Research (Duan et al., 2002) shows that the majority of DSS were purchased as commercially developed packages; other systems were developed by managers as users, developed by in-house specialists or developed as bespoke systems by software houses. In view of the normally limited resource base for IT development (Heikkila et al., 1991), it is not surprising that most small firms choose to purchase commercially developed, ready-to-use DSS software. By breaking down the development methods into three decision-making levels, it shows that commercial packages are more commonly used at the operational level (60%) than at the strategic level. In contrast, user-developed DSS are more commonly used at the strategic level than at the operational level.

Research on *in-house* and *user* development methods in small firms is scarce. The evidence from the Duan et al. (2002) survey suggests that small business managers are capable of developing their own DSS, and that a certain proportion do so. Research in Canada by Raymond and Bergeron (1992) found that user-developed DSS in small businesses are more successful than any developed by other means. A study by Lai (1994) in the USA, however, revealed no link between the method of system development and DSS success.

By far the most commonly used DSS in small manufacturing firms are commercial packages purchased off the shelf for operational decision making. The readiness of small business managers to purchase commercial packages, coupled with their recognition that DSS vendors provide valuable support, suggest that small businesses represent a market for software developers that will continue to grow. That many managers are developing their own systems to support strategic decisions might also suggest there to be a market opportunity here.

THE FUTURE NEEDS FOR DSS IN SMES

The research by Duan et al. (2002) attempts to identify the gaps between the current provision of DSS and small business managers' desired levels of DSS support. The findings reveal that:

- the current level of DSS usage is low;
- although DSS usage is limited, managers are generally satisfied with DSS they are using;
- the desired level of support is much higher than the current provision;
- the high standard deviations for current DSS use and desired levels of support indicate high variations among responses. The standard deviation of levels of satisfaction is lower than the other two variables; this suggests that there is less disagreement on this issue.

The study supports the argument that current DSS in small businesses are geared to operational rather than strategic decision making. It is evident that the low-level use of DSS found by Raymond in 1982 has not changed significantly. The desired level of support at the operational level is also much higher than that at the strategic level. Users appear to expect that DSS will provide the most benefit for operational decisions. This is perhaps as well, given the nature of the decision-making tasks at strategic level, involving complex and changing environments, high level of uncertainty and the need to include decision makers' personal intuition and judgement. The lower-level use of DSS and desired support for strategic decision making does not mean that there is no space for further improvement, however. Indeed, the fact that many managers are "going it alone" could mean that professional support will enhance strategic planning. Levy et al. (1998) report that one of their case study firms had been successful in integrating information systems into its business strategy and gained competitive advantages. However, computer support for strategic decisions is still a challenging area for future research and much effort is being expended to overcome the difficulties (Duan & Burrell, 1997; Li et al., 2000), yet again, in the context of the larger business.

CONCLUSION

Decision support systems are designed to assist managers to make more effective decisions. Potentially, they could provide great benefits to SME managers and enhance managers' decision-making capability. However, the extent of DSS implementation in small business is still low in general, although there is significant variation between different firms. The literature review of previous studies indicates that the situation has not changed significantly since Raymond's investigation in 1982, and the present study confirms this. Lack of staff time to analyse needs and identify solutions is the most significant factor holding firms back from adopting, or making further use of DSS. Use of DSS at the operational decision-making level is higher than at the strategic level. Small business managers are generally satisfied with the DSS they are using and are hoping for much better DSS support in the future. DSS development, particularly DSS for strategic decisions in small business, still represents both a challenge and an opportunity for DSS professionals and researchers.

DSS in SMEs are most commonly implemented by purchase of a commercial package, and only rarely by bespoke development. Most DSS are used for operational rather than strategic decision making. Those firms that do use DSS to support strategic decisions rely upon user-developed models.

Although DSS applications in SMEs are still relatively few in number, most DSS users report satisfaction with their systems. To reduce the gaps between current DSS provision and the managers' indicated needs, a greater focus on small business by DSS researchers and practitioners is required. Systems most likely to appeal to small business managers will have to be appropriate to their sector's needs, and capable of implementation with minimal user training. In conclusion, it can be said that the current situation in relation to DSS in small business is full of potential but requiring further professional support.

KEY TERMS

Database: A collection of related information. The information held in the database is stored in an organised way so that specific items can be selected and retrieved quickly.

Decision Support System (DSS): An interactive computer-based system, which helps decision makers utilise data and models to solve semi-structured to unstructured problems.

Executive Information System (EIS): A computer-based information delivery and communication system designed to support the needs of senior managers and executives.

Expert Systems: A computer-based system that performs functions similar to those normally performed by a human expert. It has a knowledge base, an inference engine and a user interface.

Group Decision Support Systems (GDSS): Information systems that support the work of groups (communication, decision making) generally working on unstructured or semi-structured problems.

Management Information System (MIS): A business information system designed to provide past, present, and future information appropriate for planning, organising and controlling the operations of an organisation.

Small and Medium Sized Enterprises (SMEs): The definition of SMEs varies in different countries. It is normally defined as having between 10 and 249 employees in the UK and Europe.

INTRODUCTION

Decision-making support systems (DMSS) are computer-based information systems designed to support some or all phases of the decision-making process (Forgionne, Mora, Cervantes, & Kohli, 2000). There are decision support systems (DSS), executive information systems (EIS), and expert systems/knowledge-based systems (ES/KBS). Individual EIS, DSS, and ES/KBS, or pair-integrated combinations of these systems, have yielded substantial benefits in practice.

DMSS evolution has presented unique challenges and opportunities for information system professionals. To gain further insights about the DMSS field, the original version of this article presented expert views regarding achievements, challenges, and opportunities, and examined the implications for research and practice (Forgionne, Mora, Gupta, & Gelman, 2005). This article updates the original version by offering recent research findings on the emerging area of intelligent decision-making support systems (IDMSS). The title has been changed to reflect the new content.

BACKGROUND

Decision-making support systems utilize creative, behavioral, and analytic foundations that draw on various disciplines (Sage, 1981). These foundations give rise to various architectures that deliver support to individual and group DMSS users. The architectures, which are summarized in Table 1, include (a) classic systems (Alter, 1996) such as decision support systems (DSS), expert and knowledge-based systems (ES/KBS), executive information systems (EIS), group support systems (GSS), and spatial decision support systems (SDSS) and (b) new systems (Forgionne, 1991; Forgionne, Mora, Cervantes, & Gelman, 2002a; Gray & Watson, 1996; Mora, Forgionne, Gupta, Cervantes, & Gelman, 2003; Power, 2002; Turban & Aronson, 1998) such as management support systems (MSS), decision technology systems (DTS), integrated DMSS, data warehouse (DW)-based and data mining (DM)-based DMSS (DW&DM-DMSS), intelligent DMSS (i-DMSS), and Web-based DMSS or knowledge-management DMSS.

The architectures have been applied to various public and private problems and opportunities, including the planning of large-scale housing demand (Forgionne, 1997), strategic planning (Savolainen & Shuhua, 1995), urban transportation policy formulation (Rinaldi & Bain, 2002), health care management (Friedman & Pliskin, 2002), pharmaceutical decision making (Gibson, 2002), banking management (Hope & Wild, 2002), entertainment industry management (Watson & Volovino, 2002), and military situations (Findler, 2002). Applications draw on advanced information technologies (IT), such as intelligent agents (Chi & Turban, 1995), knowledge-based (Grove, 2000) and knowledge-management procedures (Alavi, 1997), synthetic characters (Pistolesi, 2002), and spatial decision support systems (Silva, Eglese, & Pidd, 2002), among others.

DMSS ACHIEVEMENTS

Once created, DMSS must be evaluated and managed. Economic-theory-based methodologies, quantitative and qualitative process and outcome measures, and the dashboard approach have been used to measure DMSS effectiveness. These approaches suggest various organizational structures and practices for managing the design, development, and implementation effort. Most suggestions involve much more user involvement and a larger role for nontraditional specialists during the technical design, development, and implementation tasks.

To gain further insights about DMSS achievements, challenges, and opportunities posed by the development, the

Table 1. Decision-making support systems architectures

Classic DMSS Architectures	Description	Main Decision-Making Phase Supported					DMSS' SUPPORT CHARACTERISTICS
		INTELLIGENCE	DESIGN	CHOICE	IMPLEMENTATION	LEARNING	
DSS	A DSS is an interactive computer-based system composed of a user-dialog system, a model processor and a data management system, which helps decision makers utilize data and quantitative models to solve semi-structured problems.			**A**			(A) What-if, goal seeking, & sensitivity analysis.
ES & KBS	An ES/KBS is a computer-based system composed of a user-dialog system, an inference engine, one or several intelligent modules, a knowledge base, and a work memory, which emulates the problem-solving capabilities of a human expert in a specific domain of knowledge.	**A**		**B**			(A&B) Symbolic pattern-based recognition; fuzzy data; how and why explanation facilities.
EIS	An EIS is a computer based system composed of a user-dialog system, a graph system, a multidimensional database query system and an external communication system, which enables decision makers to access a common core of data covering key internal and external business variables by a variety of dimensions (such as time and business unit).	**A**			**B**		(A&B) Key performance indicators (KPI's) in graphs and text tables; data exploring and searching through drill-down, roll-up, slice and dice and pivoting operations; networking communications to internal and external bulletin boards.
GSS	A GSS an integrated computer based system composed of a communication sub-system and model-driven DMSS (DSS), to support problem formulation and potential solution of unstructured decision problems in a group meeting.		**A**	**B**			(A) Idea generation through brainstorming facilities; pooling and display of ideas; generation of alternatives and criteria. (B) Preference models; voting schemes; conflict negotiation support.
SDSS	A SDSS a computer based system composed of a user-dialog sub-system, a geographic/ spatial database sub-system, a decision model sub-systems and a set of analytical tools, which enables decision makers to treat with situations based strongly on spatial data.	**A**		**B**			(A) Spatial data searching support; visualization tools for maps, satellite images, and digital terrains. (B) What-if analysis of scenarios, goal-seeking analysis, sensitivity analysis of decision variables upon spatial data.

continued on following page

Table 1. continued

Modern DMSS Architectures	Description	Main Decision-Making Phase Supported					DMSS' SUPPORT CHARACTERISTICS	
		INTELLIGENCE	DESIGN	CHOICE	IMPLEMENTATION	LEARNING		
MSS, DTS or I-DMSS	These systems are the result of the triple-based integration (i.e., DSS, EIS, and ES/KBS) and have the aim to offer a full support to decision maker in all phases of the DMP.	**A**	**B**	**C**	**D**		(A&D)	Visual data exploring through graphs; color codes and tables; data exploration with drill-drown, roll-up, slice, and dice, pivoting operations.
							(B)	Intelligent advice through AI-based capabilities to support the models selection task.
							(C)	Numerical modeling through available numerical-based models; what-if, goal seeking and sensitivity analysis.
DW & DM DMSS	DW&DM-DMSS are computer-based system composed of a user-dialog sub-system, a multidimensional database subsystem, and an on-line analytical processing (OLAP) component enhanced with knowledge discovery algorithms to identify associations, clusters, and classifications rules intrinsic into the data warehouse.	**A**					(A)	OLAP capabilities of aggregation, slice and dice; drill-down; pivoting; trend analysis; multidimensional query; graphics and tabular data support. Knowledge discovery patterns using statistical based, tree-decision or neural networks.
Web-DMSS & KM-DMSS	Web-DMSS & KM-DMSS are computer-based system composed of an user-dialog sub-system, a text &multimedia document storage subsystem and publishing/retrieval subsystem to preserve and distribute knowledge in the organization using intranets.	**A**				**B**	(A&B) Document publishing and retrieval facilities	
i-DMSS	Are computer based system composed of an user-dialog sub-system, a multidimensional database and knowledge base subsystem and a quantitative & qualitative processing sub-system enhanced all of them with AI-based techniques, designed to support all phases of the DMP.	**A**	**B**	**C**	**D**	**E**	(A&D)	Visual data exploring through graphs; color codes and tables; data exploration with drill-drown, roll-up, slice, and dice, pivoting operations.
							(B)	Intelligent advice through AI-based capabilities to support the models selection task.
							(C)	Numerical and qualitative modeling through numerical-based or symbolic models; what-if, goal seeking, and sensitivity analysis.
							(E)	Symbolic reasoning through knowledge-based models for explanations about how and why the solution was reached.

Table 2. DMSS achievements, challenges, and opportunities

DMSS Issue	Expert Collective Opinion
Key Achievements	The evolution of DMSS software and hardware; the implementation of DMSS in a variety of organizations; the creation of DMSS tailored design and development strategies
Research Issues and Practical Problems	Providing quality data for decision support; managing and creating large decision support databases; model management and model reuse; building knowledge driven DMSS; improving communication technologies; developing a uniform and comprehensive DMSS scheme; developing an effective toolkit; developing and evaluating a synergistic integrated DMSS; collecting insights about the neurobiology of decision support for managers' less structured work; the application of agent and object-oriented methodologies; developing DMSS though well-established methodologies
Core DMSS Architectural Concepts and Opportunities	Web technology; accessibility; security; effective data, idea, and knowledge management, possibly through the use of smart agents; effective model management; effective dialog management; EIS-like features; incorporation of basic and common DMSS functionalities; mobile computing; user-centric design.

original study compiled opinions from recognized leaders in the field (Forgionne, Gupta, & Mora, 2002b). The expert verbatim views are summarized in Table 2.

Expert Opinions

The expert opinion indicates that DMSS have been recognized as unique information systems. Collectively, these experts focus on the deployment of new and advanced information technology (IT) to improve DMSS design, development, and implementation. In their collective opinion, the next generation of DMSS will involve: (a) the use of portals, (b) the incorporation of previously unused forms of artificial intelligence through agents, (c) better integration of data warehousing and data mining tools within DMSS architectures, (d) creation of knowledge and model warehouses, (e) the integration of creativity within DMSS architectures, (f) the use of integrated DMSS as a virtual team of experts, (g) exploitation of the World Wide Web, (h) the exploitation of mobile IT, and (i) the incorporation of advanced IT to improve the user interface through video, audio, complex graphics, and other approaches.

Future opportunities, trends and challenges discerned by the experts include: (a) availability of DMSS packages for specific organizational functions, such as customer relationship management, (b) system functional and technical integration, consolidation, and innovation, (c) software tool cost education, (d) the creation of a technology role for the decision maker through the DMSS, (e) the integration of the decision maker into the design and development process, (f) developing effective design and development tools for user-controlled development, (g) accommodating the structural changes in the organization and job duties created by DMSS use, (h) developing new and improved measures of DMSS effectiveness, (i) incorporating the cognitive and group dimensions of decision making, (j) utilization of smart agents, (k) distribution of DMSS expertise through collaborative technologies, (l) incorporating rich data, information and knowledge representation modes into DMSS, and (m) focusing user attention on decisions rather than technical issues. Common themes suggested by this disparate expert opinion are (a) the DMSS should focus decision makers on the decision process rather than technical issues, and (b) DMSS development may require specialized and new IT professionals, and (c) there is need for a systematic and well-managed implementation approach.

Intelligent DMSS

Since most experts value artificial intelligence in decision making support, a historical review of the literature, covering the period 1980-2004, was conducted to examine the state of the intelligent DMSS (I-DMSS) concept (Mora et al., 2006). This history indicated that neural networks and fuzzy logic have become more popular than Bayesian/belief nets, and intelligent agents, genetic algorithms, and data mining have emerged as tools of interest.

In terms of the decision making process, the intelligence and choice phases have been the most supported phases. Over time, intelligence support has increased, while choice support has decreased. Within the intelligence phase, the problem recognition step has grown in popularity.

Among dialog user interface capabilities, text/passive graphics has remained the most used tool. Model management has been most often supported by knowledge-based methodologies and quantitative models. Knowledge-based models have been declining in importance, while quantitative models have been gaining popularity. Symbolic structured mechanisms, based on rule-based systems and fuzzy logic, and quantitative structured approaches, based on neural networks and data mining, have become the most popular data management tools.

FUTURE TRENDS

The historical analysis supports some of the expert opinion. Specifically, the reported record indicates that effort is underway to (a) increase DMSS processing capabilities through intelligent agents, fuzzy systems, and neural networks and (b) improve user-interface capabilities through multimedia and virtual environments. In short, the experts and literature on AI and DMSS implicitly recognize the relevance of improving the DMSS user interface, information and knowledge representations schemes and intelligent processing capabilities through the deployment of advanced IT.

CONCLUSION

In some ways, the DMSS field has not progressed very much from its early days. There is still significant disagreement about definitions, methodologies, and focus, with expert opinion varying on the breadth and depth of the definitions. Some favor analytical methodologies, while others promote qualitative approaches. Some experts focus on the technology, while others concentrate on managerial and organizational issues. There does not seem to be a unified theory of decision-making, decision support for the process, or DMSS evaluation. Moreover, achieving successful implementation of large-scale DMSS is still a complex and open research problem (Mora et al., 2002).

In spite of the diversity, opinions are consistent regarding some key DMSS elements. Most experts recognize the need for problem pertinent data, the role of the Internet in providing some of the necessary data, the need for system integration within DMSS architectures and between DMSS and other information systems, and the importance of artificial intelligence within DMSS processing. The historical record also supports the emerging importance of intelligent decision-making support and identifies quantitative-based methodologies as the growing form of intelligence. The DMSS concept also continues to be successfully applied across a variety of public and private organizations and entities. These applications continue to involve the user more directly in the design, development, and implementation process.

The trends will create DMSS that are technologically more integrated, offer broader and deeper support for decision-making, and provide a much wider array of applications. In the process, new roles for artificial intelligence will emerge within DMSS architectures, new forms of decision technology and methodology will emerge, and new roles will be found for existing technologies and methodologies.

As the evolution continues, many tasks that had been assigned to human experts can be delegated to virtual expertise within the DMSS. With such consultation readily available through the system, the decision maker can devote more effort to the creative aspects of management. Support for these tasks can also be found within DMSS. In the process, the decision maker can become an artist, scientist, and technologist of decision-making. The DMSS-delivered virtual expertise can reduce the need for large support staffs and corresponding organizational structures. The organization can become flatter and more project-oriented. In this setting, the decision maker can participate more directly in DMSS design, development, implementation, and management. Such changes will not occur without displacements of old technologies and job activities, radical changes in physical organizations, and considerable costs. As the reported applications indicate, however, the resulting benefits are likely to far outweigh the costs.

KEY TERMS

Data Warehousing-Data Mining (DW-DM) DMSS: Computer-based system composed of an user-dialog subsystem, a multidimensional database subsystem, and an

online analytical processing (OLAP) component enhanced with knowledge discovery algorithms to identify associations, clusters, and classifications rules intrinsic in a data warehouse.

Decision Making Support System (DMSS): An information system designed to support some, several or all, phases of the decision making process.

Decision Support System (DSS): An interactive computer-based system composed of a user-dialog system, a model processor and a data management system, which helps decision makers utilize data and quantitative models to solve semi-structured problems.

Executive Information System (EIS): A computer based system composed of a user-dialog system, a graph system, a multidimensional database query system and an external communication system, which enables decision makers to access a common core of data covering key internal and external business variables by a variety of dimensions (such as time and business unit).

Expert System/Knowledge Based System (ES/KBS): A computer-based system composed of a user-dialog system, an inference engine, one or several intelligent modules, a knowledge base and a work memory, which emulates the problem-solving capabilities of a human expert in a specific domain of knowledge.

Group Support System (GSS): An integrated computer based system composed of a communication sub-system and model-driven DMSS (DSS), to support problem formulation and potential solution of unstructured decision problems in a group meeting.

Intelligent Decision Making Support Systems (i-DMSS): Computer based system composed of an user-dialog sub-system, a multidimensional database and knowledge base subsystem, and a quantitative and qualitative processing sub-system enhanced with AI-based techniques, designed to support all phases of the decision making process.

Management Support Systems (MSS), Decision Technology Systems (DTS), or Integrated Decision Making Support Systems (I-DMSS): Systems that integrate DSS, EIS and ES/KBS to offer full support to the decision maker in all phases of the decision making process.

Spatial Decision Support System (SDSS): A computer-based system composed of a user-dialog sub-system, a geographic/spatial database sub-system, a decision model sub-systems and a set of analytical tools, which enables decision makers to analyze situations involving spatial (geographic) data.

Web-DMSS & Knowledge Management (KM)-DMSS: Computer-based system composed of an user-dialog subsystem, a text and multimedia document storage subsystem, and publishing/retrieval subsystem to preserve and distribute knowledge in intranet-supported organizations.

Delivering Web-Based Education

Kathryn A. Marold
Metropolitan State College of Denver, USA

INTRODUCTION

A decade of hindsight allows us to examine the phenomenon of Web-based course delivery and evaluate its successes and failures. When Web-delivered courses mushroomed from campuses in the 1990s, they were embraced by students, faculty, and administrators alike. The prospect of "electronic tutelage" (Marold, 2002), which allowed students through Web interface to take college courses for credit any time, any place (ATAP), was immediately popular with students. The interruptions of job and schedule changes, relocation, childbirth, failed transportation to campus, and so forth no longer necessitated an interruption in progress toward a degree. Likewise, faculty saw online teaching as an opportunity to disseminate knowledge and assess student progress according to their personal preferences, and to communicate personally with their students, albeit virtually. Administrators saw the revenue without physical classroom allocations as an immediate cash cow. In the beginning, there was satisfaction all around. Although this state of affairs was not necessarily universal, generally it could be concluded that Web-based education was a very good thing.

The Evolution Of Web-Based Course Delivery

Web-based education is a variation of distance learning: the content (college courses from an accredited North American institution, for purposes of this chapter) is delivered via the World Wide Web. The Web course content covers a quarter or semester of curriculum that the student must complete and prove a level of mastery within a given timeline. For the most part, Web-based courses use existing college curriculum and timelines. Web-based education is currently the most popular form of distance education. As educators are inclined to do, it was not long before they wanted to stand back and evaluate what they had created and determine the success of Web-delivered courses as a form of distance education. With McLuhanesque procedures, a glance in the "rear view mirror" was in order (McLuhan, 1964.) The results of many measures of success show that for *some* of the students, *some* of the time, in *some* situations, Web-based education is quite successful. Likewise, for many persons in many situations and in many phases of their formal education, Web-delivered education is *not* the answer.

BACKGROUND

The advent of the World Wide Web in the early 1990s promised a more effective, user-friendly form of Internet distance education. The graphical hypertext and, indeed, the hypermedia nature of the Web could enhance course delivery. Almost immediately, Web courses began to flourish. A new mode of delivery was firmly established.

Web-Based Education's Successes and Failures

Numerous publications have exposed problems associated with the Web-based form of distance education. The population taking the courses was sometimes the problem (Haga, 2001). The attrition and failure rate of Web-delivered courses was higher than the classroom arena (Terry, 2001). The content of the course could be problematic (Haga, 2002). The credibility of course credit achieved online was sometimes suspect (Moreno, 2000). The level of courses offered online was sometimes suspect (Marold, 2003). Research findings suggest the following conclusions concerning Web-based education (see Table 1).

There are almost as many reports of success with Web-based education as there are reports of failures. Students who are successful with Web courses tend to take more of them, sometimes as many as 90 hours of the 120 hours required for a bachelor's degree. There are now entire degrees offered online. The earliest research on Web-based education reported no statistical difference in final grades between Web-based groups and classroom groups (Mawhinney, 1998; Schulman, 1999).

The conclusion that Web-delivered education, like all distance education, is only appropriate for some students cannot be denied. It is obvious that Web courses are not going to go away. It is also undeniable that regardless of how enrollments in Web-based courses are screened, there will be students who enroll in Web courses that should not be in them. It has been shown time and again that some Web students enroll for all of the wrong reasons (Haga, Marold, & Helms, 2001). It is equally obvious that Web courses fill an enormous need for many students and are, therefore, very successful in many instances.

Table 1. Successes and failures of Web-based education

Positive	Negative
Survey level courses are the most successful.	The attrition and failure rates for upper level, analytical Web-based courses often reach 50%.
Courses at the 1-2 level of Bloom's taxonomy (Bloom, 1956) of learning immersion are more successful than those at the 3-5 level.	Students at the B and C level (the vast majority of students in any institution) are the most at risk for not completing and not passing Web-delivered courses.
Students with GPA of 3.5 or better are the most successful at completing and excelling in Web-delivered courses.	
Graduate level Web-delivered courses are more successful.	Web-delivered courses are a disaster for the passive learner without time management and independent study skills.
Courses delivered via a 3rd party distributor or a portal (such as *WebCt* or *Blackboard*) are more successful than self-hosted Web courses	Both students and faculty alike indicate time spent on an Internet delivered course is more than it would be on its classroom equivalent.
Internet students generally do better than their classroom counterparts on exams. Internet students generally do worse on projects than their counterparts on assigned projects.	
Analytical and problem solving courses are least successful.	
Web-delivered courses are a godsend for the highly motivated, independent learner.	
Final grades on Web-based education courses generally do not differ significantly from those earned in the classroom. Web-based courses are here to stay. They are an accepted, credible method of course delivery	

While the students who are at risk for failure in Web-based courses that are analytical and require problem solving are those students who are generally classified as mid-level achievers, taking prerequisite courses online seems to alleviate the risk slightly (Pence, 2003). The student group at the greatest risk is the mid-level achieving group, which in a normal distribution is the largest number of students in the class (Marold & Haga, 2004). Pence suggests some alleviating factors, such as taking the prerequisite course online from the same institution. This suggests that as students become more accustomed to the requirements and idiosyncrasies of online learning, the risk decreases. Experience makes a difference. In addition, the majority of students taking online courses indicate that they would take another online course, even though they perceive them to be more work than an equivalent classroom course. Despite attrition and failure rates that sometimes reach 50%, Web-based education is clearly a student favorite.

Tables 2 and 3 show some of the research results of a decade of Web-based education.

In the above research of two separate Web-based required computer information systems junior level courses in the same department of a large urban state school, student tests were higher in the Internet version, but their project scores (application of learning) were lower.

In Table 2, there were three different courses at freshman, sophomore, and junior levels, offered online as well as in the classroom, from the same department of a large urban institution. All three courses were survey-type courses with a heavy skills component. This research was done earlier than the study shown in Table 2. The test scores were also higher for the Internet sections, and the projects lower.

Table 2. Comparing Internet scores with classroom scores (Haga, 2001)

Telecommunications	Internet	Classroom
Projects average	60.8	83.5
Exams average	64.2	62.7
Visual Basic Programming		
Projects average	69	73.3
Exams average	72	71.3

Table 3. Comparing Internet scores with classroom scores (Marold, Larsen, & Moreno, 2002)

Introduction to Computers 1010	Internet	Classroom
Projects average	92.4	92.4
Exams average	78.2	73.5
Computer Applications for Business 2010	Internet	Classroom
Projects average	90.3	91.8
Exams average	77.5	70.01
Micro-based Software 3270	Internet	Classroom
Projects average	87.5	93.8
Exams average	77.7	67.8

** Revised classroom exams average for 2010*

Table 4. Successful Web-course characteristics

• More is not better. Simplicity, organization, and clarity are paramount.
• Frequent communication is important, both synchronous (chat, messaging) and asynchronous (e-mail, forum, discussion boards).
• Smaller modules and units work better.
• More frequent, less intricate assignments are better than complex comprehensive assignments due at the end of the course.
• Student uploaded projects and assignments work better than hard copy submissions.
• Individualized assignments are more likely to be submitted.
• The more choices in assignments and projects, the better.
• Proctored exams and secure quizzes are essential for course acceptance in the community and the workplace.
• Courses shorter in duration are more successful than ones that span semesters or quarters.
• Electronic grade books and regular feedback to student assignments submitted are essential.
• Samples of student work communicate expectations for assignments.
• Profiles or student Web pages for class members build community.
• Web links to helpful course content and enrichment material are appreciated, although not used extensively.
• More than one route to the same location in a course individualizes the course.
• Calendars of due dates and course announcements provide quick reference.

Although Web-based grades differ from classroom grades on individual projects and exams, generally over a decade of looking back, we see that final grades on courses completed on the Internet and in the traditional classroom do not differ significantly (Haga, 2002; Marold, 2002; Moreno, 2000; Presby, 2001).

DESIGNING AND DELIVERING WEB-BASED EDUCATION

It is heartening to know that the success of a Web-delivered course is not directly related to the faculty's skill in instructional design and Web publication (Marold, 2002). Templates and Web design software suffice for course design. Simple courses are just as successful as complex ones. Studies that count visits to various pages in Web courses show that many of the available pages are infrequently (and sometimes never) used by a majority of online students (Haga, 2001). The same is true for extensive instructions on how to take an online course, or lists of Web links available for extra information supplementing the course material. Factors that contribute to successful Web-delivered course are shown in Table 4. These are general conclusions based upon a decade of studies of Web-based education.

For every individual characteristic listed here, one undoubtedly can find research contradicting it. From their inception, Web delivered courses have been examined and reexamined. However, in general, these are factors that have been found to make a positive difference for faculty and designers of Web-based courses.

