowledge. Although CRM and KDD began separately, the two concepts have points of convergence. This article highlighted some of the intersections between the two.

Different relationship marketing issues have emerged, and these rely increasingly on CRM and KDD technologies, especially for in-depth analysis. Various data mining techniques and KDD processes exist and provide the right tools to solve relationship marketing problems. While companies are eager to learn about their customers by using data mining technologies, it is very difficult to choose the most effective algorithms for the diverse range of problems and issues that marketers face (Kim et al., 2002). Even though Table 1 illustrates the main relationship marketing issues, challenges, and the potential analytic data mining tools, it is the analyst who decides creatively which tool is appropriate for what in which situation and how to interpret the results.

From a process point of view as well, gaining customer knowledge becomes critical for managing customer relationships, and systematic knowledge generating processes are of great benefit. For effective customer-centric marketing strategies, the discovered knowledge has to be managed in a systematic manner.

KEY TERMS

Clickstream Data: Web usage data. A virtual trail that a user leaves behind while surfing the Internet. For example, every Web site and every page of every Web site that the user visits, how long the user was on a page or site.

Customer Relationship Management (CRM): A core business strategy that promotes interactions and creates and delivers value to targeted customers to improve customer satisfaction and customer retention at a profit. It is grounded in high quality customer data and enabled by information technology.

CRM Systems: Technological part of CRM. Computers and all other information technologies used to help CRM are included.

Data Mining (DM): The process of searching and analyzing data in order to find latent but potentially valuable information and to identify patterns and establish relationships from a huge database.

Electronic Commerce (E-Commerce): Any business done electronically. The electronic business where information technology is applied to all aspects of company's operations.

Knowledge Discovery in Databases (KDD): The process of data selection, sampling, pre-processing, cleaning, transformation, dimension reduction, analysis, visualization, and evaluation for the purpose of finding hidden knowledge from massive databases.

Online Analytical Processing (OLAP): Various types of online query-driven analyses for examining stored data. OLAP enables a user to easily and selectively extract and view data from different points-of-view.

Data Communications and E-Learning

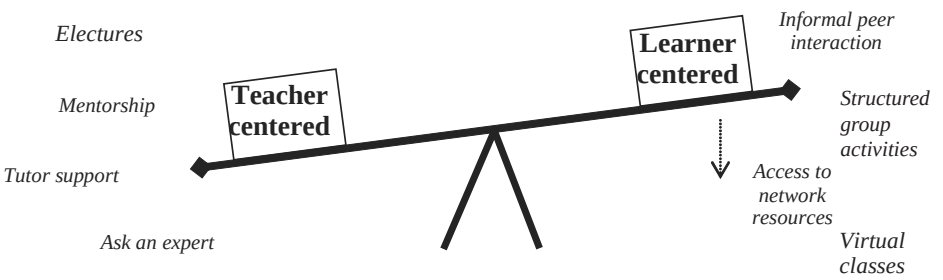
INTRODUCTION

Information and communications technology (ICT) has increasingly influenced higher education. Computer-based packages and other learning objects provide a useful supplement to students studying conventionally by illustrating aspects of the curriculum. Other packages are directed at aspects of course administration such as automated assessment (for example, see Randolph et al. (2002)). Initially such software and materials played only a supplementary role in course offerings, but this has changed rapidly. For example, Coleman et al. (1998) describe a successful early attempt to replace all lecturing with computer-aided learning. Remote delivery of courses also became a viable option because of the advent of the WWW. For example, Petre and Price (1997) report on their experiences conducting electronic tutorials for computing courses. Online education of various sorts is now routinely available to vast numbers of students (Alexander, 2001; Chen & Dwyer, 2003; Peffers & Bloom, 1999). Various terms have been used to label or describe forms of education supported by information technology. These include e-learning (e.g., Alexander, 2001; Campbell, 2004), Web-based learning (e.g. Huerta, Ryan & Igbaria, 2003; Khosrow-Pour, 2002), online learning (e.g., Simon, Brooks & Wilkes, 2003), distributed learning and technology-mediated learning (e.g., Alavi & Leidner, 2001); with e-learning probably the most commonly used term used to describe education and training that networks such as the Internet support.

E-learning has become of increasing importance for various reasons. These include the rise of the information and global economy and the emergence of a consumer culture. Students demand a flexible structure so that they can study, work and participate in family life at the same time (Campbell, 2004). This flexibility is reflected in alternative delivery methods that include online learning and Internet use. We have also become more sensitive to cultural and gender differences, and to the learning needs of the challenged. These needs may be addressed by e-learning (Campbell, 2004).

A number of studies have compared student learning and satisfaction between e-learning and traditional classroom teaching. In an early study, Hiltz and Wellman (1997) found that mastery of course material was equal or superior to that in the traditional classroom and that e-learning students were more satisfied with their learning on a number of dimensions. In particular, they found that the more students perceived that collaborative learning was taking place, the more likely they were to rate their learning outcomes as superior to those achieved in the traditional classroom. They did however identify some disadvantages to e-learning. These included ease of procrastination and information overload. More recently, Piccoli, Ahmad and Ives (2001) found that the academic performance of students in the two environments was similar, but that while e-learning students had higher levels

Figure 1. Categories of online activities



of self-efficacy, they were less satisfied with the learning process. Alexander's comment that "the use of information technology does not of itself improve learning" (Alexander, 2001, p. 241) perhaps highlights the fact that e-learning can be many things and that the intention to introduce e-learning is no guarantee of success.

The different types of teaching and learning activities that are made possible by the Internet are shown in Figure 1. Harasim and Hiltz (1995) divided these activities into two categories: learner or teacher centered. There is, however, no common agreement about which category is the best and many researchers argue for a mixture of learning activities, emphasizing group learning (Bento & Schuster, 2003; Klobas & Renzi, 2003). At the moment there still seems to be an overemphasis on teacher centered approaches, which hopefully will slowly change as a better knowledge of e-learning develops.

BACKGROUND

This article provides an illustration of blended e-learning by describing how we deliver and manage courses in a postgraduate degree in telecommunications management. We aim to foster learner centered education while providing sufficient teacher centered activities to counter some of the known concerns with entirely learner centered education. We use the Internet as the communication infrastructure to deliver teaching material globally and Lotus LearningSpace to provide the learning environment. While the primary aim of our approach is to enhance the student learning process, there are also other incentives that are consistent with this. The university is able to attract a more diverse range of students – those requiring flexibility of study and the other benefits of e-learning. Thus initiatives of this type can benefit the university while meeting the additional needs of students that are discussed in the introduction.

The use of learning and content management systems (LCMS) such as Blackboard, WebCT and Lotus LearningSpace have made e-course development less onerous for faculty. These systems provide a set of tools for publishing, communicating, and tracking student activity. Various guidelines have been suggested for evaluating and choosing software for e-learning (Klobas & Renzi, 2000). After establishing our requirements for a software tool for developing and delivering courses online, we evaluated various alternatives. The requirements that we identified included:

- Instructors should not have to program and debug HTML code;
- All courses should have the same professional look and feel without having to hire computer programmers to write special software, and students should always be presented with the same interface for all their courses;
- The software should be fully integrated (one software package should allow the instructor to do everything required, such as course development and course management);
- Professional support.

After evaluating various alternatives we choose Lotus LearningSpace (LS). Successful use of LS by instructors proved to be significantly less dependent on the technical knowledge of the instructor than was the case with some other popular LCMS. It allows the instructor to focus on the learning of the students rather than on creating and debugging HTML.

LS provides instant feedback to the students and instructor, and enables progress and problems that students encounter as they go through the curriculum to be monitored. Students also have a discussion area where they can ask questions and communicate with the instructor as well as with other students.

LS allows us to create distributed courses that students and instructors can access whether they are online or offline. Students are able to download material for a course onto their machine so they can go through the curriculum without having to have a direct Internet connection. Using the offline access method makes it easier for students to learn wherever they are located and for instructors to develop and manage course material and reduce critical network bandwidth requirements. Features that facilitate flexible student centered learning include:

- Schedule - provides students with a structured approach to assignments, materials, and assessments. Through the schedule, students can link to everything required to complete their course.
- MediaCenter - allows immediate and searchable access to all materials for the course as the instructor makes them available.
- CourseRoom - provides a discussion group facility, which hosts collaborative interchange between student groups and/or students and instructors.
- Profiles - helps students and instructors get to know their classmates to form productive teams and to network outside the course.

Features that facilitate course management include LS Central for course management and the Assessment Manager for setting up and tracking of students' progress in their courses.

USING LOTUS LEARNINGSPACE TO ENHANCE LEARNING OF DATA COMMUNICATIONS

Depending on course content and pedagogy the migration to e-learning can be more or less laborious. We have chosen one course in a telecommunication management degree to provide an example of how e-learning was implemented. Appropriately, this course is about networking technology.

The Data Communications Systems course provides an introduction to networking and networking devices focusing on Local Area Networks (LANs) and Wide Area Networks (WANs). Network design, Ethernet, ISDN, Frame Relay, and TCP/IP are introduced, including IP addressing and router protocols. There is a strong practical context that provides students with the opportunity to build, configure and problem solve in a multi-router network environment. This course also includes the first part of the Cisco Certified Network Associate (CCNA) curriculum. The Data Communications Systems course provides a good example of a difficult class to integrate with LS because of the external curriculum, which is contained on a separate Web server, and the external assessment requirement for students.

Students are required to log in to LS once they have selected the course. Students can access LS with a Lotus Notes Client or through a Web browser. The Lotus Notes Client allows students to work off-line by placing an image of what is on the LS server on their laptop or PC at home. This allows students to work while they travel and can reduce the amount of time they are required to be connected to the Internet. When they connect up to the Internet they can resynchronize their copy with the master copy located on a Lotus Notes Server; this flexibility is a major goal of e-learning. The students then use LS schedule to follow the schedule for the course (see Figure 2). Through the schedule, students can access the external curriculum, which resides on a separate Web server.

The course takes a blended learning approach with both face-to-face classes and online learning. This enables us to take advantage of the benefits of technology mediated learning, but does not risk losing the strengths of face-to-face teaching. Theory is presented to students in the form of online topics (Web-based), mini lectures, and laboratories. LS is used to integrate course material from a variety of sources, for example, the Cisco material that contributes to the CCNA. This kind of external material must be integrated seamlessly with local content so that students see a totally integrated system when it comes to the delivery of each course. The online teaching material combines Web based text and graphics to explain concepts (see Figure 3 for a sample screen). Short movies are also used to illustrate concepts that are difficult to communicate with just static text and graphics. The students are given aims and objectives at the start of each topic. The teaching material covers these topics in detail and at the end of each topic students have optional self-assessment quizzes that allow them to gauge their un-

Figure 2. Sample schedule screen

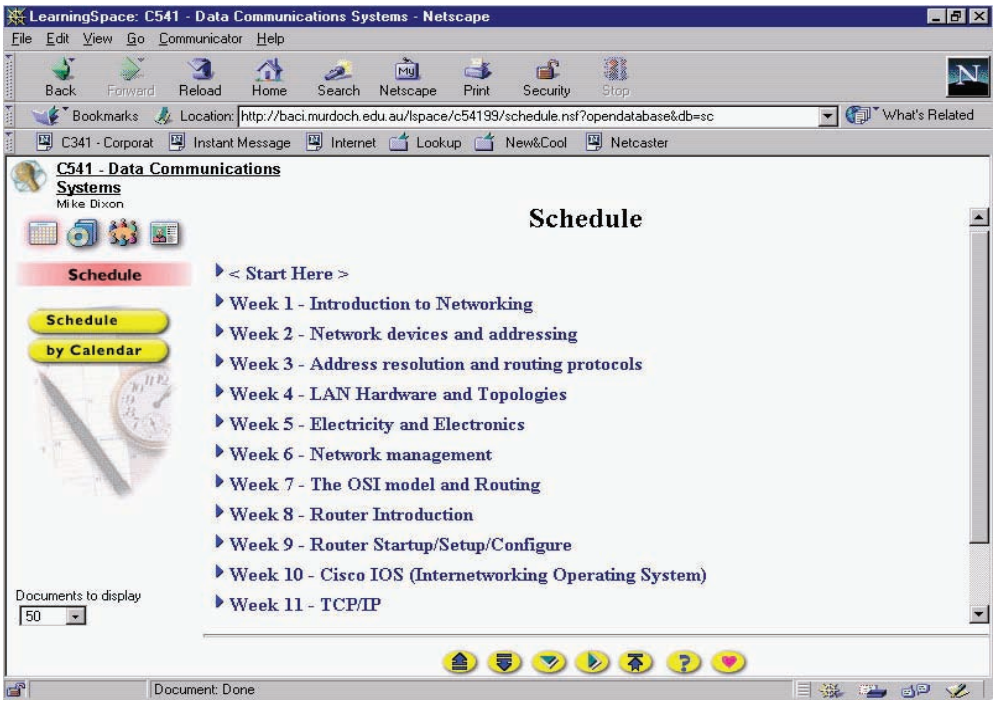


Figure 3. Sample course material screen

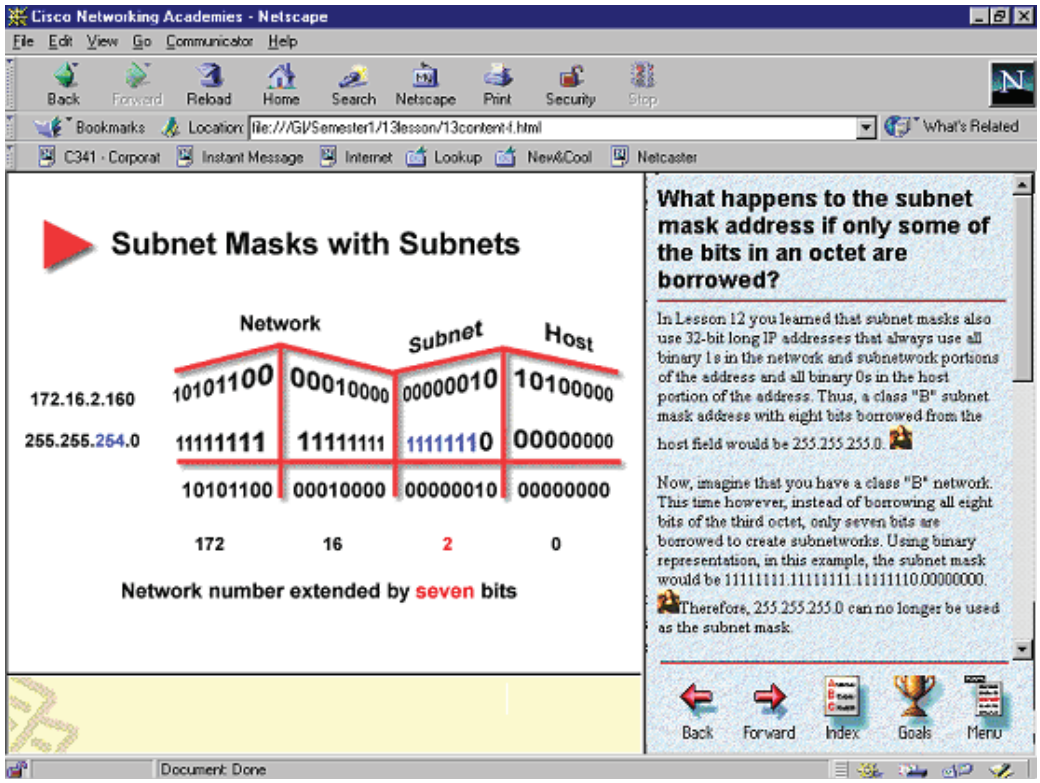

derstanding of the material. The multiple modes of content delivery cater to different cognitive styles of students.

Instructors also use these online quizzes to measure the understanding of the students before they attend classes. The instructor is able to identify students who are not keeping up to date with their work and also areas that students are having problems with. The mini lectures can then focus on the areas where students are having problems. The instructor can also discuss problem areas in the discussion group. Assignments are submitted online, graded locally and returned with the instructor's personal comments and grade.

There are two Cisco online exams for the course and students are required to pass these exams with a minimum score of 80%. Students are allowed to take the exam more than once. All students must also take a separate supervised written final exam to meet University requirements. The online Cisco exams are done on separate assessment servers, as they are part of the certification process. The Cisco Networking Academy results of all the students around the world are maintained in a database in Arizona so that instructors can analyze how their class has answered questions and compare the results of their students with those of students in other institutions around the world. The final exams for each course are taken locally in a more traditional way.

The course also includes on-campus practical work to prepare students to solve real-world networking problems. Students work in groups during the practical lab sessions. Students are given timed individual and group practical exams at the end of each major component. Students are allowed to take these exams as many times as they like but are required to pass all these exams.

These factors all contribute to facilitating student learning. Faster and more frequent feedback on the material keeps students more in touch with their progress. Testing and checkpoints with built in repetition are important for long-term retention and understanding of the material. The facility to continue to work with the teaching material until an 80% pass is achieved enhances performance. Students see important material multiple times so that their learning is reinforced and students are able to study wherever they are and still be part of the student community. The use of a virtual discussion group enhances the sense of community among the students and teachers. Combining a learner centered approach with LS allows us to achieve a quality course online.

FUTURE TRENDS

E-learning will continue to play an increasing role in education and training. Greater broadband access will enable delivery of richer content and greater interactivity. Convergence of

information technologies such as notebooks, phones and television and the development of pervasive computing will provide even greater flexibility to students. Educators and students are coming to understand that learning is lifelong and that technology is a valuable tool in supporting it.

CONCLUSION

E-learning is changing the face of university education. This article discussed an approach used to adopt a learner centered environment within an Internet based degree. As the course used to illustrate the issues in the article is about telecommunications, the Internet is a very appropriate medium for instruction. Students learn about telecommunications while accessing information through the Internet. Technology can provide flexibility of learning and hence enrich the learning experience and diversify the student mix.

KEY TERMS

Blended Learning: E-learning used in conjunction with other teaching and learning methods.

Cisco Certified Network Associate (CCNA): A data communications industry certification.

Distributed Learning: Using a wide range of information technologies to provide learning opportunities beyond the bounds of the traditional classroom.

E-Course: Another term for an online course.

E-Learning: The use of new multimedia technologies and the Internet to improve the quality of learning.

Learning and Content Management Systems (LCMS): These systems provide a set of tools for publishing, communicating, and tracking student activity.

Learning Objects: Small (relative to the size of an entire course) instructional components that can be reused in different learning contexts. Learning objects are generally considered to be digital materials deliverable over the Internet.

Online Learning: An inclusive term for any form of learning supported by computer based training.

Pervasive Computing: Technology that has moved beyond the personal computer to everyday devices with embedded technology and connectivity. The goal of pervasive computing is to create an environment where the connectivity of devices is embedded in such a way that the connectivity is unobtrusive and always available.

Technology-Mediated Learning: Learning where the learner's interactions with learning materials, other students and/or instructors are mediated through information technologies.

Web-Based Learning (WBL): Use of Internet technologies for delivering instruction.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 685-690, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Data Dissemination in Mobile Databases

Agustinus Borgy Waluyo

Monash University, Australia

David Taniar
Monash University, Australia

INTRODUCTION

The development of wireless technology has led to *mobile computing*, a new era in data communication and processing (Barbara, 1999; Myers & Beigl, 2003). With this technology, people can now access information anytime and anywhere using a portable, wireless computer powered by battery (e.g., PDAs). These portable computers communicate with a central stationary server via a wireless channel. Mobile computing provides *database applications* with useful aspects of wireless technology known as mobile databases.

The main properties of mobile computing include mobility, severe power and storage restriction, frequency of disconnection that is much greater than a traditional network, bandwidth capacity, and asymmetric communications costs. Radio wireless transmission usually requires a greater amount of power as compared with the reception operation (Xu, Zheng, Zhu, & Lee, 2002). Moreover, the life expectancy of a battery (e.g., nickel-cadmium, lithium ion) was estimated to increase time of effective use by only another 15% (Paulson, 2003). Thus, efficient use of energy is definitely one of the main issues.

Data dissemination (can also be called *data broadcasting*) is one way to overcome these limitations. With this mechanism, a mobile client is able to retrieve information without wasting power to transmit a request to the server. Other characteristics of data dissemination include: scalability as it supports a large number of queries; query performance which is not affected by the number of users in a cell as well as the request rate; and effective to a high-degree of overlap in the user's request. In this article, the terms data dissemination and data broadcasting are used interchangeably.

The ultimate challenge in data dissemination is to minimize *the response time* and *tuning time* of retrieving database items. Response time is the total of elapsed time required for the data of interest to arrive in the channel and the download time, while tuning time is the amount of time that a client is required to listen to the channel, which is used to indicate its energy consumption. In some cases, the response time is equal to the tuning time.

This article describes a state-of-the art development in data dissemination strategies in mobile databases. Several strategies for improving the query performance by disseminating data to a population of mobile users will be explained.

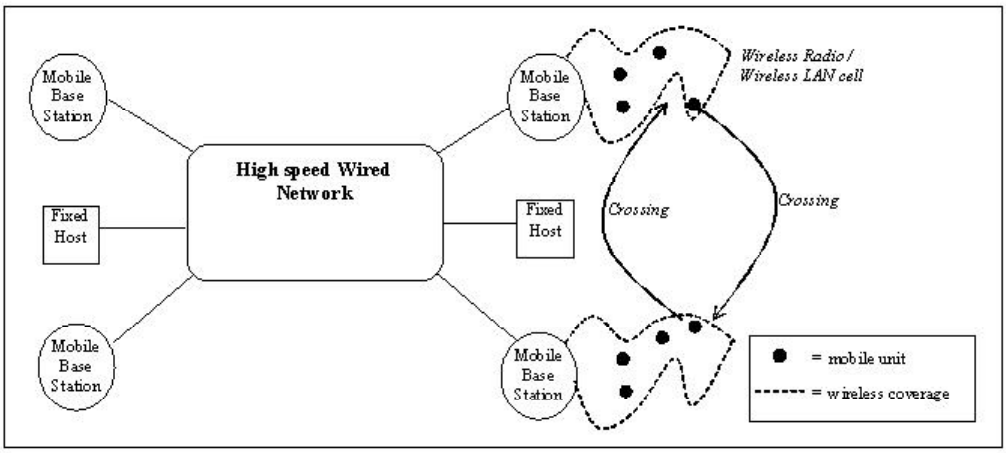
BACKGROUND

In general, each mobile user communicates with a mobile base station (MBS) to carry out any activities such as a transaction and information retrieval. MBS has a wireless interface to establish communication with the mobile client, and it serves a large number of mobile users in a specific region called a "cell". The number of mobile clients in a cell can be infinite. In mobile environment architecture, each MBS is connected to a fixed network as illustrated in Figure 1.

Mobile clients can move between cells while being active and this intercell movement is known as the handoff process (Trivedi, Dharmaraja, & Ma, 2002). Each client in a cell can connect to the fixed network via wireless radio, wireless local area network (LAN), wireless cellular, or satellite. Each of the wireless networks provides a different bandwidth capacity. However, this wireless bandwidth is too small compared with the fixed network such as asynchronous transfer mode (ATM) that can provide a speed of up to 155Mbps (Elmasri & Navathe, 2003).

Data dissemination refers to the periodic broadcasting of database items to mobile clients through one or more wireless channels (or also called broadcast channels), and the clients filter their desired data on the fly. Access to data is sequential. The behavior of the broadcast channel is unidirectional which means the server disseminates a set of data periodically to a multiple number of users. This mechanism is also known as the *push-mechanism* (Malladi & Davis, 2002; Yajima, Hara, Tsukamoto, & Nishio, 2001). It must be noted that data dissemination is different from the data replication mechanism. Conventional data replication distributes a set of database items to one or more identified clients according to a pre-determined requirement. However, data dissemination broadcasts the database items periodically to an unbounded

Figure 1. Mobile environment architecture



number of mobile clients, and the clients filter the data on air based on individual interest.

Figure 2 shows the mechanism of data dissemination. In this article, the term data item corresponds to database record or tuples, and data segment contains a set of data items. A complete broadcast file is referred to as a broadcast cycle. The terms mobile client, mobile computer, mobile unit, mobile user and client are used interchangeably.

DATA DISSEMINATION

Data dissemination schemes are classified into two categories: one is to minimize query response time, and the other minimizes tuning time.