FUTURE TRENDS

As Web courses become more common and educators become more proficient at designing and deploying them, undoubtedly their success rate will improve. As students become more accustomed to taking Web courses, they will become more proficient at completing them. As McLuhan (1964) noted, it takes a period of adjusting to a new medium before we are entirely comfortable with it. Once Web courses become part of the "every day" of our existence, Web-based education may take its legitimate place alongside other modes of delivery.

CONCLUSION

In conclusion, Web-based education is working—for some. Entire degrees are obtainable online; students, faculty, administrators, and organizations accept credits earned online. For better or for worse, Web-based education is firmly entrenched in all areas of higher education. While Web-based education has not yet achieved the same level of success as classroom delivered instruction, it is part of most institutions' programs. The fact that Web-based education is truly working in a cost-effective manner for some of the student population some of the time, assures its continuance. Like the printing press of the late 1400s for mass distribution of knowledge, Web-based education provides mass distribution of knowledge in a new, effective way.

KEY TERMS

ATAP: Any time, any place learning. A basic characteristic of Web-based education courses in that they are available to the student on a 24-7 basis.

Bloom's Taxonomy of Learning: A scale that represents an organization of learning levels (five levels) that are characterized by the student's immersion into the theory and application of principles of a course content.

Chat Sessions: Live discussions online with a variable number of participants in a Web-based class. They can be formal and led by the instructor, or they can be leaderless informal conversations. Chat sessions are synchronous.

Electronic Gradebooks: Maintaining a record of a student's progress in a Web-based education class by posting grades on the course Web pages. General gradebooks show all enrollees; personalized gradebooks can only be viewed by the individual student.

Electronic Tutelage: Learning of new complex concepts (sometimes called *scientific* concepts), not with the intervention of a physical tutor, but via electronically delivered materials; the basic theory behind Web-based education.

Synchronous and Asynchronous Communication: Synchronous communication via the Web is immediate communication, such as in chat or instant messaging. Asynchronous communication is delayed communication via the Web, such as threaded discussions, forums, or e-mail messages, where each participant does not have to be online at the same time.

Web-Based Education: A variation of distance learning; the content (college courses from an accredited North American institution, for purposes of this chapter) is delivered via the World Wide Web. The Web course content covers a quarter or semester of curriculum that the student must complete within a given timeline in return for course credit.

Web Links: Hyperlinks (hot links) to other Web sites that are embedded in the active pages of a Web-based education course.

Web Profiles: Short biographies of students enrolled in a Web-based education course. The profiles may contain Web links to students' own home pages and digitized photos of the students.

Democratic E-Governance

Ari-Veikko Anttiroiko
University of Tampere, Finland

INTRODUCTION

The changing role of the state and a managerialist view of the operations of public sector organizations gave rise to the idea of new public governance. Gradually more citizen-centered views of governance also emerged, reflecting a need to strengthen the role of citizens and communities in governance processes at different institutional levels. This development, especially since the mid-1990's, has been affected by new technologies, leading to a kind of coevolution of institutional arrangements and technological solutions that have paved the way for a better understanding of the potentials of democratic e-governance.

BACKGROUND

Discussion about governance has acquired new dimensions since the early 1990's due to the gradual erosion of the hierarchical, mainly state-centric bases of political power. The decline of the nation state and the rise of the regions and local governments as the new key players in coping with external challenges and imposing a political will within territorial communities is among the core topics. Also, after the second World War and the 1980's in particular, international organizations and regional institutions started to gain more power in international arena (Pierre, 2000).

Another widely discussed aspect of public governance relates to the functioning and ways of working of public sector organizations. The entire institutional landscape and the overall understanding of the role of public sector organizations has gradually changed practically everywhere in the world, thus fueling the discussion about public governance. One important governance agenda-setter was the OECD Public Management Committee (PUMA), which carried out work on this topic during the first half of the 1990's and as a synthesis published a policy paper entitled *Governance in Transition* in 1995 (OECD, 1995). OECD's policy lines have been more or less neoliberal, which means that governance issues were discussed and still are to a large extent within the framework of New Public Management (NPM). In essence, its message is that the approach to the management of public organizations and services needs to be based on managerialism and market-based coordination.

Contemporary understanding and use of the concept of governance has its roots in the changing role of the state and in a managerialist view of the operations of public organizations. These two discourses have been challenged by another approach, which could be called democratic governance. It emphasizes the interactions between citizens, political representatives and administrative machinery providing a special view of citizens' opportunities to influence and participate in governance processes.

DEFINITION OF GOVERNANCE

One of the reasons behind the revival of the concept of governance was the need to distinguish between the traditional, institutionally oriented conception of "government" and more dynamic and network-based ways of thinking and working in policy processes. Thus, *government* refers to the institutions and agents that perform the governmental functions, that is, to formal institutions of the state or those of decentralized territorial governments and their ability to make decisions and take care of their implementation, whereas *governance* is about the new modes and manner of governing within policy networks and partnership-based relations (Jessop, 1998; Kooiman, 1993; Pierre & Peters, 2000; Stoker, 1998).

The way the concept of governance is used here can be specified as "public governance", which aims to pursue collective interest in the context of intersectoral stakeholder relations. In this sense, governance refers to the coordination and the use of various forms of formal or informal types of nonhierarchically organized interaction and institutional arrangements in the policy-making, development and service processes to pursue collective interest (Anttiroiko, 2004).

E-TRANSFORMATION IN DEMOCRATIC GOVERNANCE

Informatization as an important side of the transformational aspect of governance profoundly affects the relationships of different actors, forms and channels of communication and interaction, and the entire fabric of network and partnership relations. The introduction of ICTs in the public sector in the 1960's in most of the advanced countries started to reshape their data processing activities, such as record keeping and financial administration. Electronic systems started to replace old manual systems. This picture changed dramatically in

the 1990's. At the core of this revolution was the Internet (Seneviratne, 1999).

Since the 1990's a need for reconstruction of technology along more democratic lines became apparent. New ICTs have a potential to restructure government and to strengthen democracy, and to create a closer relationship between public administration and citizens in particular. It has even been said that new ICTs applied by government contribute to the emergence of a different type of governance, that is, more "direct" government, as concluded by Pardo (2002).

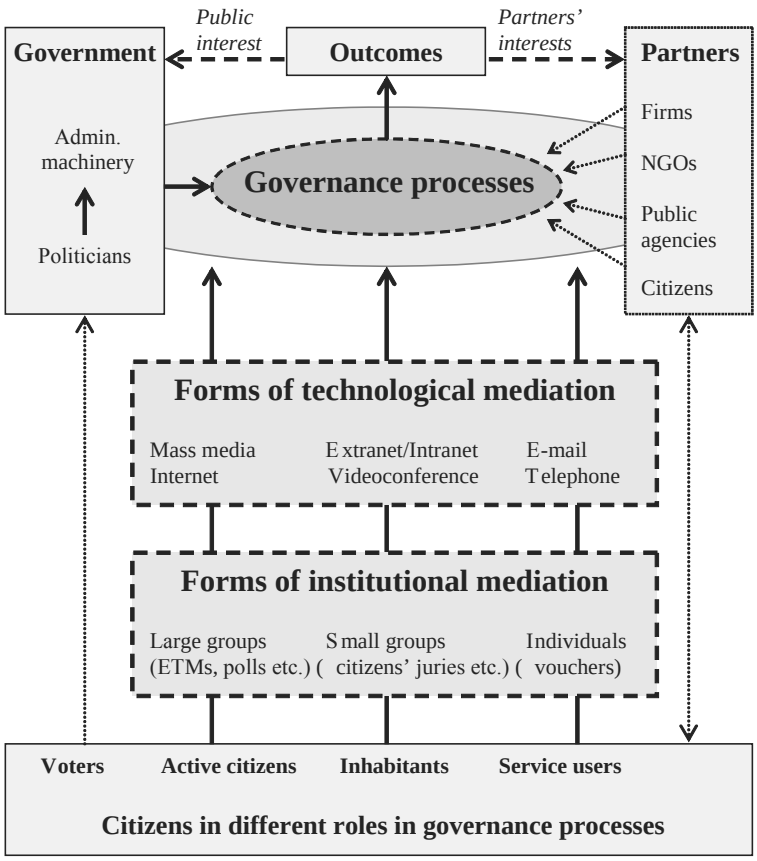
This development boils down to the idea of democratic e-governance, which combines three conceptual elements: *governance* as a process and activity area, *democracy* as an applied principle, and *information and communication technologies* as a tool. Democratic e-governance is a technologically mediated interaction in transparent policy-making, development and service processes in which political institutions can exercise effective democratic control and, more importantly, in which citizens have a chance to participate and effectively influence relevant issues through various institutionally organized and legitimate modes of participation (Anttiroiko, 2004). At a practical level democratic e-governance requires both institutional and technological mediation of civic and community interests in formal governance processes, as illustrated in Figure 1.

One of the expected strengths of citizen-centered democratic e-governance is its ability to combine a discursive public sphere with the decision-making sphere, and thus to eliminate hierarchical relations which characterize the contemporary representative systems of government.

METHODS OF DEMOCRATIC E-GOVERNANCE

There is nothing inherently "democratic" in governance. It can be and historically has been performed in various ways that cannot be called democratic. In the history of the institution of community governance the early modern times represent the era of elite control that since the 19th century began to transform into a conventional democratic mold having expression in the form of civic rights and representative system of government. This was followed by the rise of professionalism and managerialism in the 20th century.

Figure 1. Aspects of democratic e-governance (cf. Anttiroiko, 2004, p. 40)



The new phase that is emerging is in some descriptions and visions been called the era of citizen governance (Box, 1998; see also Hirst, 2000). Democratic governance requires that political institutions are capable of steering governance processes and affecting their outcomes, that citizens are given a chance to influence and participate in these processes in principle whenever they see fit, that governance processes themselves are made transparent, and that key actors are held accountable for their actions to political institutions and ultimately to society as a whole.

Institutional mediation tools of democratic governance are needed to facilitate civic involvement. A very fundamental aim is to supplement the representative system that is considered by many to be too hierarchical, inflexible, and distant from the point of view of ordinary citizens. Gross (2002) summarizes the basic requirements of e-democracy in the following way: citizens need to be able to access information, to discuss political issues, and to make decisions by voting electronically. Similar logic is followed in the UNDESA e-Participation Framework, which includes (a) increasing e-information to citizens, (b) enhancing e-consultation for deliberative and participatory processes, and (c) supporting e-decision making (UNDESA, 2005).

Conventional ways of political influence and participation in modern democracies include voting and campaigning in elections and being an active member of a political party or pressure group. Another category includes memberships of advisory committees or other bodies with a stake in policy processes and also various forms of client or customer involvement in implementation of public policies. More direct forms include voting in referendums and participation in the consultative or advisory bodies set up on an ad hoc basis. Lastly, there are various types of community group actions as well as political demonstrations that aim at changing public policy, and even various forms of civil disobedience (Birch, 1996). One way to systematize these forms on the basis of the degree of citizen influence is presented in Figure 2.

Figure 2 systematizes citizen influence within a continuum, the two extreme ends being a chance to obtain information and a direct political decision-making. The idea behind this is originally a rather old concept of eight rungs on a ladder of citizen participation which proceeds from nonparticipation through a certain degree of tokenism to the exercise of direct citizen control (Bishop & Davis, 2002).

Methods of democratic e-governance are based on the functions they serve in policy processes. On the basis of the functions of institutional and technological mediation tools, the methods applicable in e-governance can be presented as in Table 1 (Anttiroiko, 2004; see also Becker & Slaton, 2000; Gronlund, 2002; Gross, 2002; 6, 2001).

Figure 2. Continuum of citizen influence (applied from Bishop & Davis, 2002, pp. 20-21)

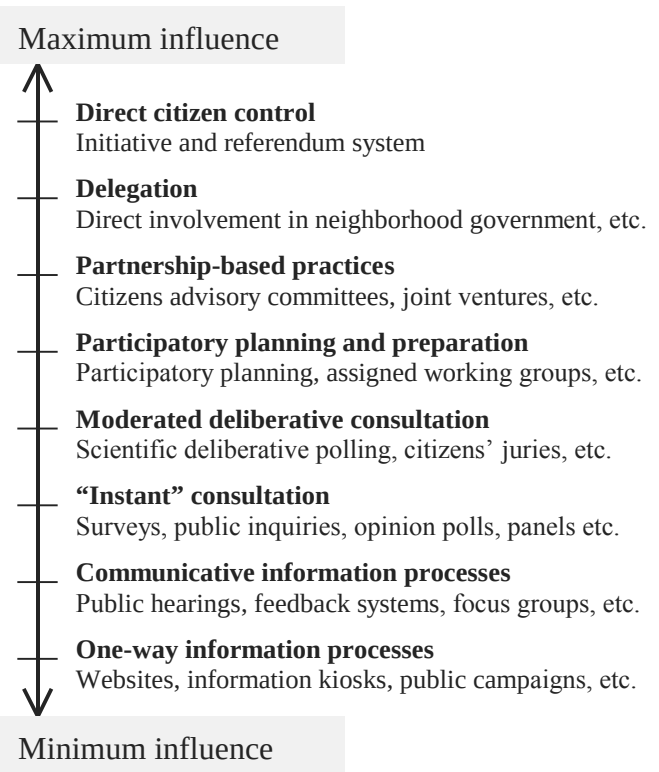


Table 1. Methods and forms of democratic e-governance

1. **Facilitating information processes**
• *Presenting, disseminating and sharing information (Websites, blogs, e-BBS, etc.)*
• *Collecting and processing data (e.g., database management tools and e-document management)*
• *Facilitating communicative or two-way information processes (e-mails and e-feedback systems)*
2. **Supporting communication and negotiation**
• *Facilitating discussion and interaction (electronic discussion forums, e-mails, mobile communication, etc.)*
• *Generating understanding and awareness (idea-generating tools, simulations, etc.)*
• *Facilitating citizen-expert interaction (e.g., consensus conferences)*
3. **Citizen consultation and involvement in preparation and planning**
• *Consultative referendum*
• *Moderated deliberative polling (scientific deliberative polling, electronic town meeting, etc.)*
• *Other forms of citizen consultation (e-citizens' juries, standing e-panels, etc.)*
• *Participatory planning*
• *Modeling decisions and advising on possible consequences (expert systems, decision support systems, etc.)*
4. **Community-based deliberation and participation**
• *Virtual communities and cyberassociations*
• *Community networks and local associations*
• *Local and neighborhood governments*
5. **Political transactions and decision-making**
• *Making proposals and initiatives (e-initiatives, e-petitions, etc.)*
• *Participating and voting in elections (e-electioneering, e-voting, etc.)*
• *Making decisions (initiative and referendum processes, including e-referendums)*
6. **Implementation and service processes**
• *Various forms of user democracy (e-feedback systems, e-vouchers, etc.)*

Since the 1970's small groups of academics, community organizers, activists, government officials, and media professionals have been experimenting with electronic media and ICTs. Since then new democratic practices have emerged and many experiments have been conducted in different parts of the world. Almost all of these have shown how interested ordinary people have been in the opportunity to participate, and how much they have appreciated being consulted and included in these processes (Becker & Slaton, 2000; see also Tsagarousianou, Tambini & Bryan, 1998).

FUTURE TRENDS

Democratization of governance is conditioned by such pervasive changes as globalization, technological development, new forms of social organization, and increased multiculturalism and individualism. It may be that a hybrid model of democratic governance is in the making, in which the new platforms and applications are evolving along with the societal and governmental structures.

Becker and Slaton (2000) have claimed that despite some setbacks genuine democracy will increase in degree and scope. This development is supported by such factors as greater influence of social movements, new methods of direct democracy, wider use of consensus building mechanisms, and new forms of e-enabled democratic political organization. These developments may give rise to new forms of democracy, which extend the application of the principles of democracy to nonhierarchically organized interaction and institutional arrangements in collective decision-making. Such a new aspect of democracy may be called network democracy.

A technological trend that is likely to have a deep long-term impact on the preconditions of democracy relates to ubiquity. The most important aspect of the emerging ubiquitous society is expected to be the new forms of interaction and transaction that are possible anywhere and at any time due to the utilization of networks and applications based on ubiquitous technologies. Thus, sooner or later various expressions of u-democracy will most likely be brought to the global democracy reform agenda.

To sum up, new technological mediation tools and the Internet in particular may prove vital in rethinking conceptions of democratic governance, giving rise to such new conceptions as ubiquitous network democracy. However, only modest democratic gains can be achieved through electronic means unless a radical redesign of democratic institutions is accomplished (Anttiroiko, 2003).

CONCLUSION

A new discourse about democratization of public governance reflects a gradual transition from the state-centric model of governance and managerial and market-based views of new public management to the politically oriented coalition-building and stakeholder-involving new public governance model that is rooted in the values of authentic democracy (cf. Barber, 1984; Becker & Slaton, 2000; Reddel, 2002). In this sense democratic e-governance is a technologically mediated interaction in governance processes in which special attention is paid to citizens' chances to participate and influence public policies.

At a practical level democratization of public governance may give rise to a network democracy and along with it technological development may provide fruitful soil for the development of ubiquitous democracy, which may converge into a new paradigm in democratic theory. Such a hybrid form of democracy may be characterized as ubiquitous network democracy, in which democratic principles are extended to nonhierarchical network-based governance with the help of ubiquitous technologies.

KEY TERMS

E-Democracy: Electronic democracy (e-democracy) as a tool-oriented conception of democracy refers to new democratic practices in which ICTs and innovative institutional arrangements are utilized (cf. teledemocracy).

E-Governance: In the public sector context governance refers to coordination, interaction, and institutional arrangements which are needed to pursue collective interest in policy-making, development and service processes in the context of nonhierarchically organized stakeholder relations. Electronic governance or e-governance is technologically mediated communication, coordination, and interaction in governance processes.

E-Government: Electronic government (e-government) is government's use of information and communication technologies, particularly Web-based applications, to support responsive and cost-effective government by facilitating administrative and managerial functions, providing citizens and stakeholders with convenient access to government information and services, facilitating interaction and transactions with stakeholders, and providing better opportunities to participate in democratic institutions and processes.

Informatization: The unprecedented growth in the speed and quantity of information production and distribution and the increased role of ICT-assisted knowledge processes, systems, and networks in society.

Network: Networks are loose sets of actors who work together in order to promote their interests within a common operational framework, which is held together by some shared interests, reciprocity, and trust. In their most characteristic form networks are flexible ways of organizing activities that require competences of several independent actors.

Network Democracy: Innovative application of the principles of democracy in the nonhierarchical network-based public governance.

New Public Management (NPM): Neo-liberally oriented public management doctrine based on a market-oriented view stating that, instead of direct political control and hierarchies, public organizations should rely on indirect control—that is, market-based coordination—in the interaction between public organizations and their environments. It emphasizes the efficiency and effectiveness of public organizations, customer focus in provision of public services, and market-based conditioning frameworks, such as privatization, competition, and contracting out.

Teledemocracy: A normative theory on democracy that is dedicated to greater, improved, and more direct citizen participation and influence in all aspects of government. It is based on the notion of transformational politics, which emphasizes the necessity to fine-tune a democratic system to meet the requirements of an increasingly complex information society. This is evident in how it favors the utilization of new ICTs in democratic processes, in such forms as electronic town meeting, scientific deliberative polling, and new democratic use of the Internet. The most prominent academic developer and advocate of teledemocracy is Professor Ted Becker, Auburn University, Alabama.

U-Democracy: Ubiquitous democracy (u-democracy) refers to new forms of democracy in which ubiquitous technologies are utilized.

Departure of the Expert Systems Project Champion

Janice C. Sipior
Villanova University, USA

INTRODUCTION

This article discusses the expert system (ES) project champion by examining the experiences of Ciba-Geigy Corporation with an ES project, impeded by the departure of the project champion. The OpBright Expert System, developed to support the identification of appropriate optical brightener products by sales representatives, was intended to provide a competitive advantage through superior customer service. With the promotion and transfer of the vital force committed to the project's success, the ES encountered a stalemate. The difficulties in maintaining momentum for the ES without a project champion are discussed. Finally, suggestions are presented to guide organizations away from the same fate.

BACKGROUND

The role of project champion has been recognized as vital to successful project development since the time of Schon's (1963) seminal work. A project champion for information systems is defined as "a key *individual*, whose *personal* efforts in support of the system are critical to its successful adoption" (Curley & Gremillion, 1983, p. 206). The project champion, for ES projects in particular, is recognized as critical to the successful application of this technology (Hayes-Roth & Jacobstein, 1994; Sipior, 2000: Wong, 1996). Champions of ES projects differ from those of other projects due to the necessity to identify, document, and distribute knowledge and expertise, facilitating knowledge-sharing. The characteristics of project champions are discussed in the next section.

Formal Position

A project champion is frequently an executive from the area of application (Willcocks & Sykes, 2000), but may come from external organizations, such as a consultants or vendors (Thomas, 1999). Champions may be managers (Beath, 1991); or hold other formal positions (Mayhew, 1999; Pinto & Slevin, 1989; Thomas, 1999). Surprisingly, champions rarely come from formal IT functions (Martinsons, 1993; Willcocks & Sykes, 2000) and may even view IT managers as too conservative, adversaries to technological innovations, and even inept (Beath & Ives, 1988). Rather than being assigned to the role, interest and personal conviction to a project compel the champion to emerge (Pinto & Slevin, 1989; Schon, 1963). Formally appointing an individual could actually lead to his demise (Howell & Higgins, 1990). Once convinced, the champion exhibits an entrepreneurial spirit (Bolton & Thompson, 2000; Pinto & Slevin, 1989; Schon, 1963).

Leadership Qualities

The champion tends to go well beyond job responsibilities, and may even go against management directives (Beath, 1991; Curley & Gremillion, 1983). Champions are characterized as more than ordinary leaders. They exhibit transformational leadership behaviors (Howell & Higgins, 1990). Such leadership is particularly valuable for implementing systems intended to bring about organizational change (Beath, 1991; Landers, 1999), such as redefining responsibilities, realigning lines of authority, shifting power centers, and adjusting reward schemes. As knowledge repositories, ES certainly has the potential to invoke change of this nature.

Base of Power

Some level of power is held by champions (Mayhew, 1999; Pinto & Slevin, 1989), attributable to formal position or personal relationships. Diminished power can result in project failure (Scott & Vessey, 2002). Champions are perceived as influential or prestigious by organizational members (Curley & Gremillion, 1983). This perception by others may be the result of a planned influence strategy to attract followers (Schon, 1963). Such influence strategies include impression building, rational justification, assertion, or persuasive communication (Howell & Higgins, 1990). Although activities of champions may be intentionally fostered, their influence tactics are not always regarded in a positive light (Beath, 1991).

Visionary Perspective for Change

The champion is willing to put himself on the line, risking his reputation, to complete the project. The champion serves

as a visionary and directs his energies to bring about change to achieve that vision (Landers, 1999; Willcocks & Sykes, 2000). Primary among the influence strategies is persuasive communication (Sumner, 2000). The vision must be clearly communicated in order that others understand and support the vision (Kotter, 1995). An unrealistic or misunderstood vision can result in failure well after the project is underway (Royer, 2003).

A CASE STUDY OF THE PROJECT CHAMPION AT CIBA-GEIGY

Ciba-Geigy Corporation, an international chemical manufacturing firm headquartered in Basel, Switzerland, continually strives to gain market position by fostering their progressive image. Ciba-Geigy emphasizes customer service, especially important to the Dyestuffs and Chemicals Division. This division produces over 2,000 products including fabric dyes, optical brighteners, and industrial chemicals, representing approximately 20% of corporate sales. The OpBright Expert System, developed to support the identification of appropriate optical brightener products, was championed by the vice president (VP) of the division as providing benefits realizable from managing internal knowledge. The VP was convinced, as was found in previous research, that effective knowledge management can impact business performance (Alavi & Leidner, 1999; Hansen, Nohria, & Tierney, 1999; Zack, 1999). Included among the anticipated benefits of OpBright are gaining competitive advantage, faster response to customers, consistent quality customer service, training new salespeople, and managing product expertise, as discussed in the following sections.

Gain Competitive Advantage

As a leading dyestuffs and chemicals producer, Ciba-Geigy recognizes the value of IT as an important means for gaining competitive advantage. Continually striving to gain market position by fostering their progressive image, Ciba-Geigy has emphasized the need to utilize IT in direct marketing. The use of laptops by the sales force, championed by the VP, provides a highly visible means for projecting this image as well as enhancing sales force performance.

Respond More Quickly to Customers

Improved communication between the sales force and the division office, in terms of such factors as speed, receipt and response, and content completeness, was realized through the use of laptops by the sales force. For example, access to the online order processing inventory and sales service system enables sales representatives to complete a sales transaction more quickly, increasing employee productivity and providing more responsive and effective customer service. This taste of success led the VP to seek further improvement. In informal meetings with the corporation's computer vendor, IBM, the VP became convinced that customer support could be enhanced through the implementation of an ES, a recognized benefit of expert system applications (Mattei, 2001).

Provide Consistent Quality Customer Service

The VP had the insight to identify the importance of offering fast, expert advice regarding the appropriate use of optical brighteners for individual customer's applications at the time of on-site sales calls. Optical brighteners are used for a wide variety of end-products. For textiles, paper products, and detergents, optical brighteners are applied to enhance coloring, that is, to make "whites whiter and brights brighter." Non-textile applications include testing for leaks, such as those in automotive parts. Salespeople are thus challenged to make appropriate and specific recommendations concerning a wide range of applications, wherein the factors to consider can vary widely. The inability of a salesperson to answer customers' questions can result in delayed or lost sales. Recognizing this impact, the VP championed the expert system as a means of increasing sales profitability. Individual customer questions could be addressed on the spot while maintaining consistency and quality in responses.

Train the Sales Force

By managing and distributing knowledge about optical brightener product features, areas of application, and troubleshooting solutions, the sales force is able to develop a greater understanding of the optical brightener product line and technical characteristics. New salespeople benefit by having unconstrained access to a "technical expert". Sales force training is thereby enhanced during formal training sessions and while on the job.

Manage Critical Product Expertise

The VP envisioned an entire family of ES, for all optical brightener applications, would be developed in the future. The domain for the first ES was appropriately narrowed to include the application of optical brighteners to fabrics only. An expert in this area of application was identified. This individual has extensive experience with the optical brightener product category, having served as a customer support technician and troubleshooter for over 15 years. His knowledge about customer requirements, properties of fabrics, and application processes enabled him to recommend appropriate optical brightener products based on features of

those products. This critical product expertise was captured, documented, and can be distributed through OpBright. Such astute management can preclude the loss of valuable corporate knowledge and expertise resulting from normal turnover or absence (Mattei, 2001), promotion (Prietula & Simon, 1989), or retirement.

Momentum without a Project Champion

The VP classified the development of the ES as a research and development (R&D) effort. No formal cost/benefit analysis was performed. Even for R&D projects, a formal analysis is recommended (Brenner & Tao, 2001). However, the cost of this first-time project was viewed as an investment in experience to be applied to future areas of application, an argument commonly made by champions in securing funding (Sharpe & Keelin, 1998). The VP was convinced that the impact of this technology would far outweigh the initial investment.

OpBright encountered a stalemate shortly after its completion. The VP was promoted and transferred to another division. The incoming VP reviewed the OpBright expert system project and restated the objective to develop a *prototype* ES. The objective was met as the prototype had been developed. Without a replacement project champion, OpBright remains at a standstill.

FUTURE TRENDS

Lessons learned, from the Ciba-Geigy case study, to avoid pitfalls attributable to the departure of the champion are discussed in the following sections. These insights may serve to guide future research; focusing on identifying strategies organizations may employ to nurture the continuation of the role of project champion.

Incorporate Expertise Management in Strategic Planning

An assessment of areas of expertise critical to organizational processes and the potential for applying ES technology, should be included within the strategic planning process. Expertise management thereby becomes a formalized managerial activity (Sipior & Garrity, 1990). Incorporating expertise management in strategic planning is clearly unique to ES in particular, differentiating ES project champions from champions of technological innovations in general.

Secure the Support of Top Management

It is well recognized that securing the support of top management is a prerequisite to the long-term success of ES projects (Sipior & Volonino, 1991; Wong, 1996). Broad support for technological innovation from the top individual alone is insufficient unless it is translated into support for specific applications of ES technology by management levels below him.

Top management support is more likely if the ES fits with corporate strategy. By incorporating expertise management within strategic planning, this fit becomes more likely (Zack, 1999). In turn, this fit will garner broader organizational commitment (Meador & Mahler, 1990). To gain the necessary support, a results-oriented approach is preferable since it enables management to buy into the impact ES can have, rather than focusing on the technology itself (Sipior & Volonino, 1991). For management support to be on-going, the results should have continued benefit.

Secure the Support of the Next Generation of Top Management

Top management support is not sufficient, unless the support of the next generation of top management is secured (Kotter, 1995). If successors are ambivalent about the ES project, as was the case for Ciba-Geigy, they certainly will not take the initiative to understand this technology and maintain project momentum.

Recognize, Support, and Nurture a Project Champion

As discussed, a project champion tends to emerge, rather than be assigned to the role. Evidence suggests both the inability to nurture such individuals as well as instances wherein this individual has been successfully developed (Schon, 1963). When a champion does not emerge naturally, a company may be able to "*find* or *make* a champion for the system" (Curley & Gremillion, 1983, p. 207).

Formalize Project Measurement, Monitoring, and Follow-up

Formalization of expert system project measurement, monitoring, and follow-up evaluation can improve the probability of project success (Brenner & Tao, 2001). Project measurement should include an evaluation at each phase of the project: (1) the validity of the technology to be employed in terms of delivering its claimed capabilities, (2) the benefits to be derived by its application, and (3) the products and services to be produced by employing the technology (Brenner & Tao, 2001). For each phase, project characteristics should be evaluated. The type of idea that generated the project could be rated from high of three to low of zero for a technological advance, new or novel technology, new twist on a known technology, or no technological advance. Additional

characteristics to consider include expertise and capabilities gained, time saved, R&D dollars saved, intellectual property expected from the project, importance of the project objective, commercial impact such as increased sales revenue, technical leverage, and internal and external relationship building. Changes in the project should be monitored as the project advances. At project implementation, the estimates from the initial project evaluation should be compared to actual project performance data. Formalizing measurement, monitoring, and follow-up evaluation forces project accountability in terms of delivering the intended results.

CONCLUSIONS

The experiences of Ciba-Geigy underscore the critical importance of the role of project champion in ES development. Conversely, the loss of this individual can threaten the very existence of a project. Organizations should thus take heed and devote attention to harnessing the enthusiasm and drive of ES project champions for advantage, before it is too late to preclude the loss of momentum generated by these individuals. Future research may be directed toward exploring the reasons for failure of projects supported by champions, and identifying strategies organizations may employ to nurture the continuation of the role of project champion for ES.

KEY TERMS

Assertion: Authoritatively convince others of the project's potential benefits so they dedicate their efforts to the project.

Charismatic Behavior: Captivate others into believing in the project as the champion himself does.

Impression Building: Portray outcomes of endeavors as highly positive achievements to promote an image of competence and success.

Inspirational Behavior: Influence others by using emotional appeals, and vivid and persuasive images, to elevate their performance.

Intellectual Stimulation: Challenge others to aspire to imaginative use of their individual skills.

Persuasive Communication: Rely more on persistence, rather than clear and concise arguments, to attain agreement.

Rational Justification: Analyze how the project advances goals and objectives and upholds values of the organization.

Transformational Leaders: Inspire others, through charisma, inspiration, intellectual stimulation, and individualized consideration, to transcend their own self-interests for a higher collective purpose.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 797-801, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Deploying Pervasive Technologies

Pietro Manzoni
Technical University of Valencia, Spain

INTRODUCTION

Communication technologies are currently addressing our daily lives. Internet, fixed-line networks, wireless networks, and sensor technologies are converging, and seamless communication is expected to become widely available. Meanwhile, the miniaturization of devices and the rapid proliferation of handheld devices have paved the path towards pervasive computing and ubiquitous scenarios.

The term *ubiquitous and pervasive computing* refers to making many computing devices available throughout the physical environment, while making them effectively invisible to the user (Weiser, 1991). Thanks to advances in the devices' processing power, extended battery life, and the proliferation of mobile computing services, the realization of ubiquitous computing has become more apparent, being a major motivation for developing location and context-aware information delivery systems.

Strongly related to ubiquitous computing is *context-aware computing*. In context-aware computing, the applications may change or adapt their functions, information, and user interface depending on the context and the client's profile (Weiser, 1993). Many research centers and industries are actively working on the issues of context-awareness or more generally on ubiquitous computing (Baldauf, Dustdar, & Rosenberg, 2007). In particular, several proposals focus on smart spaces and intelligent environments (Harter, Hopper, Steggeles, Ward, & Webster, 1999; Kindberg et al., 2002; Smart-its, 2007), where it is expected that smart devices all around us will maintain updated information about their locations, the contexts in which they are being used, and relevant data about the users.

Clearly, contextual services represent a milestone in today's mobile computing paradigm, providing timely information anytime, anywhere. Nevertheless, there are still few examples of pervasive computing environments moving out from academic laboratories into our everyday lives. This occurs since pervasive technologies are still premature, and also because it is hard to define what a real pervasive system should be like. Moreover, despite the wide range of services and potential smart applications that can benefit from using such systems, there is still no clear insight about a realistic killer application.

BACKGROUND

Pervasive computing has been in development for more than 15 years. In this section we briefly review some of the most relevant prototypes.

Various companies are already working to extend wireless technologies that will seamlessly connect to other nearby devices. However, despite the wide range of services and potential smart applications that can benefit from using such tools, there is still no clear understanding about a realistic killer. One critical question that still needs to be addressed is the identification of business scenarios that can move ubiquitous computing from academic and research laboratories into our everyday lives.

Tourism was one of the first areas to yield the business application area for the development of such potential applications. To this end, context-aware services combined with content-oriented applications could exploit wireless technology to provide personalized tours that could guide and assist tourists in museums or historical sites. One on the earlier prototypes of a mobile context-aware tour guide is the Cyberguide project (Abowd et al., 1997). The Cyberguide prototype uses the current location of users to provide visitors with services concerning location and information. For indoor applications, Cyberguide uses infrared technology as a positioning solution. On the other hand, for outdoor applications, they replace the infrared positioning module with a GPS unit. Cyberguide presents an innovative architecture, which mainly focuses on the development of location-aware applications. However, further efforts are needed to improve on context awareness. Systems similar to Cyberguide have

also been proposed by other researchers, including the GUIDE (Davies, Mitchell, Cheverst, & Blair, 1998) project proposed at Lancaster University. Cyberguide and GUIDE were influenced by earlier location-aware works such as the PARCTab at Xerox PARC (Want, Hopper, Falcao, & Gibbons, 1992), the InfoPad project at Berkeley (Long, Kooper, Abowd, & Atkeson, 1996), and the Personal Shopping Assistant at AT&T (Asthana, Cravatts, & Krzyzanouski, 1994).

The CoolTown project (Kindberg et al., 2002) at HP Laboratories focuses on building ubiquitous computing systems by embodying Web technologies into the physical environment. The Websign project (Pradhan, Brignone, Cui, McReynolds, & Smith, 2004) is a component of the CoolTown research program which allows users to visualize services related to physical objects of interest. While Websign could be adapted to offer tourist guide services, its intended use is more general, providing user interactions for services associated with physical objects. The Rememberer tool (Fleck et al., 2002) is another interesting approach, which, similarly to the CoolTown project, chooses museums as an environment to implement context-aware applications. Rememberer is a tool that offers visitors of museums services to record their visits. Each record, which can be consulted after the user's visit, consists of a set of Web pages with multimedia data describing the visit. The location of the visitor is identified using infrared technology and RFID sensors. Other works related to the CoolTown project include Spasojevic, Mirjana, and Kindberg (2001) and Semper and Spasojevic (2002).

The Digital museum project (Sakamura, 1998) at Tokyo University uses smartcards to detect the proximity of visitors and then provide information about the exhibited objects. The information provided can be based on a static profile stored previously in the smartcard. Similar work has also been done by Davin and Ing (1999) where infrared infrastructure and wireless LAN connections were used for connectivity and location awareness respectively.

Cano, Ferrández, and Manzoni (2005) used a network simulator to evaluate the feasibility and performance of using Bluetooth as the underlying networking technology to establish context-aware services. They compare results obtained from simulation with those obtained from a real test-bed. Authors observed that simulation results show a much smoother behavior than those obtained in real experiments.

The Massachusetts Institute of Technology (MIT) has a project called Oxygen (Rudolph, 2001). They envision a future where ubiquitous computing devices are as freely available and easily accessible as oxygen is today.

More recently, many of the ubiquitous and pervasive proposals are characterized by their focus on real-world deployments. In fact, some of the most valuable experiences when dealing with pervasive systems come not only from the design and implementation of a particular system, but also from the experience of trying to move those systems out of the laboratory into the real world.

Thomas, Jakob, and Mads (2006) create an interactive and pervasive system to be used in hospitals. The authors highlighted how issues that seem to be trivial in the laboratory, such as calibrating location systems or finding places for interactive displays, might become major obstacles when deploying systems in real-world settings. Other interesting works related to smart and interactive spaces can be found in Fitton et al. (2005) and Oliver et al. (2006).

Overall, we can state that, although new technologies are emerging and a number of leading technological organizations are exploring pervasive computing, the most crucial objective is not necessarily to develop new technologies, but to find ways to integrate existing technologies with a wireless infrastructure.

EXPERIENCES ON DEVELOPING PERVASIVE SERVICES

Next we present our vision on ubiquitous computing by reporting our experiences building the BlueHospital system, a pervasive prototype that provides context-aware information and location-based services to clinicians on hospitals' recovery wards. BlueHospital leverages Bluetooth technologies and Java services to offer patient information to clinical personnel based on the patient's profile and the clinicians' preferences and requirements.

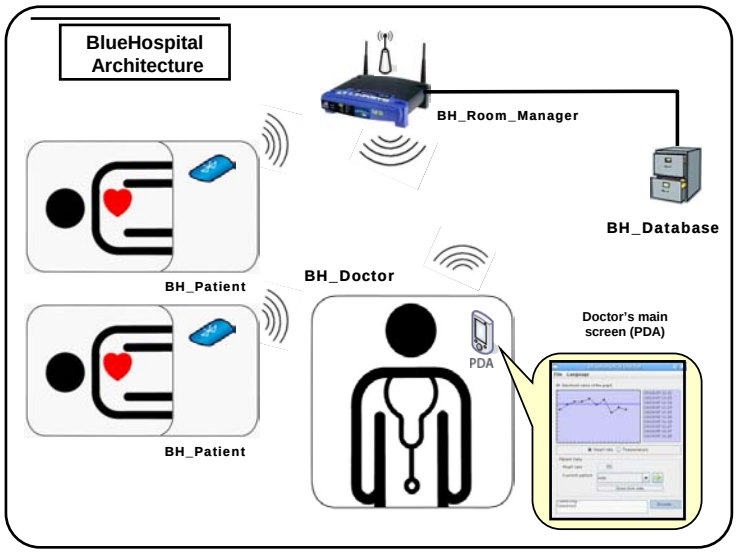
When developing a suite for a pervasive computing system, two main lessons were confirmed from our previous experience. First, we require a low-cost solution that offers computation and communication capabilities to an ordinary object. Second, minimizing power consumption and size are mandatory in order to make more apparent the realization of ubiquitous computing. To this end, we developed our own inexpensive platform prototype for ubiquitous computing, which has been implemented based on commercial off-the-shelf components.

The overall network architecture is based on the cooperation of an edge wireless network and a core wired network. The edge part is based on Bluetooth technology alone. The core network is based on a fixed 100 Mbps Ethernet local area network used to connect the edge infrastructure with the central database.

The system considers four types of entities: hospital patients (BH_Patient), room managers (BH_Room_Manager), clinical personnel (BH_Doctor), and the central database server (BH_Database_Server). Figure 1 shows a pictorial representation of the BlueHospital architecture.

A doctor provided with a Bluetooth-enabled PDA is the basic example of a mobile BH_Doctor entity. BH_Doctors are connected to the central database through the room man-

Figure 1. The BlueHospital system architecture



ager to receive information about patients, including their case history as well as comparable cases. Doctors can make diagnoses faster using all the information available at the central database, choosing the best therapy or medicine for each particular patient. There is a BH_Patient associated to each patient who has been admitted and allocated in a recovery ward. The BH_Patient connects to the room manager to register with the central database. The data being monitored consists of frequent measurement of body temperature and heart rate. There is a BH_Room_Manager associated to every recovery ward acting as a bridge between doctor and patient sensors to the central database and vice versa. Finally, the central database is able to generate precise patient profiles based on clinicians' requests and preferences.

Being a context-aware system, BlueHospital is able to provide valuable information to clinical personnel without any user interaction. When a clinician is visiting patients at recovery wards, his application will automatically search for the room manager device, which will offer any new information of interest about the patient. If a user wants to look up new information or introduce information in the system, he must send the request together with the user profile that was entered in the initial configuration process to the manager—that is, the user is a doctor, a nurse, and so forth. Knowing the user profile, the room manager can process the request combining the user profile with some additional information, and it will send it to the central data server. There the request is logged and processed, and a reply is returned to the room manager which relays it to the clinician. All the process takes place automatically, and clinicians can change their profile at any time to receive more details about the patients in their own language and adapted to their device (i.e., mobile phone, PDA, or laptop).

The BlueHospital system is also able to track clinical personnel and patients in our location- and context-aware infrastructure. Instead of using some commercial system that is perhaps more precise though expensive, we delegate to Bluetooth the location functionality. Since we only require location tracking of patients and clinicians within a room-level granularity, we developed a coarse-grained location system. All BH_Room_Manager devices in the recovery wards include a USB Bluetooth adapter with a range of up to 10 meters. When the manager discovers a new authorized Bluetooth-enabled device, it will accordingly update the tracking information within the BH_Database_Server. The proposed solution also allows using existing Bluetooth-enabled mobile phones owned by clinical personnel and patients for location tracking.

We also design our own BH_Patient device. It consists of a low-power microcontroller connected to a Bluetooth transceiver and a heart rate monitoring system through a serial UART interface, so that it can collect data from the measuring system and handle the wireless communication by sending the received data to the room manager device. In order to optimize battery life, the Texas Instruments MSP430 ultra-low-power family of microcontrollers has been selected because it is particularly well suited for power-constrained applications. A class 1 Bluetooth module has been used for wireless communication.

Concerning the BH_Room_Manager we adopt a low-cost solution based on WiFi routers that accommodate Bluetooth connectivity through an USB port, as well as a Fast Ethernet interface to connect to the central database.

Each operating ward is equipped with a BH_Room_Manager based on the ASUS WL-500g Premium wireless router (AsusTek-Computer, 2007), which contains—at a very reasonable price—almost every feature you may require to deploy a small computer network. When a connection comes in, the BH_Room_Manager will spawn a child process to deal with the mobile client's request. The child process will receive the client's profile, and it is sent to the central server. There, it will be logged and processed according to the client's profile. Eventually the required information will be sent back and passed on to the client. The parent process will carry on waiting for further client connections.

With respect to the BH_Doctor entity, we developed a PDA-oriented application using the standard Java APIs for Bluetooth wireless technology (JABWT). The application has been designed to be used by clinicians' PDAs.

The first step for each BH_Doctor application is initialization: the user must state his or her preferences as a basic set of input parameters, that is: (a) the type of device, (b) the preferred language, and (c) the user identification.

Once all the data is filled in and the user has been identified and authenticated, the application will search for information offered by the BH_Room_Manager through the Bluetooth inquiry process and service discovery protocol (SDP) searches. Once connected to the BH_Room_Manager, the application will send the stored profile to the room manager and it will eventually receive the information. Once all the information is received, the application will present it to the user. The user can then request new information (e.g., check in detail a given value) to select the period of time to be analyzed or a different patient.

Finally, the central BH_Database_Server stores in an SQL database all the information related to patients, as well as other information concerning the BlueHospital system.

The central database server has two main functions: (a) to attend connections for BH_Room_Managers requests, and (b) to manage the SQL database, that is, to handle all the information related to patients and clinicians, clinic schedules, and location tracking information. The BH_Database_Server starts and waits for a connection on the default server port. When it receives a connection request, a new process is spawned to attend it. If the connection request comes from a valid BH_Room_Managers, the data server will receive the user profile. The server will acknowledge each profile option received to provide a higher data consistency check. Once the whole profile is received, the server will log the request for security and for statistical data gathering. After logging completes, the data server will obtain (according to the received profile) the requested information from the SQL database. This information will be sent back to the room manager, which in turn will resend it to the BlueHospital application. Once the process of sending data to the room manager finishes, the connection will be dropped.

We developed both clients and server applications, providing routines to handle doctor requests about their patients, find empty recovery wards, and do profile logging and also content filtering. For example, the system may use the location tracking system to find a doctor, or it can notify a patient's ward about his or her medical treatment. Our system supports many similar scenarios aimed at providing awareness and enhancing communication.

FUTURE TRENDS

As we have previously shown, pervasive computing involves three converging areas of information and communications technology: computing devices, communications, and user interfaces. There are many visions for the future development of computing devices for pervasive systems from handheld units to near invisible devices with its own power supply. These devices will rely on some kind of wireless communication to act intelligently, being able to create the most effective form of connectivity in a given scenario. Communication can be achieved via both wireless and wired technologies, supporting switching between different networks. Finally, the user interface represents the union point between technology and human users. New devices are being developed for pervasive systems that will be able to sense information about users and the environment for advanced processing.

The appropriate combination of these three areas yield up to a wide range of applications, for example, healthcare, transport security, monitoring, tourism information, and smart networking, many of which may not yet have been identified. Emerging technologies supporting those applications include wearable computing, smart homes, intelligent environments, and augmented reality.

CONCLUSION

Research into the nature of pervasive computing has now been around for more than a decade. Nowadays pervasive applications exploit mobile wireless communication technologies to interconnect computing devices along with various sensing technologies, setting up a new kind of intelligent environment where applications can transparently search and use services without the users' intervention.

However, there are still engineering problems to be solved before the envisaged applications become a reality. Security problems, the cost of technologies, and fault tolerance issues represent only a small subset of the problems ahead. However, even though there are plenty of challenging problems to be solved, the expected reward will be great.

KEY TERMS

Augmented Reality: A new technology that involves overlaying the real world with digital information. It will further blur the line between what is real and what is computer generated by enhancing what we see, hear, feel, and smell.

Bluetooth: A short-range low-power radio technology that allows multiple compatible devices to connect to each other to transmit voice and data.

Context-Aware Application: One of a set of applications that may change or adapt their functionality depending on the context, the client profile, and the user interface.

Fast Ethernet: A collective term for a number of Ethernet standards that carry traffic at the nominal rate of 100 Mbit/s.

Pervasive Computing: The next computing paradigm based on environments with information and communication technology—everywhere, for everyone, at all times.

Ubiquitous System: A system from which the personal computer has disappeared and it has been replaced by a multitude of wireless computing devices embodied in everyday objects.

Wearable Computing: Computing devices that have been scaled down for body-wear, being always available in a transparent manner.

WiFi: Short for wireless-fidelity; a logo from the WiFi Alliance that certifies network devices comply with the IEEE 802.11 wireless standards.

Deriving Formal Specifications from Natural Language Requirements

María Virginia Mauco

INTRODUCTION

Formal methods have come into use for the construction of real systems as they help to increase software quality and reliability, and even though their industrial use is still limited, it has been steadily growing (Bowen & Hinchey, 2006; van Lamsweerde, 2000). When used early in the software development process, they can reveal ambiguities, incompleteness, inconsistencies, errors, or misunderstandings that otherwise might only be discovered during costly testing and debugging phases.

A well-known formal method is the RAISE Method (George et al., 1995), which has been used on real developments (Dang Van, George, Janowski, & Moore, 2002). One tangible product of applying a formal method is a formal specification. A formal specification serves as a contract, a valuable piece of documentation, and a means of communication among stakeholders and software engineers. Formal specifications may be used throughout the software lifecycle and they may be manipulated by automated tools for a wide variety of purposes such as model checking, deductive verification, animation, test data generation, formal reuse of components, and refinement from specification to implementation (van Lamsweerde, 2000). However, one of the problems with formal specifications is that they are hard to master and not easily comprehensible to stakeholders, and even to non-formal specification specialists. This is particularly inconvenient during the first stages of system development when interaction with stakeholders is very important. In practice, the analysis often starts from interviews with the stakeholders, and this source of information is heavily based on natural language as stakeholders must be able to read and understand the results of requirements capture. Then specifications are never formal at first. A good formal approach should use both informal and formal techniques (Bjorner, 2000).

The requirements baseline (Leite, Hadad, Doorn, & Kaplan, 2000), for example, is a technique proposed to formalize requirements elicitation and modeling, which includes two natural language models, the language extended lexicon (LEL) and the scenario model, which ease and encourage stakeholders' active participation. However, specifying requirements in natural language has some drawbacks related to natural language imprecision.

Based on the previous considerations, we proposed a technique to derive an initial formal specification in the RAISE specification language (RSL) from the LEL and the scenario model (Mauco, 2004; Mauco & Riesco, 2005a; Mauco, Riesco, & George, 2004). The technique provides a set of manual heuristics to derive types and functions and structure them in modules taking into account the structured description of requirements provided by the LEL and the scenario model. But, for systems of considerable size this manual derivation is very tedious and time consuming and may be error-prone. Besides, maintenance of consistency between LEL and scenarios, and the RSL specification is a critical problem as well as tracking of traceability relationships.

In this article, we present an enhancement to this technique, which consists in the RSL-based formalization of some of the heuristics to derive RSL types from the LEL. The aim of this formalization is to serve as the basis for a semiautomatic strategy that could be implemented by a tool. More concretely, we describe a set of RSL-based derivation rules that will transform the information contained in the LEL into abstract and concrete RSL types. These derivation rules are a useful starting point to deal with the great amount of requirements information modeled in the LEL, as they provide a systematic and consistent way of defining a tentative set of RSL types. We also present some examples of the application of the rules and discuss advantages and disadvantages of the strategy proposed.

BACKGROUND

In spite of the availability of other notations such a tables, diagrams, and formal notations, natural language is still

chosen for describing the requirements of a software system (Berry, Bucchiarone, Gnesi, Lami, & Trentani, 2006; Bryant et al., 2003; van Lamsweerde, 2000).

The language extended lexicon (LEL) and the scenario model are two well known natural language requirements models used and accepted by the requirements engineering community (Leite et al., 2000). The LEL aims at registering significant terms in the Universe of Discourse (UofD). Its focus is on the application domain language, rather than the details of the problem. It unifies the language allowing the communication with stakeholders. LEL is composed by a set of symbols that represent words or phrases that stakeholders repeat or emphasize. Each entry in the LEL has a name (and possibly a set of synonyms), and two descriptions: notion, which describes what the symbol is, and behavioral response, which describes how the symbol acts upon the system. Each symbol is classified as object, subject, verbal phrase, or state. Figure 1 shows an example of an object LEL symbol taken from the LEL of the milk production system (Mauco, 2004). Underlined words or phrases correspond to other LEL symbols. The scenario model contains a set of scenarios where each scenario describes a situation in the UofD. Scenarios are naturally linked to the LEL. This link is reflected by underlying LEL symbols every time they appear in a scenario description. Figure 2 shows an example of a scenario with all its components.

In order to take profit of natural language requirements specifications, it would be necessary to look at ways for mapping the conceptually richer world of requirements engineering to more formal designs on the way to a complete implementation (Nuseibeh & Easterbrook, 2000). Many works aiming at reducing the gap between the requirements step and the next steps of software development process have been published. Some of them describe, for example, different strategies to obtain object oriented models or formal specifications from requirements specifications (Bryant et al., 2003; Díaz, Pastor, Moreno, & Matteo, 2004; Juristo, Moreno, & Lopez, 2000; Lee & Bryant, 2002).

The RAISE method includes a large number of techniques and strategies for doing formal development and proofs, as well as a formal specification language, RSL, and a set of tools to help writing, checking, printing, storing, transforming, and reasoning about specifications (George, 2001, 2002; George et al., 1995). Usually the first RSL specification is

Figure 1. Field LEL symbol

FIELD
Notion
- Land where cows eat pastures.
- It has an identification.
- It has a precise location in the dairy farm.
- It has a size.
- It has a pasture.
- It has an hectare loading.
- It is divided into a set of plots.
- It has a list of previous plots.

Behavioral Response
- A dairy farmer divides it into a set of plots, separated by electric wires.
- Many different groups of cows can be eating in it simultaneouslv.

Figure 2. Feed a group

TITLE: Feed a group
GOAL: Register the daily ration given to a group of cows.
CONTEXT: It is done once a day. Pre: Group is not empty.
RESOURCES: Group Date Quantity of corn silage Quantity of Hay Quantity of concentrated food Feeding form
ACTORS: Dairy farmer
EPISODES:
- COMPUTE RATION.
- The dairy farmer records, in the Feeding form, the date and the quantities of corn silage, hay and concentrated food given to each cow in the group.
- COMPUTE PASTURE EATEN.

an abstract, applicative, and sequential one, which is later developed into a concrete specification, initially still applicative and then, imperative and sometimes concurrent. A specification in RSL is a collection of modules. A typical applicative module specification contains type, value, and some axiom definitions. Axioms may be used to constrain the values.

When using the RAISE method, writing the initial RSL specification is the most critical task because this specification must capture the requirements in a formal, precise way. But, at the beginning of the software development process, it would be better to use some kind of informal representations to allow stakeholders' participate actively in the requirements definition process. RSL specifications of many domains have been developed by starting from natural language descriptions containing synopsis, narrative, and terminology. The gap between these kind of descriptions and the corresponding RSL formal specification is big, and thus, it is difficult and not always possible to check whether the informal specification models what the informal description does and vice versa.

The requirements definition strategy we present in this article is an attempt to integrate natural language requirements models and formal specifications, which provides a way to fruitfully use all the information available after the requirements definition step. The RSL formal specification derived is the basis to start applying the steps of the RAISE Method, encouraging separate development, and step-wise development.

THE TECHNIQUE TO DERIVE THE RSL SPECIFICATION

As an attempt to reduce the gap between stakeholders and the formal methods world, we proposed a technique to derive an initial formal specification in RSL from natural language requirements models such as LEL and scenarios, which are closer to stakeholders' language (Mauco, 2004). The derivation of the specification is structured in three steps, not strictly sequential:

- **Derivation of types:** Derives a set of abstract as well as concrete types, which model the relevant terms in the domain. We perform the derivation of types in two steps. First we identify the types, and then we decide how to model them.
- **Definition of modules:** Produces a hierarchy of modules, which organizes all the types produced by the derivation of types step in order to obtain a more legible and maintainable specification. This hierarchy of modules can be represented using a layered architecture composed of three layers (specific layer, general layer, and middleware layer), where each layer is a set of RSL modules that share the same degree of generality. These modules would be later completed with the definition of functions, and probably they will be completed with more type definitions.
- **Derivation of functions:** Defines a set of functions that model the functionality in the UofD. Scenarios are the main source of information when defining functions, as they are natural language descriptions of the functionality in the domain. Functions are usually identified at the top level as scenarios help to generate them there. Functions at one level in the hierarchy of modules frequently have counterparts at lower levels, but with different parameters. For each function in the top-level module, we model the necessary functions in lower level modules in order to simplify the legibility and maintainability of the specification. The heuristics we propose help to identify and to model the functions by showing how to derive arguments and result types, how to classify functions as partial or total, and how to define function bodies by analyzing the components of scenarios.

At first, these heuristics have been applied manually. But, for systems of considerable size, this manual derivation is very tedious and time consuming and may be error-prone. Besides, maintenance of consistency between LEL and scenarios, and the RSL specification is a critical problem as well as tracking of traceability relationships. Then, we developed a RSL-based formalization of some of the heuristics to derive RSL types from the LEL (Mauco, Leonardi, Riesco, Montejano, & Debnath, 2005b). The aim of this formalization is to serve as the basis for a strategy that could be implemented by a tool. More concretely, we propose a set of RSL-based derivation rules that will transform the information contained in the LEL into abstract and concrete RSL types.

The RSL Derivation Strategy

In this section, we present a derivation strategy to derive the types of a RSL specification from the information modeled in the LEL. The strategy consists in taking a LEL description and parsing it into RSL abstract syntax (Figure 3), and then applying a set of RSL-based derivation rules to obtain an initial set of RSL types, modeled with a RSL map type expression (Figure 4).

To follow the principles proposed in the RAISE method, we organize the strategy in two steps:

- **Identification of types:** Considering LEL symbols classification, we define five derivation rules, which may produce as result abstract types, subtypes, or collections.
- **Development of types:** In order to remove underspecification, we propose to return to the LEL to

analyze the notion of the symbols that motivated the definition of an abstract type. Concretely, the rule defines attributes for abstract types that come from LEL symbols classified as subjects or objects.

It is important to remark that this strategy must be complemented with the participation of software engineers who will adjust and enhance the results obtained after the application of the derivation rules.

The RSL-Based Derivation Rules

This section describes the derivation rules as RSL functions. Each derivation rule specification contains a name, a brief natural language description, and the corresponding RSL specification. We illustrate the application of each rule with examples taken from a milk production system (Mauco, 2004). In some rules, we also mention how the result would have been if we had used the manual heuristics proposed in Mauco (2004).

Rule Name: IT1_abstract_type

a. **Description:** Each LEL symbol classified as subject or object becomes an abstract type.
b. **RSL Formal Specification of the Rule** (shown in Box 1).