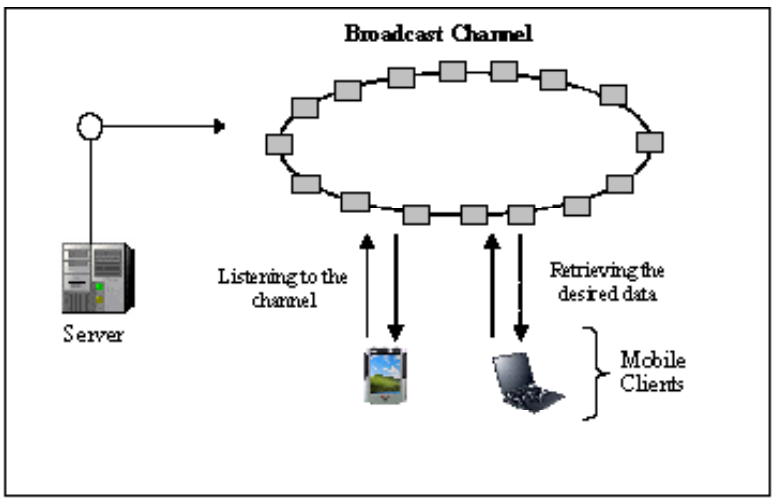
Minimizing Query Response Time

There are several data dissemination schemes, which include:

(i) Selection of Data Items to be Broadcast,
(ii) Non-Uniform Frequency Distribution of Broadcast Data Items,
(iii) Distribution of Data Items over Multiple Channels, and
(iv) Organization of Data Items.

These schemes aim to minimize the query response time by either reducing the waiting time for the desired data to arrive, or, both waiting and download time.

Figure 2. Data dissemination mechanism



a. Selection of Data Items to be Broadcast

A selection mechanism is designed to reduce the broadcast cycle length, which eventually reduces the query response time. During each broadcast cycle, additional items might be qualified as hot and some previously hot items might cool down, and therefore need to be replaced depending on the size of the cycle. A replacement algorithm is required to replace the cold data items with the new hot items. The server determines a set of appropriate database items to be broadcast, using information from queries received. Since hot items are those accessed by most clients, the access pattern of each client on the database items has to be derived from the clients back to the server. Finally, statistics will be compiled and the desired data items can be broadcast appropriately.

There are at least three replacement algorithms namely *Mean Algorithm*, *Window Algorithm*, and *Exponentially Weighted Moving Average* (*EWMA*) *Algorithm* (Leong & Si, 1997). These algorithms maintain a score for each database item to estimate the access probability of the next broadcast cycle. The scores are defined by measuring the cumulative access frequencies of each database item over the length of the observation period.

However, as the size of the database increases, the number of broadcast items may also increase accordingly. This situation will lead to an increase in response time. The next scheme can be used to improve the response time of the majority requests by manipulating the frequency of hot items to be broadcast.

b. Non-Uniform Frequency Distribution of Broadcast Data Items

The difference in bandwidth capacity between the downstream communication and upstream communication has created a new environment called the *Asymmetric Communication Environment*. In fact, there are two situations that can lead to communication asymmetry (Acharya, Alonso, Franklin, & Zdonik, 1995). One is raised as a result of the capability of physical devices. For example, servers have powerful broadcast transmitters, while mobile clients have little transmission capability. The other is due to the patterns of information flow in the application, such as the situation where the number of servers is far less than the number of clients. It is asymmetric because there is not enough capacity to handle simultaneous requests from multiple clients.

Broadcast Disk is an information system architecture, which utilizes multiple disks of different sizes and speeds on the broadcast medium. This architecture is used to address the above situations (Acharya et al., 1995). The broadcast consists of chunks of data from different disks on the same broadcast channel. The chunks of each disk are evenly scattered. However, the chunks of the fast disks are broadcast more frequently than the chunks of the slow disks. This is the opposite of a flat broadcast where the expected delay before obtaining an item of interest is the same for all broadcast items. With this differing broadcast frequency of different items, hot items can be broadcast more often than others. The server is assumed to have the indication of the clients' access patterns so that it can determine a broadcast strategy that will give priority to the hot items.

c. Distribution of Data Items over Multiple Channels

An alternative strategy to improve query response time is to distribute the broadcast data over more than one broadcast channel. Moreover, a certain pattern of distribution such as Data Stripping, Data Replication, and Data Replication can be used to handle obstacles like noise and signal distortion that may affect wireless transmission (Leong & Si, 1995). Figure 3 illustrates the three mechanisms.

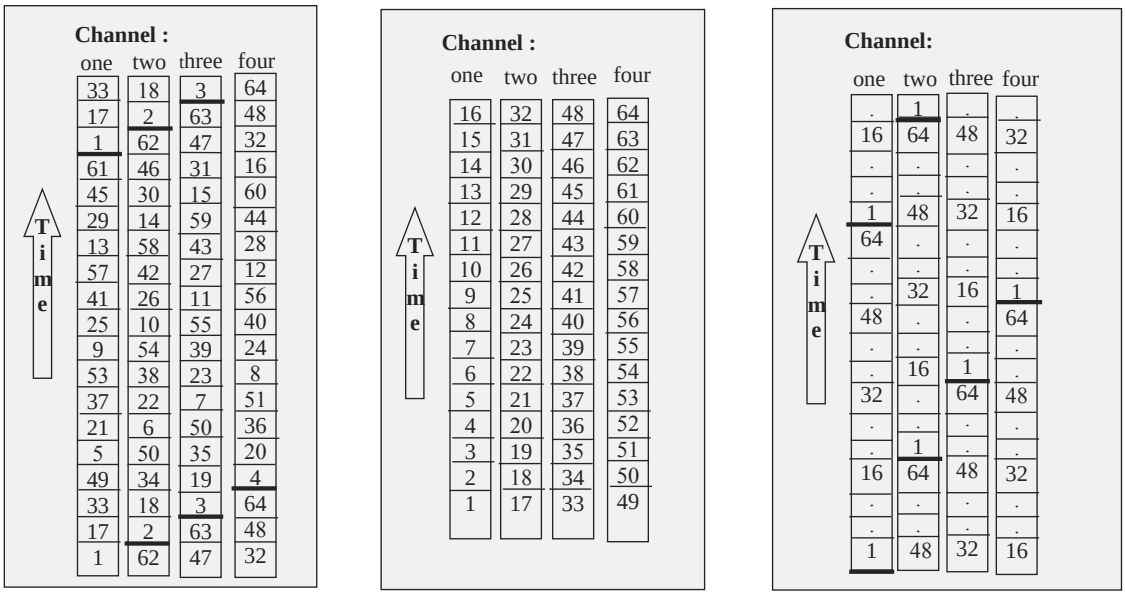
As shown in Figure 3(a), the data stripping mechanism broadcasts consecutive data items over a multiple channel array and the data items are broadcast at certain intervals to allow the client sufficient time to switch from one channel to another. The data partitioning mechanism in Figure 3(b) allows the database to be partitioned into a number of data segments, and each data segment is placed in a different channel. In Figure 3(c), the database is replicated across all channels, and is therefore called the data replication mechanism.

To avoid the effect of too large data items in a channel, a strategy to determine the optimum number of database items to be broadcast in a channel is needed (Waluyo, Srinivasan, & Taniar, 2003a). In this strategy, the query response time over an on-demand channel is used as a threshold point. Subsequently, the length of the broadcast cycle is split, and broadcast over multiple channels.

d. Organization of Data Items

The previous schemes are concerned with retrieving a single data item. However, in most cases multiple data items are involved. Organizing database items over the broadcast channel can be applied to reduce waiting time as well as download time. Traditional semantic query optimization is employed to reduce the download time when the application involves multiple entity types, and the query accesses related entities from different entity types (Si & Leong, 1999). The organization of broadcast data is designed to match the query access pattern from mobile clients as closely as possible. As the query initiated by each client varies, this problem is sometimes considered an NP-hard problem.

Figure 3. Data stripping, partitioning, and replication mechanism



(a) Data Stripping Mechanism (b) Data Partitioning Mechanism (c) Data Replication Mechanism

The difficulty is to decide the broadcast order in advance, even without much knowledge of any future query. In general, an access graph is needed to identify the optimal organization of database items over a channel. The access graph is used to represent the dependency of data items. Once the access graph is built, a certain algorithm is utilized to determine the best broadcast program. A cost model called the Semantic Ordering Model (SOM) can be used to determine the most efficient access graph (Si & Leong, 1999). SOM is defined into two models: namely, Simple and Extended SOM. Simple SOM considers only the relationship among entity types while Extended SOM incorporates historical query access patterns. The branch and bound like algorithm (Si & Leong, 1999), Heuristics algorithm (Hurson, Chehadeh, & Hannan, 2000), randomized algorithm (Bar-Noy, Naor, & Schieber, 2000), and Genetic algorithm (Huang & Chen, 2002, 2003) are some algorithms that can be used to identify the most effective organization of broadcast data items. The final broadcast program can be distributed over either a single or multiple channels.

Minimizing Tuning Time

A broadcast indexing scheme is needed to reduce the tuning time by providing accurate information for a client to tune in at the appropriate time for the required data (Lee, Leong, & Si, 2002). In this scheme, some form of directory is broadcast along with the data, and the clients obtain the index directory from the broadcast and use it in subsequent reads. The information generally also contains the exact time of the data to be broadcast. As a result, mobile clients are able to conserve the energy of their unit by switching to "*doze*" mode and back to "*active* mode" when the data is about to be broadcast.

In general, a broadcast indexing technique involves a trade-off between optimizing the client tuning time and the query response time. The consequence of minimizing one of them is the increase of the other. For instance, to minimize the response time is to reduce the length of broadcast cycles. In this case, the index can be broadcast once in each cycle but it will make the tuning time suffer since the client will have to wait for the index to arrive which happens only once in each broadcast cycle. On the other hand, when the index directory is frequently broadcast in each broadcast cycle to reduce the tuning time, the response time will be greatly affected due to the occupancy of the index in the cycle. Thus, it is necessary to find the optimal balance between these two factors.

Clustering index, non-clustering index, and multiple index methods are used to determine the index distribution over a broadcast channel (Imielinski, Viswanathan, & Badrinath, 1997). Clustering index refers to clustering of a record's attribute whenever all records that belong to the attribute have the same value consecutively. Non-clustering index defines a method for indexing the non-clustering attributes by partitioning each non-clustered attribute in the broadcast

Figure 4. Multi-level signature

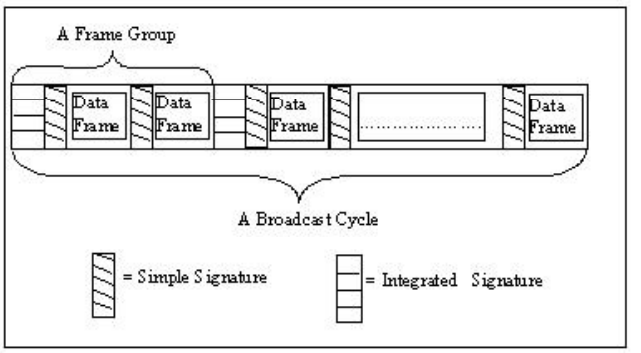


Figure 5. Hybrid indexing

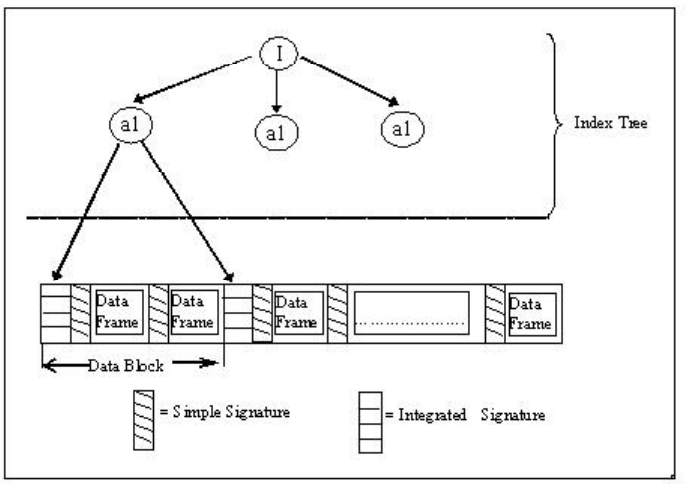

cycle into a number of segments called *meta segments*. In multiple indexes, a second attribute is chosen to cluster the data items within the first clustered attribute.

Broadcast indexing can be *tree-indexing* based, *signature* based, or *hybrid indexing* that is the combination thereof. Tree-indexing based such as Global Index structure is utilised to minimise the index response time (Taniar & Rahayu , 2002; Waluyo, Srinivasan, & Taniar, 2003b). The design of the global index model is based on *B*+ tree structure; it incorporates an index channel, and the data items are broadcast separately in data channels.

A signature based index is derived by hashing the attribute values into bit strings followed by combining them together to form a bit vector or signature (Lee & Lee, 1996). The signature is broadcast together with the data on every broadcast cycle. This mechanism is also applied to the query initiated by the client. To process the query, mobile clients need to tune into the broadcast channel and verify the query signature with the data signature by performing a certain mathematical operation such as the "AND" operation. If the signature is not matched, the client can tune to the "doze" mode while waiting for the next signature to arrive. The main issue with this method is to determine the size of the signature as well as the number of levels of the signature. There are three different signature-based index algorithms, namely *simple signature*, *integrated signature* and *multilevel signature* (Lee & Lee, 1996).

In simple signature, the signature frame is broadcast ahead of each data frame. This makes the total number of signature frames the same as the data frames. An integrated signature is applied for a group of data frames and the signature is calculated accordingly. Figure 4 shows a combination

of these two algorithms, forming a multi-level signature. This technique is designed to interleave with data items in a single channel.

A hybrid indexing technique made up of index tree and signature is expected to outperform the single indexing techniques by integrating the advantages of the two techniques into a single operation (Lee, Hu, & Lee, 1998; Hu, Lee, & Lee, 1999). This technique is shown in Figure 5.

CONCLUSION

The inherent limitations and characteristics of mobile computing such as power, storage, asymmetric communication cost, and bandwidth, have become interesting challenges and research opportunities in the field.

This article describes main issues, and several approaches in data dissemination in mobile databases that have been derived from literature. We classify each scheme into two categories: one is to minimize query response time, and the other is to minimize tuning time. Broadcasting schemes that aim to minimize response time include:

(i) Selection of Data Items to be broadcast,
(ii) Non-Uniform Frequency Distribution of Broadcast Data Items,
(iii) Distribution of Data Items over Multiple Channels, and
(iv) Organization of Data Items.

To minimize the tuning time, broadcast indexing of data items is applied. Hybrid schemes that integrate the advantages of these approaches are also of great potential. These techniques can certainly be improved in a number of ways and a vast amount of research is continuing for this purpose.

KEY TERMS

Broadcast Channel: Unidirectional wireless channel to disseminate a set of database items periodically to multiple numbers of mobile users.

Broadcast Cycle: A complete broadcast file.

Data Dissemination/Broadcasting: Periodical broadcast of database information to mobile clients through one or more wireless channels.

Data Item: Database record or tuples.

Data Segment: A set of data items.

Mobile Base Station (MBS): Fixed host that has wireless interface for communicating with mobile clients.

Mobile Computing: The ability of mobile users to keep connected to the wireless network while traveling, and to access information such as news, weather forecast, email, and query to central database server.

Mobile Database: Mobile users connected to the wireless network and equipped with database application to conduct activity like transaction and information retrieval from central database server.

Query Response Time: The total elapsed time while waiting for the data of interest to arrive in the channel and downloading the data.

Tuning Time: The total time a mobile client must listen to the channel, which is used to indicate its energy consumption.

INTRODUCTION

There is an explosion in the amount of data that organizations generate, collect, and store. Organizations are gradually relying more on new technologies to access, analyze, summarize, and interpret information intelligently. Data mining, therefore, has become a research area with increased importance (Amaratunga & Cabrera, 2004). Data mining is the search for valuable information in large volumes of data (Hand, Mannila, & Smyth, 2001). It can discover hidden relationships, patterns, and interdependencies and generate rules to predict the correlations, which can help the organizations make critical decisions faster or with a greater degree of confidence (Gargano & Ragged, 1999).

There is a wide range of data mining techniques, which has been successfully used in many applications. This article is an attempt to provide an overview of existing data mining applications. The article begins by explaining the key tasks that data mining can achieve. It then moves to discuss applications domains that data mining can support. The article identifies three common application domains, including bioinformatics, electronic commerce, and search engines. For each domain, how data mining can enhance the functions will be described. Subsequently, the limitations of current research will be addressed, followed by a discussion of directions for future research.

BACKGROUND

Data mining can be used to achieve many types of tasks. Based on the kinds of knowledge to be discovered, it can be broadly divided into supervised learning and unsupervised learning. The former requires the data to be pre-classified. Each item is associated with a unique label, signifying the class in which the item belongs. In contrast, the latter does not require pre-classification of the data and can form groups that share common characteristics (Nolan, 2002). To achieve these two main tasks, four data mining approaches are commonly used: classification, clustering, association rules, and visualization.

Classification

Classification, which is a process of supervised learning, is an important issue in data mining. It refers to discovering predictive patterns where a predicted attribute is nominal or categorical. The predicted attribute is called the class. Subsequently, a data item is assigned to one of the predefined sets of classes by examining its attributes (Changchien & Lu, 2001). One example of classification applications is to analyze the functions of genes on the basis of predefined classes that biologists set (see the section on "Classifying Gene Functions").

Clustering

Clustering is also known as *exploratory data analysis* (EDA) (Tukey, 1977). This approach is used in those situations where a training set of pre-classified records is unavailable. Objects are divided into groups based on their similarity. Each group, called cluster, consists of objects that are similar between themselves and dissimilar to objects of other groups (Roussinov & Zhao, 2003). From a data mining perspective, clustering is an approach for unsupervised learning. One of the major applications of clustering is the management of customers' relationships, which is described in the section "Customer Management."

Association Rules

Association rules that were first proposed by Agrawal and Srikant (1994) are mainly used to find out the meaningful relationships between items or features that occur synchronously in databases (Wang, Chuang, Hsu, & Keh, 2004). This approach is useful when one has an idea of different associations that are being sought out. This is because one can find all kinds of correlations in a large data set. It has been widely applied to extract knowledge from Web log data (Lee, Kim, Chung, & Kwon, 2002). In particular, it is very popular among marketing managers and retailers in electronic commerce who want to find associative patterns among products (see the section on "Market Basket Analysis").

Visualization

The visualization approach to data mining is based on an assumption that human beings are very good at perceiving structure in visual forms. The basic idea is to present the data in some visual form, allowing the human to gain insight from the data, draw conclusions, and directly interact with the data (Ankerst, 2001). Since the user is directly involved in the exploration process, shifting and adjusting the exploration goals is automatically done if necessary (Keim, 2002). This approach is especially useful when little is known about the data and the exploration goals are vague. One example of using visualization is author co-citation analysis (see the section on "Author Co-citation Analyses").

DATA MINING APPLICATIONS

As previously discussed, data mining can be used to achieve various types of tasks, such as classification, clustering, association rules, and visualization. These tasks have been implemented in many application domains. The main application domains that data mining can support include bioinformatics, electronic commerce, and search engines.

Bioinformatics

In the past decade, we have been overwhelmed with increasing floods of data gathered by the Human and other Genome Projects. Consequently, a major challenge in bioinformatics is extracting useful information from these data. To face this challenge, it is necessary to develop an advanced computational approach for data analysis. Data mining provides such potentials. Three application areas, which are commonly presented in the literature, are described next.

Clustering Microarray Data

Unsupervised learning produces clustering algorithms, which are being applied to DNA microarray data sets. Many algorithms are available for clustering, such as k-means and hierarchical clustering. These algorithms have different strengths and weaknesses, so they may cause the lack of inter-method consistency in assigning related gene-expression profiles to clusters. To overcome this problem, Swift et al. (2004) proposed a consensus strategy to produce both robust and consensus clustering of gene-expression data and assign statistical significance to these clusters from known gene functions. Robust clustering is compiling the results of different clustering methods reporting only the co-clustered instances grouped together by different algorithms—that is, with maximum agreement across clustering methods. On the other hand, consensus clustering relaxes the full agreement requirement by taking a parameter, "minimum agreement," which allows different agreement thresholds to be explored. It is reported that this approach can improve confidence in gene-expression analysis.

Classifying Gene Functions

Biologists often know a subset of genes involved in a biological pathway of interest and wish to discover other genes that can be assigned to the same pathway (Ng & Tan, 2003). Unlike clustering, which processes genes based on their similarity, classification can learn to classify new genes based on predefined classes, taking advantage of the domain knowledge already possessed by the biologists. Therefore, the classification approach seems more suitable than clustering for the classification of gene functions.

Earlier studies focus on classification of gene functions based on a single source of data, for example, Kuramochi and Karypis (2001). Recently, heterogeneous sources of data have been adopted. For example, Deng, Geng, and Ali (2005) presented a hybrid weighted naive Bayesian network model for the prediction of functional classes of novel genes based on multiple sources of data, such as DNA sequences, expressions, gene structures, database annotations, and homologies. This model can also be used to analyze the contribution of each source of data toward the gene function prediction performance.

Identifying Phenotype Data

In the aforementioned two approaches, the genes are treated as objects, while the samples are the attributes. Conversely, the samples can be considered as the objects and the genes as the attributes. In this approach, the samples can be partitioned into homogeneous groups. Each group may correspond to some particular phenotypes (Golub et al., 1999). Phenotype is observable and physical characteristics of an organism. Over the past decade, growing interest has surfaced in recognizing relationships between the genotypes and phenotypes. Tracing a phenotype over time may provide a longitudinal record for the evolution of a disease and the response to a therapeutic intervention. This approach is analogous to removing components from a machine and then attempting to operate the machine under different conditions to diagnose the role of the missing component. Function of genes can be determined by removing the gene and observing the resulting effect on the organism's phenotype.

Electronic Commerce

The widespread use of the Web has tremendous impact on the way organizations interact with their partners and customers. Many organizations consider analyzing customers'

behavior, developing marketing strategies to create new consuming markets, and discovering hidden loyal customers as the key factors of success. Therefore, new techniques to promote electronic business become essential and data mining is one of the most popular techniques (Changchien & Lu, 2001). Data mining applications in electronic commerce include customer relationship management and market basket analysis.

Customer Relationship Management

For managing customers' relationships, a frequently used approach is to analyze their usage data in order to discover user interests, and then recommendations can be made based on the usage data extracted. A hybrid approach is often used for making recommendations. For example, Wang et al. (2004) used a hybrid method to develop a recommendation system for the cosmetic business. In the system, they segmented the customers by clustering algorithms to discover different behavior groups so that customers in same group have similar purchase behavior. For each group's customers, they then used the association rules to discover their purchase behavior. In addition, they scored each product for each customer who might be interesting in it with the collaborative filtering approach and the content-based filtering. They found that this approach could recommend not only the right product to the right person, but also the right product to the right person at the right time.

Furthermore, Liu and Shih (2005) proposed two hybrid methods for recommending products. These two methods incorporate the advantages of a weighted RFM-based method and a preference-based collaborative filtering method. The former employs association rule mining to identify recommendation rules from customer groups that are clustered according to customer lifetime value (CLV), including recency, frequency, and monetary. The latter is similar to the former, except that the preference-based method groups customers based on purchase preferences. The first proposed hybrid method is to group customers separately based on CLV and purchase preferences. Then, recommendation rules extracted from the weighted RFM-based method are used to recommend products to loyal customers; recommendation rules extracted from the preference-based collaborative filtering method are used to recommend products to less loyal customers. The second hybrid method is to group customers by considering both CLV and purchase preferences and then extract recommendation rules from each group to support recommendations. The experimental results indicated that the second hybrid method outperformed the first, especially when the CLV was weighted more heavily than purchase preferences.

Market Basket Analysis

Market basket analysis is a typical example among the various applications of association rules, and it aims at identifying associations between consumers' choices of different products (Giudici & Passerone, 2003). The data analysed in a market basket analysis usually consist of all purchasing transactions carried out by the consumers in a certain unit of time. The market basket analysis is to understand the association structures between the sales of the different products available. Once the associations are found, they may help planning marketing policies.

Time and location are two important issues for market basket analysis. To address these issues, Chen, Tang, Shen, and Hu (2005) proposed a method called store-chain association rules for a multi-store environment, where stores may have different product-mix strategies that can be adjusted over time. The format of the rules is similar to that of the traditional association rules. However, the rules also contain information on location and time where the rules hold. The rules extracted by the method may be applicable to the entire chain without time restriction, but may also be store and time specific. The results of the empirical evaluation showed that this method has an advantage over the traditional methods: when stores are diverse in size, product mix changes rapidly over time, and larger numbers of stores and periods are considered.

Search Engines

Data mining is of increasing importance for search engines. Traditional search engines offer limited assistance to users in locating the relevant information they need. Data mining can help search engines to provide more advanced features. According to current applications, there are three potential advantages: (a) ranking of pages, (b) improvement of precision, and (c) author co-citation analysis. These advantages are described next.

Ranking of Pages

Data mining identifies the ranking of the Web pages for a particular topic by analyzing the interconnections of a series of related pages. The PageRank (Kamvar, Haveliwala, Manning, & Golub, 2003) applies this approach to find pertinent Web pages. In the PageRank, the importance of a page is calculated based on the number of pages that point to it. This is actually a measure based on the number of backlinks to a page. A backlink is a link pointing to a page, rather than pointing out from a page. This measure is used to prioritize pages returned from a traditional search engine using keyword search. Google applies this measure to rank the search results. The benefit is that central, important, and authoritative Web

pages are given preferences. However, the problem is that it only examines the forward direction. In addition, a much larger set of linked documents is required.

Improvement of Precision

The problem of PageRank is that it is a purely link structure-based computation, ignoring the textual content. Therefore, the precision is low. On a narrowly focused topic, it frequently returns resources for a more general topic. IBM Almaden Research Centre continued develops Clever search engine (Chakrabarti et al., 1999). The main approach is to promote the precision by combining content with link information, breaking large hub pages into smaller units, and computing relevance weight for pages. User's log is the other source that can be used to improve the precision. Zhang and Dong (2002) developed a Chinese image search engine named eeFind by using Matrix Analysis on Search Engine Log (MASEL). The basic idea of MASEL is to use the query log to find relations among users, queries, and clicks on results. The relation between pages chosen after a query and the query itself provides valuable information. After a query, a user usually performs a click to view one result page.

Author Co-Citation Analyses

Author co-citation analysis (ACA) has been widely used as a method for analyzing the intellectual structure of science studies. It can be employed to identify authors from the same or similar research fields. Chen and Paul (2001) used visualization to perform such analysis, and 3D virtual landscape was applied to represent author co-citation structures. The most influential scientists in the knowledge domain appear near the intellectual structure's center. In contrast, researchers who have unique expertise tend to appear in peripheral areas. The virtual landscape also lets users access further details regarding a particular author in the intellectual structure, such as a list of the author's most-cited papers, abstracts, and even the full content of that author's articles.

FUTURE TRENDS

The previous three application domains demonstrate that data mining is a very useful technology and opens new opportunities for data analysis. However, there are still many limitations, which we need to be aware of and should be investigated in future work.

Preparation of Data

It is important to know that the effective implementation of data mining methods depends to a large extent on the availability and quality of the data. Therefore, a cleaning and data transformation step before analysis is usually needed. In addition, we have to understand the characteristics of each application and set clear data mining targets so that truly useful information can be produced with appropriate data mining techniques.

Good Communication

Data mining is an interdisciplinary research area, which involves experts from different domains. One of the significant problems for interdisciplinary research is the wide range and level of domain expertise that are present among potential users so it can be difficult to provide access mechanisms appropriate to all (Kuonen, 2003). Therefore, it is important to have good communications between data mining technologists and users, as well as communications among users from different domains.

Multimedia Mining

Basically, the Web content consists of a variety of media types such as text, image, audio, video, and so forth. Multimedia mining is used to mine the unstructured information and knowledge from these online multimedia sources. However, most current research in the area of data mining still focused on text data, and multimedia mining has received less attention than text mining (Kosala & Blockeel, 2000) and opens a new window for future research to explore.

Evaluation of Effectiveness

As described in the previous section, data mining enhances the functions of the applications in different domains. However, the effectiveness of these applications is still a question. Certainly, there is a need to conduct more empirical studies to verify the effectiveness and evaluate the performance of these applications. In particular, we need more evaluations from users' points of view. Better and more detailed evaluations can lead to better understanding of users' needs and help to develop more effective applications.

CONCLUSIONS

In summary, data mining can search for interesting relationships and global patterns from various types of resources. These relationships and patterns represent valuable knowledge about the objects that are reflected by many applications in the real world. In this article, we have given some background to data mining and have provided an overview of three application domains, including bioinformatics, electronic commerce, personalized environments, and search

engines. It should be noted that data mining has also been applied to other application domains, such as digital libraries, Web-based learning, health care, and so forth. This is another direction for future research to investigate what major functions are required for each application domain and to develop concrete criteria for the evaluation of their effectiveness. These works can be integrated together to generate guidelines, which can be used for commercial and research communities to select suitable data mining techniques. The ultimate goal is to enhance the functions and performances of these applications by exploiting the full potential of data mining techniques.

KEY TERMS

Author Co-Citation Analysis: The analysis of how authors are cited together.

Bayesian Network: A directed acyclic graph of nodes representing variables and arcs representing dependence relations among the variables.

Bioinformatics: An integration of mathematical, statistical, and computational methods to organize and analyze biological data.

Collaborative Filtering: A technique that is used for making recommendations by computing the similarities among users.

Content-Based Filtering: A technique that involves a direct comparison between the content or attributes of a user's profile and the document to make recommendations.

Electronic Commerce: Commercial activities that facilitate the buying and selling of goods and services over the Internet.

Microarrays: A high-throughput technology that allows the simultaneous determination of mRNA abundance for many thousands of genes in a single experiment.

Multimedia Mining: A new field of knowledge discovery in multimedia documents, dealing with non-structured information such as texts, images, videos, audio, and virtual data.

Noisy Data: Errors in the data, due to the nature of data collection, measurement, or sensing procedures.

Search Engines: Web services that help search through Internet addresses for user-defined terms or topics.

Data Mining in Franchising

INTRODUCTION

Franchising has been a popular approach given the high rate of business failures (Justis & Judd, 2002; Thomas & Seid, 2000). Its popularity continues to increase, as we witness an emergence of a new business model, Netchising, which is the combination power of the Inter*net* for global demand-and-supply processes and the international fran*chising* arrangement for local responsiveness (Chen, Justis, & Yang, 2004). For example, *Entrepreneur* magazine—well known for its Franchise 500 listing—in 2001 included Tech Businesses into its Franchise Zone that contains Internet Businesses, Tech Training, and Miscellaneous Tech Businesses. At the time of this writing, 40 companies are on its list. Netchising is an effective global e-business growth strategy (Chen, Chen, & Wu, 2006), since it can "offer potentially huge benefits over traditional exporting or foreign direct investment approaches to globalization" and is "a powerful concept with potentially broad applications" (Davenport, 2000, p. 52).

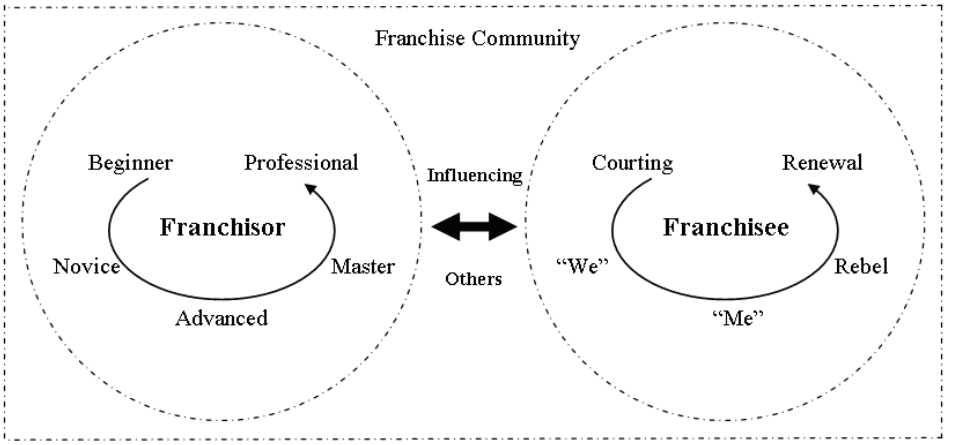
In his best seller, *Business @ the Speed of Thought*, Bill Gates (1999) wrote, "Information technology and business are becoming inextricably interwoven. I don't think anybody can talk meaningfully about one without talking about the other" (p. 6). Gates' point is quite true when one talks about data mining in franchise organizations. Despite its popularity as a global e-business growth strategy, there is no guarantee that the franchising business model will render continuous success in the hypercompetitive environment. This can be evidenced from the constant up-and-down ranking of the Franchise 500. Thus, to see how data mining can be "meaningfully" used in franchise organizations, one needs to know how franchising really works. In the next section, we show that (1) building up a good "family" relationship between the franchisor and the franchisee is the real essence of franchising, and (2) proven working knowledge is the foundation of the "family" relationship. We then discuss in the following three sections the process of how to make data mining "meaningful" in franchising. Finally, future trends of data mining in Netchising are briefly described.

FRANCHISING: THE FRANCHISOR/ FRANCHISEE RELATIONSHIP

Franchising is "a business opportunity by which the owner (producer or distributor) of a service or a trademarked product grants exclusive rights to an individual for the local distribution and/or sale of the service or product, and in return receives a payment or royalty and conformance to quality standards. The individual or business granting the business rights is called the *franchisor*, and the individual or business granted the right to operate in accordance with the chosen method to produce or sell the product or service is called the *franchisee*" (Justis & Judd, 2002, pp. 1-3). Developing a good "family" relationship between the franchisor and the franchisee is the key aspect of a successful franchise (Justis & Judd, 2002). Figure 1 describes how such a "family" relationship is built in the franchise community.

In Figure 1, the franchisor is expected to be flexible in dealing with business concerns to expedite the growth process. The learning process is incrementally developed through five stages (Justis & Judd, 2002): (1) beginner—learning how to do it; (2) novice—practicing doing it; (3) advanced—doing it; (4) master—teaching others to do it; and (5) professional—becoming the best that you can be. Once attaining the advanced stages of development, most preceding struggles have been overcome. However, further convoluted and challenging enquiries will arise as the franchise continues expansion. This is especially factual once the system reaches the "professional" stage, where various unpredicted and intricate problems could arise. Bud Hadfield (1995), the founder of Kwik Kopy franchise and the International Center of Entrepreneurial Development, aptly stated, "The more the company grows, the more it will be tested" (p. 156). To capture the learning process, a counterclockwise round arrow surrounding the franchisor is used to depict the increasing intensity of learning as the franchisor continues to grow. To understand how the "family" relationship is developed, one needs to know the five phases of franchisee life cycle (Schreuder, Krige, & Parker, 2000): (1)

Figure 1. Understanding how the franchisor/franchisee "family" relationship works



Courting—both the franchisee and the franchisor are eager with the relationship; (2) "we"—the relationship starts to deteriorate, but the franchisee still values the relationship; (3) "me"—the franchisee starts to question the reasons for payments related issues with the attitude that the success so far is purely of his/her own work; (4) rebel—the franchisee starts to challenge the restrictions being placed upon; and (5) renewal—the franchisee realizes the "win-win" solution is to continue teaming up with the franchisor to grow the system. Similar to the franchisor, a counter-clockwise round arrow surrounding the franchisee is used in Figure 1 to depict the increasing intensity of franchisee life cycle as the franchisee continues learning and growing.

As the franchisee progresses through the life cycle, the "family" relationship gradually develops an influencing process (Justis & Vincent, 2001), as depicted in Figure 1 with a bi-directional arrow: (1) working knowledge, proven abilities of expanding the franchise system profitably; (2) positive attitude, constructive ways of presenting and sharing the working knowledge; (3) good motivation, providing incentives for learning or teaching the working knowledge; (4) positive individual behavior, understanding and leveraging the strengths of the participants to learn and enhance the working knowledge; and (5) collaborative group behavior, having the team spirit to find the best way to collect, dissimilate, and manage the hard-earned working knowledge. By going through the processes of learning and influencing, both the franchisor and the franchisee gain the progressive working knowledge in the franchise community. The franchisor, the franchisee, and the franchise community in Figure 1 are surrounded with dashed lines, indicating that there is no limit to the learning process.

MANAGING FRANCHISE ORGANIZATIONAL DATA

There are many "touchpoints" within the franchise community where the franchisor and the franchisee can influence each other. Based on the customer service life cycle (CSLC) model, Chen, Chong, and Justis (2002) proposed a framework (Table 1) to harness the Internet to serve the customers for the franchising industry. The 11 sub-stages in Table 1 are based on two well-known franchising books by Justis and Judd (2002) and Thomas and Seid (2000). The model in Table 1 may be used as a comprehensive guide for a franchise to develop its Web site, especially at the stages of Requirements and Acquisition.

Table 1 also is a comprehensive framework for a franchise to model the data needed to serve its customers, that is, franchisees and their customers. A well-designed Internet strategy, often enabled by application service providers (Chen, Ford, Justis, & Chong, 2001), shall empower the franchisor and the franchisees to collect, use, renew, store, retrieve, transmit, and share the organizational data needed to do the collaborative work in the various phases of the CSLC model. Specifically, three types of data are needed:

- **Operational Data:** The daily activities at (1) the franchisor headquarters, including six major entity types: employees; business outlets owned by franchisees or companies; prospective franchisees; product development; suppliers (e.g., marketing agents, accountants, insurance providers, attorneys, and real estate agents); and government offices (e.g., taxes and worker compensation); and (2) the franchisee business outlet, including six major entity types: customers, employees, contacts with the headquarters, product inventory, suppliers, and government offices.

Table 1. The customer service life cycle model in franchising

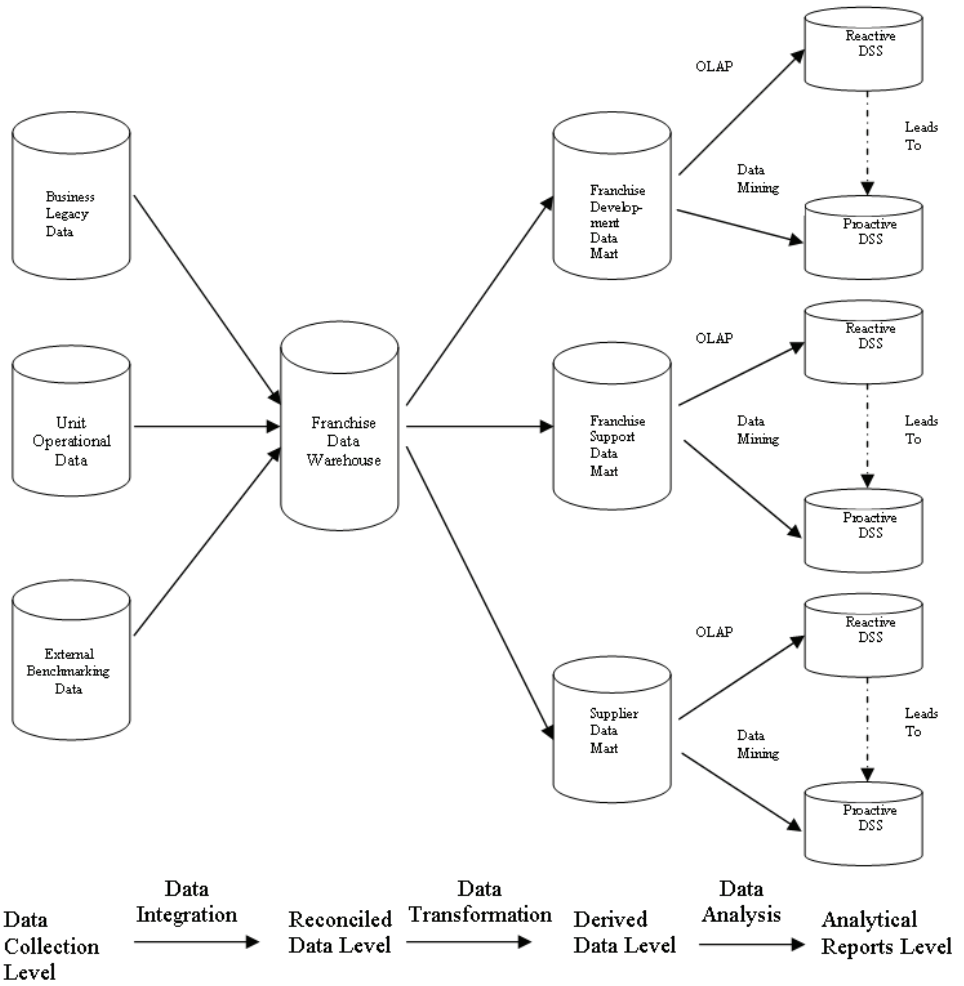
CSLC	Sub-stages	Example: Technology Strategies of WSI Internet (www.wsicorporate.com)
Requirements	Understanding How Franchising Works	Internet
	Investigating Franchise Opportunities	Internet • Global Gateway • Internet Solutions • Portfolio & Technologies • About Us • Franchise Opportunities • Experts Online • Interactive Online
	Obtaining Franchisee Prospectus	Internet • E-mail
	Making the Choice	Internet
Acquisition	Preparing Business Plan	Internet
	Financing the Franchised Business	Internet
	Signing the Contract	Internet
Ownership	Marketing & Promoting the Franchise Products/Services	Internet/Intranet/Extranet • Need a Website? • Live Call • Employment @ WSI • Hot News • WSI ICE Flash • Message from the President
	Managing the Franchise System	Internet Intranet • Serving Franchisees' Customers Extranet
	Building the Relationship between the Franchisor and the Franchisee • The Courting Phase • The "We"-Phase • The "Me"-Phase • The Rebel Phase • The Renewal Phase	Internet Intranet • Knowledge Centre • Training at Headquarters • Newsletter • Meetings • Toll-free Phone Line Extranet • Purchasing Cooperatives
Renewal or Retirement	Becoming a Professional Multi-unit Franchisee or Retiring from the Franchise System	Internet Intranet Extranet

- **External Data:** The relationship management activities in the franchise community, including three major entity types: the relationship with customers, the relationship with partners and suppliers, and the performance benchmarks in the industry.
- **Legacy Data:** the activities that have been working well or gradually adapted since the franchise system came into existence. Examples include (1) rewarding activities to the top performers among the franchisees; (2) efficient procedural activities for the employees at the headquarters supporting the franchisees; and (3) effective and friendly face-to-face activities for the field representatives to serve the franchisees at their outlets.

MANAGING FRANCHISE ORGANIZATIONAL INFORMATION

An architecture, adapted from Inmon (1996), of data mining in franchise organizations with respect to the franchisor/franchisee relationship management depicted in Figure 1 is shown in Figure 2. The architecture consists of four levels: (1) data collection level, holding operational, external, and legacy data collected from the franchise business environment; (2) reconciled data level, holding data warehouse data that are subject-oriented, integrated, time-variant, and non-volatile (Inmon, 1996); (3) derived data level, containing several data marts (e.g., franchisees, customers, competitors, and suppliers) derived from the data warehouse based on various franchisee/customer-centered segmentations; and (4) the analytical reporting level, producing various relationship performance reports (e.g., business outlet periodical summary, financial, scorecards, and mysterious shopping) for the decision makers using the decision support systems (DSS) for their decision making. To move from the data collection level to the reconciled data level, data integration is needed. It is a very time consuming process that involves the activities such as cleansing, extracting, filtering, conditioning, scrubbing, and loading. To move from the reconciled data level to the derived data level, data transformation is needed, which involves the activities such as replication,

Figure 2. An architecture of data mining in franchise organizations



propagation, summary, aggregate, and metadata. To move from the derived data level to the analytical reporting level, data analysis is needed, which involves two major activities: online analytical processing (OLAP) and data mining.

A typical OLAP analysis consists of pre-defined multi-dimensional queries. Some examples in franchising include:

- Show the gross margin by product category and by franchise outlets from Thanksgiving to Christmas in the last five years.
- Which franchise outlets are increasing in sales and which are decreasing?
- Which kinds of customers place the same orders on a regular basis at certain franchise outlets?
- How many franchisees did we lose during the last quarter of 2001, compared to 2000, 1999, and 1998?

Other OLAP activities include spreadsheet analysis, data visualization, and a variety of statistical data modeling methods. Since the query activities are pre-defined, we call the supporting systems reactive DSS.

Data mining, on the other hand, is used to identify hidden relationship patterns of the data residing in the data marts. Typical data mining modeling analysis can be classified into the following three categories:

- **Classification and Prediction:** Using techniques such as RFM (recency, frequency, and monetary), regression, decision tree, and neural network;
- **Association Rules:** Using techniques such as market basket analysis, correlation analysis, cross-sell analysis, and link analysis;
- **Cluster Analysis:** Using techniques such as partition, hierarchy, outlier, and density analysis.

Table 2, adapted from Delmater and Hancock (2001), shows that data mining techniques can be used to help serve franchisees' customers at the different stages of the CSLC model.

Since the data mining queries and related activities are not pre-defined, we call the supporting systems proactive DSS. A major drawback of proactive data mining is the fact that without vigilant preliminary examination of data characteristics, the mining activities may end in vain (Delmater & Hancock, 2001). In order to achieve higher success rate of data mining, we suggest (on the right side of Figure 2) that OLAP-based queries need to be conducted first. For example, one may find, through daily OLAP queries, that certain segments of customers buy certain products frequently. This pattern may lead to perform thorough and proactive analysis of the customer-product relationship. The results may help the company provide legendary service to its clients and generate higher profits.

MANAGING FRANCHISE ORGANIZATIONAL KNOWLEDGE

As mentioned in the discussions of Figure 1, the key for building the franchisor/franchisee "family" relationship is in the franchise organizational learning. In addition, there are five vital factors for a successful learning program: knowledge, attitude, motivation, individual behavior, and group behavior. Thus, working knowledge is the real foundation of a successful franchise "family" relationship. The working knowledge is structured in many forms of profiles that are embedded in the operational manuals of the franchise business processes. Table 3 gives some examples of those working knowledge profiles with respect to the CSLC business processes associated with the sub-stages in Table 1.

A working knowledge profile is developed when a certain task of the CSLC process is repeated several times with superior results. Consider the site profile used at the "marketing & promoting the franchise products/services" sub-stage in Table 3. The site profile is used to assist the new franchisee with locating a high-quality business site. Typically it is the real estate department at the franchisor headquarters that is responsible for the profile development. The site profile is unremittingly being tested and enhanced. Various OLAP/data mining analytical reports, monitoring the performance of the sites, are generated at the Analytical reports level shown in Figure 2. Based on those reports, the real estate experts and their teams are able to fine-tune the attributes and the parameters within the site profile. Most often, the corresponding data collection procedures in the CSLC sub-stage also need to be revised and perfected so that better report scorecards can be generated.