Box 1. RSL formal specification of the rule IT1_abstract_type

```
IT1_abstract_type : L.Sym_name × L.LEL × Types →~ Types
IT1_abstract_type(sym, lel, types) ≡ types † [D.get_name(sym) ↦ ""]
pre sym ∈ lel ∧ let (names, not, bresp, clas) = lel(sym)
    in clas = L.subject ∨ clas = L.obj end
```

c. **Application of the rule to the case study:** Figure 1 shows the LEL symbol field, which was classified as object. By applying IT1_abstract_type rule we obtain the abstract type field.

Rule Name: IT2_abstract_type

a. **Description:** Each LEL symbol classified as a verbal phrase describing a "registration" behavior becomes an abstract type.
b. **RSL formal specification of the rule:** (shown in Box 2)
c. **Application of the rule to the case study:** Considering LEL symbol Assigns cow to a group, classified as verbal phrase, the rule finds its notion or behavioral response contains verbs describing a registration behavior. So, it is modeled as the abstract type Assigns_cow_to_a_group. Verbal phrases, which do not represent registration behavior, are considered later, when defining RSL functions.

Rule Name: IT3_subtype

a. **Description:** Each LEL symbol that references in its name another LEL symbol, previously defined as a type T, becomes a subtype of T.
b. **RSL formal specification of the rule:** (shown in Box 3
c. **Application of the rule to the case study:** Analyzing the name of the LEL symbol Dairy cow the rule finds another LEL symbol, Cow, previously modeled as an abstract type. Then, the following subtype expression is defined:

    - type
      Cow, /* already defined*/
      Dairy_cow = {|dc: Cow :- is_dairy_cow(dc)|}

Rule Name: IT4_subtype

a. **Description:** Each LEL symbol classified as state becomes a subtype if it references another LEL symbol in its name, or an abstract type if it does not.
b. **RSL formal specification of the rule:** (shown in Box 4)
c. **Application of the rule to the case study:** Our case study contains only three LEL symbols classified as states: Lactation, Pregnant, and On Heat. As none of them mentions in its name another LEL symbol, the application of rule IT4_subtype gives as result one abstract type for each.

Rule Name: IT5_collection

a. **Description:** Each LEL symbol classified as subject or object and whose name is in plural becomes a list.
b. **RSL formal specification of the rule:** (shown in Box 5)
c. **Application of the rule to the case study:** This rule cannot be applied in our case study because the LEL does not contain symbols with plural names.

It is common practice not to include in the LEL symbols defining a collection of another LEL symbol when the actions that could be applied to the collection are the classical ones such as adding, removing, or recovering elements. When applying the manual heuristics, subjects and objects whose names were in singular were analyzed to find out if they could have more than one instance in order to model the corresponding collection. The formalization of the heuristic as a fixed rule excludes this kind of analysis and then valuable information is missing. Thus, human intervention is unavoidably in order to correct these problems and enhance the final result.

```

Rule Name: DT1_comp_type

a. **Description:** Defines a record type expression for abstract types coming from LEL symbols classified as subjects or objects. Record components are nouns or LEL symbols mentioned in an entry of the notion of these kind of LEL symbols.
b. **RSL formal specification of the rule:** (shown in Box 6)
c. **Application of the rule to the case study:** This rule is the one that deals with the development of abstract types. For example, for the abstract type Field defined by rule IT1_abstract_type, rule DT1_comp_type completes its definition by defining the following record type expression:

```
type
  Field::
     pasture
     identification
     dairy_farm
     size
     hectare_loading
     set
     plots
     list
```

One of the main problems of this rule is that it misses noun groups. As the rule defines every noun as a potential record component, it generates more and sometimes inappropriate components. However, noun groups detection may be included following linguistic approaches (Díaz et al., 2004; Juristo et al., 2000).

FUTURE TRENDS

Concerning future work, we are analyzing the formalization of a set of derivation rules to define RSL functions and modules based on the manual heuristics presented in Mauco (2004). To define these kind of rules, we would have to formalize the scenario model in RSL. Besides, it would be necessary to incorporate linguistic approaches (Díaz et al., 2004; Juristo et al., 2000) to achieve a better processing of the natural language-based requirements models.

Traceability plays a crucial role in any software development process. The derivation rules we have proposed provide a way to track "traced-to" and "traced-from" relationships, and they also help to cope with the problem of maintaining consistency between LEL and scenarios, and the RSL specification. However, a more detailed and deeper analysis should be made.

It would also be interesting to have a tool to assist in the derivation process. This tool could be later integrated with the RAISE tools in order to have assistance in the RSL specification complete development process. Tool support for formal methods will be critical in the next 10 years (Bowen et al., 2006).

Natural language-oriented models are still widely used in requirements modeling due to their well-known advantages. This kind of requirements models have to be reinterpreted by software engineers into a more formal design on the way to a complete implementation. So, bridging the gap between requirements specifications and formal specifications continues to be one of the challenges for the future. In particular, in the context of the RAISE method, our proposal of a semiautomatic transformation to map LEL and scenarios knowledge into a RSL specifications is a first step into this direction.

CONCLUSION

To contribute to bridge the gap between requirements engineering and formal methods, we have presented a technique to be used in the first stages of development using the RAISE method. We proposed and defined a three-step process that could be applied to any domain to derive an initial formal

Box 6. RSL formal specification of the rule DT1_comp_type

```

specification in RSL from LEL and scenarios, two natural language models belonging to the requirements baseline. In this way, we could take profit of informal descriptions reducing the gap between them and the final RSL specification. Moreover, by using the three-step process we proposed, the effort to define complete requirements models is worth doing because, though partially, they could be later mapped onto a RSL formal specification.

In addition, we have described a proposal to define, in a semiautomatic way, an initial set of RSL types starting from the LEL. The RSL-based derivation rules we proposed may be implemented by a tool, thus allowing one to automatically obtain a first initial RSL specification currently obtained in a manual way. Derivation rules are a concrete automation of some of the manual heuristics of our three-step process, and then they involve fix decisions about certain modeling issues. They are a useful starting point to deal with the great amount of requirements information modeled in the LEL, as they provide a systematic and consistent way of defining a tentative set of RSL types. Though a manual derivation produces a better and more accurate specification definition as it allows one to cope with the power of expression of natural language, the specification obtained by applying the derivation rules could be later refined by a human, who will correct and complete it.

The technique we have developed gives, as a result, a set of modules hierarchically structured, aiming at increasing the maintainability and legibility of the specification. The hierarchy of RSL modules obtained can be mapped onto a layered architecture, which is the basis to start applying the steps of the RAISE method and provides the specific properties all its developments should have. The use of a layered architecture is particularly useful when designing complex systems because it facilitates and encourages not only reuse but also separate and step-wise development. Thus, the RSL initial specification derived could be later developed into a concrete one according to the steps provided by the RAISE method. With a concrete specification the SML translator (George, 2001) could be used in order to have a quick prototype and get a feeling of what the specification really does.

KEY TERMS

Formal Methods: This term refers to the variety of mathematical modeling techniques that are applicable to computer system (software and hardware) design. Formal methods may be used to specify and model the behavior of a system and to mathematically verify that the system design and implementation satisfy system functional and safety properties. These specifications, models, and verifications may be done using a variety of techniques and with various degrees of rigor.

Formal Specification: It is the expression, in some formal language and at a some level of abstraction, of a collection of properties some system should satisfy. A specification is formal if it is expressed in a language made of three components: the syntax (rules for determining the grammatical well-formedness of sentences), the semantics (rules for interpreting sentences in a precise, meaningful way in the domain considered), and the proof theory (rules for inferring useful information from the specification.

RAISE Method: The RAISE method encompasses formulating abstract specifications, developing them to successively more concrete specifications, justifying the correctness of the development, and translating the final specification into a programming language, and it is based on a number of principles such as separate development, step-wise development, invent and verify, and rigor. RAISE is an acronym for "rigorous approach to industrial software engineering," and it gives its name to a formal specification language, the RAISE specification language, the associated method, and a set of tools.

RAISE Specification Language (RSL): It is a formal specification language intended to support the precise definition of software requirements and reliable development from such definitions to executable implementations. It supports specification and design of large systems in a modular way, and thus it permits separate subsystems to be separately developed. It also provides a range of specification styles (axiomatic and model-based; applicative and imperative; sequential and concurrent) as well as it supports specifications ranging from abstract (close to requirements) to concrete (close to implementations).

Requirements Baseline: It is a mechanism proposed to formalize requirements elicitation and modeling. It is a structure which incorporates descriptions about a desired system in a given application domain. Although it is developed during the requirements engineering process, it continues to evolve during the software development process. It is composed of five complementary views: the lexicon model view, the scenario view, the basic model view, the hypertext view, and the configuration view.

Requirements Engineering: It comprehends all the activities involved in eliciting, modeling, documenting, and maintaining a set of requirements for a computer-based system. The term "engineering" implies that systematic and repeatable techniques should be used to ensure that system requirements are consistent, complete, relevant, etc.

Requirements: They are descriptions of how the system should behave, or of a system property or attribute. They are defined during the early stages of a system development as a specification of what should be implemented. They should be statements of what a system should do rather than a statement of how it should do it.

Universe of Discourse (UofD): It is the overall context in which the software will be developed and operated.

Design and Applications of Digital Filters

Gordana Jovanovic Dolecek
INSTITUTE INAOE, Puebla, Mexico

INTRODUCTION

Digital signal processing (DSP) is an area of engineering that "has seen explosive growth during the past three decades" (Mitra, 2005). Its rapid development is a result of significant advances in digital computer technology and integrated circuit fabrication (Jovanovic Dolecek, 2002; Smith, 2002). Diniz, da Silva, and Netto (2002) state that "the main advantages of digital systems relative to analog systems are high reliability, suitability for modifying the system's characteristics, and low cost".

The main DSP operation is digital signal filtering, that is, the change of the characteristics of an input digital signal into an output digital signal with more desirable properties. The systems that perform this task are called digital filters. The applications of digital filters include the removal of the noise or interference, passing of certain frequency components and rejection of others, shaping of the signal spectrum, and so forth (Ifeachor & Jervis, 2001; Lyons, 2004; White, 2000).

Digital filters are divided into finite impulse response (FIR) and infinite impulse response (IIR) filters. FIR digital filters are often preferred over IIR filters because of their attractive properties, such as linear phase, stability, and the absence of the limit cycle (Diniz, da Silva & Netto, 2002; Mitra, 2005). The main disadvantage of FIR filters is that they involve a higher degree of computational complexity compared to IIR filters with equivalent magnitude response (Mitra, 2005; Stein, 2000).

For example let us consider an FIR filter of length N = 11 with impulse response

$$h(n) = \begin{cases} 0.8^n & for \quad 0 \le n \le 10 \\ 0 & otherwise \end{cases}, \tag{1}$$

as shown in Figure 1a.

In Figure 1b the initial 20 samples of the impulse response of an IIR filter

$$h(n) = \begin{cases} 0.8^n & for \quad 0 \le n \\ 0 & for \quad n < 0 \end{cases}. \tag{2}$$

are plotted.

Figure 1. Impulse responses of FIR and IIR filters

b. IIR filter

Equation 3.

$$y(n) = x(n) * h(n) = h(n) * x(n) = \sum_k h(k)x(n-k) = \sum_k x(k)h(n-k)$$

BACKGROUND

Digital Filters in Time and Transform Domain

The operation in time domain which relates the input signal $x(n)$, impulse response $h(n)$ and the output signal $y(n)$, is called the *convolution*, and is defined in Equation 3.

The output $y(n)$ can also be computed recursively using the following *difference equation* (Mitra 2005; Proakis & Ingle, 2003),

$$y(n) = \sum_{k=0}^{M} b_k x(n-k) + \sum_{k=1}^{N} a_k y(n-k), \quad (4)$$

where $x(n\text{-}k)$ and $y(n\text{-}k)$ are input and output sequences $x(n)$ and $y(n)$ delayed by k samples, and b_k and a_k, are constants. The order of the filter is given by the maximum value of N and M. The first sum is a *nonrecursive*, while the second sum is a *recursive* part. Typically, FIR filters have only nonrecursive part, while IIR filters always have the recursive part. As a consequence, FIR and IIR filters are also known as nonrecursive and recursive filters, respectively.

From (3) we see that the principal operations in a digital filter are multiplications, delays and additions. Using equation (3) we can draw the structure of the digital filter which is also known as a *Direct form* and is shown in Figure 2. More details about filter structures can be found for example in Mitra (2005).

The representation of digital filters in the transform domain is obtained using the *Fourier transform* and *z-transform*.

The Fourier transform of the signal $x(n)$ is defined as

$$X(e^{j\omega}) = \sum_{n=-\infty}^{\infty} x(n)e^{j\omega n}, \quad (5)$$

where ω is digital frequency in radians and $e^{j\omega n}$ is an exponential sequence. In general case, the Fourier transform is a complex quantity.

The convolution operation becomes multiplication in the frequency domain,

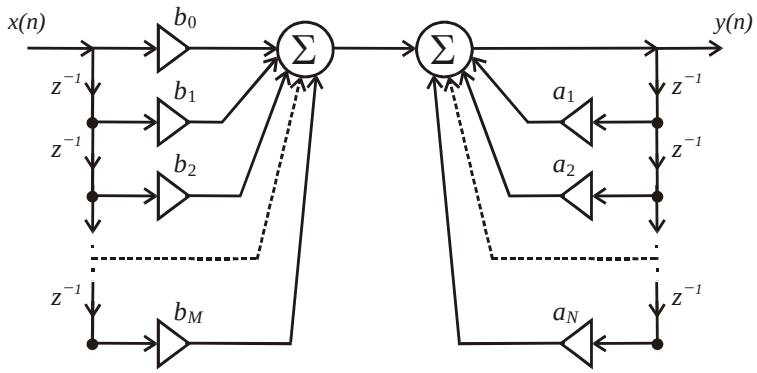
$$Y(e^{j\omega}) = X(e^{j\omega})H(e^{j\omega}), \quad (6)$$

where $Y(e^{j\omega})$, $X(e^{j\omega})$, and $H(e^{j\omega})$, are Fourier transforms of $y(n)$, $x(n)$ and $h(n)$, respectively. The quantity $H(e^{j\omega})$ is called the *frequency response* of the digital filter, and it is a complex function of the frequency ω with a period 2π. It can be expressed in terms of its real and imaginary parts, $H_R(e^{j\omega})$ and $H_I(e^{j\omega})$ or in terms of its magnitude $|H(e^{j\omega})|$ and phase $\varphi(\omega)$,

$$H(e^{j\omega}) = H_R(e^{j\omega}) + jH_I(e^{j\omega}) = |H(e^{j\omega})|e^{j\phi(\omega)}. \quad (7)$$

The amplitude $|H(e^{j\omega})|$ is called the *magnitude response* and the phase $\varphi(\omega)$ is called the *phase response* of the digital filter. For a real impulse response digital filter, the magnitude response is an even function of ω, while the phase

Figure 2. Direct form structure



response is a real odd function of ω. In some applications, the magnitude response is expressed in the logarithmic form in decibels as

$$G(\omega) = 20\log_{10}\left|H(e^{j\omega})\right| \quad \text{dB} \quad , \tag{8}$$

where $G(\omega)$ is called the *Gain function*.

For the sequence $x(n)$, z-transform is defined as

$$X(z) = \sum_{n=\infty}^{\infty} x(n)z^{-n} \, , \tag{9}$$

where z is a complex variable. All values of z for which (9) converges are called the *region of convergence* (ROC).

Z-transform of the unit sample response $h(n)$, denoted as $H(z)$, is called *system function*. Using z-transform of the Equation (4) we arrive at

$$H(z) = \frac{Y(z)}{X(z)} = \frac{\sum_{k=0}^{M} b_k z^{-k}}{1 - \sum_{k=1}^{N} a_k z^{-k}}. \tag{10}$$

The roots of the numerator, or the values of z for which $H(z)=0$, define the locations of the *zeros* in the complex z plane. Similarly, the roots of the denominator, or the values of z for which $H(z)$ become infinite, define the locations of the *poles*. Both poles and zeros are called *singularities*. The plot of the singularities in z-plane is called the *pole-zero pattern*. The zero is usually denoted by a circle (o) and the pole by a cross (x). An FIR filter has only zeros (poles are in the origin), whereas an IIR filter can have either both zeros and poles, or only poles, (zeros are in the origin). All poles of the linear-phase filter are in the origin and zeros are in ether in symmetrical positions in respect of the unit circle or on the unit circle. Its unit sample response has symmetry (Mitra, 2005; Proakis & Ingle, 2006). If the FIR filter does not have the linear phase (the unit sample response does not have symmetry) its zeros are not in symmetrical positions around the unit circle. This filter has all zeros inside the unit circle and is called a minimum-phase filter (Mitra, 2005). IIR filter which passes all frequencies without attenuation is called allpass filter. The zeros and poles of this filter are in a symmetrical positions relating to the unit circle. The filter is stable if all poles are inside the *unit circle* in z-plane. (FIR filters with the poles in origin, and IIR filters with the poles inside the unit circle.) More details about characteristics and applications of different FIR and IIR filters can be found in (Kuo, 2006; Lyons, 2004; Mitra 2005; Proakis & Ingle, 2003; Stearns, 2002; Smith, 2002, Weeks, 2006)

Transform of LP into HP Filter

Instead of designing a high-pass filter by brute force, we can transform it into a low-pass filter. We replace the desired cutoff frequencies of the high-pass filter ω_p and ω_s, by the corresponding low-pass specifications as follows:

$$\omega'_p = \pi - \omega_p$$
$$\omega'_s = \pi - \omega_s \, . \tag{11}$$

Given these specifications, a low-pass FIR filter can be designed. From this auxiliary low-pass filter, the desired high-pass filter can be computed by simply changing the sign of every other impulse response coefficient. This is compactly described as,

$$h_{HP}(n) = (-1)^n h_{LP}(n), \tag{12}$$

where $h_{HP}(n)$ and $h_{LP}(n)$ are the impulse responses of the high-pass and the low-pass filters, respectively.

Examples of Filtering

Example 1

In this example we consider a signal composed of two cosine signals $x_1(n)$ and $x_2(n)$, shown in Figures 3a, and 3b.

$$x_1(n) = \cos(0.2\pi n), x_2(n) = \cos(0.6\pi n).$$

$x(n)=x_1(n)+x_2(n)$

Two peaks at 0.2π and $0.6\,\pi$ in the spectral characteristic correspond to the cosine components x_1 and x_2, respectively.

Suppose we now apply low-pass (LP) filtering to the sum of these two cosine signals. The result of filtering is shown in Figures 3c and d. Notice that the second high pass cosine signal has been eliminated. To eliminate the low-pass cosine signal, we design the high-pass (HP) filter. The filtered signal is shown in Figures 3e and f.

Example 2

The following figure presents an example of a speech signal (McClellan, Schafer & Yoder, 1998). We consider one part of the signal (the samples from 1,300 to 1,500), which is shown in Figures 4b and c. The low-pass filter which passes all spectral components below $0.25\,\pi$ and eliminates all spectral components higher than 0.3π (Figure 4c). The speech signal filtered by the filter is shown in Figure 4d. Notice that the resulting signal becomes smoother when higher frequencies

are eliminated. Therefore, low-pass filtering can be used to remove large fluctuations in the signal.

More details for digital filters for audio signal processing can be found in Meana (2007); Huang and Benesty (2004); Spanias, Painter, and Atti (2007).

Example 3

In this example we illustrate the effect of filtering of an image, generated in MATLAB, shown in Figure 5a. The noise is added to the image and the result is shown in Figure 5b. Two filters are applied to eliminate the noise. Figure 5c shows the result of applying a simple averaging filter, while Figure 5d shows the effect of applying a special filter called the median filter. Notice that the median filter is much better in removing noise.

More details about image signal processing can be found in Bose and Meyer (2006); Barnet (2007); Woods (2006); Bovik (2000).

FUTURE TRENDS

For years much effort has been made to reduce the complexities of the FIR filters (Chan, Tsui & Zhao, 2006; Izydorczyk, 2006; Lin, Chen & Jou, 2006; Macleod & Dempster, 2005; Maskell, Jussipekka & Patra, 2006; Xu, Chang & Jong, 2006). This field of research "continues to be in full of vigor as new design problems arise and innovative design techniques emerge" (Lu, 2006).

Another two direction of the research include IIR designs that are nonlinear and nonconvex and FIR filter design with certain structures that lead to nonconvex second-order or higher order design (Lu, 2006).

Another important trend is in design of variable digital filters which can be designed using either FIR or IIR filters (Yli-Kaakinen & Saramaki, 2006).

Figure 5. Removing the noise from the image

a. Image signal

b. The image with added noise

d. Filtering with median filter

CONCLUSION

The digital filter changes the characteristics of the input digital signal in order to obtain the desired output signal. Digital filters either have a finite impulse response, (FIR), or an infinite impulse response, (IIR). FIR filters are often preferred because of desired characteristics, such as linear phase and no stability problems. The main disadvantage of FIR filters is that they involve a higher degree of computational complexity compared to IIR filters with equivalent magnitude response. In many applications where the linearity of the phase is not required, the IIR filters are preferable because of the lower computational requirements.

KEY TERMS

Convolution y(n)=x(n)*h(n): Time domain operation which relate the output of the digital filter y(n) with the input signal x(n) and the impulse response of the filter h(n).

Cutoff Frequencies: The frequencies which determine the passband (the frequencies which are passed without attenuation), and the stop-band (the frequencies which are highly attenuated).

Difference Equation: Time domain relation between the output and the input of digital filter in terms of coefficients which are characteristics of the filter. Generally contains recursive and nonrecursive parts.

Frequency Response $H(e^{j\omega})$**:** The discrete-time Fourier transform of the impulse response of the system is called the Frequency response. It provides a frequency-domain description of the system. In general, it has a complex value.

High-Pass Digital Filter: Digital filter which passes only high frequencies defined by the passband cutoff frequency and attenuates all frequencies from 0 to cutoff stopband frequency.

Impulse Response $h(n)$: The response of a digital filter to a unit sample sequence, which consists of a single sample at index $n = 0$ with unit amplitude.

Low-Pass Digital Filter: Digital filter which passes only low frequencies defined by the passband cutoff frequency and attenuates all high frequencies from the cutoff stopband frequency to π.

Magnitude Response $\left|H(e^{j\omega})\right|$: Absolute value of the complex frequency response.

Phase Response: Phase of the complex frequency response.

Singularities: Poles and zeros of system function. Poles of system function are zeros of its denominator while zeros are zeros of its nominator.

System Function: Z-transform of the impulse response of the filter. FIR filters has only the nominator, while an IIR filter has denominator or both nominator and denominator.

Design and Development of Communities of Web Services

Zakaria Maamar
Zayed University, UAE

INTRODUCTION

In the field of Web services (Benatallah, Sheng, & Dumas, 2003; Bentahar, Maamar, Benslimane, & Thiran, 2007; Medjahed & Bouguettaya, 2005), a community gathers Web services that offer similar functionalities. Hotel booking and car rental are samples of functionalities. This gathering takes place regardless of who developed the Web services, where the Web services are located, and how the Web services function to satisfy their functionalities. A Web service is an accessible application that can be discovered according to its functionality and then invoked in order to satisfy users' needs. In addition, Web services can be composed in a way that permits modeling and executing complex business processes. Composition is one of Web services' strengths as it targets user needs that cannot be satisfied by any single available Web service. A composite Web service obtained by combining available Web services may be used (Figure 1). The use of communities in composition scenarios offers two immediate benefits. The first benefit is the possibility of accelerating the search of Web services required to satisfy user needs by looking for communities rather than screening UDDI (universal description, discovery, and integration) and ebXML registries. The second benefit is the late execution binding of the required Web services once the appropriate communities are identified. Both benefits stress the need of examining Web services in a different way.

Current practices in the field of Web services assume that a community is static and Web services in a community always exhibit a cooperative attitude. These practices need to be revisited as per the following arguments. A community is dynamic: New Web services enter, other Web services leave, some Web services become temporarily unavailable, and some Web services resume operation after suspension. All these events need to be closely monitored so that inconsistent situations are avoided. Moreover, Web services in a community can compete on nonshareable computing resources, which may delay their performance scheduling. Web services can also announce misleading information (e.g., nonfunctional details) in order to boost their participation opportunities in composition scenarios. Finally, Web services can be malicious in that they can try to alter other Web services' data or operations.

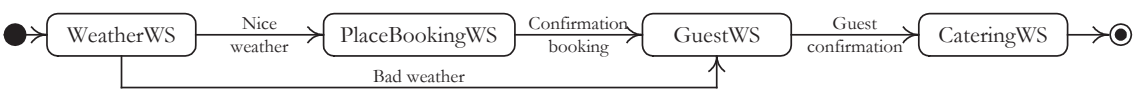
To look into ways of making Web services communities active, we describe in this article some mechanisms that would enable Web services among other things to enter a community, to leave a community after awhile, to reenter the same community if some opportunities loom, and to be rewarded for being part of a community. These mechanisms would be developed along three perspectives, which we refer to as the following.

- Community management: How do we establish or dismantle a new or existing community of Web services?
- Web services attraction and retention: How do we invite and convince new Web services to join a community? How do we retain existing Web services in a community?
- Interaction management: How are interactions between Web services regulated in a community? How do we deal with conflicts in a community?

BACKGROUND

The term *community* means different things to different people. In *Longman Dictionary*, community is "a group

Figure 1. Example of composition scenario



of people living together and/or united by shared interests, religion, nationality, etc." In the field of knowledge management, communities of practice constitute groups within (or sometimes across) organizations who share a common set of information needs or problems (Davies, Duke, & Sure, 2003). A community is not a formal organizational unit but an informal network of entities with common interests and concerns.

When it comes to Web services, Benatallah et al. (2003) define community as a collection of Web services with a common functionality, although these Web services have distinct nonfunctional properties. Medjahed and Bouguettaya (2005) consider community as a means to provide an ontological organization of Web services sharing the same domain of interest (Budak Arpinar, Aleman-Meza, Zhang, & Maduko, 2004). Finally, Maamar, Lahkim, Benslimane, Thiran, and Sattanathan (2007) define community as a means to provide a description of a desired functionality without explicitly referring to any concrete Web service (already known) that will implement this functionality at run time.

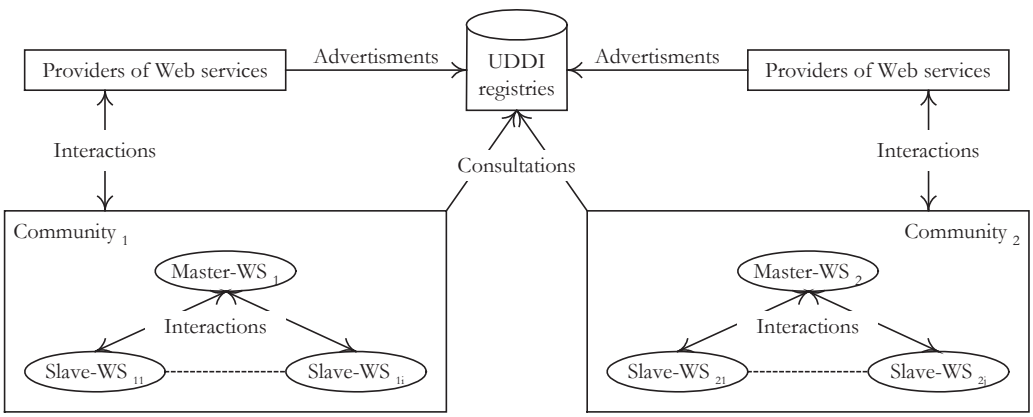
It is worth examining the similarity between a society of software agents and a community of Web services. A society is a group of agents of different types and capabilities that come together in order to collaborate and meet some common goals (Narendra, 2001). This does not apply in communities. Web services in a community do not collaborate. They rather compete to participate in composite Web services since they all offer the same functionality but in a different configuration. The collaboration for the sake of developing a composite Web service takes place at the community level where component Web services from independent communities work together. Each community contributes one Web service to the composite Web service.

CONCEPTS AND OPERATIONS IN COMMUNITIES

Figure 2 represents an environment of communities of Web services, providers of Web services, and UDDI (or ebXML) registries. Communities are dynamically established and dismantled according to protocols defined in the community management perspective. UDDI registries receive advertisements of Web services from providers. Several UDDI registries can be made available to providers for advertisement needs. In this context, competitor providers do not want to have their Web services posted on the same UDDI registries (Budak Arpinar et al., 2004).

The environment in Figure 2 offers some characteristics that need to be stressed. First, the regular way of describing, announcing, and invoking Web services is still the same, although Web services are now elements of communities. Second, the mechanisms that UDDI registries regularly offer in terms of announcing and discovering Web services are still the same. Finally, the selection of Web services out of communities is transparent to users and independent of the way these Web services are gathered into communities. A master component always leads a community. This component is itself implemented as a Web service in compliance with the rest of the Web services in a community, which are now denoted as slaves. A master-slave Web services relationship is framed in the interaction management perspective. One of the responsibilities of the master Web service is to attract Web services to join its community using rewards (Bentahar et al., 2007). This happens as part of the Web services attraction and retention perspective. As a result, the master Web service regularly screens UDDI registries so that it knows the latest advertisements of Web services.