This process of enhancing the working knowledge profile will achieve its high peak when both the franchisor and the franchisees are arriving at the professional and renewal stage

Table 2. Franchisees' customers data mining using the CSLC approach

CSLC	Explanation	Data Mining Activities (and Techniques Used)
Requirements	Finding and reaching the customers	• Lead Generation • Market Analysis & Segmentation (Classification and Prediction) • Mining Web Site Visitors (Association Rules) • Text Mining Usenet Newsgroups (Cluster Analysis)
Acquisition	Selling to the customers	• Customer Acquisition Profiling • Customer Segmentation Strategy (Classification and Prediction) • Online Shopping Tracking (Association Rules) • Pricing Strategy (Association Rules) • Customer-centric Selling (Association Rules) • Text Mining Contact E-Mails (Cluster Analysis) • Scenario Notification (Association Rules)
Ownership	Satisfying the customers after the sales	• Customer Service • Inquiry Routing (Association Rules) • Text Mining E-Mails & Inquiries (Cluster Analysis) • Scenario Notification (Association Rules) • Staffing Level Prediction (Classification and Prediction)
Retirement or Renewing	Retaining the customers so that you can continue coming back	• Customer Retention • Sharper Customer Focus through Loyalty Program (Classification and Prediction) • Detecting Customer Complaints through Text Mining (Cluster Analysis) • Detecting Inappropriate Customer Services (Cluster Analysis) • Individual Customer Profiles (Classification and Prediction) • Scenario Notification (Association Rules)

Table 3. The CSLC model of franchise working knowledge

CSLC Sub-stages	Examples of Working Knowledge Profiles
Understanding How Franchising Works	• Lead Generation Profile • Website Visitor Profile
Investigating Franchise Opportunities	• Benchmark Profile • Successful Franchisee Profile
Obtaining Franchisee Prospectus	• Prospectus Profile
Making the Choice	• Competitor Profile
Preparing Business Plan	• Business Plan Profile
Financing the Franchised Business	• Financing Institute Profile • Non-traditional Franchising Profile
Signing the Contract	• Franchisee Profile
Marketing & Promoting the Franchise Products/Services	• Site Profile • Customer Profile • Product Profile
Managing the Franchise System	• Support Team Profile • Employee Profile • Supplier Profile
Building the Relationship between the Franchisor and the Franchisee	• Event Management Profile • Best Practices Profile • Crisis Management Profile
Becoming a Professional Franchisee or Retiring from the Franchise System	• Multi-unit Franchisee Profile • Co-branding Profile • Opportunities Profile • Social Network Profile

Figure 3. Working knwoledge repository in franchise organizations

		User Skill Levels				
		Beginner in the Courting Phase: Beginner Guide	Novice in the "We"-Phase: Practicing	Advanced in the "Me"-Phase: Doing	Master in the Rebel Phase: Teaching Others	Professional in the Renewal Stage: Improving and Leveraging
Working Knowledge Levels	Collaborative Team	Process of Influencing Others for Knowledge Sharing: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior				
	Franchisee Outlet	Working Knowledge Profiles for Running the Franchisee Outlet: Customer Profile, Employee Profile, Product Profile				
	Franchisor Headquarters	Working Knowledge Profiles for Running the Franchisor Headquarters: Franchisee Profile, Site Profile, Product Profile, Employee Profile, Event Management Profile				
	Franchise Community	Working Knowledge Profiles for Relationship Management with the Community: Supplier Profiles, Community Profiles				

of growth. A significant phenomenon of being a professional franchisor and a renewal franchisee are their ability to leverage the assets of the hard-earned working knowledge profiles into dynamic capabilities and high-business-value-creation completive-advantage strategies (Chen, Seidman, & Justis, 2005; Chen, Yuan, & Dai, 2004). The new products or services coming out of the process of leveraging the working knowledge profiles may transform the franchise business into a more, sometimes surprisingly, profitable enterprise. The capability of leveraging the assets of franchise working

knowledge into profitable products or services is at the heart of a successful franchise.

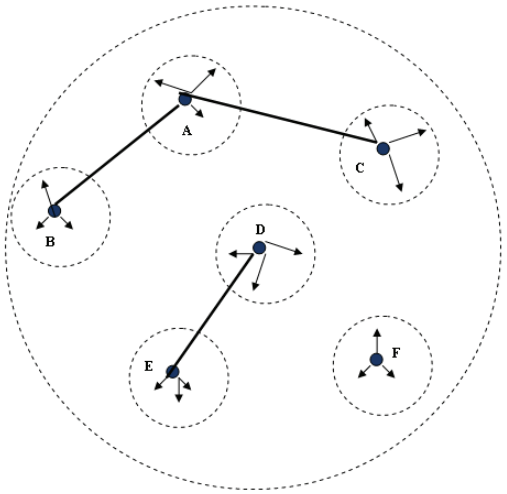
For instance, consider the site selection working knowledge at McDonald's. The Franchise Realty Corporation real estate business, a result of site selection asset leveraging, is the real moneymaking engine at McDonald's. This as can be evidenced from the following speech of Ray Kroc, founder of McDonald's, to the MBA class at the University of Texas at Austin in 1974: "Ladies and gentlemen, I'm not in the hamburger business. My business is real estate" (Kiyosaki, 2000, p. 85). In the book McDonald's: Behind the Arches (Love, 1995, p. 152), Ray Kroc commented further, "What converted McDonald's into a money machine had nothing to do with Ray Kroc or the McDonald brothers or even the popularity of McDonald's hamburgers, French fries, and milk shakes. Rather, McDonald's made its money on real estate…" McDonald's makes money out of real estate by leasing properties from landlords and then subleasing the stores to the franchisees. The professional franchisees, many of which are multiunit operators, can then focus on expending the business without worrying about finding good locations for the growth. This moneymaking real estate strategy is what separates McDonald's from other fast-food chains (David, 2003).

Knowledge repository systems, consisting of working knowledge profiles such as the one shown in Figure 3 (Chen, Hammerstein, & Justis, 2002), can be linked into the franchisor headquarters and the franchisee outlets for knowledge sharing and learning. Such a repository has two dimensions. First, there is a working knowledge level for the collaborative team, the franchisee outlet, the franchisor headquarters, and the franchise community. Second, there are user skill levels, including beginner in the courting Phase, novice in the "we"-phase, advanced in the "me"-Phase, master in the rebel phase (since the rebel ones tend to be those who know the system very well and are capable of influencing others to follow them), and Professional in the renewal stage of franchisee life cycle. The foundation of the framework is the working knowledge of the five crucial elements—knowledge, attitude, motivation, individual behavior, and group behavior—used by the collaborative team, to effectively influence others in building the franchise "family" relationship. The working knowledge profiles at the franchisee outlet, the franchisor headquarters, and the franchise community can be modularized according to user's level. An intranet-based curriculum of working knowledge modules can then be designed for the users to learn the working knowledge profiles effectively.

FUTURE TRENDS

The third industrial revolution, combining Internet technology with globalization, produces various new data mining opportunities for the growth of franchise organizations. For example, knowledge network applications, using data mining techniques such as social network analysis, can be developed to connect professional franchisees in the world. The goal is to enable the franchise system to venture into new global emerging markets, for example, China, through international franchising and develop innovative products/services through asset leveraging. This could be done because franchise capabilities, structured in the working knowledge repository shown in Figure 3, enable the professional franchisees to work with the franchisor to continuously improve and leverage the current franchise working knowledge. An example of knowledge networks of professional franchisees can be illustrated in Figure 4. There are six professional franchisees (A-F) in the figure with three clusters (A-C, D-E, and F) of knowledge networks. Each professional franchisee (a dot) has his/her personal knowledge network (arrows pointing out of the dot) tested and built over the years while doing day-to-day problem solving at the franchisee outlet. The knowledge network may include the customers' likes and dislikes, the kind of employees to hire, the competitors' and suppliers' pricing strategies, and the social needs in the local community. Each professional franchisee is surrounded with a circle with dashed lines, meaning there is no limit to the personal knowledge network. In order to solve the problems more effectively, professional franchisees may share with each other their approaches. Thus, clusters (connected dots) of knowledge network are formed for solving various problems more effectively (Chen, Justis, & Wu, 2006).

Figure 4. Knowledge networks of professional franchisees



CONCLUSIONS

Franchising has been popular as a growth strategy for small businesses; it is even more so in today's global and e-commerce world (Chen, Chen, & Wu, 2005). The essence

of franchising lies in managing the "family" relationship between the franchisor and the franchisee. In this article we showed that data mining plays an important role in growing and nurturing such a "family" relationship. Specifically, we discussed: (1) how franchise organizational data can be managed effectively using the methodology of customer service life cycle; (2) how franchise organizational information is deciphered from the customer-centered data using OLAP and data mining analytical techniques; and (3) how the franchise organizational knowledge is leveraged to grow the franchise system. The ability to continue leveraging the organizational knowledge assets based on the good "family" relationship is really what a franchise business is about.

KEY TERMS

Customer Service Life Cycle (CSLC): Serving customers based on a process of four stages: requirements, acquisition, ownership, and retirement. Many companies are using the approach to harness the Internet to serve the customers.

Data Mart: A small database with data derived from a data warehouse.

Data Mining: Analytical techniques used to find out the hidden relationships or patterns residing in the organizational data.

Data Warehouse: A database that is subject-oriented, integrated, time-variant, and non-volatile.

Franchisee: The individual or business that receives the business rights and pays the royalties for using the rights.

Franchisee Life Cycle: The stages a franchisee goes through in the franchise system: courting, "we," "me," rebel, renewal.

Franchising: A business opportunity based on granting the business rights and collecting royalties in return.

Franchisor: The individual or business that grants the business rights.

Franchisor/Franchisee Learning Process: The stages of learning, including Beginner, Novice, Advanced, Master, and Professional.

Franchisor/Franchisee Relationship Management: The vital factor for the success of a franchise, including knowledge, attitude, motivation, individual behavior, and group behavior.

Data Mining in Tourism

Indranil Bose
The University of Hong Kong, Hong Kong

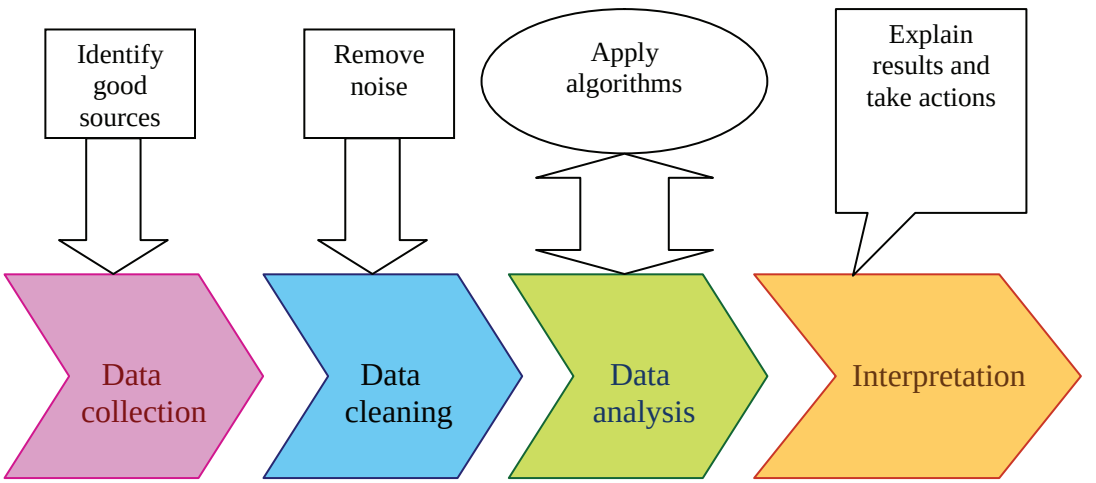
INTRODUCTION

Everyday, millions of people travel around the globe for business, vacations, sightseeing, or other reasons. An astronomical amount of money is spent on tickets, accommodations, food, transportation, and entertainment. According to World Travel and Tourism Council, travel and tourism represents approximately 11% of the worldwide gross domestic product (GDP) (Werthner & Ricci, 2004). Tourism is an information-based business where there are two types of information flow. One flow of information is from the providers to the consumers or tourists. This is information about goods that tourists consume such as tickets, hotel rooms, entertainments, and so forth. The other flow of information which follows a reverse direction consists of aggregate information about tourists to service providers. In this chapter we will discuss the second form of information flow about the behavior of tourists. When the aggregated data about the tourists is presented in the right way, analyzed by the correct algorithm, and put into the right hands, it could be translated into meaningful information for making vital decisions by tourism service providers to boost revenue and profits. Data mining can be a very useful tool for analyzing tourism-related data.

BACKGROUND

According to Tan, Steinbach, and Kumar (2006), "Data mining is the process of automatically discovering useful information in large data repositories" (p. 2). It uses machine learning and statistical and visualization techniques to discover and present knowledge in a form that is easily comprehensible to humans. Data mining involves four key steps: (1) data collection, (2) data cleaning, (3) data analysis, and (4) interpretation and evaluation. During data collection the most suitable data need to be collected from the most appropriate sources. There is often a need to consolidate data from a number of sources. Cleaning or cleansing is the process of ensuring that all values in a data set are consistent and correctly recorded (Hui, Pandey, Steinbach, & Kumar, 2006). Obvious data errors are detected and corrected, and missing data is replaced in this step. The third and the most important stage of data mining is the analysis of the data using known techniques. Usually the analysis is done using statistical- or machine-learning-based approaches. The choice of the technique depends on the type of problem and also the availability of appropriate data mining software (Bose & Mahapatra, 2001). The most difficult part in data mining

Figure 1. Different steps in data mining



is interpretation of results obtained during data analysis. The analysis results may show a high degree of accuracy, but unless the accuracy can be related to the context of the data mining problem, it is of no use. Once some meaningful interpretation of the data analysis results can be done, the final step is to take action(s) so that the gathered knowledge can be put into practical use. In the case of tourism data mining, the data mining process goes through the same four steps. Figure 1 identifies the four steps involved in data mining and is similar to the one used in Bose and Pal (in press).

TOURISM DATA MINING

In this section we discuss the different types of machine learning techniques and explain how they have been used for analyzing data related to tourism. Usually two types of machine learning activities are common in tourism—association learning and classification learning. In association learning, the learning method searches for associations or relationships between features of tourist behavior. For example, the algorithm may try to find out if tourists who are interested in shopping also prefer to stay near the center of a city. That is, there is no specific target variable in this type of data mining, and so this is popularly known as unsupervised learning. A second style of machine learning is classification learning. This learning scheme takes a set of classified examples from which it discovers a way of classifying unseen examples. This is a form of supervised learning, in which there is a specific target variable**.** For example, by using classification analysts may be interested to classify tourists into two groups—high spenders and low spenders for luxury items. In this case the target variable is expenditure on luxury items. Based on a set of demographic and other variables the classification algorithm will establish the specific attributes of a tourist that qualify them as a high spender or a low spender. Next, we describe the various machine learning techniques used in tourism data mining.

Artificial neural networks (ANN). ANNs are nonlinear predictive models that learn through training (Jain, Mao, & Mohinuddin, 1996). They are composed of interconnected neurons. Each neuron receives a set of inputs. Each input is multiplied by a weight. The sum of all weighted inputs determines the activation level. A very powerful algorithm that is used in training ANNs is called *backpropagation*. Here, weights of the connection are iteratively adjusted to minimize the error based on the difference between desired and actual outputs.

Clustering. This is the process of dividing objects into groups whose members are similar in some way(s) (Han, Kamber, & Tung, 2001). Although there are many clustering algorithms, the commonly used ones are exclusive clustering and distance-based clustering. In an exclusive clustering algorithm if a certain datum belongs to a definite cluster then it cannot be included in another cluster. In distance-based clustering, if two or more objects are "close" according to a given distance they are grouped into the same cluster. Self-organizing feature map (SOFM) is a special type of an ANN-based algorithm that performs clustering.

Rough sets (RS). RS theory is proposed to address the problem of uncertainty and vagueness in the classification of objects (Slowinski & Vanderpooten, 2000). It is founded on the hypothesis that every object is associated with some information, and objects that are associated with the same information are similar and belong to the same class. The first step of RS is discretization of independent attributes where numeric attributes are converted to categorical attributes. The second step is formation of reducts that provide same quality of classification as the original set of attributes. The last step is classification of unknown data based on decision rules and reducts.

Support vector machines (SVM). SVM classifies an input vector into known output classes. It starts with several data points from two classes and obtains the optimal hyperplane that maximizes the separation of the two classes. For nonlinearly separable data, it uses the kernel method to transform the input space into a high dimensional feature space, where an optimal linearly separable hyperplane can be constructed. Examples of kernel functions are linear function, polynomial function, radial basis function, and sigmoid function (Chang & Lin, 2001).

Use of Data Mining in Tourism

Tourism policy makers, retail business executives, directors of scenic spot management companies, and government organizations want to know the relationship between tourism activities and preferences of tourists so that they can plan for required tourism infrastructures, such as accommodation sites and transportation. They also need detailed analysis to help them make operational, tactical, and strategic decisions. Examples of these include scheduling and staffing, preparing tour brochures, and investments. Due to the need for this analysis, formal statistical techniques were introduced in tourism. However, statistical techniques suffer from the drawback that several assumptions about distributions of data have to be made before any analysis can be conducted. If these assumptions are violated there is no guarantee that the results will be valid. This limitation of statistical methods has prompted researchers to use machine-learning-based data mining for tourism data analysis. The three main uses of data mining techniques in the tourism industry are: (1) forecasting expenditures of tourists, (2) analyzing profiles of tourists, and (3) forecasting number of tourist arrivals. In the following sections examples are presented to demonstrate how data mining techniques are used to support these activities.

Forecasting Tourist Expenditures

ANNs with different architectures were built to forecast the tourist expenditures in the Balearic Islands by Palmer, Montano, and Sese (in press). The performances of different architectures were contrasted by comparing the mean absolute percentage error (MAPE) incurred, and it was shown that the forecasting accuracy of ANNs varied with the architecture. In another study that predicted shopping expenditures by tourists visiting Hong Kong, RS was used (Law & Au, 2000). Using nine explanatory variables and four levels in the dependant variable, the researchers devised 15 decision rules that could forecast shopping expenditures of tourists with 94% accuracy. The use of RS for predicting tourist expenditures in dining in Hong Kong was reported by Au and Law (2002). While using 10 explanatory variables and 18 induced decision rules, the researchers reported 83% accuracy in predicting dining expenditures of tourists.

Analyzing Profiles of Tourists

To forecast the profiles of tourists in Cape Town, South Africa, ANN was used by Bloom (2005). The researcher used survey data collected from 694 respondents who visited Cape Town in 2000-2001. The SOFM method was used for categorizing tourists into three groups: (1) vibrant and energetic (39.8%), (2) established and settled (34.3%), and (3) pleasure seekers (25.9%). SOFM was also used to identify segments in the market of West Australian senior tourists (Kim, Wei, & Ruys, 2003). Using three factors: (1) demographic, (2) travel motivation, and (3) concerns, the respondents were clustered into four groups: (1) active learners, (2) relaxed family body, (3) careful participant, and (4) elementary vacationer. Tourism development at any given place is often dependant on whether the local residents are in favor of it or not (Pérez & Nadal, 2005). A survey was conducted among 791 residents in the Balearic Islands, and clustering was used to categorize the local residents into (1) developmental supporters (11%), (2) prudent developers (26%), (3) ambivalent and cautious (24%), and (4) protectionists (20%).

Forecasting Arrivals of Tourists

ANNs have been a popular choice in forecasting tourist arrivals to a location. Backpropagation-based ANN has been used to forecast tourist arrivals from the United States to Durban, South Africa based on available data from 1992-1998 (Burger, Dohnal, Kathrada, & Law, 2001). ANNs were also used to predict the number of arrivals of Japanese tourists to Hong Kong using data on six explanatory variables, collected from a variety of sources over the period 1967-1996 (Law & Au, 1999). The ANN model yielded the lowest MAPE of 10.59% and performed significantly better than statistical models. The same study was repeated for forecasting Taiwanese tourist arrivals to Hong Kong using data from the same time period and the same variables (Law, 2000). Again, ANN yielded the best forecasting result with an MAPE of 2.76%. In a study that extended the previous studies by considering tourist arrivals from six different countries to Hong Kong (i.e., USA, Japan, Taiwan, Korea, UK, and Singapore) ANN again proved its supremacy over statistical methods. RS has also been used for travel demand analysis (Goh & Law, 2003). In this study, using data collected between 1985-2000 and with visitors to Hong Kong from 10 countries, the RS model was able to predict increases or decreases in the number of tourist arrivals with an accuracy of 87.2%. It was also found that volume of trade and GDPs were the most important predictor variables. Recently, the method of SVM has been used for predicting tourist arrivals to Barbados and has yielded a lower MAPE when compared to several statistical models (Pai & Hong, 2005).

Assessment of Data Mining for Tourism

In this chapter three specific applications of tourism data mining have been discussed. Other application areas of data mining include tour path planning using genetic algorithms (Yao, Huang, & Lee, 2003), where the itinerary of visiting multiple attractions is modeled as a traveling salesman person. Another novel application includes the use of ANN for identifying activities pursued by tourists at a popular beach in Australia (Green, Blumenstein, Browne, & Tomlinson, 2005). This is done by using ANN on images of beach scenes and segmenting these images to identify tourists in the scenes.

In general, it can be said that ANN is the most popular data mining technique in tourism. This is possibly because of the fact that ANNs can provide high performance in terms of accuracy for tourism data and do not seem to be affected much by the presence of noise. Clustering using SOFM is also a preferred technique for tourism data analysis due to its simplicity of operation. Another reason for the popularity of these two techniques is that prepackaged software that uses these techniques is readily available on the market and can be used for data analysis with very little training.

FUTURE TRENDS

From the previous discussion we can see that various data mining techniques have been used successfully for tourism-related data analysis in recent times. Most of the techniques have been employed using prepackaged software. Researchers have not devoted much effort to developing data mining software specifically dealing with tourism. There are some techniques such as Bayesian belief networks, case-based reasoning, and decision trees that have not been used much.

This may be due to the lack of availability of prepackaged software that uses these techniques. In the future, we expect to see tourism data mining using these techniques.

The other approach which we may see in the future is that of ensemble data mining in which more than one method is used for analyzing the data. When an ANN is used for forecasting tourist expenditures in a certain country, the performance may not be very good due to overtraining. However, if clustering is carried out before the ANN forecast, the investigation can be much more meaningful because the data is grouped and preprocessed to an extent. There may be opportunities to combine ANN with RS or SVM with clustering in a similar fashion.

CONCLUSION

It is only recently that tourism data mining has caught the attention of researchers and definitely much remains to be done. Only three main tourism data mining application areas have been identified in this paper. It is likely that more areas will come up in the future such as tourism recommendation analysis, tourism promotion response analysis, and so forth. Data mining holds much promise for improving these activities. Finally, only a limited number of data mining methods have been used so far. There are opportunities to use other popular data mining methods as well as ensemble data mining methods for analysis of tourism data.

KEY TERMS

Artificial Neural Networks (ANN): ANN is a pattern matching technique that uses training data to build a model and uses the model to predict unknown samples. It consists of input, output, and hidden nodes and connections between nodes. The weights of the connections are iteratively adjusted in order to get an accurate model.

Clustering: It is a technique that classifies instances into classes by calculating the distance between them and other instances. The instances that have the least distance between them are grouped into the same class. It is a type of unsupervised learning.

Decision Tree: It is technique for classifying data. The root node of a decision tree represents all examples. If these examples belong to two or more classes, then the most discriminating attribute is selected and the set is split into multiple classes.

Genetic Algorithms: These algorithms mimic the process of natural evolution and perform explorative search. The main component of this method is chromosomes that represent solutions to the problem. It uses selection, crossover, and mutation to obtain chromosomes of highest quality.

Mean Absolute Percentage Error (MAPE): MAPE is used as a figure of merit to identify whether a data mining method is performing well or not. The lower the MAPE, the better the performance of the data mining method.

Rough Sets (RS): RS is a technique used for classification. It is based on the notion of approximate class membership of an unclassified observation. The main steps in RS analysis include discretization, formation of reducts, and enumeration of rules.

Self-Organizing Feature Map (SOFM): SOFM is a data mining method used for unsupervised learning. The architecture consists of an input layer and an output layer. By adjusting the weights of the connections between input and output layer nodes, this method identifies clusters in the data.

Support Vector Machines (SVM): SVM is a data mining method useful for classification problems. It uses training data and kernel functions to build a model that can appropriately predict the class of an unclassified observation.

Tourism Recommendation System: Information technology may be used to make recommendations to tourists about sightseeing venues, restaurants, entertainment locations, shopping, and so forth. These systems will revolutionize future travel by making recommendations using data on demographics and preferences of tourists.

Data Streams as an Element of Modern Decision Support

Damianos Chatziantoniou

George Doukidis
Athens University of Economics and Business, Greece

INTRODUCTION

Traditional decision support systems (DSS) and executive information systems (EIS) gather and present information from several sources for business purposes. It is an information technology to help the knowledge worker (executive, manager, analyst) make faster and better decisions. So far, these data were stored statically and persistently in a database, typically in a data warehouse. *Data warehouses* collect masses of operational data, allowing analysts to extract information by issuing decision support queries on the otherwise discarded data. In a typical scenario, an organization stores a detailed record of its operations in a database, which is then analyzed to improve efficiency, detect sales opportunities, and so on. Performing complex analysis on these data is an essential component of these organizations' businesses. Chaudhuri and Dayal (1997) present an excellent survey on decision-making and online analytical processing (OLAP) technologies for traditional database systems.

In many applications however, it may not be possible to process queries within a database management system (DBMS). These applications involve data items that arrive online from multiple sources in a continuous, rapid and time-varying fashion (Babcock et. al., 2002). These data may or may not be stored in a database. As a result, a new class of data-intensive applications has recently attracted a lot of attention: applications in which the data is modeled not as persistent relations but rather as transient *data streams*. Examples include financial applications (streams of transactions or ticks), network monitoring (stream of packets), security, telecommunication data management (stream of calls or call packets), web applications (clickstreams), manufacturing, *wireless sensor networks* (measurements), RFID data, and others. In data streams we usually have "continuous" queries (Terry et. al., 1992; Babu & Widom, 2002) rather than "one-time." The answer to a *continuous query* is produced over time, reflecting the stream data seen so far. Answers may be stored and updated as new data arrives or may be produced as data streams themselves. Continuous queries can be used for monitoring, alerting, security, personalization, etc. Data streams can be either *transactional* (i.e., log interactions between entities, such as credit card purchases, web clickstreams, phone calls), or *measurement* (i.e., monitor evolution of entity states, such as physical phenomena, road traffic, temperature, network).

How to best model, express and evaluate complex queries over data streams is an open and difficult problem. This involves data modeling, rich querying capabilities to support real-time decision support and mining, and novel evaluation and optimization processing techniques. In addition, the kind of decision support over data streams is quite different from "traditional" decision-making: decisions are "tactical" rather than "strategic." Research on data streams is currently among the most active areas in database research community. Flexible and efficient stream querying will be a crucial component of any future data management and decision support system (Abiteboul et al., 2005).

BACKGROUND

The database research community has responded with an abundance of ideas, prototypes and architectures to address the new issues involved in data stream management systems (DSMS). STREAM is Stanford University's approach for a general-purpose DSMS (Arasu et. al., 2003); *Telegraph* and *TelegraphCQ* (Madden & Franklin, 2002: Chandrasekaran et. al., 2003) are prototypes focused on handling measurements of sensor networks, developed in Berkeley; *Aurora* is a joint project between Brandeis University, Brown University and MIT (Carney et. al., 2002) targeted towards stream monitoring applications; AT&T's Hancock (Cortes et. al., 2000) and *Gigascope* (Cranor et. al., 2003) projects are special-purpose data stream systems for network management; Tribeca (Sullivan, 1996) and NiagaraCQ (Chen, et. al., 2000) are other well-known projects from Telcordia and University of Wisconsin respectively. The objective of all these projects is to develop systems that can support the challenging analysis requirements of streaming applications.

Furthermore, a plethora of articles, papers and tutorials appeared recently in the research literature. Some of the most well known survey articles follow. Faloutsos (2004) discusses indexing and mining techniques over data streams; Koudas and Srivastava (2003), present the state-of-the-art

algorithms on stream query processing; Muthukrishnan (2003), reviews data stream algorithms and applications; Babcock et. al. (2002), present an excellent survey on data stream prototypes and issues; Garofalakis et. al. (2002), discuss various existing models and mining techniques over data streams.

APPLICATIONS

Stream applications span a wide range of everyday life. Real-time analytics is an essential part of these applications and becomes rapidly more and more critical in decision-making. It is apparent from the list of areas below that efficiently querying and processing data streams is a necessary element of modern decision support systems.

- **Telecommunications:** The telecommunications sector is undoubtedly one of the prime beneficiaries of such data management systems due to the huge amount of data streams that govern voice and data communications over the network infrastructure. Examples of stream analysis include fraud detection, real-time billing, dynamic pricing, network management, traffic monitoring and so on. Streams (calls, packets) have to be mined at real-time to discover outliers and patterns (fraud detection); correlated, joined and aggregated to express complex business rules (billing, dynamic pricing); and monitored—computing averages and min, max values over periods of time—to uncover unusual traffic patterns (network management).
- **Sensors:** Sensor technology becomes extremely widespread and it will probably be the next killer application: large number of cheap, wireless sensors attached to products, cars, computers, even sport players and animals, tracking and digitizing behavior, traffic, location and motion. Examples involve electronic property stickers (super markets, libraries, shopping carts, etc.), vehicle sensors (to electronically pay tolls, route traffic, set speed, etc.), and location-identification sensors (to report location, serve content, detect routes, etc.) A "sensor" world leads to a "stream" world. Millions of input data every few seconds need to be analyzed: aggregate (what is the average traffic speed), correlate (two products sell together), alert (quantity of a product is below a threshold), localize and monitor.
- **Finance:** Financial data streams come in many different forms: stock tickers, news feeds, trades, etc. Financial companies want to analyze these streams at real-time and take "tactical" business decisions (opposed to "strategic" decisions, associated to OLAP or data mining). For example, Charles Schwab wants to compute commission on each trade at real-time; Fidelity would like to route content in trades at real-time. Traderbot (www.traderbot.com) is a Web-based financial search engine that evaluates queries (both traditional and continuous) over real-time streaming data (e.g., "find all stocks between €20 and €200 where the spread between the high tick and the low tick over the past 30 minutes is greater than 3% of the last price and in the last 5 minutes the average volume has surged by more than 300%.")
- **Web management:** Large Web sites monitor Web logs (clickstreams) online to enable applications such as personalization, performance monitoring, and load balancing. Some web sites served by widely distributed web servers (e.g., Yahoo) may need to coordinate many distributed clickstream analyses, e.g. to track heavily accessed Web pages (e.g., CNN, BBC) as part of their real-time performance monitoring (Babcock et al., 2002}.
- **Network management:** Network traffic management systems monitor a variety of continuous data streams at real-time, such as packet traces, packet flows and performance measurements in order to compute statistics, detect anomalies, adjust routing, etc. The volume of data streams can be humongous and thus, query processing must be done very carefully.
- **Military:** One of the most interesting applications in military is battalion monitoring—where sensors are installed on every vehicle, human, etc.—having thousands of sensors reporting state in real-time. In these applications we want to know each time where vehicles and troops are. Examples include queries such as "tell me when three of my four tanks have crossed the front line" and "tell me when someone is pointing a gun at me."

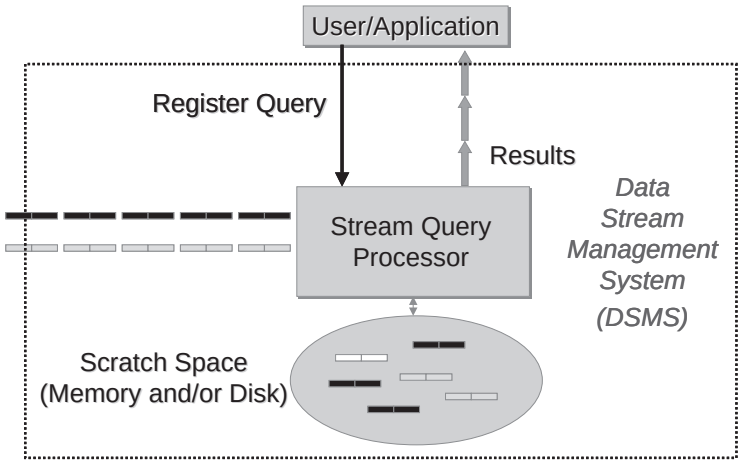
ISSUES AND CHALLENGES

Performing decision-making queries on top of data streams is a major challenge. For example, only one-pass algorithms are allowed (because data can be seen only once) and memory has to be managed very carefully (what to keep and what to discard). The need for a data stream management system comes in two forms: either the volume of data is huge and can not be stored in persistent relations (e.g., packet network traffic)—but still some data analysis has to be carried out, or an answer is required for a report at real-time (e.g., monitoring, alerting, fraud-detection.) As a result, DSMS are quite different in nature from traditional DBMS. Data is transient instead of persistent; queries may be "continuous" instead of "one-time"; processing techniques differ significantly, primarily due to main-memory management requirements. In Table 1 we list the differences between traditional database and data stream management systems (Babcock et al., 2002).

Table 1. Differences betweens DSMS and DBMS

DBMS	DSMS
Persistent relations	Transient streams
One-time queries	Continuous queries
Random access	Sequential access
"Unbounded" disk store	Bounded main memory
Only current state matters	History/arrival-order is critical
Passive repository	Active stores
Relatively low update rate	Possibly multi-GB arrival rate
No real-time services	Real-time requirements
Assume precise data	Data stale/imprecise

Figure 1. A generalized DSMS architecture



A generalized DSMS architecture is shown in Figure 1 (Babcock et al., 2002).

A user or application registers a (continuous) query with the stream system. As new stream data arrives, the answer of the registered query is updated. The stream query processor deals with the incoming data and has to decide on a significant number of important issues: should it shed data to keep up with the rate of the stream (leading to approximate answers)? How to best utilize main-memory space? How to handle multiple registered queries in an optimal way (maximizing resource utilization)? Finally, some scratch space may be required for intermediate computations.

The differences between DSMS and DBMS present several novel challenges for a system handling and analyzing data streams, both in terms of functionality and processing.

In terms of functionality (how to *use* data streams, i.e., reporting):

- Defining complex stream sessions (e.g., a network 'flow' or a finance 'burst')
- Representing nested stream structures (e.g., a sub-session within a session)
- Defining hierarchical statistical stream functions (similar to roll-up, drill-down in OLAP)
- Allowing multiple sources and/or multiple formats, possibly combine with persistent data
- Allowing user-defined functions—UDFs (e.g., a non-traditional financial computation)

In terms of evaluation (how to *process* data streams):

- Handling multiple, continuous, rapid, time-varying, ordered streams
- Having computations only in main-memory

- Queries may be continuous (not just one-time):
  - Have to be evaluated continuously as stream data arrives
  - Answer updated over time
- Queries may be complex
  - Beyond element-at-a-time processing
  - Beyond stream-at-a-time processing
  - Beyond traditional decision-making queries (scientific, data mining)
- Queries may involve nested structures
- Users may select for query answers to be
  - Exact (worst performance, sometimes not possible due to the stream rate)
  - Approximate (requires load shedding, (i.e. discarding data, better performance))

QUERYING AND EVALUATING DATA STREAMS

The challenges mentioned in the previous section lead to a number of major issues in querying and processing data streams. Understanding these aspects is crucial in developing a stream system. Different systems follow different methodologies in processing data streams (as presented in section 0).

Windows

Being able to formulate queries on top of data streams is a major component of any stream system. Most system prototypes extend SQL in some way in order to make it suitable for stream processing. For example, AT&T's Gigascope defines GSQL and Stanford's STREAM proposes CQL. Most stream query languages reference and produce both relations and streams.

Relations, Streams⟶***Stream Query Languages***⟶Relations, Streams

It is important, however, to transform infinite, unbounded streams to finite relations which then can be manipulated by a query processor. Defining *windows of streams* through some window specification syntax is the mechanism to turn (part of) a stream to a relation. For example, one could define a window as the one-thousand most recent stream tuples. Figure 2 shows graphically this concept.

Windows can be based on ordering attributes (e.g., a sliding or shifting window), tuple counts, explicit markers (called punctuations), etc. An application or a query may define more than one window and "join" them together.

Query Evaluation

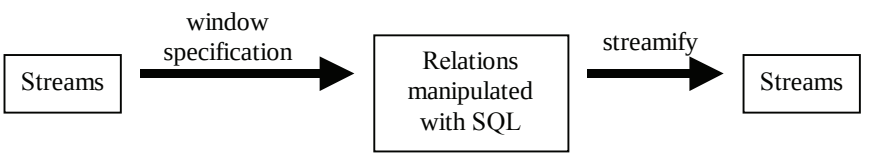
The unique characteristics of data streams lead to different evaluation algorithms and query processing: data elements arrive continuously, possibly at variable arrival rate; data streams are potentially unbounded in size; general retrieval of past elements is very difficult, if not impossible. As justly pointed out by Garofalakis et al. (2002), "you only get one look." This does not exclude the presence of conventional data stored in some traditional database system.

As a result, algorithms operate mainly in main-memory and involve one-pass techniques (or few-passes, if the input data stream can be organized in input blocks). Operators include—besides the traditional ones (selection, projection)—operations specific for combining and aggregating multiple streams, such as sliding window join and merging (Arasu et al., 2006). Optimization is very different than traditional DBMS. The goal in DSMS is to maximize the tuple output rate for a query (i.e., instead of seeking the least cost plan, seek the plan with the highest tuple output rate). Specialized data structures (synopses) that allow fast modifications and summarize efficiently information are frequently used. Finally, architectures are usually data-flow oriented (i.e., operators are assembled together in a workflow-style diagram).

Adaptive Query Processing

Traditional query processors use a request-response paradigm for query answering, where users pose a query, the optimizer finds the "best" query plan and proceeds with query evaluation. However, the introduction of continuous queries along with the possibility of a large number of registered queries with the stream manager changes this model significantly.

Figure 2. Turning streams to relations



An aspect of continuous query is the need for adaptability to change: unbounded queries will run long enough to experience changes in system and data properties as well as system workload during their run. A continuous query engine should adapt gracefully to these changes, in order to ensure efficient processing over time (Madden, Shah, et. al., 2002). The goal of an *adaptive query processing* system is to maximize utilization of storage and computation (in terms of operator sharing) of multiple simultaneous queries present in the system.

Exact vs. Approximate Answers

Traditional database systems compute exact answers for queries. However, there are cases that approximate answers as either "good enough" (e.g., histograms, sketches, traditional DBMS) or "the only possibility" (e.g., DSMS where main-memory limitations and one-pass algorithms reduce the class of queries with exact answers). High quality approximate answers are often acceptable instead of exact answers. Several approximation algorithms for data streams applications have been developed in recent years. This work has led to some general techniques for data reduction and synopsis construction, such as sketches, random sampling, histograms, and wavelets. The research on these summarization techniques led to some work on approximate query answering. An overview of stream algorithms for computation of synopsis structures appears in Guha (2005).

Load Shedding

Systems have a limit on how much incoming stream tuples can handle. As a result, when the arrival rate is too high (e.g., during spikes), queues will build up and the system will become overloaded. In this case, some *load shedding* (i.e., discarding some incoming stream data)—is necessary for the system to continue functioning properly (Babcock et al., 2004; Tatbul et al., 2003). In general, there are two kinds of load shedding, semantic and random. Semantic shedding is based on filtering, that is, there is a filter (a predicate) that is applied on each stream tuple with selectivity 1-p. Random shedding is based on dropping randomly incoming data with a probability p%, eliminating thus p% of the input load.

A stream system should be able to answer three questions: when, where and how much load shedding. The first issue—when load shedding should take place—requires constant monitoring of the system. The second one involves deciding the place in a query plan that load shedders will be added. For example, Aurora, a DSMS prototype, defines a stream query as a network (a workflow) of operators. Load shedding can be modeled as another operator, placed within this network. Dropping tuples as early as possible saves resources but there may be a problem later, if streams fan out to multiple queries. The last issue has to do with estimating of how much shedding is required (percent of random drops or filtering appropriately).

Mining Streams

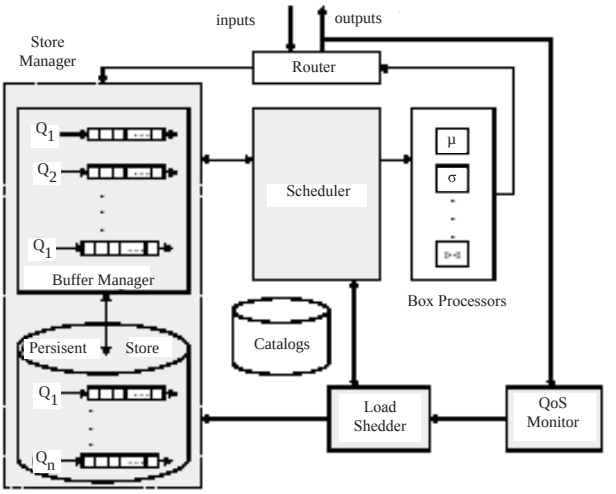
An orthogonal issue to processing streams is mining and indexing streams at real time (Garofalakis et. al., 2002). The goal of this topic is to find patterns in a sequence of measurements (financial, sensor, etc.) Besides the traditional mining patterns (classification, clustering and association rules), there exist many time series patterns that are of special interest in stream analysis (Faloutsos, 2004; Lerner et. al., 2004).

SYSTEM PROTOTYPES

The interest on data streams has led many research organizations (mainly in the U.S.) in the development of data stream prototypes. We list below some of the most well known systems.

- **Aurora:** Aurora is a joint project between Brandeis University, Brown University and MIT targeted towards stream monitoring applications. The processing mechanism is based on the optimization of a set of operators, connected in a data flow graph. Queries (three modes: continuous, ad-hoc and view) are formulated through a graphical "boxes and arrows" interface. Aurora's architecture is shown in Figure 3 (Carney et al., 2002).
  The designers of the Aurora stream system claim five unique features that distinguish it from other stream proposals: a workflow-orientation, a novel collection of operators, efficient scheduling, quality of service concerns and novel optimization methods.
  A workflow orientation is necessary due to the frequent preprocessing required for data streams. This way, users design an application (a workflow) with a "boxes" and "arrows" GUI and the system can optimize it more efficiently. The set of operators include "boxes" for filtering, mapping, aggregation (windowed) and join, similar to other stream systems. However, there are some distinct features: windowed operations have a timeout capability, the system deals with "out-of-order" messages (delayed messages), extensibility (user-defined functions) and re-sampling. Scheduling is a major component of Aurora system and it aims on reducing CPU cost of running the scheduler and maximizing the quality of service.
  An Aurora workflow is a dynamic object. When new applications get connected to the workflow, the number of boxes and arrows changes. Also adhoc queries that are run just once and then discarded have a similar effect. Furthermore, Aurora workflows may be quite

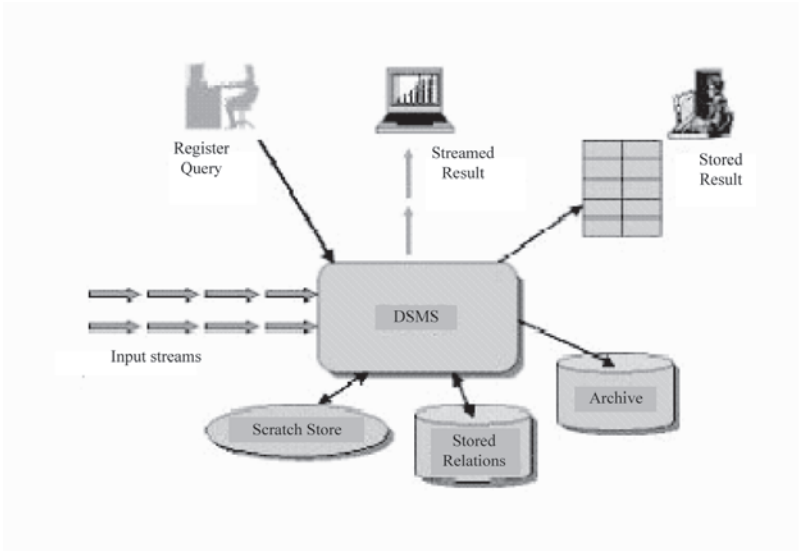
Figure 3. Aurora's architecture



large. As a result, Aurora performs only run-time optimization.

- **Gigascope:** AT&T's Gigascope project is a special-purpose data stream system for network applications, such as traffic analysis, intrusion detection, router configuration analysis, network monitoring and performance monitoring and debugging. The central component of Gigascope is a stream manager which tracks the query nodes that can be activated. Query nodes are processes. When they are started, they register themselves with the registry of the stream manager.
  Gigascope's query language, GSQL, is an SQL-like language with stream features. All inputs to and outputs of a GSQL query are data streams. Currently GSQL supports selection, join, aggregation and stream merge. A GSQL query is analyzed, translated to C/C++ code, and then executed. Optimization of GSQL queries consists of rearranging the query plan and generated-code optimizations. Another important optimization is pushing selections as far down as possible, even to the network level. To achieve this, the query processor of Gigascope "breaks" queries into high-level and low-level query nodes. Low-level query nodes are separate processes consisting of simple filtering conditions.
- **STREAM:** The Stanford stream data manager (STREAM) project at Stanford is developing a general-purpose DSMS for processing continuous queries over multiple continuous data streams and stored relations. The architecture of STREAM is shown in Figure 4 (Arasu et. al., 2003).
  The incoming input streams produce continuous data and drive query processing. Scratch store is used for the intermediate processing of the incoming data and can be stored in memory or on disk. An Archive storage is used for storing some (or all) of the data stream for possible off-line processing of expensive mining queries. Users or applications may register continuous queries and get the answers as output data streams or relational results that are updated over time. During the processing of continuous queries, traditional relational tables can be utilized. Currently STREAM offers a Web system interface through direct HTTP, and a Web-based GUI to register queries and view results.
  STREAM people developed a declarative query language, continuous query language (CQL) for continuous queries over data streams and relations. They model a stream as an unbounded, append-only bag of (tuple, timestamp) pairs, and a relation as a time-varying bag of tuples supporting updates, deletions and insertions. The key idea is to convert streams into relations using special windowing operations, perform transformations on relations using standard relational operators and then convert back (optionally) the transformed relational data into a streamed answer (Arasu et al., 2003). CQL uses SQL as its relational query language, SQL-99 amendments provide the window specification language, and it includes three relation-to-stream operators. When a continuous query specified in CQL is registered with STREAM, it is compiled into a query plan. The query plan is merged with existing query plans whenever possible, in order to share computation and memory.
- **TelegraphCQ:** TelegraphCQ is a prototype focused on handling measurements of sensor networks. Developed in Berkeley, it is based on adaptive and multi-query

Figure 4. Overview of STREAM architecture



processing and uses a mix of SQL and scripting programming languages for expressing complex queries. Its architecture is shown in Figure 5 (Chandrasekaran et al., 2003).

Telegraph, the predecessor of TelegraphCQ, consists of an extensible set of composable dataflow modules or operators that produce and consume records in a manner analogous to the operators used in traditional database query engines. The modules can be composed into multi-step dataflows, exchanging records via an API called Fjords (Madden & Franklin, 2002) that can support communication via either "push" or "pull" modalities.

TelegraphCQ supports continuous queries defined over relational tables and data streams with a rich set of windowing schemes (e.g., landmark and sliding windows).

Other stream projects include Tribeca, developed in Telcordia for network management; NiagaraCQ, a project of University of Wisconsin to monitor internet data (XML-format); Cougar and Amazon of Cornell University, aimed to monitor distributed sensor networks. We present in Table 2 a comparison table between Aurora, Gigascope, STREAM and Telegraph.

Figure 5. TelegraphCQ's architecture

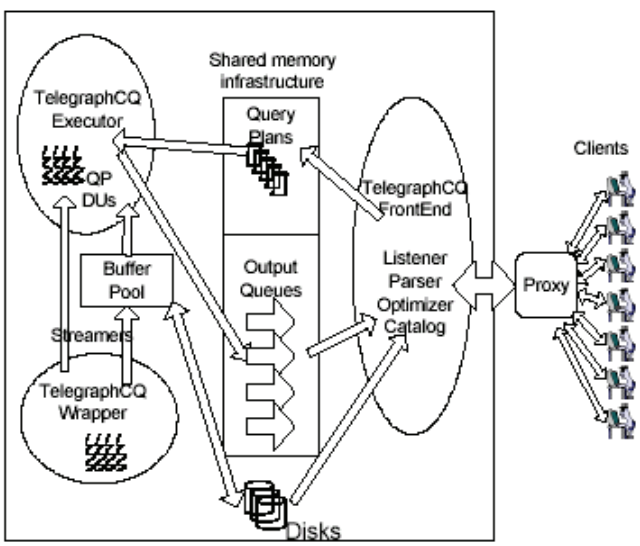


Table 2. Comparing different stream prototypes

Stream System	Input	Output	Query Language	Answers	Evaluation
Aurora	Relations, Streams	Relations, Streams	Operators (boxes and arrows)	Approximate	Run-time optimization
Gigascope	Streams	Streams	GSQL (SQL-like)	Exact	Splitting query to high- and low-level
STREAM	Relations, Streams	Relations, Streams	CQL (SQL-like)	Approximate	Static analysis, relational optimization
Telegraph	Relations, Streams	Relations, Streams	SQL-based, scripting	Exact	Adaptive query processing, multi-query

CONCLUSION

Equipping traditional database management systems with decision support capabilities has been studied extensively in the last decade. Building data warehouses, forming data cubes, creating data marts, carrying out data mining tasks and performing on-line analytical processing and multi-dimensional analysis are well-known subjects in the context of decision-making. However, an emerging trend in data management and data streams, is very different in nature from traditional database applications: queries are different, models and frameworks are special, query processing is peculiar and, subsequently, decision support is defined differently. The keywords in this domain are: real-time, continuous, and tactical decisions. A lot of progress has been recently made in this field by several research institutions to build various (either general or specific-purpose) data stream management systems with rich data analysis capabilities. Given the popularity of sensors and the need for real-time analytics, the ability of data analysis on top of data streams will be a crucial component of future data management and decision support systems.

KEY TERMS

Continuous Queries: The answer to a continuous query is produced over time, reflecting the stream data seen so far. Answers may be stored and updated as new data arrives or may be produced as data streams themselves.