Figure 2. Representation of communities of Web services



In a community, the master Web service is designated in two different ways. The first way is to have a dedicated Web service play the role of master for the time being in a community. This Web service is independently developed from other Web services that are advertised in UDDI registries. It is noted that the leader Web service in a community does not participate in any composition. As a result, this Web service is only loaded with mechanisms related to community management. The second way of designating a master Web service is to identify a Web service out of the Web services that reside in a community. This identification happens either on a voluntary basis or by election. Because of the temporary no-participation restriction of a master Web service in compositions, the nominated Web service is compensated by its peers. The call for elections in a community happens frequently so that the burden on the same Web services leading a community is minimized and hopefully avoided.

Community Management Perspective

A community gathers Web services with similar functionalities. This gathering is a designer-driven activity that includes two steps. The first step is to define the functionality (e.g., flight booking) of the community by binding to a specific ontology (Medjahed & Bouguettaya, 2005). This binding is crucial since providers use different terminologies to describe the functionality of their respective Web services. For example, flight booking, flight reservation, and air-ticket booking are all about the same functionality. The second step is to deploy the master Web service that will lead the community and take over multiple responsibilities. One of them is to invite and convince Web services to sign up for its community. The survivability of a community, that is, to avoiding dismantlement, depends to a certain extent on the status of the existing Web services in this community. Another responsibility is to check the credentials of Web services before they get admitted into a community. The credentials could be related to quality of service (QoS), protection mechanisms, interaction protocols, and so forth. Credential checking boosts the security level within a community and enhances the trustworthiness level of a master Web service toward the slave Web services.

Dismantling a community is another designer-driven activity, which happens upon request from the master Web service. This one oversees the events in a community such as the arrival of new Web services, the departure of some Web services, the identification of Web services to take part in composite Web services, sanctions on Web services because of misbehavior, and so on. When a master Web service observes first that the number of Web services in a community is less than a certain threshold and second that the number of participation requests in composite Web services that arrive from users over a certain period of time is also less than another threshold, then the community will be dismantled. Both thresholds are set by the designer. Web services to withdraw out of a community are invited to join other communities subject to assessing the functionality similarity with other existing communities' functionalities.

Web Services Attraction and Retention Perspective

Attracting new Web services and retaining existing Web services in a community fall into the responsibilities of the master Web service. A community could vanish if the number of Web services running in it drops below a certain threshold.

Attracting Web services requires the master Web service to consistently consult the different UDDI registries in looking for new Web services. These latter services could have recently been posted on UDDI registries or have had the description of their functionality changed. Changes in the functionality of a Web service raise challenges as this Web service may no longer be appropriate for a community. As a result, this Web service is invited to leave the community. When a candidate Web service is identified based on the functionality it offers, the master Web service interacts with its provider (Figure 2). The purpose is to ask the provider to register its Web service with the community of this master Web service. Some arguments to convince the provider include a high rate of participation of the existing Web services in composite Web services (a good indicator of the visibility of a community of Web services to the external environment and the reputation of Web services)(Maximilien & Singh, 2002), short response time when handling users' requests, and efficiency of the security mechanisms against malicious Web services.

Retaining Web services in a community for a long period of time is a good indicator of the following elements.

- Although Web services in a community are in competition, they expose a cooperative attitude. For instance, Web services have not been subject to attacks from peers in the community. This backs the security argument that the master Web service uses to attract Web services.
- A Web service is satisfied with its participation rate in composite Web services. This satisfaction rate is set by its provider. Plus, this is in line with the participation-rate argument that the master Web service uses to attract Web services.
- Web services know peers in the community that could replace them in the case of failure, with less impact on the composite Web services in which they are involved.

Web services attraction and retention shed light on a third scenario, which is when Web services are invited to leave a community. A master Web service could issue such a request upon assessment of the following criteria.

- The Web service has a new description of the functionality it provides. The description does not match the functionality of the community.
- The Web service is unreliable. On different occasions, the Web service failed to participate in composite Web services due to recurrent operation problems.
- The credentials of the Web service were "beefed up" to enhance its participation opportunities in composite Web services. Large differences between a Web services' advertised QoS and delivered QoS indicate performance degradation (Ouzzani & Bouguettaya, 2004).

Interaction Management Perspective

In a community, participation-related interactions in compositions between the master Web service and the slave Web services are framed using the contract-net protocol (CN; Smith, 1980). This protocol is built upon the idea of contracting and subcontracting jobs between two types of agents known as the initiator and the participant. At any time, an agent can be an initiator, a participant, or both. The sequence of steps in the contract-net protocol is as follows: (a) The initiator sends to participants a call for proposals in relation to a certain job to carry out, (b) each participant reviews the call for proposals and bids if interested (i.e., it is a feasible job), (c) the initiator chooses the best bid and awards a contract to that participant, and (d) the initiator rejects other bids.

Mapping the contract-net protocol onto the operation of a community occurs as follows. When a user (through some assistance; Schiaffino & Amandi, 2004) selects a community based on its functionality, the master Web service of this community is contacted in order to identify a specific slave Web service that will implement this functionality at run time. The master Web service sends all slave Web services a call for bids (CN_{step1}). Before contacting the master Web service, the slave Web services assess their status by checking their ongoing commitments in other compositions (CN_{step2}; Maamar, Benslimane, & Narendra, 2006). Only the slave Web services that are interested in bidding inform the master Web service. The latter screens all the bids before it chooses the best one (CN_{step3}). Afterward, the winning slave Web service is notified so it can get itself ready for execution when requested (CN_{step3}). The rest of the slave Web services that expressed interest but were not selected are notified as well (CN_{step4}).

FUTURE TRENDS

The design, management, and development of communities of Web services open up additional research venues that need to be looked into. Two are identified here, namely alliance development and OWL-S (ontology Web language for Web services) for community management.

Alliance Development

In *Longman Dictionary*, alliance is "an arrangement in which two or more countries, groups, etc. agree to work together to try to change or achieve something." One of the scenarios affecting the internal organization of a community is the setting up of alliances among Web services. An alliance is like a microcommunity whose development is triggered because of some mutual agreements between providers of Web services as part of their partnership strategy. Providers can join forces by referring to or recommending other peers' Web services and vice versa. Alliances constitute an attractive solution for exception handling. A Web service could be to a certain extent easily substituted with a peer in the same alliance before looking for another peer in other alliances in the same community. Similar to the dynamic nature of a community, an alliance has a dynamic nature as well: New alliances could be formed, new members could be admitted to as well as excluded from alliances, and some alliances could be either discarded or merged.

OWL-S for Community Specification

The specification of a community could happen using OWL-S. OWL-S organizes the description of a Web service along three categories: profile, process model, and grounding. The application of these categories in a community should happen as follows: what the community does (profile), how the community operates internally (model), and how the community accepts requests (grounding). In line with the profile, model, and grounding categories, a community could also be defined along the following three dimensions.

- Functional dimension: This describes the functionality associated with the community in terms of purpose, description ontology, and constraints. This dimension supports what needs to be done to advertise a community's functionality.
- Behavioral dimension: It describes the control flow of the functionality as depicted by the functional dimension. The control flow concerns task decomposition, chronology, and dependency. This dimension supports what needs to be done to achieve the functionality.
- Information dimension: It describes the data that are used throughout the performance of the functionality as

depicted by the behavioral dimension. This description includes the source of data, the semantic exchange of data, and the security of data. This dimension supports what needs to be provided to the functionality.

CONCLUSION

In this article, we discussed the mechanisms that should make communities of Web services active. Web services offering the same functionality are gathered into a single community in which a master Web service leads. This master is responsible for attracting new Web services to the community, retaining existing Web services in the community, and identifying the Web services in the community that will participate in composite Web services, among other things. The identification of these Web services happens in accordance with the contract-net protocol, which frames the interactions between the initiator and participant Web services. Dismantling a community could happen as well for various reasons, such as too small of a number of Web services residing in this community.

KEY TERMS

Alliance: An alliance is an arrangement in which two or more countries, groups, and so forth agree to work together to try to change or achieve something.

Community: It is a group of people living together and/or united by shared interests, religion, nationality, and so on.

Composition: It targets users' needs that cannot be satisfied by any single available Web service: A composite Web service obtained by combining available Web services may be used instead.

Contract-Net Protocol: It contracts and subcontracts jobs between two types of agents known as the initiator and the participant.

Ontology Web Language for Web Services (OWL-S): OWL-S supplies Web service providers with a core set of markup-language constructs for describing the properties and capabilities of their Web services in unambiguous, computer-interpretable form.

Universal Description, Discovery, and Integration (UDDI): It is a specification that provides a platform-independent way of describing services, discovering businesses, and integrating business services using the Internet.

Web Service: It is a software application identified by a URI whose interfaces and binding are capable of being defined, described, and discovered by XML (extensible markup language) artifacts, and that supports direct interactions with other software applications using XML-based messages via Internet-based applications.

Design and Implementation of Scenario Management Systems

M. Daud Ahmed
Manukau Institute of Technology, New Zealand

David Sundaram
University of Auckland, New Zealand

INTRODUCTION

Scenarios have been defined in many ways, for example, a management tool for identifying a plausible future (Porter, 1985; Schwartz, 1991; Ringland, 1998; Tucker, 1999; Alter, 1983) and a process for forward-looking analysis. A scenario is a kind of story that is a focused description of a fundamentally different future (Schoemaker, 1993), that is plausibly based on analysis of the interaction of a number of environmental variables (Kloss, 1999), that improves cognition by organizing many different bits of information (De Geus, 1997; Wack, 1985; van der Heijden, 1996), and that is analogous to a "what if" story (Tucker, 1999). It can be a series of events that could lead the current situation to a possible or desirable future state. Scenarios are not forecasts (Schwartz, 1991), future plans (Epstein, 1998), trend analyses, or analyses of the past. Schoemaker (1993) also explains that scenarios are for strategy identification rather than strategy development. Fordham and Malafant (1997) observe that decision scenarios allow the policymaker to anticipate and understand risk, and to discover new options for action. Ritson (1997) agrees with Schoemaker (1995) and explains that scenario planning scenarios are situations planned against known facts and trends, but deliberately structured to enable a wide range of options and to track the key triggers that would precede a given situation or event within the scenario.

In this article we propose an operational definition of scenarios that enables us to manage and support scenarios in a coherent fashion. This is then followed by an in-depth analysis of the management of scenarios at the conceptual level as well as at the framework level. The article goes on to discuss the realization of such a framework through a component-based layered architecture that is suitable for implementation as an n-tiered system. We end with a discussion on current and future trends.

BACKGROUND

The basic structure and behavior of the scenario is similar to the decision support system (DSS) components *model* and *solver* respectively. In information systems literature, a use case instance irrespective of transaction or decision context is considered as a scenario. But scenarios are primarily related to complex business change management processes; they might address semi-structured and unstructured decision problems. Hence we define scenario as a complex decision situation analogous to a model that is instantiated by data and tied to solver(s). In its simplest form, scenario is a complex combination of data, model, and solver.

Decision makers have been using the concepts of scenarios for a long time, but due to their complexity, their use is still limited to strategic decision-making tasks. Scenario planning varies widely from decision maker to decision maker, mainly because of lack of a generally accepted principle for scenario management. Albert (1983) proposes three approaches for scenario planning: expert scenario approach, morphological approach, and cross-impact approach. Ringland (1998) describes three-step scenario planning: brainstorming, building scenarios, and decisions and action planning. Schoemaker (1995) outlines a 10-step scenario analysis process. Huss and Honton (1987) identify three categories of scenario planning: intuitive logics, trend-impact analysis, and cross-impact analysis. These planning processes are useful but they are not entirely supported by the available decision support systems frameworks. Either or both of the existing scenario planning processes and the DSS frameworks needs to be modified for planning scenarios within DSS.

SCENARIO MANAGEMENT SYSTEMS

Few of the decision support system frameworks emphasize a lifecycle approach based fully featured scenario planning, development, analysis, execution, and evaluation environment. DSS components such as data, model, solver, and visualization have been extensively used in many DSS framework designs, but they did not consider scenario as a component of DSS. Scenario plays such an important role in the decision-making process that it is almost impractical to develop a good decision modeling environment while leaving out this component.

Figure 1. Scenario-driven decision system framework

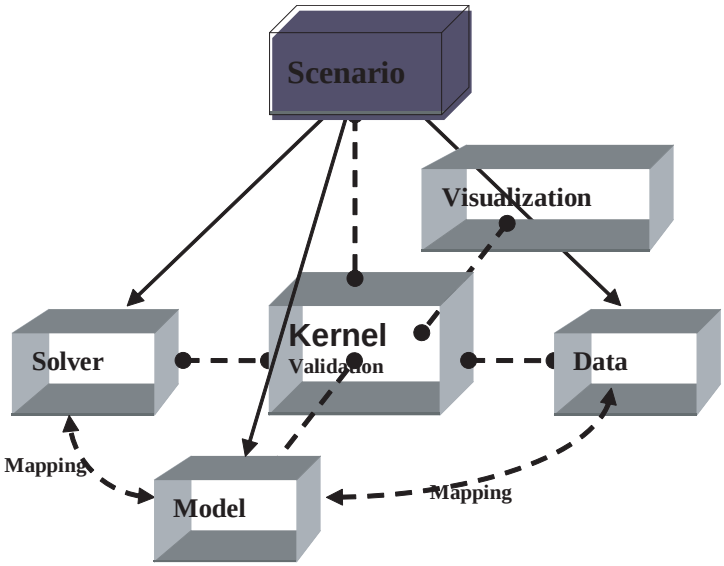

Figure 2. SDSSG system architecture

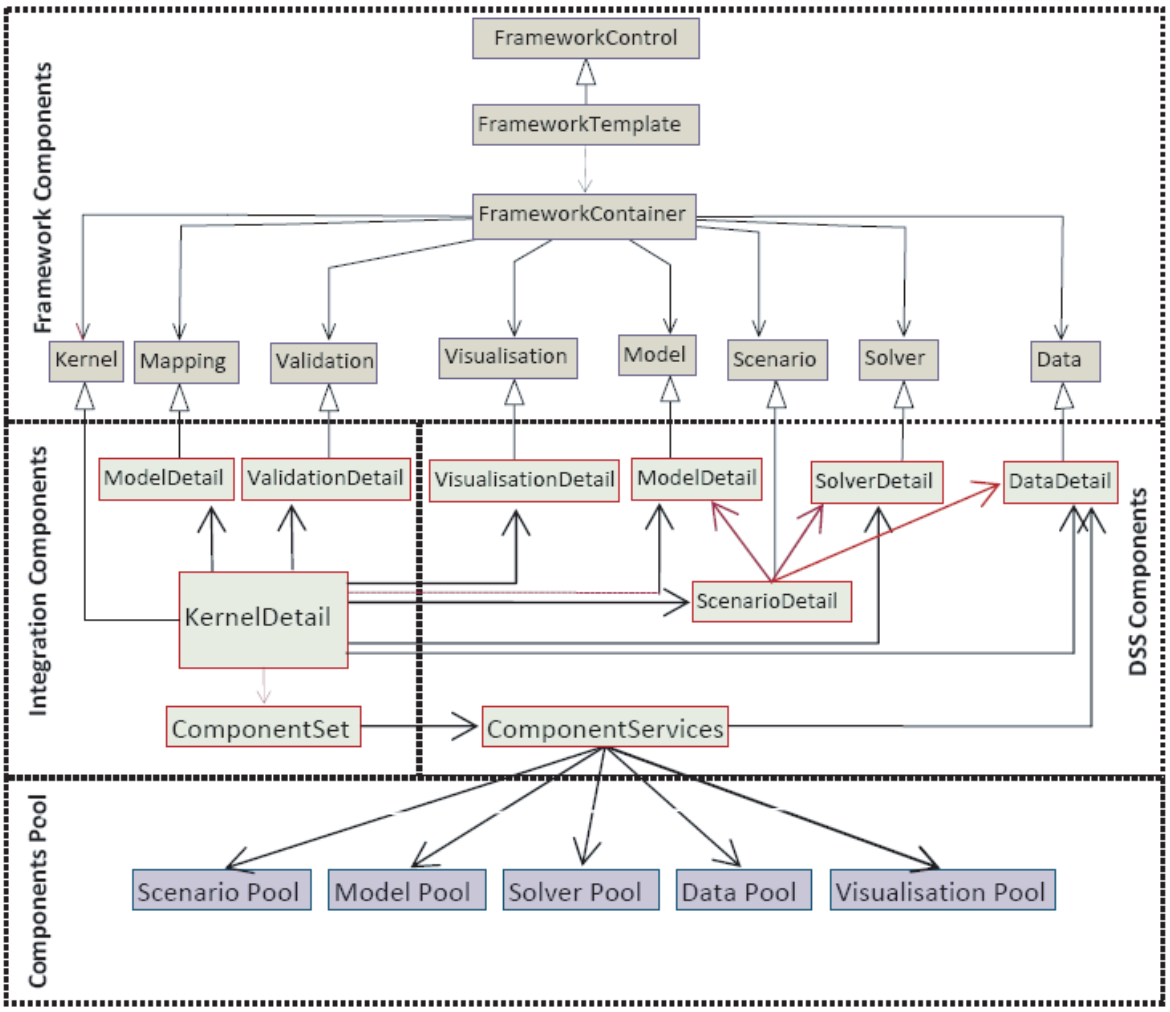


To overcome these shortcomings we propose a scenario-driven decision support systems generator (SDSSG) framework, as illustrated in Figure 1, to effectively manage scenarios and their lifecycle. The SDSSG components are categorized into decision support components (DSC) and integration components (IC). DSC includes the data, model, solver, scenario, and visualization components, and IC includes kernel, mapping, and validation components. The kernel is supported by a component set that interacts with a components pool that includes the data pool, model pool, solver pool, scenario pool, and visualization pool as outlined in SDSSG system architecture.

The system architecture showing the component is presented in Figure 2. While the architecture is generic enough that it can be used to support DSS, it has been extended keeping in mind the requirements of scenario management. The architecture supports scenario planning, development, analysis, execution, and evaluation. Figure 2 illustrates the inheritance, aggregation, and dependency relationship among the architectural components. However their attributes and behaviors are omitted for the sake of simplicity.

Components of the SDSSG Architecture

The design of the architecture roughly follows the framework described above and is broken up into four parts: framework components, integration components, DSS components, and components pools. The framework components are the highly abstract-level components, and integration and DSS components are concrete-level components. The components pool is independent from the SDSSG system components. The components pool contains five different types of components that are used for component state management.

We use object-oriented concepts for designing the decision support and integration components. The concepts of abstraction, encapsulation, inheritance, and polymorphism are basic concepts for component development. Modularity, sub-system, and packaging concepts have been used for managing the components. The fields, properties, methods, and events are used to develop the structure, behavior, and message services of the components while the class is used to develop the object, and the reuse of the object is ensured by designing proper component interfaces.

Framework Components

The framework components of the SDSSG architecture are composed of abstract-level model, solver, data, scenario, kernel, validation, and mapping components. These components are described under decision support components and integration components. In addition a FrameworkControl, a FrameworkTemplate, and a FrameworkContainer are also included to support the flexible replacement of decision support components at runtime.

Decision Support Components

The decision support components of the SDSSG architecture are DataDetail, ModelDetail, SolverDetail, VisualisationDetail, and ScenarioDetail. These components are created by inheriting the abstract-level framework components of the same type. ModelDetail refers to the real-life problems, DataDetail represents parameter instance of the model, and SolverDetail is the operation that can be executed on the model. The solver is the separated behavior(s) of the model from its structure. The scenario is the complex combination of the data, model, and solver. Visualization facilitates flexible presentation of data, executed model, or scenario. In addition we have used a ComponentServices component that is responsible for interaction with component pools for retrieval and update of components.

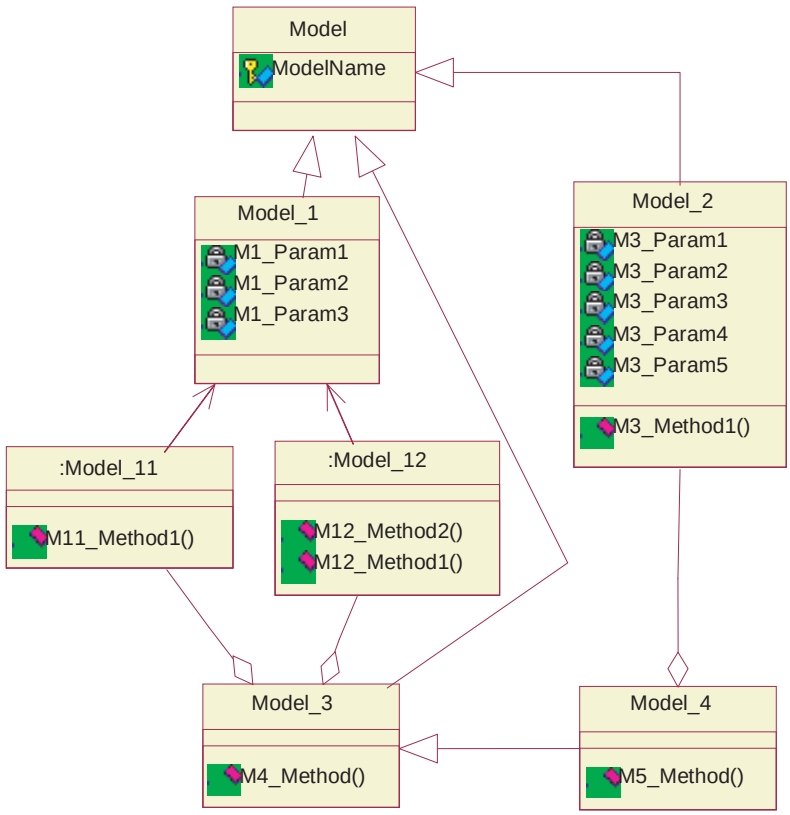
Model Component

The model component may contain many interrelated models as shown in Figure 3. The top-level abstract model has an association with the framework template. This model is detailed through inheritance and aggregation, and then associated with the kernel and scenario. Figure 3 shows that the concrete-level model is developed using other base-level models. In the process of detailing or developing concrete models, we use the concepts of abstraction, inheritance, and aggregation. The model can also contain an instantiated model as shown in Figure 3. It can be of the primitive type or the compound type (Geoffrion, 1987). Primitive-type models are directly derived using base data-type variables as well as executed model values of the base-level models. The compound-type model either inherits or aggregates the base models or may both inherit and aggregate as well as add some other independent parameters. The top-level model class is associated with the framework template while the concrete model classes are associated with the kernel.

Solver Component

The solver component is made up of algorithms for applying behaviors on the model instance. The design concept is almost similar to the design of the model component as discussed above. Each solver contains methods related to specific operations and is implemented through overloading, overriding, and shadowing techniques of object-oriented methodology.

Figure 3. A simple model hierarchy



Data Component

The data component is designed to represent facts of business operations and decision scenarios. The data component can be a subset of a database, a data table, or a record or a serialized object or a formatted file/document. It may be any or all of binary, xml, text, relational data, and ADO.NET object formats. It describes value and data type of discrete information. An abstract-level data object is detailed for its suitable use with the model and the scenario. This component is also used in other components—namely, kernel, ComponentSet, and ComponentServices.

Visualization Component

The visualization component is designed for presentation of model or scenario-executed data or text. Most of the visualizations are flexible and created at runtime.

Scenario Component

A unique problem is central to scenarios, but the instances and implementation environment could be diverse. As we have described, the scenario in its simplest form is a combination of data, model, and solver. The architecture allows generating a number of simple, pipelining, and aggregate scenarios. Scenario information can be saved to the scenario pool. Previously developed scenarios can be retrieved from the scenario pool, and the same can be customized using models and solvers. The scenarios can be used as specific DSSs or as complex data for input to the next level of model for further analysis. Different scenarios can be computed simultaneously, and sensitivity and goal-seek analysis can be done using different scenarios. The architecture is suitable for analyzing internally coherent scenarios or scenario bundles, and examining the joint consequences of changes in the environment for supporting the decision maker's strategy.

ComponentsServices Component

The ComponentServices component is designed to work with the component pool using universal data access technology (e.g., OLE DB, ODBC). This component works between the component set and the component pool. It contains several parameters and methods that support export, and import all sorts of component information to and from data, model, solver, and scenario pools. Some of the methods have been predefined, but they can be changed at the runtime to suit the changed component pool management system.

Integration Components

The integration component is composed of the details of kernel, validation, mapping, and ComponentSet. These components are described below.

Kernel and User Interface

The kernel is the integration tool of the system that integrates the decision support components (i.e., data, model, solver, visualization, scenario) and other associated integration components (such as component set, mapping, and validation). The class diagram of the kernel and the associated components are shown in Figure 4.

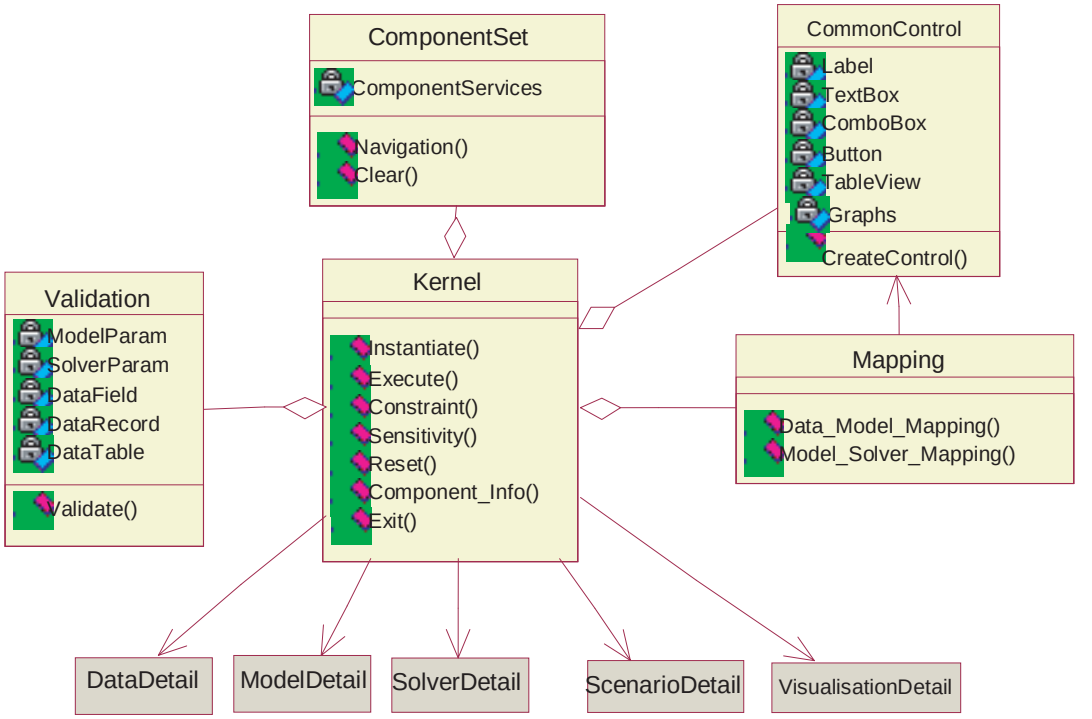
The kernel component works as the center of communication between and among the decision support components. Components or component instances are called inside the kernel when any member of the component is instantiated or invoked at runtime. The kernel is designed for both flexible coupling and tight coupling of data, model, solver, and scenario. The mapping component plays a vital role for flexible coupling. For the tightly coupled system, usage of data, model, and solver are predefined. The model understands which data is to be picked up on the basis of data and model activation to instantiate the model and which solver is to be called to execute the model.

In addition to activating and using the component functions, the kernel generates runtime user interfaces for communicating with and integrating with other components of the system with the support of CommonControl Class. This is a container of many controls.

Mapping Component

The mapping is a process-oriented generic component that enables the model component to communicate with data and

Figure 4. Kernel and its associated components



solver components properly while they are completely separate from one another. In SDSSG, the mapping component is composed of data-model and model-solver mapping. During the mapping, this component collects the name and data type of attributes of the selected data, model, and solver from the component set and presents them on a dynamically created user interface. This process is designed in such a way that the decision maker does not need to change any attribute name in the component set.

The mapping component facilitates the communication between two attributes having different names. The decision maker then arranges the attributes of the components for communication. The model is the center for mapping the attributes. The model attributes are fixed, and the user selects the data attributes for model-data mapping and selects the solver name and solver attributes for model-solver mapping. The mapping component also facilitates transformation of data types (e.g., from integer type to string type, or string type to double type, etc.). The system can automatically transform lower-level data types to higher-level data in a hierarchical data structure of the base data type (e.g., integer to double value), but any transformation from higher-level data types to lower-level data types must be done through explicit operation. This operational method for transformation can be built-in with the model, solver, or kernel.