Data Stream Management Systems (DSMS): A data management system providing capabilities to query and process data streams and store a bounded part of it.

Data Streams: Data items that arrive online from multiple sources in a continuous, rapid, time-varying, possibly unpredictable fashion.

Load Shedding: The discarding of input data by the DSMS when the input stream rate exceeds system capacity. It can either be semantic (based on certain semantic rules) or random.

Measurement Data Streams: Data streams representing successive state information of one or more entities, such as sensor, climate or network measurements.

Network Traffic Management: Monitoring a variety of continuous network data streams at real-time, such as packet traces, packet flows and performance measurements in order to compute statistics, detect anomalies and adjust routing.

Stream Window: A mechanism to extract a finite set of records from an infinite stream. This mechanism selects stream items based on time periods, counting, or explicit starting and ending conditions.

Transactional Data Streams: Data streams representing log interactions between entities, such as credit card transactions, phone calls and Web click streams.

Database Benchmarks

Jérôme Darmont
ERIC, University of Lyon 2, France

INTRODUCTION

Performance measurement tools are very important, both for designers and users of Database Management Systems (DBMSs). *Performance evaluation* is useful to designers to determine elements of architecture, and, more generally, to validate or refute hypotheses regarding the actual behavior of a DBMS. Thus, *performance evaluation* is an essential component in the development process of well-designed and efficient systems. Users may also employ *performance evaluation*, either to compare the efficiency of different technologies before selecting a DBMS, or to tune a system.

Performance evaluation by experimentation on a real system is generally referred to as benchmarking. It consists of performing a series of tests on a given DBMS to estimate its performance in a given setting. Typically, a *benchmark* is constituted of two main elements: a database model (conceptual schema and extension), and a workload model (set of read and write operations) to apply on this database, following a predefined protocol. Most *benchmarks* also include a set of simple or composite performance metrics such as response time, throughput, number of input/output, disk or memory usage, and so forth.

The aim of this article is to present an overview of the major families of state-of-the-art database benchmarks, namely, relational benchmarks, object and object-relational benchmarks, XML benchmarks, and decision-support benchmarks; and to discuss the issues, tradeoffs, and future trends in database benchmarking. We particularly focus on XML and decision-support benchmarks, which are currently the most innovative tools that are developed in this area.

BACKGROUND

Relational Benchmarks

In the world of relational DBMS benchmarking, the *Transaction Processing Performance Council (TPC)* plays a preponderant role. The mission of this non-profit organization is to issue standard benchmarks, to verify their correct application by users, and to regularly publish performance tests results. Its benchmarks all share variants of a classical business database (*customer-order-product-supplier*) and are only parameterized by a scale factor that determines the database size (*e.g.*, from 1 to 100,000 GB).

The *TPC* benchmark for transactional databases, TPC-C (TPC, 2005a), has been in use since 1992. It is specifically dedicated to On-Line Transactional Processing (OLTP) applications, and features a complex database (nine types of tables bearing various structures and sizes), and a workload of diversely complex transactions that are executed concurrently. The metric in TPC-C is throughput, in terms of transactions.

There are currently few credible alternatives to *TPC-C*. Although, we can cite the Open Source Database Benchmark (OSDB), which is the result of a project from the free software community (SourceForge, 2005). OSDB extends and clarifies the specifications of an older benchmark, AS^{3}AP. It is available as free C source code, which helps eliminate any ambiguity relative to the use of natural language in the specifications. However, it is still an ongoing project and the benchmark's documentation is very basic. AS^{3}AP's database is simple: it is composed of four relations whose size may vary from 1 GB to 100 GB. The workload is made of various queries that are executed concurrently. OSDB's metrics are response time and throughput.

Object-Oriented and Object-Relational Benchmarks

There is no standard benchmark for object-oriented DBMSs. However, the most frequently cited and used, OO1 (Cattel, 1991), HyperModel (Anderson, Berre, Mallison, Porter, & Schneider, 1990), and chiefly *OO7* (Carey, DeWitt, & Naughton, 1993), are *de facto* standards. These benchmarks mainly focus on engineering applications (*e.g.*, computer-aided design, software engineering). They range from OO1, which bears a very simple schema (two classes) and only three operations, to *OO7*, which is more generic and proposes a complex and tunable schema (ten classes), as well as fifteen complex operations. However, even *OO7*, the more elaborate of these benchmarks, is not generic enough to model other types of applications, such as financial, multimedia, or telecommunication applications (Tiwary, Narasayya, & Levy, 1995). Furthermore, its complexity makes it hard to understand and implement. To circumvent these limitations, the *OCB* benchmark has been proposed (Darmont & Schneider, 2000). Wholly tunable, this tool aims at being truly generic. Still, the benchmark's code is short, reasonably easy to implement, and easily portable. Finally, *OCB* has been extended into the Dynamic Evaluation Framework (DEF),

which introduces a dynamic component in the workload, by simulating access pattern changes using configurable styles of changes (He & Darmont, 2005).

Object-relational benchmarks such as BUCKY (Carey, DeWitt, & Naughton, 1997) and BORD (Lee, Kim, & Kim, 2000) are query-oriented and solely dedicated to object-relational systems. For instance, BUCKY only proposes operations that are specific to these systems, considering that typical object navigation is already addressed by object-oriented benchmarks. Hence, these benchmarks focus on queries implying object identifiers, inheritance, joins, class and object references, multivalued attributes, query unnesting, object methods, and abstract data types.

XML Benchmarks

Since there is no standard model, the storage solutions for XML (eXtended Markup Language) documents that have been developed since the late nineties bear significant differences, both at the conceptual and the functionality levels. The need to compare these solutions, especially in terms of performance, has lead to the design of several benchmarks with diverse objectives.

X-Mach1 (Böhme & Rahm, 2001), XMark (Schmidt, Waas, Kersten, Carey, Manolescu, & Busse, 2002), XOO7 (an extension of OO7) (Bressan, Lee, Li, Lacroix, & Nambiar, 2002) and XBench (Yao, Ozsu, & Khandelwal, 2004) are so-called application benchmarks. Their objective is to evaluate the global performances of an XML DBMS, and more particularly of its query processor. Each of them implements a mixed XML database that is both data-oriented (structured data) and document-oriented (in general, random texts built from a dictionary). However, except for XBench that proposes a true mixed database, their orientation is more particularly focused on data (XMark, XOO7) or documents (X-Mach1).

These benchmarks also differ in:

- the fixed or flexible nature of the XML schema (one or several Document Type Definitions or XML schemas);
- the number of XML documents used to model the database at the physical level (one or several);
- the inclusion or not of update operations in the workload.

We can also underline that only XBench helps in evaluating all the functionalities offered by the XQuery language.

Micro-benchmarks have also been proposed to evaluate the individual performances of basic operations such as projections, selections, joins, and aggregations, rather than more complex queries. The Michigan Benchmark (Runapongsa, Patel, Jagadish, & Al-Khalifa, 2002) and MemBeR (Afanasiev, Manolescu, & Michiels, 2005) are made for XML documents storage solution designers, who can isolate critical issues to optimize, rather than for users seeking to compare different systems. Furthermore, MemBeR proposes a methodology for building micro-databases, to help users in adding datasets and specific queries to a given performance evaluation task.

Decision-Support Benchmarks

Since decision-support benchmarks are currently a *de facto* subclass of relational benchmarks, the TPC again plays a central role in their standardization. *TPC-H* (TPC, 2005c) is currently their only decision-support benchmark. It exploits a classical *product-order-supplier* database schema, as well as a workload that is constituted of twenty-two SQL-92, parameterized, decision-support queries, and two refreshing functions that insert tuples into, and delete tuples from, the database. Query parameters are randomly instantiated following a uniform law. Three primary metrics are used in *TPC-H*. They describe performance in terms of power, throughput, and a combination of these two criteria.

Data warehouses nowadays constitute a key decision-support technology. However, *TPC-H's* database schema is not a star-like schema that is typical in data warehouses. Furthermore, its workload does not include any On-Line Analytical Processing (OLAP) query. *TPC-DS*, which is currently under development (TPC, 2005b), fills in this gap. Its schema represents the decision-support functions of a retailer under the form of a constellation schema with several fact tables and shared dimensions. *TPC-DS*' workload is constituted of four classes of queries: reporting queries, *ad-hoc* decision-support queries, interactive OLAP queries, and extraction queries. SQL-99 query templates help in randomly generating a set of about five hundred queries, following non-uniform distributions. The warehouse maintenance process includes a full ETL (Extract, Transform, Load) phase, and handles dimensions according to their nature (non-static dimensions scale up while static dimensions are updated). One primary throughput metric is proposed in TPC-DS. It takes both query execution and the maintenance phase into account.

As in all the other *TPC benchmarks*, scaling in *TPC-H* and *TPC-DS* is achieved through a scale factor that helps defining the database's size (from 1 GB to 100 TB). Both the database schema and the workload are fixed.

There are, again, few decision-support benchmarks out of the *TPC*, and their specifications are rarely integrally published. Some are nonetheless interesting. APB-1 is presumably the most famous. Published by the OLAP Council, a now inactive organization founded by OLAP vendors, APB-1 has been intensively used in the late nineties. Its warehouse dimensional schema is structured around four dimensions: *Customer*, *Product*, *Channel*, and *Time*. Its workload of ten queries is aimed at sale forecasting. APB-1 is quite simple and proved limited to evaluate the specifici-

ties of various activities and functions (Thomsen, 1998). It is now difficult to find.

Eventually, while the *TPC* standard benchmarks are invaluable to users for comparing the performances of different systems, they are less useful to system engineers for testing the effect of various design choices. They are indeed not tunable enough and fail to model different data warehouse schemas. By contrast, the *Data Warehouse Engineering Benchmark (DWEB)* helps in generating various *ad-hoc* synthetic data warehouses (modeled as star, snowflake, or constellation schemas) and workloads that include typical OLAP queries (Darmont, Bentayeb, & Boussaïd, 2005a). *DWEB* is fully parameterized to fulfill data warehouse design needs.

ISSUES AND TRADEOFFS IN DATABASE BENCHMARKING

Gray (1993) defines four primary criteria to specify a "good" *benchmark:*

1. *relevance:* the benchmark must deal with aspects of performance that appeal to the largest number of potential users;
2. *portability:* the benchmark must be reusable to test the performances of different DBMSs;
3. *simplicity:* the benchmark must be feasible and must not require too many resources; and
4. *scalability:* the benchmark must adapt to small or large computer architectures.

In their majority, existing benchmarks aim at comparing the performances of different systems in given experimental conditions. This helps vendors in positioning their products relative to their competitors', and users in achieving strategic and costly software choices based on objective information. These benchmarks invariably present fixed database schemas and workloads. Gray's scalability factor is achieved through a reduced number of parameters that mainly allow varying the database size in predetermined proportions. It is notably the case of the unique scale factor parameter that is used in all the TPC benchmarks.

This solution is simple (still according to Gray's criteria), but the relevance of such benchmarks is inevitably reduced to the test cases that are explicitly modeled. For instance, the typical *customer-order-product-supplier* that is adopted by the *TPC* is often unsuitable to application domains other than management. This leads benchmark users to design more or less elaborate variants of standard tools when they feel these are not generic enough to fulfill particular needs. Such users are generally not confronted with software choices, but are rather designers who have quite different needs. They mainly seek to evaluate the impact of architectural choices, or performance optimization techniques, within a given system or a family of systems. In this context, it is essential to multiply experiments and test cases, and a monolithic benchmark is of reduced relevance.

To enhance the relevance of benchmarks aimed at system designers, we propose to extend Gray's scalability criterion to *adaptability*. A performance evaluation tool must then be able to propose various database or workload configurations, to allow experiments to be performed in various conditions. Such a tool may be qualified as a benchmark generator, or as a tunable or generic benchmark. However, aiming at a better adaptability is mechanically detrimental to a benchmark's simplicity. This criterion, though, remains very important and must not be neglected when designing a generic tool. It is, thus, necessary to devise means of achieving a good adaptability, without sacrificing simplicity too much. In summary, a satisfying tradeoff must be reached between these two orthogonal criteria.

We have been developing benchmarks following this philosophy for almost ten years. The first one, the Object Clustering Benchmark (*OCB*), was originally designed to evaluate the performances of clustering algorithms within object-oriented DBMSs. By extending its clustering-oriented workload, we made it generic. Furthermore, its database and workload are wholly tunable, through a collection of comprehensive but easily set parameters. Hence, *OCB* can be used to model many kinds of object-oriented database applications. In particular, it can simulate the behavior of the other object-oriented benchmarks.

Our second benchmark is the *DWEB* data warehouse benchmark. *DWEB's* parameters help users in selecting the data warehouse architecture and workload they need in a given context. To solve the adaptability *versus* simplicity dilemma, we divided the parameter set into two subsets. Low-level parameters allow an advanced user to control everything about data warehouse generation. However, their number can increase dramatically when the schema gets larger. Thus, we designed a layer of high-level parameters that may be easily understood and set up, and that are in reduced number. More precisely, these high-level parameters are average values for the low-level parameters. At database generation time, the high-level parameters are automatically exploited by random functions to set up the low-level parameters.

FUTURE TRENDS

The development of XML-native DBMSs is quite recent, and a tremendous amount of research is currently in progress to help them become a credible alternative to XML-compatible, relational DMBSs. Several performance evaluation tools have been proposed to support this effort. However, research in this area is very dynamic, and new benchmarks will be needed to assess the performance of the latest discoveries. For instance, Active XML incorporates web services for data integration

(Abiteboul, Benjelloun, Manolescu, Milo, & Weber 2002). An adaptation of existing XML benchmarks that would exploit the concepts developed in TPC-App, could help in evaluating the performance of an Active XML platform.

No XML benchmark is currently dedicated to decision-support either, while many XML data warehouse architectures have been proposed in the literature. We are currently working on a benchmark called XWB, which is aimed at evaluating the performances of such research proposals. Furthermore, there is a growing need in many decision-support applications (e.g., customer relationship management, marketing, competition monitoring, medicine) to exploit complex data, that is, in summary, data that are not only numerical or symbolic. XML is particularly adapted to describe and store complex data (Darmont, Boussaïd, Ralaivao, & Aouiche, 2005b) and further adaptations of XML decision-support benchmarks would be needed to take them into account.

Finally, a lot of research also aims at enhancing the XQuery language, for instance with update capabilities, or with OLAP operators. Existing XML and/or decision-support benchmarks will also have to be adapted to take these new features into account.

CONCLUSION

Benchmarking is a small field, but it is nonetheless essential to database research and industry. It serves both engineering or research purposes, when designing systems or validating solutions, and marketing purposes, when monitoring competition and comparing commercial products.

Benchmarks might be subdivided in three classes. First, standard, *general-purpose benchmarks* such as the TPCs do an excellent job in evaluating the global performance of systems. They are well-suited to software selection by users and marketing battles by vendors, who try to demonstrate the superiority of their product at one moment in time. However, their relevance drops for some particular applications that exploit database models or workloads that are radically different from the ones they implement. *Ad hoc benchmarks* are a solution. They are either adaptations of general-purpose benchmarks, or specifically designed benchmarks such as the XML micro-benchmarks we described above. Designing myriads of narrow-band benchmarks is not time-efficient, though, and trust in yet another new benchmark might prove limited in the database community. Hence, the solution we promote is to use *generic benchmarks* that feature a common base for generating various experimental possibilities. The drawback of this approach is that parameter complexity must be mastered, for generic benchmarks to be easily apprehended by users.

In any case, before starting a benchmarking experiment, users' needs must be carefully assessed so that the right benchmark or benchmark class is selected, and test results are meaningful. This sounds like sheer common sense, but many researchers simply select the best known tools, whether they are adapted to their validation experiments or not. For instance, data warehouse papers often refer to TPC-H, while this benchmark's database is not a typical data warehouse, and its workload does not include any OLAP query. *Ad-hoc* and generic benchmarks should be preferred in such situations, and though trust in a benchmark is definitely an issue, relevance should be the prevailing selection criteria. We modestly hope this article will have provided its readers with a fair overview of database benchmarks, and will help them in selecting the right tool for the right job.

KEY TERMS

Benchmark: A standard program that runs on different systems to provide an accurate measure of their performance.

Database Benchmark: A benchmark specifically aimed at evaluating the performance of DBMSs or DBMS components.

Database Management System (DMBS): Software set that handles the structuring, storage, maintenance, update, and querying of data stored in a database.

Database Model: In a database benchmark, a database schema and a protocol for instantiating this schema, that is, generating synthetic data or reusing real-life data.

Performance Metrics: Simple or composite metrics aimed at expressing the performance of a system.

Synthetic Benchmark: A benchmark in which the workload model is artificially generated, as opposed to a real-life workload.

Workload Model: In a database benchmark, a set of predefined read and write operations or operation templates to apply on the benchmark's database, following a predefined protocol.

Database Integration in the Grid Infrastructure

Emmanuel Udoh
Indiana University – Purdue University, USA

INTRODUCTION

The capability of the Web to link information over the Internet has popularized computer science to the public. But it is the grid that will enable the public to exploit data storage and computer power over the Internet analogous to the electric power utility (a ubiquitous commodity). The grid is considered the fifth generation computing architecture after client-server and multitier (Kusnetzky & Olofson, 2004) that integrates resources (computers, networks, data archives, instruments, etc.) in an interoperable virtual environment (Berman, Fox, & Hey, 2003). In this vein, grid computing is a new IT infrastructure that allows modular hardware and software to be deployed collectively to solve a problem or rejoined on demand to meet changing needs of a user.

Grid computing is becoming popular in the enterprise world after its origin in the academic and research communities (e.g., SETI@home), where it was successfully used to share resources, store data in petabytes/exabytes, and ultimately lower costs. There are several reasons for the embrace of the enterprise grids. In the nineties, the IT world was confronted with the high cost of maintaining smaller, cheaper and dedicated servers such as UNIX and Windows. According to Oracle (2005), there was the problem of application silos that lead to underutilized hardware resources; monolithic and unwieldy systems that are expensive to maintain and change; and fragmented and disintegrated information that cannot be fully exploited by the enterprise as a whole. Various surveys put the average utilization of servers in a typical enterprise to often much less than 20% (Goyal & Lawande, 2006; Murch, 2004). But with the increasingly available cheaper, faster and affordable hardware such as server blades, and operating systems like the open source Linux, the IT world embraced grid computing to save money on hardware and software. With the growing importance of grid computing, it is easy to conjecture why many new terms have been coined for it. In the literature and industry, other terms used interchangeably for grid computing are utility computing, computing on demand, N1, hosted computing, adaptive computing, organic computing and ubiquitous computing (Goyal & Lawande, 2006; Murch, 2004; Oracle, 2005).

The grid is an all-encompassing, 21st century computing infrastructure (Foster, 2003; Joseph & Fellenstein, 2004) that integrates several areas of computer science and engineering. A database is an important component of the application stack in the industry and is increasingly being embedded in the grid infrastructure. This article focuses on integration of database grids or grid-accessible databases in the industry using Oracle products as examples. Vendors like Oracle and IBM are providing grid-enabled databases that are supposed to make enterprise systems unbreakable and highly available. Oracle has been in the forefront in this endeavor with its database products. In recognition of the significant new capabilities required to power grid computing, Oracle has named its new technology products Oracle 10g (g for grid). Oracle provides seamless availability through its database products with such features like streams, transportable tablespaces, data hubs, ultra-search and real application clusters. Although companies will not like to distribute resources randomly on the Internet, they will embrace enterprise database grids, as they embraced Internet in the form of Intranets. To the business world, database grids will help achieve high hardware utilization and resource sharing, high availability, flexibility, incrementally scalable low cost components and reduced administrative overhead (Kumar & Burleson, 2005; Kusnetzky & Olofson, 2004).

BACKGROUND

The grid technology is still evolving, and databases are increasingly being incorporated into its infrastructure. IBM has contributed immensely in this endeavor with its autonomic and grid computing projects, but Oracle is the clear-cut industry leader in enterprise database grids. Oracle, a member of the enterprise grid alliance (EGA) that promotes tools and standards for enterprise computing, has been preparing and targeting the grid market since the Oracle9i release with products like Oracle real application clusters (now morphed to automatic storage management system). This article will therefore discuss enterprise grid computing in terms of the features available in Oracle 10g database products.

The main features that clearly differentiate grid computing from other forms of computing architectures, such as client server or multitier, are virtualization and provisioning. Virtualization creates a logical view or abstraction that allows the pooling together of resources (e.g., data, computing power, storage capacity, and other resources) for consumption by other applications, while provisioning determines how to meet on demand the specific needs of consumers.

As consumers request resources through the virtualization layer (which breaks the hard-coded connection between providers and consumers (Oracle, 2005), provisioning guarantees resources are allocated for the request. To achieve these objectives, a grid implements a layered architecture as depicted in Figure 1a.

In a semblance of the generalized grid architecture, the Oracle grid builds a stack of its software in a virtual environment, as shown in Figure 1b. The bottom layer hosts the storage units such as a storage area network (SAN), while the next horizontal layer contains the infrastructure such as the hardware and software that create a data storage and program execution environment (infrastructure grid). The next layer, the application server, contains the program logic and flow that define specific business processes (application grid). The topmost layer (information grid) hosts applications such as user applications, enterprise resource planning and portal software that can be accessed over the network without the application being architected to support the device or network. This virtualized environment has a unified management structure as well as an infrastructure for security.

As depicted in Figure 1b, Oracle 10g software stack, which is configured to self-manage, acts as a single computing resource to the user even in a geographically distributed environment. This allows organizations to protect and optimize their investment in hardware and software and also access newer system features in a more reliable, powerful and scalable environment. To keep this unified structure manageable and also eliminate the application silo model, Oracle enterprise manager has a grid control that monitors, provisions, clones and automates even in heterogeneous environments (Khilani, 2005).

MAIN FOCUS

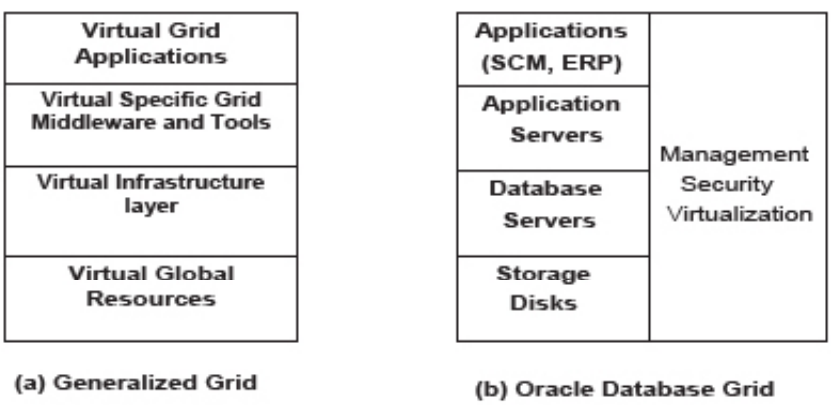
The evolving enterprise database grid brings substantial benefits to the industry but poses a major challenge in integration and adoption. With yearly global business volume in excess of $10 billion dollars, databases are critical components in the enterprise application stack. The existing database infrastructure in companies are aggregates of many years of investments in a wide range of interfaces and tools for performance and security. Noting all the hype about grids, it is natural that its adoption will be resisted by employees, who are unwilling to change existing processes and technology. Researchers believe that building grid-enabled database infrastructures from scratch is both unrealistic and a waste of effort and resources (Watson, 2003). Instead, existing database management systems should be integrated into the grid in an incremental manner, absorbing the existing investments without being disruptive. Oracle's grid-enabled database takes cognizance of this reality, and hence this article focuses on database grid integration and adoption vis-a-vis Oracle grid products.

At the department of computer science (CS), Indiana University–Purdue University, Fort Wayne, an Oracle database grid was introduced to aid the administration of the database program (for research and education). Experience from this program supports these transitioning steps for the integration and adoption of an enterprise database grid: identification, standardization, consolidation and automation.

Identification

Organizations have different IT infrastructures that may influence decisions to integrate their enterprises in database grids.