Validation Component

The validation component is responsible for checking the input data type of the model and the solver after the mapping. In model-data validation checking, the data type of the model attribute is fixed and checks whether the data attributes are similar or convertible to the data type of the model attribute.

For model-solver validation, the data type of the solver attribute is fixed and checks whether the data types of the attributes of the model instance are similar or convertible to the data type of the solver attribute.

Component Set

The component set is an independent component that performs as a temporary repository of the component information and works as a data access layer with the support of the ComponentServices component. The component set can be filled with records from the data pool, model pool, solver pool, and scenario pool. A component set can be loaded with a set of records, model, solver, and scenario data. The component set is also responsible for uploading the data from the data grid to the user interface. There are two locations for uploading the data. One area is customized for a specific domain while the other area is a general interface that can be used for uploading a component table. In this way the framework is able to work with many databases and data tables. Once data are added to the component set, the component schema is also updated with the new data. The schema can easily be converted to an XML base. The component set can also be reconstructed from the XML base. Therefore, the system works without a database system or without having connection to the central DBMS system. This conversion facilitates the portability of the system.

Components Pool

The components pool contains the data pool, model pool, solver pool, and scenario pool, which are collections of domain data, model information, solver information, and scenario information respectively. The model pool, solver pool, and scenario pool can contain generalized as well as domain-specific model, solver, and scenario information. The records of model and solver pools are dependent on the structure of the models and solvers to be used in the system, while the scenario records are dependent on the structure of the scenario as well as the type of scenario to be analyzed. The method of the scenario component is a generalized method that is responsible for developing scenario instance from the information of the scenario pool, as well as using the data table, model pool, and solver pool. The scenario method is domain independent, but the scenario instance is domain specific. The component pool can be developed using a database language outside the decision support system. The component pool is fully separated and independent from the SDSSG application. This enables us to create, update, maintain, and manage the component pool without involving the application program. The SDSSG is capable of using the data tables that have the required data.

IMPLEMENTATION OF THE SDSSG ARCHITECTURE

The architecture can be implemented as a single-, two- or three-tiered architecture. Since object-oriented and component-based concepts are the central focus of our framework and architecture, Microsoft's .NET framework, was considered as the implementation platform and C# was used for implementing the system architecture. Component technologies (e.g., Dynamic Link Library, Component Object Model), database management systems (e.g., SQL 2000 Server, Microsoft Access), and extensible markup language (XML) were also used in building the system. The important features of the implementation are described in the following sections.

Component Independence and Interoperability

Each and every architectural component is designed as an independent unit using the .Net framework concept that supports the COM+ specification. They are compiled to intermediate language as DLL. The components are compiled to native code by a runtime compiler when they are called to execute a task. The components are independent until they are not actively participating in the process. The intermediate language-based components and their compilation at runtime make them interoperable with COM/COM+ components.

Runtime Code and Scenario Management

The user can write database access codes at runtime to work with different DBMSs. The construction of scenario from data, model, and solver from the component pool also depends on the runtime written command. The runtime-generated and executed scenarios are managed through a runtime scenario pool for developing upper-level scenarios, as well as sensitivity and goal-seek analysis.

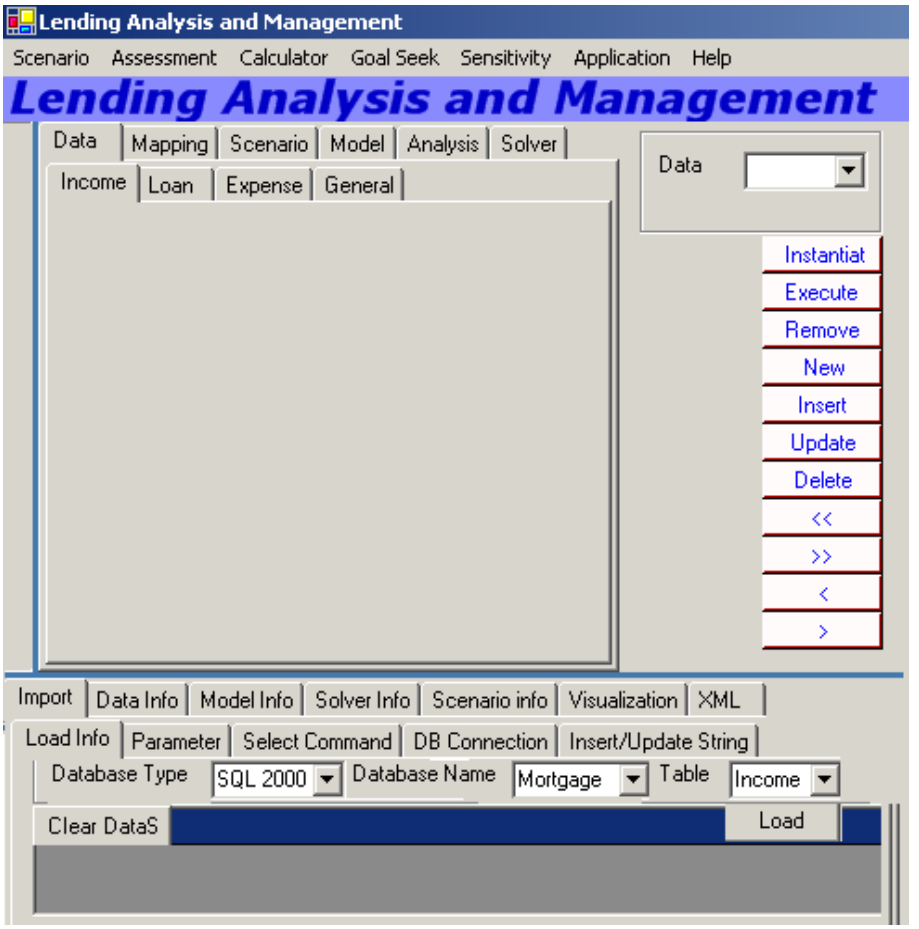
Component Versioning and Extensibility

The framework template is specifically designed for customization of the architecture by replacing its component(s) with different versions of the same component. So the architecture is extensible to accommodate multiple versions of a component.

Data Access and Component Set

The system is able to import data from a database system that has an ODBC or OLE DB interface, text data, or XML-

Figure 5. The SDSSG implementation in the mortgage domain



formatted data. It uses ADO.net architecture that supports the data structure independence. The data is managed through a temporary disconnected runtime repository named Component Set, which can hold multiple component tables at a time. The component performs as a runtime DBMS schema and supports defining relationships between the component tables that help in developing the scenario instance.

Presentation

The execution results of the scenarios are presented in dynamically runtime-created visualization for evaluation through comparison. The visualization can accept a replacement/update of a scenario. A new scenario can be added to the visualization or can be deleted from the visualization.

Ease of System Use

The implemented SDSSG system is suitable for both the naïve user as well as the DSS builder. The naïve user can easily use the semi-automated, tightly coupled system while the DSS builder can use a versatile, flexible-coupled system. Some of the process can be done using a flexible-coupled system while the rest of the process can be completed using a tightly coupled system.

Implementation Domain

The SDSSG framework, architecture, and implementation were tested within the context of the mortgage domain (see Figure 5). Specifically, we implemented affordability scenarios, lending scenarios (equal installments, reducing installments, interest only, etc.), and payment scenarios. Within each of these scenarios, we explored sensitivity and goal-seek analyses.

Once a base scenario has been developed, we explore a number of alternative scenarios, including the best-case and worst-case scenarios through sensitivity analysis. We used the system to compare multiple scenarios of similar type (homogeneous comparison) or different types (heterogeneous comparison) or both homogeneous and heterogeneous at a time in a single visualization.

The system was tested and evaluated for sensitivity analysis for refinancing from different lending sources, and increase or decrease of the interest rate, loan amount, initial payment, installment, and pay period. Apart from this we also explored sensitivity analysis on complex interlinked scenarios, which in turn were made up of sub-scenarios. The system supports complex analyses from the very lower-level scenarios to higher-level/aggregate scenarios. Scenarios analyzed from the bottom up may or may not satisfy the prime objective. In this circumstance, a top-down scenario analysis (goal-seek analysis) could bring to light the optimum acceptable scenarios.

FUTURE TRENDS

We have designed the SDSSG framework and architecture using the modeling-based DSS concept and implemented it using the modeling as well as process-based development methods. It supports scenario planning, scenario modeling, scenario development, and execution and decision support for the decision maker at runtime. This system integrates scenario with the model-based DSS, but it overlooks the integration of knowledge-based DSS into the SDSSG framework and architecture. The proposed process-based development method is suitable to incorporate the knowledge-based sub-system in the decision-making process. The knowledge sub-system or case-based reasoning helps the decision maker reference the past decision scenarios as well as the decisions. The integration of knowledge-based DSS with the SDSSG will be a unique decision support system that would help exhaustive scenario analysis as well as uniform learning throughout the organization.

CONCLUSION

The existing scenario planning and analysis systems are very complex, they are not user friendly, they cannot support multiple scenarios modeling at one time, and they do not provide any facilities for scenario evaluation or comparison between multiple scenarios. The scenario-based decision support process is mostly being used for developing corporate strategies. But scenarios are useful for tactical and operational level decisions as well.

This research develops a generic scenario-driven flexible decision support systems generator framework and architecture that supports complex decision-making processes. It supports sensitivity and goal-seek analysis. It uses decision support components, integration components, and component pools for scenario planning, development, and analysis. Scenario has been introduced as a new DSS component that is developed as a complex combination of other decision support components—namely, data, model, and solver. The proposed framework and architecture are domain and platform independent, component based, and modular. The architecture is composed of multiple layers, for example, component pool layer, data access layer, decision support services layer, integration layer, and user services layer. Each layer performs specific functions, which are suitable for implementation of the architecture as a single-, two-, or three-tiered system. Architectural components can be updated with new versions; they are interoperable with other

platforms. A prototype was developed using the framework and architecture. The implementation has been evaluated with the objectives and design goals in the context of the mortgage domain. Significant extensions to this framework and architecture have been proposed and implemented, while retaining the core constructs in other domains with different paradigms (Ahmed & Sundaram, 2007). Key principles from this research have formed the foundation stone in implementations in the field of sustainability modeling and reporting (Ahmed & Sundaram, 2008).

KEY TERMS

Aggregate Scenarios: The structure of different scenarios or results from multiple scenarios are combined/aggregated together to develop a more complex scenario.

Decision Support Systems/Tools: In a wider sense, can be defined as systems/tools that affect the way people make decisions. In our present context it is defined as systems that increase the intelligence density of data and support interactive decision analysis.

Goal-Seek Analysis: Accomplishes a particular task rather than analyzing the changing future. This goal-seek analysis is just a reverse or feedback evaluation where the decision maker supplies the target output and gets the required input.

Intelligence Density: The useful 'decision support information' that a decision maker gets from using a system for a certain amount of time, or alternately the amount of time taken to get the essence of the underlying data from the output.

Pipelining Scenarios: One scenario is an input to another scenario in a hierarchical scenario structure. In this type of scenario, the lower-level scenario can be tightly or loosely integrated with the higher-level scenario.

Scenario: A complex problem situation analogous to a model that is instantiated by data and tied to solver(s). A scenario can be presented dynamically using different visualizations. A scenario may contain other scenarios.

Sensitivity Analysis: Allows changing one or more parametric value(s) at a time and analyzes the outcome for the change. It reveals the impact on itself as well as the impact on other related scenarios.

Simple Scenarios: The simple scenario is not dependent on other scenarios, but completely meaningful and usable.

Design Levels for Distance and Online Learning

Judith V. Boettcher
Designing for Learning and the University of Florida, USA

INTRODUCTION

The importance of design for instructional programs — whether on campus or online or at a distance — increases with the possible combinations of students, content, skills to be acquired, and the teaching and learning environments.

Instructional design —as a profession and a process— has been quietly developing over the last 50 years. It is a multidisciplinary profession combining knowledge of the learning process, humans as learners, and the characteristics of the environments for teaching and learning. The theorists providing the philosophical bases for this knowledge include Dewey (1933), Bruner (1963), and Pinker (1997). The theorists providing the educational and research bases include Vygotsky (1962), Knowles (1998), Schank (1996), and Bransford, Brown, and Cocking (1999).

Instructional design offers a structured approach to analyzing an instructional problem and creating a design for meeting the instructional content and skill needs of a population of learners usually within a specific period of time. An instructional design theory is a "theory that offers explicit guidance on how to better help people learn and develop" (Reigeluth, 1999).

BACKGROUND

This entry describes a multi-level design process for online and distance learning programs that builds on a philosophical base grounded in learning theory, instructional design, and the principles of the process of change as reflected in the writings of the theorists listed above. This design model builds on traditional instructional design principles, as described by Gagne (1965), Dick & Carey (1989), and Moore & Kearsley (1996). It integrates the strategic planning principles and the structure of the institutional context as described in Kaufman (1992) and Boettcher & Kumar (1999), and also integrates the principles of technological innovation and the processes of change as described by E. M. Rogers (1995) and R. S. Rosenbloom (1998).

This entry describes a six-level design process promoting congruency and consistency at the institution, infrastructure, program, course, activity, and assessment level. It also suggests a set of principles and questions derived from that framework to guide the instructional design process.

SIX LEVELS OF DESIGN

Effective instructional design for online and distance learning benefits from instructional planning at six levels. Figure

Figure 1. Six levels of design for learning

Six Levels of Design	Design Responsibility	Sponsor/Leader	Design and Review Cycle
Institution	Entire campus leadership and community	Provost, CIO and Vice-presidents	3-5 Years
Infrastructure	Campus and Technology Staff	Provost, CIO and Vice-presidents	2-3 Years
Degree, Program	College/Deans/Faculty	Dean and Chairs	1-3 Years
Course	Faculty	Dept Chair	1-2 Years
Unit/Learning Activity	Faculty	Faculty and or Faculty team	1-2 Years
Student Assessment	Faculty	Faculty and or Faculty team	1-2 Years

1 summarizes these six levels of design, and identifies the group or individuals usually responsible for the design at that level and the length of the design cycle at each level. Ideally, the design at each of these six levels reflects philosophies of teaching and learning that are consistent with the institutional mission and consistent with the expectations of the students and society being served.

Level One: Institutional Design

The design work to be done at an institutional level is similar to the strategic planning and positioning of an institution. Institutional planning generally begins with an institution's current vision and mission statements and then proceeds through a data collection and input process that addresses a set of questions such as the following:

Institutional Questions:

- What programs and services comprise our primary mission? For whom?
- To what societal needs and goals is our institution attempting to respond?
- What life goals are most of our students working to achieve?
- What type of learning experiences are our students searching for?
- What changes in our infrastructure are needed to match our desired services, programs, and students?
- Does our institution have any special core competencies, resources, or missions that are unique regionally or nationally that might form the basis for specialized online and distance programs? What are the strengths of our mature faculty? Of our young faculty?

Level Two: Infrastructure Design

People often think that buildings, classrooms, Web applications, communication services, and servers are neutral as far as having an effect on teaching and learning. Nothing could be more misleading. Design of the infrastructure includes design of all the elements of the environment that impact the teaching and learning experiences of faculty and students and the staff supporting these experiences. It includes design of the following:

- Student services, faculty services, and learning resources.
- Design of administrative services, including admission processes, financial processes, and institutional community life events.
- Design of physical spaces for program launching events, hands-on, lab, or network gathering events, as well as celebratory graduation events.

Physical and Digital Plants

Infrastructure design for online and distance teaching and learning programs focuses on the design of the network and Web infrastructure. Infrastructures for online learning have offices, classrooms, libraries, and gathering spaces for the delivery and management of learning and teaching. However, these offices and classrooms are accessed through Web services, rather than through physical buildings. The good news about online infrastructures is that they support an unparalleled new responsiveness, feedback, and access for learning activities.

After almost ten years of building online campuses, we now know that a "digital plant" infrastructure is needed to support the new flexible online and distance environments. We know that this new digital plant needs to be designed, built, planned, maintained, and staffed. The infrastructure to support the new programs cannot be done with what some have called "budget dust" (McCredie, 2000). It is not nearly as easy or inexpensive as we all first thought. Some experts suggest that, a "full implementation of a plan for technology support on campus costs about the same as support of a library — approximately 5% of the education and general budget" (Brown, 2000).

Components of a Digital Infrastructure

What exactly is a digital plant infrastructure? One way of describing this infrastructure is to think of it in four major categories of personal communication tools, networks, hardware for servers, and software applications. A key component of the digital infrastructure is the group of individuals who make the systems work. This digital plant is shown in Figure 2 (Boettcher and Kumar, 2000).

Some of the questions that might be used to guide the development of the digital infrastructure follow.

Personal communication tools and applications:

- Will all students have their own computer? Their own laptop?
- Do we expect students all to be proficient with word processing applications, mail, Web applications, researching on the Internet? With collaborative tools and with one or more course management systems?

Networks that provide access to Web applications and resources and to remote, national, and global networks:

- What physical wired or wireless networks are needed to support Web applications, such as e-mail servers, directory servers, and Web application services?
- How often will higher bandwidths be needed for video conferencing for programs? For meetings? For downloading large files? For streaming video?

Dedicated servers and software applications that manage campus services:

- What types of interactive Web services will be provided? What hardware and software will be required?•What type of administrative systems and course management system will we use?
- What do we need to do to assure student, faculty, and staff accessibility from anywhere at anytime?

Software applications and services from external providers, such as research and library services that are licensed to the institutional community, Internet services, and outsourced services, such as network services:

- What licensed services are required and desired?
- What budget is required to support these services currently and into the future?

Technology decisions for students have always been part of the instructional design process for distance learning. A comforting way of thinking about the technology for the infrastructure design level is in terms of the generations of technologies used in distance learning. (Sherron and Boettcher, 1997). Distance learning was made possible with the widespread availability of technologies, such as the mail, radio, telephone, television, and audio and videocassettes. In the 21st century we simply have more technology and more choices.

Now let's look at the design of programs and courses. Design issues at these levels are principally the responsibility of the institutional academic leadership.

Level Three: Program Design

At the program level of design, instructional planners answer questions about the type of program to be offered, to whom, and over what period of time and at what cost. When venturing into new business areas, the following two guidelines are useful: (1) focus on programs that can leverage institutional core competencies and strengths, (2) plan a phased approach, gaining experience in delivering programs in one or two areas before launching others, and (3) recognize that online and distance learners generally are interested in achieving or completing an instructional goal that can assist in their current or future career path.

It is in the next four levels of design that the principles of Vygotsky are most applied, building on Vygotsky's (1962, 1978) view of the learner as a goal-oriented learner within a specific learning context using specific resources as directed by a teacher. These four core elements of all learning experiences provide a framework for the design process:

- The person doing the learning — the learner
- The person guiding and managing the learning —the faculty/teacher/mentor
- The content /knowledge/skill to be acquired/or problem to be solved
- The environment or context within which the learning experience occurs

Program Level Planning Questions:

Program planning design has four categories of planning — curriculum, design/development process, faculty, and student.

Curriculum questions:

- What is the degree or certificate program to be offered online? Will it be a full master's degree (10 to 16 courses), an undergraduate minor (four to six courses) or a certificate program (two to four courses)?
- What types of courses are envisioned? Will these courses be a fully developed "course in a box" with a minimal amount of interaction or a highly interactive and collaborative course requiring or using many online resources and applications?

Design and development questions:

- Who are the faculty who will design, develop and deliver the courses in the program?
- Who will lead the effort to develop the degree or certificate program for online or distance delivery? Which organization will be marketing the program?
- What course management system or similar Web tool will be used for the content management? What tools and resources will be available and supported for the interaction and collaboration activities?
- What is the schedule for design and development and delivery of courses and program? For the marketing and recruiting of the students?

Faculty questions:

- What training will be available to faculty as they transition to online teaching and learning programs?
- What tools and resources and support will be available to faculty?
- Will faculty have any released time or budget for teaching and learning resources in the new online or distance environment?
- What type of access to the network is recommended and available? Will dial-up be sufficient, or will DSL or cable access be recommended or required?

Student questions:

- Who are the students who will enroll in this course of study? How will we find them and market the program to them?
- What will our students bring to the program experience?
- What tools and resources will the student in this program or certificate program require or be likely to use?
- Where will the students be doing their learning and with what types of content resources and applications? What level of network access is required or recommended?

The question of technology access for students was particularly important in the mid-1990s, when technology access was relatively scarce. However, the latest data from the Campus Computing Study of 2002 suggests that more than 75% of all students own their own desktop or notebook computer (Green, 2002). If all students have their own computers and access to the Internet, this access greatly impacts the design of communication activities and course experiences.

Course Design — Level Four

Design at the course level is usually considered to be the responsibility of the faculty member. In online and distance courses, however, the stand-alone course is the exception rather than the rule. Most online and distance courses are part of a curriculum, certificate, or degree program. This means course-level design occurs within the context of the larger program and that many of the design decisions are made in collaboration with other faculty within the academic program or department. Faculty at the course level are primarily responsible for design decisions on content, objectives, student goals, learning experiences, and assessment for a particular course. Many of these questions for this design level parallel questions at the program level design. The following questions are more specific to a single course:

Course questions:

- Where does this course fit within the context of the degree or certificate program to be offered online? Is it an early course focused on core discipline concepts, peer discussions, and standard problems or a later course focusing on applications and complex scenarios?
- What is the core set of knowledge, skills, and attitudes/values to be acquired by the students?
- What is the set of content resources required and recommended? What content resources will students use to customize the learning experience for their needs and state of knowledge and personal interests?
- Will students be a cohesive cohort group?

Design and development questions:

- What types of instructional activities and experiences will support student learning of the knowledge, skills, and attitudes of the students?
- What course management system or similar Web tool will be used for the content management? For the interaction and collaboration activities?
- What is the schedule for design and development and delivery of this course?

Faculty questions:

- What training is needed for a faculty member to transition to online teaching and learning programs?
- What tools and resources and support will be needed to support the delivery of this course?

Student questions:

- Who are the students taking this course? What are their hopes and expectations? What future courses will depend on the knowledge, skills, and attitudes acquired in this course?
- What knowledge and expertise do the students bring to the course? What is their zone of proximal development (Vygotsky, 1978)?
- What types of teaching and learning strategies best suit the students in this course? What are the life style and learning styles of the students?
- When and where will the students be likely to gather for their collaborative work? When and where will they do their more self-study activities?
- Where will the students be doing their learning? What level of network access is required or recommended?

The next two design levels are within the course parameters and generally are the responsibility of the faculty designing the course.

Level Five: Unit/Learning Activity

Many of the design questions for the unit/learning activity level and the student assessment level are derived from a design model that focuses on integrating student life style and learning styles into instructional planning (Boettcher, 2003). Examples of cognitive learning style design questions include: "How do students process information?"; "How do students respond in their minds when challenged with new concepts and rich content structures?", "What knowledge do students bring to the learning experience?"

The life style of the learner is also addressed in these questions. Life style includes all the elements in a learner's current life situation. Where will the learner be working? Will they have a personal space where they can control sound, temperature, disturbances, and network access? Will they

have to "ask" their family if they can access the network? A life-style focus encourages analysis of the where, when, with whom, and with what resources the learner is going to be doing their learning work.

Learning work consists of constructing new knowledge, applying and integrating knowledge, and solving problems with that new knowledge. Mobile, wireless technologies enable learners to study anywhere at any time. Initially, the ability to study anywhere seemed to hold the promise of solving many problems associated with access to learning. However, we have not addressed the question of just when and just where this "anytime" is likely to occur.

Learning activity questions:

- What is the knowledge, skill or attitude that is the desired outcome of this learning activity?
- What kinds of problems can students solve now? What kinds of problems do we want students to be able to solve at the conclusion of the experience?
- What instructional strategy or experience will support the learner learning the desired knowledge, skill, or attitude?
- When, where, with whom, and with what resources is the instructional activity envisioned to occur?
- What role will the teacher/mentor/faculty play during this activity? Will the teacher be present physically or at a distance, synchronously or asynchronously?
- When will a learner know that he/she knows? What feedback or result from a problem being solved will make the learner's knowledge evident?

Level Six: Assessment of Student Learning

Assessment is fundamental to the design process. Assessment planning helps to balance the goals of learning effectiveness and teaching and learning efficiency. In productive, customized, enriched learning experiences, each learner begins with an existing, personal store of knowledge representation. Learning experiences expand and enrich that knowledge base in individual and personal ways. Productive learning experiences mean that all students complete a learning experience with an expanded, yet different, store of knowledge. The goal is that learners learn core principles so that the core principles can be effectively applied, but the particular way the knowledge base is constructed in individuals is unique.

What we can design into instructional planning is that all learners share some of the same experiences and that assessment focuses on the common learning that is achieved. Assessment can also provide for demonstration of knowledge and skills in more complex environments and for some elements of customized knowledge acquisition. Here are some selected questions for assessing student learning:

Assessment Questions

- How will the learners know the goals and objectives for the learning? It is good to plan for core concepts, practice of core concepts, and customized applications of concepts.
- Will learners be generating a set of their own goals for learning? How will the faculty mentor and learner communicate and agree on goals for learning, particularly for customized applications of concepts?
- In what ways and where will the students be evaluated and graded?
- How will students demonstrate their competency in concept formation? In solving problems?
- If we don't see the students on a regular basis, can we design ways to "see" their minds virtually through conversation and experiences?

The portfolio project within the National Learning Infrastructure Initiative (NLII) is also useful as an assessment of complex learning (www.educause.edu/nlii/keythemes/eportfolios.asp).

FUTURE TRENDS

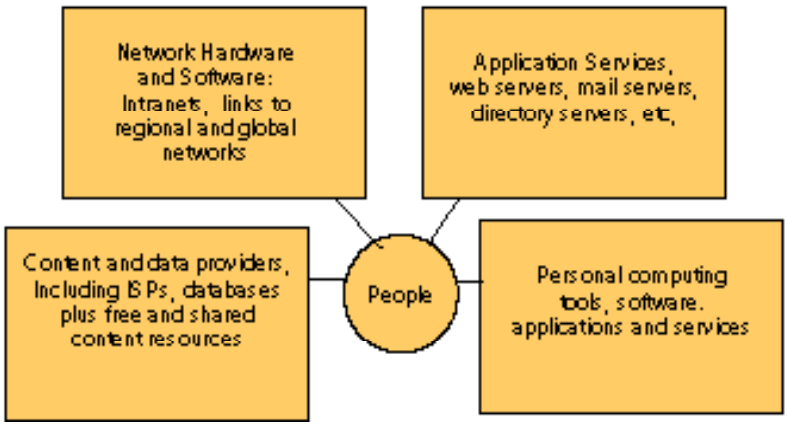
The process of instructional design is a professional task requiring knowledge of educational research, learning processes, and, increasingly, a respect for context, and a comfort level with innovation and instructional technologies. It is a labor-intensive task requiring interaction with content experts and administrators and institutional representatives. Much of the current instructional design processes focus on the analyses of needs and contexts for learning for learners, their tools and their resources — as a group. Future work in instructional design will focus more on the learner as an individual with unique knowledge structures and thus promote the needs for a rich contextual learning environment that is multi-leveled and customizable.

The design of instructional planning will become more of a priority as the demand for effective and efficient learning grows as a result of time pressures, budget pressures, and increasing demands for accountability in education.

CONCLUSION

These instructional design principles reaffirm the iterative nature of design work and the sharing of design work among the hierarchical groups of an institution. Instructional design, when done well, results in delighted and productive learners

Figure 2. Teaching and learning infrastructure - "digital plant"



and faculty pleased with their roles and their work. Consistently applied, instructional design principles keep teaching and learning focused on the who, when, where, how, and why of teaching and learning and help to ensure that the money and time invested in learning programs provide an appropriate return for individuals and for society. Instructional design is a powerful tool that moves teaching and learning into the science of learning and knowing.

KEY TERMS

Instructional Design: The process of analyzing the students, content, and intended context of an instructional program to provide detailed specifications for an instructional program or curriculum to achieve effective and efficient student learning within an affordable and accessible delivery format.

Instructional Design Theory: A "theory that offers explicit guidance on how to better help people learn and develop" (Reigeluth, 1999).

Instructional Strategy: An instructional strategy is a communication activity used to engage the learner in an educational experience and to assist the learner in acquiring the planned knowledge, skill, or attitude. Instructional strategies include lectures, discussions, reading assignments, panel presentations, study and media projects, problem analysis and solutions, field trips and assessment activities.

Learning Infrastructure: The set of physical and digital buildings, applications, services, and people that provide and support the environments for learning.

Learning Theory: A set of hypotheses or beliefs that explain the process of learning or acquiring knowledge and skill.

Online Course: A set of instructional experiences using the digital network for interaction, learning and dialogue. An online course does not require any face-to-face meetings in a physical location. Similar courses such as web-centric courses (also called hybrid or blended courses) are similar to online courses, but require regular scheduled face-to-face classes or meetings.