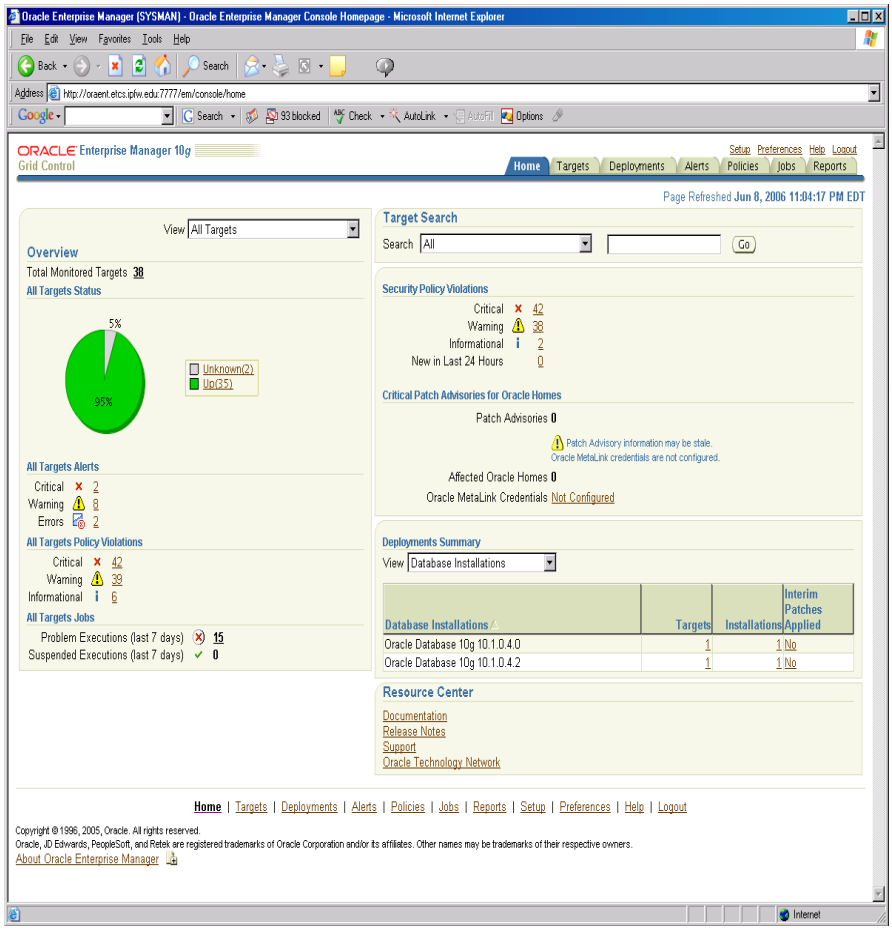
Figure 1. Structure of generalized grid and Oracle database grid



An approach is to identify a suitable activity or sweet spot that will facilitate the adoption of the grid, not necessarily in a big swoop but small scaled and incremental. Goyal and Lawande (2006) give some characteristics of a sweet spot, such as a task with a compelling use case that has broader acceptance in a company or a task with measurable goals and benefits on a small scale that could be executed within a realistic time frame. For instance, organizations may have periodic acquisition plans for software and hardware, a problem monitoring IT infrastructure, resource allocation or desire for improvement of business flows. In such situations, enterprises can acquire new, low cost modular servers during the cycle of hardware acquisition for database and application servers, deploy grid control as a solution for management constraints, or apply provisioning technologies such as transportable tablespaces and streams for resource allocation problems.

At the CS department, Fort Wayne, we were confronted with the problem of managing our Oracle servers (database, application server, storage and instrument) due to the absence of a DBA. This was a sweet spot that caused us to introduce Oracle database grid products. Oracle database grid control (ODGC–Figure 2) solved this management constraint based on the philosophy of managing many as one (Khilani, 2005; Kumar & Burleson, 2005). ODGC adopts a holistic management view to monitor diverse Oracle products, and also provision, clone and automate jobs, even providing with alerts and warnings in heterogeneous environments. Its self-monitoring features ensure that critical components of grid control are always available and functional (Khilani, 2005; Kumar & Burleson, 2005). ODGC is bundled with a management grid control console (client), a management service (middleware) and a management agent (backend) in a three-tiered architecture. It can monitor any node (target) with a management agent that collects host and database-related statistics. To add a new system to the management target list involves simply installing the management agent on that system. Thus, as an IT department grows, more serv-

Figure 2. Oracle grid control at the CS department, Fort Wayne



ers can be easily added for load balancing. In addition to the centralized management structure, the grid control provides a unified security/identity management interface based on the single sign-on technique, which allows a user to log on once to a network and then access multiple applications with a single password.

Standardization

As an attempt to achieve high productivity, organizations normally invest in the best of available technologies and processes, regardless of interoperability of the systems. This practice has caused the IT world to make huge financial outlay for interoperability (Chrabakh & Wolski, 2006). The grid approach supports using interoperable products as a way to curb variability and complexity prevalent in current data centers. According to Goyal and Lawande (2006), one way to achieve technology standardization is to limit the number of vendors and products that support industry standards for interoperability. This approach reduces the amount of resources for deployment and testing of single product lines and paves the way for easier future consolidation. While technology standardization focuses on reduction of heterogeneous hardware and software (vendors and products), process standardization is geared toward the architecture for development, deployment and management. Process standardization reduces the variability of a system life cycle and associated errors. In this vein, IT process standards such as ITIL could be adopted as a guide. This approach ensures that proven best management practice is observed in the life cycle of systems, thus streamlining activities and reducing cost.

To achieve standardization of the hardware and software at the CS department, Fort Wayne, the Oracle grid products are only operated on Linux servers (much cheaper than symmetric multiprocessor–SMP) and Linux operating systems (Red Hat). This ensures uniform maintenance of the hardware and software resources, thereby easing administration.

Consolidation

In consolidating technology and IT processes, organizations need to initiate a long term strategy to strengthen all aspects of grid-enabling IT infrastructure, by reducing fragmented data centers. A few data centers eases management in one place and encourages economy of scale. Consolidation supports the methodology of grid computing at every step of system development, deployment and management, for example, consolidating storage with integrated structure like a storage area network (SAN) improves performance. Furthermore, modular servers can be used to consolidate databases and application servers. According to Goyal and Lawande (2006), integration may be physical by moving data to one database or logical by using products like data hubs. This substantially reduces power, cooling, space requirements and management costs. Consolidation maximizes the gains of standardization. Currently, CS department at Fort Wayne is implementing a storage area network that will provide a storage subsystems to multiple hosts at the same time.

Automation

Automation of tasks and processes reduces human errors and lowers costs in an enterprise. After standardization and consolidation, automation is easier to implement. For instance, standardized operating systems and storage layouts can be automated, as scripts and automation tools can be easily deployed. However, best management practice favors automating simple, repetitive and laborious tasks at the onset. Such tasks can be identified beginning from initial deployments to maintenance of systems.

At the CS department, Fort Wayne, patches, alerts, testing, deployment of servers and maintenance can be scheduled for automation with the Oracle grid control. A valuable automation is that of patching, which allows downloads from the Oracle's Metalink Web site. This feature helps keep the systems in sync and more secured.

FUTURE TRENDS

Enterprise database grid computing is increasingly being adopted by major corporations. The acceptance of this trend will continue in the future as its benefits become more obvious. More than any other factor, the fact that vendors are increasingly offering grid-enabled technologies will encourage rapid adoption in the future. Furthermore, grid computing is evolving; and many relevant standards are currently being developed. For instance, there is currently a lack of established standards for dynamic and autonomic resource provisioning, which hinders vendor interoperability (Pollock & Hodgson, 2004; Wolski, 2003). Improvements in such standards will be incorporated in new grid products. However, the current lack of grid standards should not deter the adoption of grid computing. Enterprises can adopt grid methodology (a service-centric view on IT infrastructure: Yan & Chapman, 2006) and leverage their current investments, because companies are now creating new products that are grid-enabled (Dooley, Milfeld, Guiang, Pamidighantam, & Allen, 2006). Furthermore, there will be more developments in service-oriented architecture that will certainly impact grid applications. Ultimately, enterprise database grids will benefit from improvements in semantic grid, which will enable meaningful information processing or parsing of deep relationships between data without human intervention.

CONCLUSION

The emerging grid infrastructure will substantially reduce the cost of deploying and managing enterprise applications. With further grid product offerings and improvements in hardware and grid protocols, enterprise grid computing will be embraced by many organizations in the future. It is recommendable to adopt grid technology starting with a sweet spot and then incrementally integrating all aspects of the enterprise. Once the benefits of the grid are demonstrated on a small scale, scaling out can be initiated in subsequent operations. Staff resistance to adoption can be overcome through effective communication, team building and incentives to adaptation. Oracle offers a family of products that support database grid for an efficient data-driven business. Enterprise database grid is not a disruptive technology because it leverages existing investments and best practices in an organization.

KEY TERMS

Applications Grid: It shares and reuses application code but uses software technologies like service-oriented architectures that facilitate sharing business logic among multiple applications.

Grid Computing: A style of computing that dynamically pools IT resources together for use based on resource need. It allows organizations to provision and scale resources as needs arise, thereby preventing the underutilization of resources (computers, networks, data archives, instruments).

Information Grid: This grid shares information across multiple consumers and applications. It unlocks fragmented data from proprietary applications by treating information as a resource to be shared across the grid.

Infrastructure Grid: This grid pools, shares and reuses infrastructure resources such as hardware, software, storage and networks across multiple applications.

Provisioning: The allocation of resources to consumers on demand. A system determines specific need of the consumer and provides the resources as requested.

Semantic Web: Information processing model in which computers using resource description framework (RDF) and other technologies can explicitly associate meanings or parse relationships between data without human intervention.

Service-Oriented Architecture (SOA): This is a form of software design that allows different applications to interact in business processes regardless of specific technology like programming languages and operating systems

Silos/Islands of Applications/Computing: Condition whereby servers or computing resources are idle most of the time when the peak load is not reached. Such IT systems are not designed to share resources with each other, thus creating islands of information and computing infrastructure within a single enterprise.

Virtualization: A form of abstraction that provides location- and technology-transparent access of resources to the consumer. It decouples the tight connections between providers and consumers of resources, thus allowing sharing of the same resources by multiple users as needs arise.

Database Integrity Checking

Hendrik Decker
Universidad Politécnica de Valencia, Spain

Davide Martinenghi
Free University of Bozen/Bolzano, Italy

INTRODUCTION

Integrity constraints (or simply "constraints") are formal representations of invariant conditions for the semantic correctness of database records. Constraints can be expressed in declarative languages such as datalog, predicate logic, or SQL. This article highlights the historical background of integrity constraints and the essential features of their simplified incremental evaluation. It concludes with an outlook on future trends.

BACKGROUND

Integrity has always been an important issue for database design and control, as attested by many early publications (e.g., Bernstein & Blaustein, 1982; Bernstein, Blaustein, & Clarke, 1980; Codd, 1970, 1979; Eswaran & Chamberlin, 1975; Fraser, 1969; Hammer & McLeod, 1975; Hammer & Sarin, 1978; Nicolas, 1978, 1982; Wilkes, 1972); later ones are too numerous to mention. Expressing database semantics as invariant properties persisting across updates had first been proposed by Minsky (1974). Florentin (1974) suggested expressing integrity constraints as predicate logic statements. Stonebraker (1975) proposed formulating and checking integrity constraints declaratively as SQL-like queries.

Functional dependencies (Armstrong, 1974; Codd, 1970) are a fundamental kind of constraints to guide database design. Referential integrity has been part of the 1989 SQL ANSI and ISO standards (McJones, 1997). The SQL2 standard (1992) introduced the CHECK and ASSERTION constructs (i.e., table-bound and table-independent SQL query conditions) as the most general means to express integrity constraints declaratively (Date & Darwen, 1997). Since the 1990s, uniqueness constraints, foreign keys, and complex queries involving EXISTS and NOT became common features in commercial databases. Thus, arbitrarily general and complex integrity constraints can now be expressed and evaluated in most relational databases. However, most of them offer efficient support only for the following three simple kinds of declarative constraints:

- **Domain Constraints:** Restrictions on the permissible range of attribute values of tuples in table columns, including scalar SQL data types and subsets thereof, as well as options for default and null values.
- **Uniqueness Constraints:** As enforced by the UNIQUE construct on single columns, and UNIQUE INDEX and PRIMARY KEY on any combination of one or several columns in a table, preventing multiple occurrences of values or combinations thereof.
- **Foreign Key Constraints:** For establishing a relationship between the tuples of two tables, requiring identical column values. For instance, a foreign key on column emp of relation works_in requires that the emp value of each tuple of works_in must occur in the emp_id column of table employee, and that the referenced column (emp_id in the example) has been declared as primary key.

For more general constraints, SQL manuals usually recommend using procedural triggers or stored procedures instead of declarative constructs. This is because such constraints may involve nested quantifications over huge extents of several tables. Thus, their evaluation can easily become prohibitively costly. However, declarativity does not need to be sacrificed for efficiency, as shown by many methods of simplified integrity checking as cited in this survey. They are all based on the seminal paper (Nicolas, 1982).

SIMPLIFIED INCREMENTAL INTEGRITY CHECKING

A common idea of all integrity checking methods is that not all constraints need to be evaluated, but at most those that are possibly affected by the incremental change caused by database updates or transactions. Anticipating updates by patterns, most incremental integrity checking methods allow for simplifications of constraints to be generated already at schema compilation time. Such compiled simplifications are parametric conditions to be instantiated, possibly further optimized, and evaluated upon given update requests. For generating them, only the database schema, the integrity constraints, and the update patterns are needed as input.

Their evaluation, however, may involve access to the stored data at update time. Methods that generate compiled simplifications are described, for example, by Christiansen and Martinenghi (2006), Decker (1987), and Leuschel and De Schreye (1998). For unanticipated ad-hoc updates, the generation of simplifications takes place at update time. Optimizations for efficient evaluation of simplified constraints are addressed, for example, by Sheu & Lee (1987).

Simplifications can be distinguished by the database state in which they are evaluated. *Post-test* methods must evaluate their simplifications in the *new*, updated state, for example, Decker and Celma (1994), Grant and Minker (1990), Lloyd, Sonenberg, and Topor (1987), Nicolas (1982), and Sadri and Kowalski (1988). *Pre-test* approaches, for example, Bry, Decker, and Manthey (1988), Christiansen and Martinenghi (2006), Hsu and Imielinski (1985), McCune and Henschen (1989), and Qian (1988), only access the *old* state before the update, that is, they need not execute the update prematurely, since undoing an updated state if integrity is violated is costly. In case of integrity violation, the eagerness of pre-tests to avoid rollbacks is a clear performance advantage over post-tests.

For convenience, a finite set of constraints imposed on a database D is called an *integrity theory* of D. For a database D and an integrity theory IC, let $D(IC)$ = *satisfied* denote that IC is satisfied in D, and $D(IC)$ = *violated* that it is violated. Further, for an update U, let D^U denote the updated database. Any simplification method M can be formalized as a function that takes as input a database, an integrity theory and an update, and outputs either *satisfied* or *violated*. Thus, soundness and completeness of M can be stated as follows:

Let D be any database, IC any integrity theory, and U any update. Suppose that $D(IC)$ = *satisfied*. Then, an integrity checking method M is *sound* if the following holds:

If $M(D, IC, U)$ = *satisfied* then $D^U(IC)$ = *satisfied*.

It is *complete* if the following holds:

If $D^U(IC)$ = *satisfied* then $M(D, IC, U)$ = *satisfied*.

This formalism is applicable to most integrity checking methods in the literature. Many of them are sound and complete for significant classes of relational and deductive databases, integrity theories, and updates. Some methods, however, are only shown to be sound, that is, they provide sufficient conditions that guarantee integrity satisfaction of D^U, for example, Gupta, Sagiv, Ullman, and Widom (1994); further checking is required if these conditions are not satisfied. The main advantage is that the evaluation of $M(D, IC, U)$ is typically much simpler than that of $D^U(IC)$.

Most integrity checking methods can be described by distinguishing three (possibly interleaved) phases, namely the *generation*, *optimization*, and *evaluation* of simplified tests. Next, these phases, numbered I, II, III, are illustrated by an example.

EXAMPLE

Consider a relational database with tables for workers and managers, defined as follows:

```
CREATE TABLE(worker(CHAR name, CHAR department))

CREATE TABLE(manager (CHAR name)).
```

Suppose there is an integrity constraint requiring that no worker is a manager, expressed as a denial by the following SQL condition, which forms the body of a related SQL assertion:

```
NOT EXISTS (SELECT * FROM worker, manager WHERE
worker.name = manager.name).
```

If the number of workers and managers is large, then checking whether this constraint is violated or not can be very costly. The number of facts to be retrieved and tested is in the order of the cardinality of the cross product of worker and manager, whenever the constraint is checked. Fortunately, however, the frequency and amount of accessing stored facts can be significantly reduced when going through phases I -III. Beforehand, a possible objection at this stage should be dealt with.

SQL programmers might feel compelled to point out that the previous constraint is probably much easier checked by some trigger such as the following one in MS SQL Server syntax:

```
CREATE TRIGGER no_worker_manager ON worker FOR
INSERT : IF EXISTS

(SELECT * FROM inserted, manager WHERE inserted.name
= manager.name) ROLLBACK.
```

Its evaluation would only need to access manager and a cached relation inserted containing the row to be inserted to worker, but not the stored part of worker. However, it is easily overlooked that the sample integrity constraint entails that somebody who is promoted to a manager must not be a worker, thus necessitating a second trigger for insertions into manager. In general, each occurrence of each atom occurring in a constraint requires a separate trigger, and it is by far not always as obvious as in the simple previous example how they should look. Apart from being error-prone, hand-

coded triggers may also bring about unpredictable effects of mutual interactions that are hard to control. As opposed to that, the generic approach illustrated next can be fully automatized.

Now, let INSERT INTO worker VALUES ('Fred', 'sales') be an update. Then, phases I-III involve the following.

I. Generation

The constraint that no worker must be manager is clearly relevant for the given update and hence must be checked, but only for the newly inserted worker Fred. Any integrity constraint that is not relevant for insertions into the worker table need not be checked. For example, a constraint requiring that each department must have some least number of workers need not be checked for insertions but only for deletions in the worker table. Also, all constraints that do not involve the relation worker are not relevant.

Hence, as a result of phase I, the SQL condition

```
NOT EXISTS (SELECT * FROM worker, manager WHERE
worker.name = manager.name)
```

can be simplified to the following much less expensive expression:

```
NOT EXISTS (SELECT * FROM worker, manager WHERE

worker.name = 'Fred' AND worker.name = manager.
name).
```

If the worker table is involved in definitions of database views, then there may be implicit update consequences on such views. These, in turn, need to be run through I-III.

II. Optimization

Since the existence of a worker satisfying the subcondition worker.name = 'Fred' is assured by the update, the simplified condition in I can be further optimized to

```
NOT EXISTS (SELECT * FROM manager WHERE name
= 'Fred').
```

III. Evaluation

Evaluation of the query whether Fred is a manager means to look up a single fact in a stored relation. That, of course, is much less costly than evaluating all integrity constraints in their full generality, as would be necessary without having done I-III.

The previous example is very simple. However, by running phases I-III, the same proportions of simplification are obtained systematically for arbitrarily complex constraints.

FUTURE TRENDS

Future trends to be reckoned with for integrity checking can be grouped by the following thematic issues: growing demands, business rules, closing gaps between theory and practice, distributed and replicated databases, agents, extensions of the relational model, semi-structured data, XML, Web databases, and inconsistency tolerance. Editions in 1999 and 2003 of the SQL standard have tried to do justice to several of these trends by proposing norms for non-scalar data types, markup annotations, recursive view definitions, and triggers, which, however, have hardly been taken up uniformly by database vendors (cf. Gorman, 2001).

The importance of database integrity is likely to grow further, hand in hand with increasing concerns for the quality and reliability of data. Also, the declarativity of data integrity is bound to become more important because of the growing complexity of data and applications, the development and maintenance of which would otherwise become too troublesome. A success story about commercial use cases of declarative integrity constraints is the growing demand of business rules (Date, 2000; Ross, 2005). Another prospering application area, based on the use of integrity constraints in semantic query optimization (Grant & Minker, 1990), is consistent query answering, as indicated by Bertossi (2006).

Yet, commercial databases lag behind the state of the art of integrity checking in academia. Besides a lack of support for the simplification of ASSERTION statements, also the support for declarative constraints on views is scant, if not completely missing, in many database products. In general, technologies related to integrity constraints that are still to be transferred from theory to practice are aplenty (cf., e.g., Decker, 1998, 2002). Not only in practice, but also in theory, a void that continues to gape is related to simplified integrity checking for concurrent transactions. Locking policies and coordination algorithms, used to avoid or resolve conflicts and deadlocks of concurrent read-write accesses, may cause a considerable overhead. Performance is burdened even more by additional locks that may be necessary for integrity checking. A locking policy for checking the integrity of concurrent transactions and possible mitigations of the associated overhead are discussed by Martinenghi and Christiansen (2005).

Not only with regard to concurrency, but also in general, integrity support in decentralized networks of databases is even worse than for centralized systems. For instance, no declarative way of ensuring referential integrity across tables stored in different sites exists. This and other problems of integrity checking in distributed databases are addressed,

(e.g., Bright & Chandy, 2003; Ibrahim, 2002, 2006). Some relief that may make up for part of this deficit can be expected from a convergence of distributed databases and agents technology. An approach to handle integrity constraints in this context is described, for example, by Sadri, Toni, and Torroni (2002). Both theory and practice of integrity support need to advance also for replicated databases. Beyond distributed databases, there is the problem of the integrity of data on the Web, which certainly is going to receive more attention in the future; for a primer, see work by Aldana, Yagüe, and Gómez (2002).

In recent years, there has been a surge of interest in the design and control capacities of integrity constraints in XML-based data models and languages (Vianu, 2003). An initial focus on primary and foreign keys (Fan & Libkin, 2002) currently is being extended to more general kinds of constraints for XML (cf., e.g., Fan, 2005; Zhuge & Xing, 2005).

One of the reasons for the lack of support for database integrity in practice is an alleged inapplicability of constraint checking methods in the presence of inconsistencies. Simplification methods usually assume that, for checking integrity incrementally, the state before the update must satisfy integrity. Clearly, this assumption is not very realistic since hardly any real-life database of significant size can be expected to be completely free of any inconsistency. Fortunately, however, this assumption can be abandoned. As shown by Decker and Martinenghi (2006), many (though not all) methods provide simplified conditions that are necessary and sufficient for checking that all cases of integrity constraints that have been satisfied before the update will remain so afterward, even in presence of any number of violated cases. Ramifications of this result are expected to further boost the adoption of integrity checking technology in practice.

CONCLUSION

We have outlined basic concepts and principles for checking the semantic integrity of stored data that are more advanced than the usual SQL support for data integrity, but can be expressed in conventional SQL and processed by standard SQL engines. In the literature, integrity constraints are often represented in the language of first-order predicate logic. A systematic translation of constraints expressed in predicate logic into SQL is described by Decker (2002). There, also a fully automated and provably correct mechanism for translating declarative constraints into efficient triggers is specified. It takes advantage of simplifications as outlined previously. More details about general principles of integrity checking are documented by Martinenghi, Christiansen, and Decker (2006).

KEY TERMS

Business Rule: Statement for defining or constraining the evolution of data pertaining to an enterprise's business. Business rules can be represented and enforced by integrity constraints.

Declarative vs. Procedural: Since the evaluation of declarative integrity constraints can be very costly, potentially troublesome procedural triggers and stored procedures are often used instead. The main thrust of this article is about reducing the cost of declarative integrity constraints.

Inconsistency Tolerance: A practically indispensable property. Integrity checking is inconsistency-tolerant if the invariance of all satisfied cases of integrity constraints across updates can be ensured, even if some other cases are violated.

Integrity: Semantic consistency, that is, the correctness of stored data with regard to their intended meaning, as expressed by integrity constraints. Not to be confused with namesake issues related to data security, serializability of concurrent transactions or sound failure recovery.

Integrity Checking: Systematic test for checking whether integrity constraints remain satisfied or become violated by some update.

Integrity Constraint: Integrity constraints are invariant properties of the database that evolve via updates. Often, it is convenient to state them as denials, that is, *yes/no* queries that are required to return the empty answer in each database state.

Integrity Enforcement: Actions taken to ensure that integrity remains satisfied across database updates. If integrity is violated by some update, then that update is rejected or some other corrective action is taken.

Integrity Satisfaction, Integrity Violation: Integrity is satisfied if each integrity constraint in the database schema, queried as a denial, returns the empty answer. Integrity is violated if any one of these integrity constraints returns a non-empty answer. Then, the database is also said to be inconsistent.

Semantic Integrity: The adjective "semantic" distinguishes a set of explicitly defined integrity constraints from structural constraints that are implicitly enforced by the used data model.

Simplification: A methodological approach to reduce complexity and costs of integrity checking. Also the simplified forms of integrity constraints generated by such methods are called simplifications.

Static vs. Dynamic Integrity Constraints: Static integrity constraints are semantic properties that are invariant across evolving database states. Dynamic integrity constraints refer explicitly to several (mostly consecutive) states or to their transitions, typically involving temporal or procedural constructs.

Trigger: An SQL statement that generates an action (e.g., an update or a reset) upon some anticipated event (e.g., an update request). Triggers are a procedural means to enforce integrity.

Database Support for M-Commerce and L-Commerce

Hong Va Leong
The Hong Kong Polytechnic University, Hong Kong

INTRODUCTION

M-commerce (mobile commerce) applications have evolved out of e-commerce (electronic commerce) applications, riding on recent advancement in wireless communication technologies. Exploiting the most unique aspect inherent in m-commerce, namely, the mobility of customers, l-commerce (location-dependent m-commerce) applications have played an increasingly important role in the class of m-commerce applications. All e-commerce, m-commerce, and l-commerce applications rely on the provision of information retrieval and processing capability. L-commerce applications further dictate the maintenance of customer and service location information. Various database systems are deployed as the information source and repository for these applications, backed by efficient indexing mechanisms, both on regular data and location-specific data.

Bean (2003) gave a good report on supporting Web-based e-commerce with XML, which could be easily extended to m-commerce. An m-commerce framework, based on JINI/XML and a workflow engine, was defined by Shih and Shim (2002). Customers can receive m-commerce services through the use of mobile devices such as pocket PCs, PDAs, or even smart phones. These mobile devices together with their users are often modeled as mobile clients. There are three types of entities central to m-commerce and l-commerce applications: mobile device, wireless communication, and database. In this article, we focus our discussion on mobile-client enabled database servers, often referred to as mobile databases. Mobile databases maintain information for the underlying m-commerce and l-commerce applications in which mobile devices serve as the hardware platform interfacing with customers, connected through wireless communication.

Location is a special kind of composite data ranging from a single point, a line, a poly-line, to a shape defining an area or a building. In general, locations are modeled as spatial objects. The location of a static point of interest, such as a shop, is maintained in a database supporting spatial features and operations, often a spatial database (Güting, 1994). The location of a moving object, like a mobile customer, needs to be maintained in a moving object database (Wolfson, Sistla, Xu, Zhou, & Chamberlain, 1999), a database that supports efficient retrieval and update of object locations. To enable l-commerce, both spatial databases and moving object databases need to support location-specific query processing from mobile clients and location updates they generated.

The two major types of data access requirements for a mobile database are data dissemination and dedicated data access. Data dissemination is preferred, since it can serve a large client population in utilizing the high bandwidth downlink channel to broadcast information of common interest, such as stock quotations, traffic conditions, or special events. On the other hand, dedicated data access is conveyed through uplink channels with limited bandwidth. To disseminate database items effectively, the selected set of hot database items can be scheduled as a broadcast disk (Acharya, Alonso, Franklin, & Zdonik, 1995). Proper indexes can be built to facilitate access to broadcast database items (Imielinski & Badrinath, 1994). Redundancy can be included in data (Leong & Si, 1995) and index (Tan & Ooi, 1998) to combat the unreliability of wireless communication.

For dedicated data access, queries and updates to databases are transmitted from the client to the server. L-commerce services involve processing of location-dependent queries (Madria, Bhargava, Pitoura, & Kumar, 2000). The high frequency of updates to the location of moving objects calls for special indexing technique. The call-to-mobility ratio serves as a good indicator on the tradeoff of indexing mechanisms. The moving object databases should enable efficient execution of queries such as k-nearest neighbor, reversed nearest neighbor (Benetis, Jensen, Karĉiauskas, & Ŝaltenis, 2006), and nearest surrounder search (Lee, Lee, & Leong, 2006). In addition, they should support continuous queries (Prabhakar, Xia, Kalashnikov, Aref, & Hambrusch, 2002), such as continuous k-nearest neighbor, being executed continuously and returning location-dependent results (Lee, Leong, Zhou, & Si, 2005). Reversing the role of query and data, it is equally important to process data streams effectively (Babu & Widom, 2001) such as incoming sensor data streams (Mokbel, Xiong, Hammad, & Aref, 2005) for traffic monitoring in navigational applications.

A related and interesting research problem is the location privacy of a mobile client. For instance, the application server should not be able to deduce the exact location of Alice, when she raises a query to look for a nearest restaurant on the State Street. Yet, the information returned to Alice should enable her to determine the nearest restaurant. Location cloaking technique (Gedik & Liu, 2005) and location anonymizer (Mokbel, Chow, & Aref, 2006) would be used to ensure a

form of k-anonymity, such that Alice is indistinguishable from other k-1 clients around the State Street.

BACKGROUND

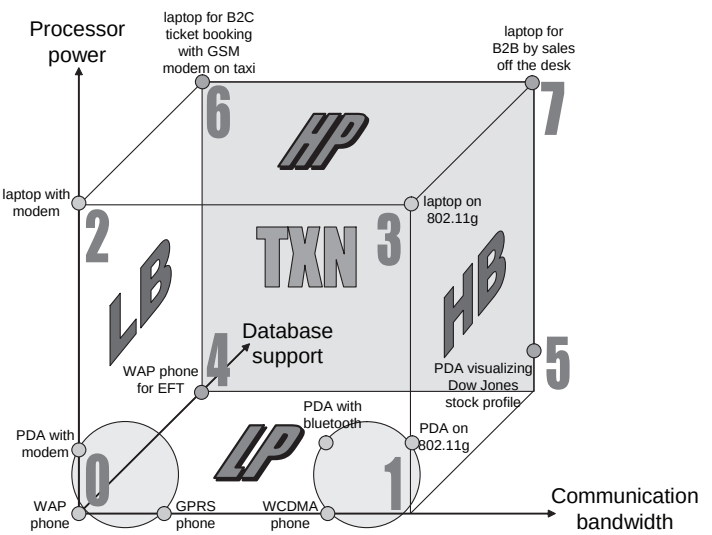
The three fundamental elements for m-commerce applications, namely, mobile device, wireless communication, and database support can be considered orthogonal. First, the variety of mobile devices differs vastly in computational power, ease of programming, interoperability of operating environments, and support for auxiliary devices. Some mobile clients are based on high-end laptops, while others are based on low-end PDAs or cellular phones. Second, wireless communication offers varying bandwidth and reliability, based on low-bandwidth and unreliable GSM connections, medium-bandwidth GPRS/EDGE and Bluetooth connections, or high-bandwidth 802.11g and WCDMA/CDMA2000 connections. Third, the database may be as primitive as a file system or simple relational database like MS Access, or as complex as the high performance Oracle with transactional and spatial data support. Transactions ensure a sequence of database operations to be executed consistently. This leads to a "cube"-like taxonomy as shown in Figure 1. The support of l-commerce requires a new location maintenance module at the database. However, for most practical applications involving the location of moving objects, transactional access is not required on the location, owing to the inherent imprecise nature of the changing location over time.

In Figure 1, the taxonomy for m-commerce and l-commerce support is displayed. Planes LP and HP represent the low computing power equipment and high computing power equipment respectively, whereas planes LB and HB reflect the availability of low and high communication bandwidth. With the availability of transactions in the TXN plane, this gives rise to eight different regions.

Region zero represents the support of standard file or simple database access from PDA connecting through low-speed modem or phone. Processing is basically performed at the server, since it is too expensive for clients to support complex mechanism. To reduce bandwidth consumption, information distillation/extraction (Cowie & Lehnert, 1996) may be performed to reduce the amount of information transmitted. Simple client/server data access paradigm suffices. Region one assumes an improved wireless network, with large scale WCDMA/CDMA2000 (3G) or small scale 802.11g (WiFi). Recent 802.16 (WiMAX) development and deployment lead to improved bandwidth in medium scale mobile environment. As a result, data access is more effective and conventional client/server data processing techniques can be adopted in a rather straightforward manner.

Region two corresponds to a mobile client with higher computational power. Information transmitted can be transcoded to reduce the bandwidth consumption. Interactive and intelligent mechanisms such as multi-resolution browsing (Leong & Si, 2005) can be employed. Database items are cached to combat the low communication bandwidth, unreliable communication, and frequent disconnection. Research work addressing this issue was pioneered by the Coda file system in 1992 (Satyanarayanan, 2002), in which files are cached by clients and updates made during client disconnection are reintegrated upon reconnection. Caching in an object-oriented database was studied by Chan, Leong, Si, and Wong (1999). Configurations in region three allow

Figure 1. Taxonomy on m-commerce and l-commerce support



easy access to data from server. With ample bandwidth and processing power, prefetching of database items allows the preparation for potential network disconnection (Jing, Helal, & Elmagarmid, 1999). Numerous research works on mobile data access have been conducted with respect to regions two and three.

Plane TXN represents the transactional equivalence of the four regions. Regions four and five involve the use of PDAs or phones to access databases in a transactional manner. Owing to the low device capability, the only effective mechanism is to execute the transaction at the server. Clients only implement the user interface, supplying the required data and displaying the result sets. Information distillation could be needed for the low bandwidth configurations in region four. The use of a proxy server helps to simplify the client/server design, since the proxy will be responsible for contacting different parties involved in the transaction. Finally, for regions six and seven, there are a lot more research potentials, since the client is more powerful in executing more complex algorithms. For instance, it would be appropriate to implement on the client a variant of the optimistic concurrency control protocol (Bernstein, Hadzilacos, & Goodman, 1987) for region six and two phase locking with lock caching (Franklin, Carey, & Livny, 1997) for region seven configurations.

In practical m-commerce applications, clients are moving around. This results in l-commerce applications, involving location-dependent queries (Madria et al., 2000). The configuration and taxonomy remain similar, except for better database support need. Research and application focus should be on the low communication bandwidth, as well as on client mobility. This corresponds to plane LB. Under such configurations, a large client population communicates with database servers over wireless communication channels (Alonso & Korth, 1993). A geographical information system component enables location-dependent queries to be resolved through geo-referencing (Choy, Kwan, & Leong, 2000). Moving object databases can keep track of the whereabout of clients (Wolfson et al., 1999) effectively.

STRONG DATABASE SUPPORT

M-commerce and l-commerce applications involve access to one or more databases, often being accessed concurrently by multiple clients. Location management is an element inherent in l-commerce. Efficient operations through moving object databases should be provided (Wolfson et. al., 1999). Transactions are executed to ensure the database consistency despite concurrent access. The correctness criterion of serializability on concurrent transactions can be enforced through concurrency control protocols. Concurrency control protocols in a client/server or a mobile environment can be classified according to their nature (Franklin et al., 1997; Jing et al., 1999). In m-commerce and l-commerce applications, simultaneous access to multiple databases, which are administered by different organizations, is a norm rather than an exception. One should provide consistent accesses to those multiple databases with a transaction-like behavior, known as global serializability (Breitbart, Garcia-Molina, & Silberschatz, 1992). The distributed activity accessing the multiple databases is called a global transaction. Tesch and Wäsch (1997) presented an implementation of global transactions on the ODMG-compliant multidatabase systems. Creating such a multidatabase system could involve a lot of coordination efforts, both at the system level and the enterprise managerial level. The execution cost of the global transactions, in terms of concurrency control and atomic commitment, can be high. Thus, global transactions have not been widely adopted, despite their usefulness and convenience. Rather, multiple subtransactions were commonly executed on individual databases without enforcing global serializability.

In a mobile environment, it is appropriate to relax the overly restrictive serializability correctness criteria. It is often acceptable for a mobile client not to see the updates made by concurrently executing mobile clients, in exchange for a faster execution and a higher probability of committing its transaction. This is particularly true about the location of a moving object, which is inherently imprecise. Recency and freshness of location value is considered more important. Isolated-only transactions (Satyanarayanan, 2002) were proposed to reduce the impact of client disconnection. N-ignorance (Krishnakumar & Bernstein, 1994), bounded inconsistency (Wong, Agrawal, & Mak, 1997), and update consistency (Shanmugasundaram, Nithrakashyap, Sivasankaran, & Ramamritham, 1999) were some of the common weaker forms of correctness criteria. In these approaches, they try to ignore some of the operations in a transaction or allow them to be executed out-of-order in some controlled manner.

Transaction processing throughput in a mobile environment can be improved by utilizing the broadcast bandwidth effectively. The database can be broadcast and transactions can be processed against the database items broadcast. This is very useful for read-only transactions (Pitoura & Chrysanthis, 1999) simply by tuning for a consistent set of database items over the broadcast. To enable update transaction processing, the hybrid protocol by Mok, Leong, & Si (1999) ensures serializability by performing validation for update transactions, and utilizing the uplink channel to request for additional database items not available over the broadcast. Consistency across database items is ensured through the use of timestamps. In update consistency (Shanmugasundaram et al., 1999), a mobile client is only required to see updates made at server consistent with the values it reads, without having to follow the same serialization order as those observed by other mobile clients; it can be enforced by the cycle-based algorithm.

With the embracement of the Internet computing paradigm, more and more enterprises are willing to publicize their databases as part of their drive toward B2B or B2C E-commerce. Under most cases, these databases can be accessed from outside the enterprise via a Web interface. The ability to access consistent information using global transactions becomes more practical and manageable. Although updates to databases are normally restricted across departments or enterprises, more and more databases become enabled for the execution of read-only transactions by external parties, through the provision of Web-services (Hoang, Kawamura, & Hasegawa, 2004). Weakly consistent global transactions could be executed based on a sequence of Web-service requests. Furthermore, the presence of a high proportion of read-only transactions even renders the concurrency control for global transactions far more efficient.

Under certain B2B setting, it would be advantageous to automate the workflow process across enterprises (Vonk & Grefen, 2003). It is important to ensure the transactional execution of a low level workflow process, albeit the more relaxed consistency requirement on higher level process. Naturally, the overall process can be modeled as a nested transaction, which is destined to be long-lived that global serializability could be too restrictive in delivering good performance. Instead, the adoption of special transactions to roll back unintended effects is more appropriate (Tesch & Wäsch, 1997). With respect to the B2C setting, mobile clients would normally only initiate local transactions or simple global transactions spanning across a small number of databases, rather than a long-lived workflow process. The limitation of communication bandwidth and occasional network disconnection implies a longer transaction execution cycle.

FUTURE TRENDS

Owing to the complexity of global transaction processing and the resource limitations of mobile clients, it is sensible to migrate the coordination effort to the proxy server and the Web server, thereby relieving the mobile clients from the complex processing. This is especially true in the context of regions four and five. As a result, there would be the decoupling of the transaction processing mechanism from the application logic, with basic transactional support at the proxy. The application logic can further be delivered conveniently through the adoption of mobile agents (Yau, Leong, & Si, 2003), preferably intelligent agents that can make sensible decision on behalf of the client, only reporting back the outcome and obtaining confirmation from the client. For instance, mobile agents can act on behalf of the client for event-driven transactions like stock selling transactions or auctioning. Support for global transactions can be provided primarily on the wired network through the agent.

Web services allow the bundling of higher level or more complex operations on the databases to be invoked by clients (Hoang et al., 2004), simplifying the need to ensure local serializability of transactions on a particular database. For regions six and seven configurations, more complicated control can be established at the clients, whose higher computing power can also be dedicated to filter for information more effectively, with reference to its local cache, and to provide value-added operations on the data. One could leverage on the computing power of these mobile clients for m-commerce and l-commerce, by engaging in the popular paradigm of peer-to-peer computing (Avancha, D'Souza, Perich, Joshi, & Yesha, 2003) and pervasive cooperative computing. For instance, group-based location reporting exploiting peer-to-peer computing power is effective in reducing the update cost for changing client locations (Lam, Leong, & Chan, 2007).

The location of a client in l-commerce is a piece of sensitive information that deserves protection. There is an increasing concern on the privacy issue of mobile clients, in the context of location-dependent service (Mokbel et. al., 2006) and data mining (Verykios et al., 2004). A server is able to deduce the movement and even spending pattern of a client. Privacy should be protected and the quality of service should not be undermined excessively. This is a highly challenging task to strike a good balance. Finally, effective visualization of the result set and navigation through the result sequence to decide on the next step is important, since low-end mobile devices are normally equipped with a relatively small display, a constraint that is only mitigated at a much slower pace than advancement in network bandwidth and processing power.

CONCLUSION

Database support is an important and fundamental issue in m-commerce and l-commerce applications. With respect to the vast difference in the power and capacity of mobile devices, the varying wireless communication bandwidth, and the new dimension of client mobility and network disconnection, adjustments need to be made to render appropriate database support to these applications. In this article, we gave a generic classification along the three major characteristics for m-commerce and l-commerce environments. The different issues on database support were surveyed and discussed. In the future, there should be a division of research efforts, in providing effective transactional support at the server or proxy through agents or Web services, while leveraging on the capability of the peer clients in information organization and presentation. There is also a serious quest for better value-added computing support and solutions, including data-intensive stream processing and client privacy preservation.

KEY TERMS

Continuous Query: A continuous query is a query, which is re-evaluated continuously. For example, the query "give me the most updated temperature" will return different readings depending on the current moment. Some continuous queries are also location-dependent. For instance, the query "show me the nearest gas station" will continually execute a location-dependent query. Advanced query processing technique is needed, in conjunction with moving object databases.

Geographical Information System: A geographical information system is an information system that stores and manipulates data for geographical entities such as streets, road junctions, railway, land-use, or even terrain. The data is associated with the location of the entities to allow fast geo-referencing.

Location-Dependent Query: A location-dependent query is a query whose results depend on the current location of the query issuer. For example, the query "which is the nearest gas station?" will return different gas stations depending on the current location of a driver.

Mobile Database: A mobile database is a database accessible to mobile clients. There are appropriate mechanisms to take into account of the limitation of the wireless bandwidth, the use of downlink broadcast channel, and the effect of client mobility.

Moving Object Database: A moving object database is a database that maintains efficiently the location information about moving objects, with proper indexing on the object location.

Serializability/Global Serializability: Serializability is the generally accepted correctness criterion for concurrent execution of transactions. The concurrent execution should produce the same effect and lead to the same database state as one possible sequential execution of the same set of transactions. Global serializability is the correctness criterion for concurrent execution of global transactions over many database systems. It is a stronger correctness criterion than serializability.

Spatial Database: A spatial database is a database that maintains spatial data, including the topology and relationship between points, lines and shapes, and supports spatial operations and queries, such as the area of a shape, the distance between two entities, whether a shape is covered by or next to another.

Transaction/Global Transaction: A transaction is a sequence of operations on a database that should appear as if it were executed non-interfered, even in the presence of other concurrent transactions. A transaction should satisfy the ACID properties, namely, atomicity, consistency, isolation, and durability. A global transaction is a distributed transaction that is executed on two or more database systems.

Decision Support Systems in Small Businesses

Yanqing Duan
University of Luton, UK

Mark Xu
University of Portsmouth, UK

INTRODUCTION

Decision support systems (DSSs) are widely used in many organisations (Arslan et al., 2004; Belecheanu et al., 2003; Dey, 2001; Gopalakrishnan et al., 2004; Lau et al., 2001; Puente et al., 2002). However, there is a common tendency to apply experience and techniques gained from large organisations directly to small businesses, without recognising the different decision support needs of the small business. This article aims to address the issues related to the development and the implementation of DSSs in small business firms. Our arguments are based on evidence drawn from a large body of DSS literature and an empirical study conducted by the authors in the UK manufacturing sector.

BACKGROUND

Early DSS were developed in parallel with management information system (MIS) in the 1970s. MIS is developed to primarily generate management information from operational systems, whilst DSS as defined by Gorry and Scott Morton (1971) is information systems that focus on supporting people in the unstructured and semi-structured decision-making process. A typical DSS consists of four main components: the database, the model base, the user interface and the users. Central to the DSS are the models and analytical tools that assist managers in decision making and problem solving. Concomitant with advances in the technology of computing, most DSS provide easy access to data and flexible control models with a friendly user interface design; some DSS also incorporate a variety of analytical tools and report/graphic generators. The main purpose of DSS is not to replace managers' ability to make decisions, but to improve the effectiveness of managers' decision making.

DSS in practice can hardly be separated from other types of computer-based systems, as it is often integrated with those systems, for example operational databases, spreadsheets, report generators, and executive support systems. Thus the boundary of DSS has now been extended, and DSS broadly refers to any computer-based information system that affects or potentially affects how managers make decisions. This includes data and model oriented systems, reporting systems, executive support systems, expert systems and group decision support systems.

The success and continued growth of small and medium sized enterprises (SMEs) are critically important to local and national prosperity, but their problems are not always accorded the same importance as those of larger organisations. Compared to the research devoted to large organisations on the use of information systems, SMEs have attracted much less attention. It is also the case that the problems inherent in providing support for small business management are more commonly studied from a social or economic viewpoint. Very few studies indeed have addressed decision support needs in the context of the use of information technology.

Managers of small businesses have often been disappointed with software packages because of the inability of these to adapt well to their needs (Heikkila et al., 1991). There are dangers in seeing small businesses as miniature versions of large businesses; many problems differ, and even similar problems require different solutions. Small enterprises normally have limited resources and less skilled managerial staff. They have higher failure risks and commonly do not have suitable access to the information they need.

DSS IMPLEMENTATIONS

Small business may represent a productive domain for attempts to introduce greater levels of computer-based decision support. Ray (1994) suggests that small business managers and their staff have positive attitudes towards the use of computers in business. Cragg and King (1993) report that many companies have plans to increase their use of computer applications, and found that the wish for better information was the motivating force in all case studies conducted. In the majority of the firms studied by Khan and Khan (1992), managers believed that a computerised system improved their performance in selected areas, but that there is still room for significant further development.

Gordon and Key (1987) point out that if small business managers' problem-solving skills are deficient in any of the critical areas of management decision-making, then they must improve those skills through the use of appropriate educational programmes, consultants, decision support tools,

or some combination of these. Unfortunately, the owner-manager (because of involvement in the day-to-day operation of the firm) has not the time, resource or expertise needed to evolve an appropriately analytical approach (Raymond et al., 1989, cited in Naylor & Williams, 1994). There would seem to be as strong a case for the potential benefits of DSS to the smaller business as for its larger counterpart, provided suitable software is available, and it is effectively used by the managers concerned.

Limited research has investigated the success factors for the use of information technology (including DSS) in small businesses (Delone, 1988; Lai, 1994; Raymond & Bergeron, 1992) and the design and development of specific DSSs for SMEs (Chaudhry et al., 1996; Houben et al., 1999). Some work has been done specifically to identify those areas that have not been adapted to DSS, but show potential for its introduction for the small business (Duan et al., 2002). Most research (Levy, 1999) indicates that computer use is still confined to operational activities, although a few studies (Naylor & Williams, 1994) found that some SMEs have realised the value of their information systems as decision support tools and had begun to use them for more complex activities. Other researchers suggest that there are many areas in which DSS can be better developed and utilised to help managers in critical decision-making processes, such as marketing, sales promotion, cash-flow management and customer services. It has been argued that small businesses can improve their organisational performance and increase their competitiveness with appropriate information systems (Levy et al., 1999). The increasing emphasis on competitiveness in small business has led to a new focus on the competitive advantage promised by appropriate use of information technology (Levy et al., 1999; Lin et al., 1993).

A study conducted within the UK manufacturing SMEs by Duan et al. (2002) shows that the extent of DSS use is generally limited and the use of DSS varies considerably among the firms surveyed. However, even where there was a reported low level of DSS use, managers' satisfaction was relatively high. The applications with which managers were most satisfied were: cash management, budget preparation and materials requirements planning. Despite the relatively low usage of DSS generally, the majority of SME managers indicated that they use computers personally to aid business decisions; this suggests that there is, at least, widespread use of desktop computing in managers' offices.

Regarding the inhibitors to the greater use of DSS, lack of staff time to analyse needs and identify solutions is the most significant factor identified. Lack of finance for systems purchase or development, lack of experience of systems development, lack of information on available DSS packages, and unavailability of appropriate software were other factors commonly cited (Duan et al., 2002).

DSS DEVELOPMENT METHODS

DSS for small businesses can be developed and implemented in different ways. Four routes were identified, such as:

- Off-the-peg - purchase of a commercially developed package;
- Bespoke - designed by a software house for the specific application;
- In-house - developed by the firm's own specialist staff;
- User - developed by managers as users.