Zone of Proximal Development: This is a key concept in Lev Vygotsky's theory of learning. The Zone of Proximal Development (ZPD) is the "distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under the adult guidance or in collaboration with more capable peers" (Vygotsky, 1986).

INTRODUCTION

Design patterns (Gamma, Helm, Johnson, & Vlissides, 1995) extract good solutions to standard problems in a particular context. Modern software industry has widely adopted design patterns to reuse best practices and improve the quality of software systems. Each design pattern describes a generic piece of design that can be instantiated in different applications. Multiple design patterns can be integrated to solve different design problems. To precisely and unambiguously describe a design pattern, formal specification methods are used. Each design pattern presents extensible design that can evolve after the pattern is applied. While design patterns have been applied in many large systems, pattern-related information is generally not available in source code or even the design model of a software system. Recovering pattern-related information and visualizing it in design diagrams can help to understand the original design decisions and tradeoffs.

In this article, we concentrate on the issues related to design pattern instantiation, integration, formalization, evolution, visualization, and discovery. We also discuss the research work addressing these issues.

BACKGROUND

Formalization

Design patterns are typically described informally for easy understanding. However, there are several drawbacks to the informal representation of design patterns. First, informal specifications may be ambiguous and imprecise. They may not be amendable to rigorous analysis. Second, formal specifications of design patterns also form the basis for the discovery of design patterns in large software systems. Third, design patterns are generic designs that need to be instantiated and perhaps integrated with other patterns when they are applied in software system designs. There can be errors and inconsistencies in the instantiation and integration processes by using informal specifications. Finding such errors or inconsistencies early at the design level is more efficient and effective than doing it at the implementation level. In addition, it is interesting to know whether some of these processes are commutative at the design level (Dong, Peng, & Qiu, 2007b).

The initial work on the formal specification of architecture and design patterns has been done in Alencar et al. (Alencar, Cowan, & Lucena, 1996). The composition of two design patterns based on a specification language (DisCo) has been discussed in Mikkonen (1998). A formal specification approach based on logics is presented in Eden and Hirshfeld (2001). Some graphical notations are also introduced to improve the readability of the specifications. The structural and behavioral aspects of design patterns in terms of responsibilities and rewards are formally specified in Soundarajan and Hallstrom (2004). Taibi and Ngo (2003) propose specifying the structural aspect of design patterns in the first order logic (FOL) and the behavioral aspect in the temporal logic of action (TLA). Formal specification of design patterns and their composition based on the language of temporal ordering specification (LOTOS) is proposed in Saeki (2000).

Evolution

Change is a constant theme in software system development. Most design patterns describe some particular ways for future changes and evolutions. In this way, the designers can add or

remove certain design elements with minimal impact on other parts of the system. However, such evolution information of each design pattern is normally implicit in its descriptions. When changes are needed, a designer has to read between the lines of the document of a design pattern to figure out the correct ways of changing the design. Misunderstanding of a design pattern may also result in missing parts of the evolution process. It might be a disaster if a change causes any inconsistency, any violation of pattern constraints and properties, and consequently, a system crash. It is important to regularize, formalize, and automate the evolution of design patterns.

Design pattern evolutions in software development processes have been discussed in Kobayashi and Saeki (1999), where software development process is considered as the evolutions of analysis and design patterns. The evolution rules are specified in Java-like operations to change the structure of patterns. Noda (2001) consider design patterns as a concern that is separated from the application core concern. Thus, an application class may assume a role in a design pattern by weaving the design pattern concern into the application class using Hyper/J. Improving software system quality by applying design patterns in existing systems has been discussed in Cinnéide and Nixon (2001). When the user selects a design pattern to be applied in a chosen location of a system, automated application is supported by applying transformations corresponding to the minipatterns.

Visualization

When a design pattern is applied in a large system design, pattern-related information is normally lost because the information on the role a model element plays in the pattern is often not available. It is unclear which model elements, such as class, attribute, or operation, participate in the pattern. There are several problems when design patterns are implicit in software system designs. First, software developers can only communicate at the class level instead of the pattern level because they do not have pattern-related information in system designs. Second, each pattern often documents some ways for future evolutions, as discussed previously, that are buried in the system design. The designers are not able to change the design using relevant pattern-related information. Third, each pattern may preserve some properties and constraints. It is hard for the designers to check whether these properties and constraints hold when the design is changed. Fourth, it may require considerable efforts on reverse-engineering design patterns from software systems.

Early work on explicitly visualizing design patterns in UML has been investigated in Vlissides (1998), where all approaches surveyed can only represent the role a class plays in a pattern, not the roles of an attribute (or operation). They cannot distinguish multi-instances of a pattern either. Current approaches on visualizing design patterns can be categorized into two kinds, UML-based approaches (France, Kim, Ghosh, & Song, 2004; Lauder & Kent, 1998; Vlissides, 1998) and non-UML-based approaches (Mapdlsden, Hosking, & Grundy, 2002; Reiss, 2000). The UML-based approaches can be further divided into single-diagram (Vlissides, 1998) and multidiagram (France et al., 2004; Lauder & Kent, 1998).

Discovery

Design document is often missing in many legacy systems. Even the document is available; it may not exactly match the source code that may be changed and migrated over time. Missing pattern-related information may compromise the benefits of using design patterns. The applications of design patterns may vary in different layouts, which also pose challenges for recovering and changing these design pattern instances. It is important to effectively and efficiently recover the design pattern from the source code.

Several approaches have been proposed to discover a design pattern from either source code or design model diagrams, such as the UML. A review of these approaches has been presented in Dong (Dong, Zhao, & Peng, 2007d). Among them, Antoniol (2004) uses the abstract object language (AOL) as the intermediate representation for pattern discovery. Tsantalis et al. (Tsantalis, Chatzigeorgiou, Stephanides, & Halkidis, 2006) applies a graph matching algorithm to calculate the similarity of two classes in pattern and system. Machine learning algorithms, such as decision tree and neural network, have been applied to classify the potential pattern candidates in (Ferenc, Beszedes, Fulop, & Lele, 2005, Gueheneuc, Sahraoui, & Zaidi, 2004).

FROM THEORY TO PRACTICE

In this section, we present our approaches on the formalization, evolution, visualization, and discovery of design patterns. In addition to the theory of our approaches, we provide several tools for practical uses of our approaches.

Formalization

Over the past decade, we have applied several formal methods, such as first-order logic, temporal logic of action (TLA) (Lamport, 1994), Prolog, Calculus for Communicating System (CCS) (Milner, 1989), to specify design pattern structure and behavior. More specifically, we applied first-order logic to specify the structural aspect of a design pattern and the TLA to specify the behavior of each design pattern in Dong (Dong, Alencar, & Cowan, 2000). The structural aspect is described by predicates for describing classes, state variables, methods, and their relations. The

integration of two design patterns is the union of two sets of the predicates corresponding to the structures of the two patterns. We specify the behavioral aspect using the TLA since it is an axiomatic style of semantic definition suitable for describing both safety and fairness properties. We define the behavioral semantic of each design pattern in terms of TLA formulas. In addition to TLA, we used CCS to specify the behavioral aspect of design patterns in Dong (Dong, Alencar, & Cowan, 2006a), where we define the behavior of each pattern in terms of CCS processes. The objects and their communications in each pattern are represented in the processes and their communications. We define the interface, input/output messages, and actions of each process. We then defined the behavioral instantiation and integration based on the process definitions.

Formal specification allows describing the structural and behavioral aspects of design patterns more precise and concise. It also facilitates automated verification techniques, including model checking and theorem proving.

Model checking techniques typically include a model specification language that specifies a finite state model and a property specification language that defines the properties of a system in, for example, temporal logic. A model checker is a tool that explores the finite state model to match the properties. We have explored model checking techniques in Dong et al. (2006a). By specifying the properties of each pattern, we used a model checker to check them against the behavioral specification of the pattern. In this way, we can check the consistencies of the integration of design patterns and discover errors early at the design level.

Theorem proving is another verification technique that ensures the correctness of a design. By applying rigorous mathematical knowledge, formal model abstracts the structure and behavior of a design pattern, and the operations between them, which enables us to summarize, predict, prove, or exclude certain general properties of design pattern operations. Based on our definitions of the structural and behavioral aspects of deign patterns, we have proved several theorems related to the structural integrity, safety, and liveness properties in Dong et al. (2000). While manual proving theorems can be tedious and error-prone, we also explore the application of Prolog for deducing facts from a formal specification of patterns in Alencar et al. (Alencar, Cowan, Dong, & Lucena, 1999).

While each design pattern needs to be instantiated when it is applied in a system, it may also be integrated with other patterns to solve multiple design problems. It is interesting to know whether the instantiation and integration processes are commutative. Proving the conditions that these processes are commutative is important because it can save a lot of time of the designers on trial-and-error. In this way, we are able to predict the possible outcome of a design and to disclose potential problems. The commutability problem has been explored systematically under our formal model in Dong et al. (2007b).

Evolution

The evolution process of design patterns has been initially studied in Alencar et al. (1999), where Prolog is used to capture the structural evolution processes of design patterns. The structural aspect of a design pattern is described in terms of Prolog facts. Thus, the evolution of a design pattern application can be achieved by the addition or removal of new or old Prolog facts.

While there are many different ways to evolve design patterns, we classified them into two-level transformations, the primitive level and pattern level, in Dong et al. (Dong, Yang, Lad, & Sun, 2006b). The primitive level transformations include the addition/removal of an object-oriented modeling element, such as class, attribute, operation, association, generalization, aggregation, composition, realization, dependency. The pattern level transformations are a group of primitive level transformations that reappear in many design patterns. We categorized five pattern-level transformations:

1) simple addition/removal of an independent class and the corresponding relationships between this class and the classes in the original pattern;
2) addition/removal of one independent class with attributes and/or operations and the corresponding relationships between this class and the classes in the original pattern;
3) addition/removal of an attribute/operation in several classes consistently;
4) addition/removal of a group of correlated classes;
5) addition/removal of a group of classes and some attributes or operations in the classes involved in the original pattern instance.

With this classification of the evolution processes of design patterns, we are able to automate these evolutions with tool support. We used XMI to describe our two-level evolutions. Using an XMI file processor, design pattern evolutions can be automated by transforming from the original UML model of a design pattern to the destination UML model of the pattern. In particular, we explored two main model transformation techniques, XSLT and QVT, to automate the evolution processes.

By semiautomating the evolution process, our tool provides the following features: first, analyzing the legacy code and presenting in a visible manner the pattern-related system pieces that can be evolved and the possible evolutions for each system piece; second, when certain evolution is selected, input fields for the required information are

displayed to ensure no missing information and the integrity for the evolution; and third, ensuring the consistency by facilitating the reasoning.

Visualization

Our research of design pattern visualization is a UML-based approach (Dong, Yang, & Zhang, 2007c). We have extended the UML with a new profile for design pattern that defines new stereotypes (PatternClass, PatternAttribute, and PatternOperation) for tracking design patterns in UML diagrams. Each stereotype may be attached by a tagged value: role@name[instance]. The pattern-related constraints for stereotypes are defined based on OCL. These new stereotypes and tagged values are attached to a modeling element to explicitly represent the role the modeling element plays in a design pattern so that the user can identify the pattern in a UML diagram. Based on this profile, we also develop a Web service (tool), called VisDP, for explicitly visualizing design patterns in UML diagrams based on coloring and mouse movement. In this way, our tool can hide all pattern-related information and allows the user to visualize design patterns on demand. All pattern-related information is displayed only when requested.

Discovery

We propose a novel approach based on matrix and weight to discover design patterns from source code (Dong, Lad, & Zhao, 2007a). In particular, the system structure is represented in a matrix with the columns and rows to be all classes in the system. The value of each cell represents the relationships among the classes. For each specific relationship, there is a unique prime number associate with it. For example, the "Generalization" relationship can be prime number 2, and "Aggregation" can be prime number 3. The cell value for any two classes is the multiplication of each associated prime to the power of occurrence of the relationship. If two classes have both the "Generalization" and "Aggregation" relationships, the cell value is $2^1 \times 3^1 = 6$.

After we get the matrix representation of the system, we can apply direct matching method to find the pattern instance. The structure of each design pattern is also represented in another matrix. The discovery of design patterns from source code becomes matching between the two matrices. The direct matching results of the structural analysis may include false positive instances due to missing behavioral analysis. Our approach may proceed to check back the XML files or directly into the source code for behavior characteristics. Some patterns may be hard to distinguish since they have the same structural and behavioral characteristics. In such case, our approach also analyzes the semantic information of the pattern instances, like naming convention. We automated the structural, behavioral, and semantic analyses in our DP-Miner tool (Dong et al., 2007a).

We also apply template matching method to pattern discovery (Dong, Sun, & Zhao, 2008). The basic idea is to calculate the normalized cross-correlation value of two vectors f and g. Normalized cross correlation defines the $cos\theta$ value, where θ is the angle between vector f and g. The maximum value is 1 when f and g is an exact match, that is, $\theta = 0$. A two-dimensional matrix can be flatted into one-dimensional vector by appending the following rows values to the first row. If two matrixes are similar to each other, we are expecting to see a small angel between the two flatted vectors, in other words, a high normalized cross-correlation value. Our template matching approach encodes both pattern and system knowledge into two overall matrixes, and calculates their similarity score by cross correlation. We also implement a Web-based tool to facilitate the template matching for pattern recovery. The advantage of template matching approach is that it cannot only find the exact matches of pattern instances, but also identify their possible variants.

FUTURE TRENDS

Our future direction on formalization is to use our formal model and its derivation methodology in security-related applications, where the correctness of pattern operations is vitally important to the completeness of a successful system. We are also interested in combining the use of formal derivation together with model checking, to grasp a deep understanding of system properties, and gain more confidence on the system correctness.

We will characterize the constraints of evolutions of each design pattern, and provide techniques and tools for checking such constraints after evolutions. In addition, we are investigating the model transformation techniques based on other techniques to improve our current approach.

Our research on visualization can be extended from design patterns to architectures. We are interested in architecture visualization that can explicitly display critical architecture information in large software architecture.

Applying machine learning and data-mining methods are future trends for pattern discovery. In addition, we will continue to further optimize our tool for better performance. Furthermore, pattern discovery techniques may be also extended to architectural pattern discovery.

CONCLUSION

In this chapter, we present the research issues related to design patterns. These issues range from theory to practice,

including formalization, evolution, visualization, and discovery of design patterns. We discussed the research problems related to these issues and describe the existing solutions to these problems. In addition, we introduced our formal and automated engineering solutions to these problems. Future research directions are also pointed out. Design patterns are good designs that are at the heart of software development. Research work on software design is critically important to the success of software systems.

KEY TERMS

Design Patterns: Design patterns represent solutions to problems that arise when developing software within a particular context. Design patterns capture the static and dynamic structure and collaboration among key participants in software designs.

Design patterns are generic design pieces that need to be instantiated before uses. The instantiation of a design pattern describes the process of applying generic design pieces into a system design.

The integration of design patterns describes the process of composing multiple design patterns to solve a number of design problems. Design patterns can be integrated by overlapping common parts from different patterns or adding new relationships between parts from different patterns.

The formalization of design patterns is to apply rigorous methods to specify design patterns or to verify their properties. These formal methods include logic-based and process-based methods.

The evolution of a design pattern is a process to add or remove design elements to/from existing design pattern applications in a software system. It takes place when new requirements, platforms, technologies, or environments change and therefore software system need to be adapted to such change.

The visualization of design pattern provides techniques and tools for explicitly visualizing the instances of design patterns applied in a large software system design. These visualization techniques and tools can help software designers for tracing, identifying, and checking design patterns in the software system design, and making right design decision of applying design patterns.

Design pattern discovery techniques are used to recover design pattern instances applied in existing source code. It becomes a key issue for many research areas, such as reverse engineering and code refractory, because it helps for program comprehension and design visualization.

Designing Agents with Negotiation Capabilities

Jana Polgar
Monash University, Australia

SOFTWARE AGENTS TODAY

Agents are viewed as the next significant software abstraction, and it is expected they will become as ubiquitous as graphical user interfaces are today. Agents are specialized programs designed to provide services to their users. Multiagent systems have a key capability to reallocate tasks among the members, which may result in significant savings and improvements in many domains, such as resource allocation, scheduling, e-commerce, and so forth. In the near future, agents will roam the Internet, selling and buying information and services. These agents will evolve from their present day form - simple carriers of transactions - to efficient decision makers. It is envisaged that the decision-making processes and interactions between agents will be very fast (Kephart, 1998).

The importance of *automated negotiation systems* is increasing with the emergence of new technologies supporting faster *reasoning engines* and mobile code. A central part of agent systems is a sophisticated reasoning engine that enables the agents to reallocate their tasks, optimize outcomes, and negotiate with other agents. The *negotiation strategy* used by the reasoning engine also requires high-level inter-agent communication protocols, and suitable collaboration strategies. Both of these sub-systems – a *reasoning engine* and a *negotiation strategy* - typically result in complicated agent designs and implementations that are difficult to maintain.

Activities of a set of *autonomous agents have to be coordinated*. Some could be mobile agents, while others are static intelligent agents. We usually aim at decentralized coordination, which produces the desired outcomes with minimal communication. Many different types of *contract protocols* (cluster, swaps, and multiagent, as examples) and *negotiation strategies* are used. The evaluation of outcomes is often based on marginal cost (Sandholm, 1993) or game theory payoffs (Mass-Colell, 1995). Agents based on constraint technology use complex search algorithms to solve optimization problems arising from the agents' interaction. In particular, coordination and negotiation strategies in the presence of incomplete knowledge are good candidates for constraint-based implementations.

SELECTED NEGOTIATION AND REASONING TECHNIQUES

Negotiation space is determined by two components: *negotiation protocol* and *negotiation strategy*. The *negotiation protocol* defines the rules of behavior between the participants in terms of interactions, deals, bidding rules, temporal constraints and offers, as components of the protocol. Two agents must first agree on the negotiation protocol before any interaction starts.

The *negotiation strategy* is a specification of the sequence of actions the agent intends to make during the negotiation. Strategies should be compatible with the negotiation protocol. The focus of any negotiation strategy is to maximize outcomes within the rational boundaries of the environment. The classification of negotiation strategies is not an easy task since the negotiation strategy can be realized by any algorithm capable of evaluating outcomes, computing appropriate actions, and following the information exchange protocol.

The *negotiation mechanism* is the actual implementation of negotiation strategy and negotiation protocol. This field is evolving fast, with emergence of new agent platforms, wireless encounters and extended mobility.

Negotiation is a search process. The participants jointly search a multi-dimensional space (e.g., quantity, price, and delivery) in an attempt to find a single point in the space at which they reach mutual agreement and meet their objectives. The *market mechanism* is used for many-to-many coupling or interactions between participants. *Auctions* are more appropriate for one-to-many negotiations. The market mechanism often suffers from inability to efficiently scale down (Osborne, 1990) to smaller numbers of participants. On the other hand, one-to-many interactions are influenced by strategic considerations and involve integrative bargaining, where agents search for *Paretto efficient* agreements (tradeoffs).

NEGOTIATION STRATEGIES

Analytical Approach (Game Theory)

The principles of bargaining and negotiation strategies in multiagent systems have attracted economists. Early foundations and mathematical models were investigated by Nash (1950), and the field is still very active. The *game theory* is a collection of analytical tools designed to understand and describe bargaining and interaction between decision makers. Game theory uses mathematical models to formally express real-life strategies (Fudenberg, 1991; Osborne, 1994).

The high-level abstraction allows the model to be applied to a variety of situations. The model places no restrictions on the set of actions available to the player. With regard to mathematical models, there already exist many sophisticated and elaborated strategies for specific negotiation problems. The Contract Net Protocol (CNP) (Sandholm, 1993; Smith, 1980) represents the model of decentralized task allocation where agents locally calculate their marginal costs for performing sets of tasks. The pricing mechanism in Sandholm (1993) generalizes the CNP to work for both cooperative and competitive agents. In Zeng (1996), bilateral negotiation based on the Bayesian method is presented. It demonstrates the static nature of the model. The learning effect is achieved by using dynamic updates of a knowledge base, which is consulted during the negotiation process.

Most of the studies assume perfect rationality (flawless deduction, marginal costs are computed exactly, immediately and without computational cost), and the infinite horizon of strategic bargaining. These are not realistic assumptions. More advanced studies deal with coalition formation and negotiation strategies in the environment of multiple self-interested or cooperative agents with bounded rationality (Sandholm, 1993) and bargaining with deadlines.

Analytical approach has the advantage of stable and reliable behavior. The main disadvantage is the static nature of the model, resulting in potential predictability of the outcomes. The other problems are associated with the notion of perfect rationality.

Contracts in automated negotiations consisting of self-interested agents are typically designed as binding (impossible to breach). In cooperative distributed problem solving, commitments are often allowed to be broken based on some local reasoning. Frequently, the protocols use continuous levels of commitment based on a monetary penalty method (Sandholm, 1993). Unfortunately, the inflexible nature of these protocols restricts an agent's actions when the situation becomes unfavorable. The models that incorporate the possibility of decommitting from a contract with or without reprisals (Sen, 1994; Smith, 1980) can accommodate some changes in the environment and improve an agent's status. However, all of these protocols are somewhat restricting with respect to evolving, dynamic situations.

Evolutionary Strategies

With *evolutionary strategies*, the data used as the basis for negotiation, as well as the algorithm operating on the data, evolve. This approach provides more efficient learning, supports the dynamics of the environment, and is adaptable. However, only a few implementations have been attempted, and these have been of only simple negotiation strategies (Aridor, 1998). *Genetic algorithms* are probably the most common techniques inspired by evolution, in particular by the concepts of natural selection and variation. The basic genetic algorithm is derived from the hypothesis that the candidate solutions to the problem are encoded into "chromosomes". Chromosomes represent a solution or instance of the problem hand encoded into a binary string. The algorithm then operates on this binary string. It begins with a randomly generated set of candidate solutions. The set of candidate solutions is generated as a random string of ones and zeroes. Each chromosome is evaluated and the fitness of the chromosome could be the value of the objective function (or the utility if we want to maximize the outcome). A new population is created by selecting individuals to become parents. A thorough description of the genetic algorithm approach can be found in Goldberg (1989).

A very large amount of research has been carried out in the application of evolutionary algorithms to situations that require decisions. Examples include coalition games, exchange economies, and double auctions. This approach was inspired by the concept of variation and natural selection. The intelligent agents are modeled using classifier systems to select decisions. Although the recent research shows that multiagent systems of classifiers are capable of learning how to play *Nash-Markov equilibrium*, the current limitations of computational resources and the instability of "home-grown" implementations significantly constrain the nature of the strategies. The important question is what design and implementation techniques should be used to ease this conflict and to provide the resources required for genetic learning to operate in an unrestricted way. It is believed that the ability of agents to learn simple games would be beneficial to electronic commerce.

Constraint Agents

The potential of constraint-based agents is still to be fully realized and appreciated. One of the possible frameworks for constraint-based agents is outlined in Nareyek (1998). This framework considers agents as a means for simplifying distributed problem solving. An agent's behavior and the quality of solutions depend on the underlying action-task planning system. The recent results with some constraint planners and constraint satisfaction problems (CSP) indicate the potential advantages of this approach.

Agents operating with only partial knowledge of the surrounding environment are prime candidates for the implementation of reasoning using constraint solvers. Agents can share and exchange knowledge in a distributed fashion. The suggestion-correction process used in negotiation strategies corresponds to mapping constraint satisfaction problems to search algorithms and heuristics (Tsang, 1993). The planning and scheduling systems can be treated as CSPs that allow the use of constraint solvers to support the planning activity of an agent. However, similar to analytical tools, constraint solvers represent static models of CSP. In order to achieve flexibility in the decision-making process, the solver has to be able to incorporate an agent's essential characteristics:

Reactive behavior is characterized by the agent's ability to absorb new information and restrict or relax its actions. When constraint solvers face the relaxation of constraints, they recompute the entire problem. The relaxation in constraint planners and schedulers nearly always results in reduced stability and possibly reduced quality of solutions. Despite the recent implementation of constraint solvers in graphical applications (Borning, 1995; Sadeh, 1995), with real-time computation and stability, the constraint relaxation and adaptive behavior still represent some difficulties for practical applications.

An agent's *rational behavior* and fast reaction to the changes in its environment is difficult to support with constraint solvers. Some scheduling systems incorporate this idea and extend or replace deliberative planning with behavior rules (ILOG, 1996). The majority of existing constraint solvers compute the search for solutions off-line. An approach to eliminate this problem is the development of an anytime algorithm (Zilberstein, 1995) and constraint hierarchies (Zanden, 1996). Some CSPs are suitable for iterative local search techniques, such as annealing, taboo search or genetic algorithms (Kautz, 1996). Additional information on suitability can be found in Tsang (1993).

Representation of time in traditional planning systems is based on Allen's model of temporal relations (Allen, 1985). This representation does not seem to be suitable for multi-agent interaction with complex temporal relationships and commitment protocols. Problems arise with respect to concurrency and events that last over a period of time.

Social abilities mean interaction, negotiation, coordination, and/or cooperation among agents. A language or interaction protocol typically supports these social skills. The ultimate goal of cooperation and coordination is to reach a globally optimal solution independent of the language or protocol used. If we map the cooperation goals into distributed problem-solving strategies and let each agent play the role of a cooperating computational unit instead of an autonomous negotiator, it is then possible to deploy distributed constraint satisfaction problem-solving strategies.

Multiagent solutions to the distributed constraint problems require new types of design frameworks based on replaceable components that can accommodate the local autonomy of agents, several negotiation strategies, cooperative problem solving, online search for solution, and support for an agent's rational behavior.

Agent design must accommodate static agents as well as trends in mobile agents. The lightweight architecture required for mobile agents, and an efficient and flexible negotiation strategy, are not mutually exclusive. The main issue is to provide a framework that guarantees that the negotiating agent is not overloaded with the complex intelligence that may not be used. We see an agent as a lightweight core with the ability to "borrow" the intelligence it requires from the hosting environment.

The major problem with this component-based framework in which one or more constraint solvers are used as plug-in components arises from the difficulties associated with the description of the constraint satisfaction problem. The representation of the problem can be either under-constrained or over-constrained. In either case, the agent is dealing with incomplete knowledge and it cannot determine which of the generated solutions is optimal and suitable to use in further negotiation.

One of the most important criteria used to judge constraint solvers is their performance. In order to provide reactive and pro-active behavior, it is important for the solver to generate the solution quickly enough to maintain responsiveness. This becomes more difficult to achieve as the number of constraints and variables becomes larger.

A pre-built constraint solver may be able to maintain constraints efficiently. However, declarative definitions of constraints are difficult to use in high-level agent building tools.

There has been very little work in incorporating constraint solvers into reasoning and negotiation strategies of agent systems. The slow acceptance of constraint solvers seems to have been caused by four reasons:

1. Many constraint solvers only support a limited range of constraints.
2. It is difficult to understand and control constraint solvers. When the programmer sets up a set of constraints, it may not be obvious how the constraint solver will maintain them.
3. If the search space is large then online performance of constraint solvers may not be satisfactory for some application domains (e.g., Eaton, 1997).
4. Multi-agent systems are represented by highly distributed search space (distributed constraint optimization problems (DCOP)).

DCOP have been considered an important subject of research for multi-agent systems and multi-agent cooperative mediation (Mailler & Lesser, 2004). DCOP aim at finding optimal assignment to a set of variables dispersed over a

number of agents that have some interdependencies. So far, the descriptions of the problem proposed include distributed partial constraint satisfaction problem (Hirayama & Yokoo, 1997), distributed valued constraint satisfaction problem (Lemaitre & Verfaillie, 1997), and DCOP (Yokoo & Durfee, 1991). Typical problem with these asynchronous protocols is the exponential increase in communication. The protocol suggested in Mailler and Lesser (2004) allows the agents to overlap the context used for their local decision making. During the mediation session, the mediator agent computes a partial solution and recommends the value assignments to other agents.

CONCLUSION AND FUTURE TRENDS

Agents are fairly complex and ambitious software systems. They will be entrusted with advanced and critical applications, such as network administration, database and application monitoring, workflow/business process support, and enterprise integration. As such, agent-based systems must be engineered with valid software engineering principles and not constructed in an ad hoc fashion.

Analytical strategies are tools based on a static mathematical model to evaluate outcomes and generate appropriate action. With *evolutionary* or *genetic approaches*, the learning process is more effective and models are adaptable. The advances in *constraint technology* enable the design and implementation of planning and scheduling tasks to be treated as constraint satisfaction problems. The agent concept then can be used to support dynamic adaptation and collaboration of local or distributed problem-solving modules.

Design and implementation of any reasoning strategies and collaboration protocols can lead to complex systems, and these issues can also lead to computer code that is difficult to maintain. The protocols of interaction are complicated and they typically have many levels or states. If a reasoning engine is very large and complex, it restricts and slows an agent's mobility, rationality, and real-time responsiveness. In recent years, patterns of agent collaboration and negotiation, and some useful components and architectures have emerged. Reusable components and generative patterns can greatly improve the quality of agent designs and implementations.

Any agent, and mobile agents in particular, should have the capability to adapt their negotiation strategy and protocol according to the tasks at hand. In order to match tasks with the appropriate negotiation and collaboration strategies, the agent should have the ability and the means to select a negotiation strategy as a component and then "plug it in" for use.

Nwana (1998) discusses the contradiction between the research in agent coordination and reasoning, and the reality of implementing real applications. He suggests that we should continue with "borrowing and consolidation" using already established AI work. This evolutionary path requires adaptable design techniques to support the trends in AI. Instead of building specific negotiation strategies and protocol cores for each problem domain, we build agents with robust, adaptable core capabilities. The agents' negotiation strategy and protocols are then components or pattern-based building blocks that are "borrowed" and matched with the task at hand.

Future trends in the design of negotiating agents will undoubtedly track those in software engineering in general. Interesting and valuable future developments are expected to appear in the areas of separation of concerns and aspect-oriented programming (AOP). Object-oriented techniques, components and patterns have revolutionized software engineering. However, as software applications get more ambitious and complicated, object technology reaches its limits, especially due to its inability to address behavior and functionality that crosscuts an object hierarchy. Research completed by Kendall (1999) has considered how the separation of concerns and AOP can be used to improve the quality of agent designs. Role modeling is another key area for future research, and this area is also detailed in Kendall (1999).

KEY TERMS

Agent: A program designed to provide specialized and well-defined services. An agent can be *static* – executing on the computer where it was installed, or *mobile* – executing on computer nodes in a network.

Bayesian Method: Means of quantifying uncertainty, based on the probability theory. The method defines a rule for refining a hypothesis by factoring in additional evidence and background information. It uses results of previous events to predict results of future events.

Evolutionary Game Theory: Study of equilibria of games played by population of players where the "fitness" of the players derives from the success each player has in playing the game. It provides tools for describing situations where a number of agents interact. Evolutionary game theory

improves upon traditional game theory by providing dynamics describing how the population will change over time.

Genetic Algorithm: Class of algorithms used to find approximate solutions to difficult-to-solve problems, inspired and named after biological processes of inheritance, mutation, natural selection, and generic crossover. Genetic algorithms are a particular class of evolutionary algorithms.

Negotiation Mechanism: The actual implementation of negotiation strategy and negotiation protocol.

Negotiation Strategy: Specification of the sequence of actions the agent intends to make during the negotiation.

Paretto Efficient Agreement: State of things in which no player (in game theory) is worse off than the others. It typically refers to the distribution of resources. The agreement could lead to cooperation of players.

Reasoning Engine: A computer program that enables the agents to negotiate with other agents and that involves negotiation strategy.

Designing Learner-Centered Multimedia Technology

Sandro Scielzo

Haydee M. Cuevas
University of Central Florida, USA

INTRODUCTION

The ubiquitous use of information technology (IT) promotes a fast-paced and dynamic training environment with enormous potential for performance increases in a variety of domains. This reality has many important ramifications, including how best to incorporate multimedia IT into computer-based training (CBT). Well-designed CBT offers us tremendous potential to effectively and efficiently train the workforce, foster learning in academic environments, and improve performance over and above what is currently achieved. Following a learner-centered design approach, in this article, we present an in-depth look at the use of multimedia CBT, as it relates to aptitude-treatment interactions; that is, how various CBT designs can differentially interact with individual learner aptitudes, such as spatial and verbal ability, to influence training outcomes. The goal of this article is to emphasize the importance of learner-centered design when developing multimedia computer-based instructional material for the growing needs of many sectors of society.

BACKGROUND

CBT has long been touted as a cost-effective and efficient medium for instruction due to, in part, IT availability (e.g., McDermott, 2006). Over the past few decades, a number of theoretical frameworks have flourished, aimed at understanding how multimedia information is processed and how best to design CBT to maximize the amount of information retained from such instruction. For example, Paivio's (e.g., 1971) Dual Coding Theory underscored the importance of using multiple compatible modalities—such as text and images, which are parallel-processed within human working memory—in order to a) generate a strong encoding of processed information, and b) increase memory retrieval of the encoded information when compared to traditional methods employing only one modality (e.g., simply text, narrated lectures, etc.). However, the technological aspect of multimedia training was not yet developed and IT was still in its infancy in relation to CBT. Although IT was not yet widespread, the relevance of Paivio's theory to current CBT design is the focus on the human's capacity for processing multimodal information. Mayer (2001) later espoused this concept in his *Cognitive Theory of Multimedia Learning*, specifically addressing the manner in which CBT multimedia information is processed. Mayer and colleagues devised a number of learner-centered principles guiding CBT instructional design (e.g., Mayer, 1999, 2001) with the goal of helping society capitalize on the ubiquity of IT (e.g., Galvin, 2003; Najar, 1998).

The importance of following learner-centered design principles and guidelines becomes even more paramount for maximizing the potential of IT in a CBT environment. This emerging focus on learner-centered CBT design illustrates a crucial balancing act: on one hand, CBT design needs to capitalize on IT's power and availability; on the other hand, human cognitive limitations need to be considered when developing complex CBT. However, current learner-centered CBT design may be insufficient when individual learner aptitudes come into play. To further improve the efficiency of CBT design, it is pivotal to understand how individual learner characteristics can differentially influence training outcomes (e.g., Mayer, 2001). With this objective in mind, in this article, we present an empirical examination of the interaction between CBT design and individual aptitudes in relation to their impact on the training's learning outcomes and instructional efficiency.

DESIGNING EFFICIENT CBTS: THE MEDIATING ROLE OF INDIVIDUAL APTITUDES

Investigating the influence of specific learner aptitudes, such as spatial and verbal ability, on processing multimedia

information has been an integral component of our research (e.g., Cuevas, Fiore, Bowers, & Salas, 2004; Cuevas, Fiore, & Oser, 2002; Scielzo, Fiore, Dahan, Lopez, & Stafford, 2006; Scielzo, Cuevas, & Fiore, 2005; Scielzo, Fiore, Cuevas, & Klein, 2003). The importance of understanding the complex relationship between individual differences and multimedia information processing offers the opportunity to further refine CBT design guidelines by specifically looking at the manner in which design implementations (treatment) and individual differences (aptitudes) interact. As a result, a more precise learner-centered theory of CBT design can be obtained. Furthermore, evaluating the effectiveness of CBT design requires a number of training outcome measures including (a) assessment of learners' knowledge acquisition, and (b) the instructional efficiency of the CBT program itself, discussed next.

Learner-Centered Computer-Based Training and Assessment

Our approach to assessing learning in CBT utilizes increasingly complex measures of knowledge acquisition—from basic, factual knowledge to more complex integrative knowledge—in order to provide a more complete view of learning as it relates to performance. Our past research investigating CBT design found that the differential effect of training manipulations was often revealed via more complex knowledge assessment measures, that is, only those measures requiring learners to comprehend how various concepts *relate to one another* were able to successfully isolate the effects of training manipulations (e.g., Cuevas et al., 2004; Cuevas et al., 2002; Fiore, Oser, & Cuevas, 2000; Fiore, Cuevas, & Oser, 2003; Fiore, Cuevas, Scielzo, & Salas, 2002; Scielzo et al., 2003).

In addition, instructional efficiency (e.g., Kalyuga, Chandler, & Sweller, 1999; Paas & Van Merrienboer, 1999) has been shown to be an important CBT assessment technique that offers further insight into the effectiveness of varying training manipulations. Instructional efficiency combines standardized measures of knowledge performance and subjective mental workload (perceived cognitive effort during training or performance) to determine overall CBT efficiency; that is, instructional efficiency considers performance levels in relation to the subjective appraisal of how mentally tasking it was to achieve these levels of learning or performance. Specifically, instructional efficiency is a normalized index ranging from -1 to +1, with positive scores indicating higher instructional efficiency (i.e., mental effort exerted is less, relative to the standard effort required to achieve that level of performance) and negative scores indicating lower instructional efficiency (i.e., mental effort exerted is greater, relative to the standard effort required to achieve that level of performance). Baseline (or standard level of efficiency) is represented by zero. Overall, instructional efficiency is an important measure that provides further information to enable instruction system designers to more sensitively distinguish between CBT designs yielding similar levels of performance.

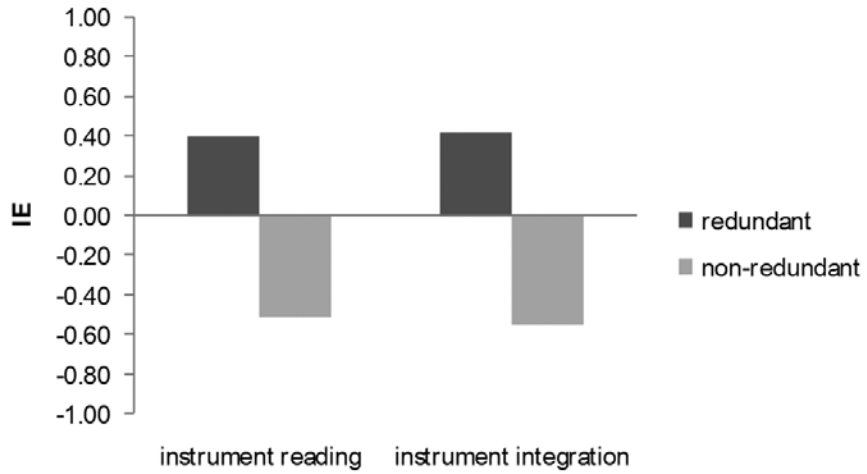
Finally, studies have shown that CBT design manipulations may interact with individual learner aptitudes to influence training outcomes. Aptitude-treatment interactions (see Snow, 1989), in relation to multimedia CBT have been documented to be particularly prominent for spatial (e.g., Chun & Plass, 1997; Mayer, 2001; Scielzo et al., 2006) and verbal (e.g., Cuevas et al., 2002; Chun & Plass, 1997; Mayer, 2001) ability. The next section briefly summarizes empirical findings that more explicitly highlight the mediating role of individual differences on the effect that a given CBT design may have on training outcomes.

Summary of Empirical Findings

Our research on complex multimedia CBT has investigated a number of design manipulations thought to differentially impact training outcomes in terms of knowledge acquisition and instructional efficiency. In our earlier work, individual differences, such as spatial and verbal ability, were covaried out to evaluate the more general effects of design manipulations. For example, when looking at the influence of the differential combination of modalities in a dual-coding paradigm (i.e., presenting one modality vs. two modalities), we found that the beneficial effects of including graphical representations to illustrate concepts presented in text extended to more complex training paradigms requiring the acquisition and integration of numerous concepts over multiple training modules (i.e., training rudimentary aspects of the principles of flight; Fiore et al., 2003). Specifically, results indicated that multimedia CBT combining text and graphical representations supported comprehension and integration in a complex training paradigm. Importantly, by covarying out spatial ability, this effect was isolated using a measure of knowledge integration requiring the ability to understand the relationship of inter-related concepts presented across multiple training modules. These findings, in part, suggest that dual-coding effects (i.e., the claim that encoding instructional material via two modalities improves information retrieval when compared to encoding material via only one modality) do extend to more complex multimedia CBT, but that these effects may only be diagnosable when using measures designed to assess the integration of concepts (Fiore et al., 2003; see also Cuevas et al., 2002).

Expanding upon this line of research, we investigated the effects of differential combination of modalities in a temporal paradigm (i.e., presenting modalities simultaneously or sequentially) and found that the principle of redundancy (Mayer, 2001), indicating that combining narration, text and animations simultaneously is detrimental on knowledge performance due to high levels of workload, did not extend

Figure 1. Instructional efficiency (IE) scores based on instrument reading and instrument integration measures



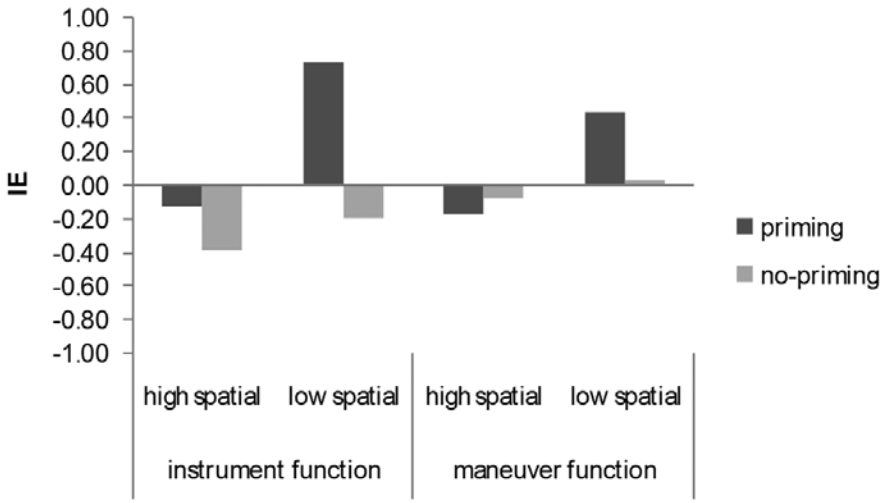
to more complex training paradigms such as the domain of aviation (Scielzo et al., 2003). Specifically, results indicated that multimedia CBT combining text, narration and animations can favorably enhance performance when the domain studied is complex. As in our earlier work, this effect was isolated using more complex measures of knowledge integration (instrument reading and instrument integration). These findings suggest that the principle of redundancy (i.e., the claim that multimedia CBT redundancy is detrimental to knowledge acquisition) may need to be revised to explain the differential training outcomes found across domains, ranging from relatively simple (e.g., Kalyuga et al., 1999, 2004) to relatively complex (Scielzo et al., 2003).

In terms of instructional efficiency, unpublished results of this study analyzed for this chapter revealed a similar trend, with a CBT redundant format yielding greater instructional efficiency (for details on the experimental methodology, see Scielzo et al., 2003). Specifically, univariate statistics showed a significant effect of redundancy on the two more complex measures of knowledge integration: instrument reading, F (1, 32) = 9.07, p = .005 (partial η^2 = .22), and instrument integration, F (1, 32) = 6.92, p = .013 (partial η^2 = .18) [a]. Both measures indicated that CBT instruction with three modalities (text, narration, and animations) was more efficient than instruction with two modalities (narration and animations) (see Figure 1).

In later research, we directly examined the mediating effect of individual differences in learner aptitudes on training outcomes. For example, Scielzo et al. (2005) investigated the effect of a training intervention (embedded content-free prompts asking learners to elaborate on the information presented) on overall retention of the training material and the CBT's instructional efficiency within the context of a dynamic distributed decision making task. Overall, the study found that the training intervention's effect was differentially affected by participants' verbal ability. Specifically, incorporating prompts into the CBT (e.g., asking participants to complete content-free question stems such as "*How would you use_____to_____?*") significantly improved retention of the information presented for participants with low verbal ability. No difference was found for participants with high verbal ability. In addition, when evaluating outcomes for participants with low verbal ability, only the CBT designed with the training intervention yielded positive instructional efficiency scores (i.e., higher performance was achieved with less perceived cognitive effort). When evaluating outcomes for participants with high verbal ability, the CBT's instructional efficiency was consistently positive across both training conditions. These results illustrate the importance of considering individual differences in learner aptitudes such as verbal ability in CBT design by showing that low-verbal participants may benefit from training manipulations that have little or no effect on high-verbal participants.

In another study using our "principles of flight" training paradigm, Scielzo et al. (2006) investigated the effect of text priming in a temporal context and the potential mediating effect of spatial ability. Priming was achieved by first showing textual information (written text), followed by a verbal narration with a respective visual animation. Priming was compared to a no-priming condition that presented the three modalities (text, narration, and animation) simultaneously. Overall, results showed that text priming yielded significantly higher performance than nonpriming for trainees whose spatial ability was low, while high spatial ability trainees favored from the nonpriming training implementation. Further analysis of this study's results, not yet published, examined

Figure 2. Instructional efficiency (IE) scores based on instrument function and maneuver function measures



the effects of priming vs. nonpriming on instructional efficiency[b]. Results showed a strong, but nonsignificant, trend in the expected direction on the two more complex knowledge integration measures (see Figure 2). Although not significant, the importance of this study similarly resides in highlighting the important role of aptitude-treatment interactions, and how different training interventions can lead to opposite results when factoring in the mediating effect of individual differences in learner aptitudes.

FUTURE TRENDS

The issues discussed in this chapter lead to broad theoretical and practical implications for future research. Theoretically, researchers need to more precisely define the mediating effects of individual differences in learner aptitudes (e.g., verbal and spatial ability) on CBT design and training outcomes to better understand the learning and knowledge acquisition process. Once a stronger theoretical foundation is established, a number of practical implications to address individual differences with learner-centered CBT design can emerge. For example, *intelligent tutoring systems* (e.g., Akras & Self, 2002) can be incorporated into CBT design to automatically adapt the instruction to match trainees' individual strengths and limitations. Another promising approach focuses instead on developing training aimed at improving specific learner aptitudes. For example, Rehfeld (2006) has shown that spatial ability can be improved via mental rotation training (see also Kass, Ahlers, & Dugger, 1998). Overall, future developments in CBT design will need to address individual differences to further their potential in terms of knowledge gains and overall instructional efficiency.

CONCLUSION

The overall objective of this article was to illustrate the important role of individual differences in training outcomes within CBT environments. The research findings presented in this article showed how learner aptitudes interact with CBT design manipulations to influence outcomes on the measures that are more indicative of higher levels of knowledge acquisition. Our findings also highlighted the relation between individual differences and the training program's instructional efficiency, showing that trainees with lower aptitudes benefited more from CBT learner-centered design (i.e., greater performance achieved with less perceived cognitive effort). Overall, the findings reported in this article support the need to better utilize information technology to design more effective computer-based training programs that can flexibly adapt to individual differences in learner aptitudes, and thereby, maximize overall learning outcomes.

Snow, R. (1989). Aptitude-treatment interaction as a framework for research on individual differences in learning. In P. Ackerman, R. J. Sternberg, & R. Glaser (Eds.), *Learning and individual differences*. New York: W.H. Freeman.

KEY TERMS

Aptitude-Treatment Interaction: The interaction of learners' individual differences (i.e., aptitudes) with experimental manipulations (i.e., treatment). In the context of computer-based training, aptitude-treatment interactions illustrate the differential effect of design manipulations when factoring-in specific learners' aptitudes (e.g., verbal and spatial ability).

Cognitive Theory of Multimedia Learning: A theory of multimedia information processing for computer-based

training paradigms. This theory underscores the importance of supporting the three fundamental cognitive processes leading to learning: information selection, organization, and integration.

Computer-Based Training: The use of computers as a medium to convey instructional material. Typically, computer-based training replaces the instructor and allows learners to interact with multimedia content in a self-paced environment.

Dual-Coding Theory: A theory of learning that indicates the benefit from learning via two noncompeting modalities (in terms of accessing the same attentional resources) such as text and images. The dual-coding benefit refers to the increased probability of information retrieval when compared to encoding information with only one modality.

Individual Differences: Learners variability in terms of knowledge, skills, and attitudes. In a computer-based training environment, individual differences play a potential mediating role between training manipulations and learning.

Instructional Efficiency: An index of training efficiency that combines learners' subjective appraisal of mental workload in the training environment with learners' performance on knowledge testing. The instructional efficiency index ranges from -1 to +1, with negative scores indicating lower instructional efficiency, and positive scores indicating higher instructional efficiency. Baseline instructional efficiency is indicated by zero.

Learner-Centered CBT: A computer-based training interface designed to account for learners' individual differences by either adapting to the learners' aptitudes, such as intelligent tutoring systems, or by providing an interface designed to accommodate a specific learner aptitude (e.g., low verbal or spatial aptitude).

ENDNOTES

[a] The design was a 2 temporal (simultaneous vs. sequential) x 2 redundancy (redundant vs. nonredundant) between subjects design, with spatial ability as a covariate. Forty-three participants were trained on the principles of flight. GLM univariate analyses of covariance were used with an alpha level of .05.

[b] The design of the study was a 2 priming (priming vs. no-priming) x 2 spatial ability (high vs. low) between subjects design. Twenty-eight participants were trained on the principles of flight. GLM univariate analyses of covariance were used with an alpha level of .05 (see Scielzo et al., 2006).

Designing Web Systems for Adaptive Technology

Stu Westin
University of Rhode Island, USA

INTRODUCTION

For over a decade the term *digital divide* has been used to refer to discrepancies between various population segments in terms of access to information technologies. The digital divide is in opposition to the ideal of *equality of access* in which all citizens are afforded uniform access to information and information technology. Discussions on this topic seem to most often focus on such factors as race, income, education, geography, and the like. There is, however, a significant and growing group of "digital have-nots" that is frequently overlooked. This group comprises individuals who have some form of physical, sensory, and or mental disability. While the need for full enfranchisement of this group can be effectively argued on legal as well as ethical grounds, it can be shown to make sound business sense as well.

Consider this statistic from the most recent U.S. Census. A startling 21.8% of Americans above the age of 16 have at least one disability that results in a "substantial limitation" of one or more "major life activities." Examples of such disabilities are vision problems (3.5%), hearing problems (3.3%), difficulty using hands (3.0%), and learning disabilities such as dyslexia (1.4%) (U.S. Department of Commerce, 2000, pp. 62-63). Each of these disabilities carries negative consequences regarding accessibility to Web-based resources.

The prevalence of disability increases with age. For example, according to 2005 data, 12.1% of Americans in the age group 16-64 have at least one disability. The percentage jumps to 40.5% when considering those of age 65 and above (U.S. Department of Commerce, 2006, Table S1801). Much of this dramatic increase in occurrence is due to declining vision, hearing, and dexterity (Bergel, Chadwick-Dias, & Tullis, 2005; Fox, 2004; Loiacono, McCoy, & Chin, 2005; Steinmetz, 2006).

The youngest American baby boomers are now in their forties. The average age of the population of the U.S. and of most other developed nations will increase substantially over the next few decades, as will the concomitant prevalence of physical disability (Bergel et al., 2005). This demographic shift is due partly to the post World War II "population bubble," but it is also due to the tremendous increase in life expectancy in modern times (an increase of 30 years since 1900, according to U.S. Administration on Aging statistics) (Mosner & Spiezle, 2003). The segment of the American population comprising individuals of age 50 and above will grow from the current 38% to 47% by the end of the next decade (Moos, 2005).

Also growing dramatically is the average age of the workforce. Workers are delaying retirement for numerous reasons, while the rate at which younger workers enter the workforce is declining (Mosner & Spiezle, 2003). In an increasingly Web-oriented information-based economy, worker productivity hinges on accessibility to Web-based systems. This issue demands more attention as the age of the workforce (read prevalence of physiological impairments among workers) increases.

This article considers some of the issues surrounding accessibility to Web systems and services by individuals with imperfect abilities. It is argued that, beyond the moral and legal reasons for accommodating this group, there are numerous advantages for business and commerce that can be achieved.

BACKGROUND

As is the case with all technologies, the design and organization of Web content can greatly impact accessibility of that content by persons with certain physical or mental impediments or disabilities. Consider, for example, those individuals who have even minor mobility or dexterity problems. This might include persons of advanced age, as well as those who suffer from arthritis, rheumatism, Parkinsonism, effects of stroke, or similar maladies. For this group an activity as simple as clicking a particular hot-zone on an image map can be difficult, depending on the size and the complexity of the object. Even activities as common as using the scrollbar to move through the content of a Web page can be troublesome to individuals with motion impairments.

It should be noted that even conditions that are not considered disabling can negatively affect access to poorly designed Web content in certain circumstances. For example, about 8% of males worldwide are color deficient (often called color blindness). The vast majority of these individuals have problems discerning red or green. The prevalence and sever-

ity of this condition often increases with age. A commercial Web page that states *Products listed in red are currently out of stock* may convey little information to the color deficient electronic shopper.

The terms *assistive technology* and *adaptive technology* are used to describe technologies which are intended to help provide independence to disabled individuals. The two terms are often used interchangeably in the literature, but in the case of adaptive technology (AT), the focus is on providing access to products and systems which were initially designed for use by people who are not disabled. The Web is an example of such a system. Adaptive and assistive technologies, when applied to computing and information systems, are sometimes referred to as "electronic curb cuts." This term makes an analogy to the decades-old federally mandated removal of curbs at pedestrian crossing points to facilitate use by persons in wheelchairs.

In the case of the Web, the adaptive technological problems can be particularly vexing because of its stateless, two-tiered (i.e., client/server) architecture. That is, the adaptive technologies reside on the client side, but the Web content can be designed and served with no knowledge of how the AT is configured, or even that such is being used. Consequently, Web content that is designed without regard for such technologies can render the content useless for the end user.

An approach to Web content design that aimed at reducing or eliminating barriers to accessibility, and at facilitating the effectiveness of AT is said to be an *accessible Web design*. Related to this is the notion of *universal design* where the intent is to meet the needs of the broadest range of clients, regardless of their individual abilities, disabilities, circumstances, or environments. In the words of Mates (2006, ch. 2, sec. 2)

The Web page designer addressing universal design and accessibility is more concerned with information dissemination for all, rather than visual appeal for most. When designing the document, an attempt is made to make all the material displayed as accessible as possible, whether it is a menu item, graphic, or video clip. Creating accessible Web pages may not take additional money, just more time and consideration.

Adaptive technology on the Web can be as simple as tweaking your browser settings to display the largest text size, or to specify default colors for text and background. Most current Microsoft products, including IE, provide a set of options aimed at broadening accessibility. In the case of IE the user is able to prevent a Web page from overriding his or her choice of text colors, font styles, or font sizes. There is also an option to force the use of a local (i.e., user supplied) style sheet for rendering the presentation.

Users with poor vision or with learning disabilities, for example, will often configure their browsers to display oversized text in a non-serif style (e.g. Arial) with a high-contrast color scheme (e.g. black on white). Features which might be distracting, such as background images and italic type, may be removed and all text may be displayed in bold style to further enhance contrast. The implication of this with respect to Web content design is that the presentation rendered on the client side may be very different from that which is conceived in the mind of the designer. Any meaning or information that is presented only through color, text style, or the like may be lost. The principles of universal design are aimed at avoiding this.

While the above description of employing AT–modifying standard browser behavior through intrinsic features–is relevant to this discussion, more substantial accommodations are often made through third-party solutions. In this case, hardware or software devices and mechanisms are designed with a specific accommodation in mind. Two common examples of this are large-print access systems and screen-reading systems. These two types of AT are now briefly described within the context of Web-based content so that some of the complexities and special requirements of such systems can be understood. The intention here is to illustrate how the efficacy of such systems is affected by Web content design. A full discussion of third-party AT solutions is beyond the scope of this article.

WEB-BASED EXAMPLE: LARGE-PRINT ACCESS SYSTEMS

Large-print access systems usually comprise a screen magnification software component and may or may not include a special large monitor device suitable for handling the large display image. Large-print access systems are used to accommodate individuals with impaired vision, but with sufficient vision to discern shapes. The systems also are of aid to individuals with certain forms of cognitive or learning disabilities. These systems are expected to become more commonplace as our population ages.

With large-print access systems, the complication with respect to Web content accessibility stems from the fact that the systems can severely distort the visual presentation, and the nature of this distortion can vary substantially. In some cases, the entire page is magnified so there is relatively little geometric distortion, but only a portion of the page may be visible at one time, depending on the size of the display device. In extreme cases only one or two words may be displayed on the screen at a time.

Other software products of this type will enlarge only the textual content but leave graphic content untouched. Note that words contained within images may therefore be unreadable. Still other products will only magnify the area of

the screen that surrounds the mouse pointer, or will magnify an area of the screen and will move the magnified area down the page at a fixed rate. In this latter case, the user is forced to process the information from top to bottom, regardless of the design of the content.

WEB-BASED EXAMPLE: SCREEN-READING SYSTEMS

When a disability is such that large-print technology is unsuitable–say in the case of blindness, severe dyslexia, or literacy problems–a screen-reading system may be employed. The intent of these systems, also known as audio- or speech-output systems, is to allow the user to "listen" to whatever content is presented on the screen. Output is in the form of a simulated voice which is driven by screen-reading software. Screen-reading systems are practical for any computing application where text-based output is generated. When the output moves beyond a pure text presentation of words, the efficacy of the systems can suffer if the information is improperly structured.

In the case of Web applications screen-reading system software relies heavily on punctuation and on the source markup tags to determine how textual content should be presented aurally. For example, proper use of the <H1> and the <H2> tags on a page would be required for the software to accurately interpret content as a primary heading or as a secondary heading. Text size or presentation format would not be a factor in this decision. Similarly, appropriate use of the <UL> tag followed by a series of <LI> tags would be required for the software to present the content aurally as a bulleted list of items rather than as a sequence of paragraphs, each headed with a dot icon. As for graphic elements, for example, charts, icons, animations, background images, button images, and so forth, the screen-reader relies exclusively on the ALT (alternate text) attribute or on the LONGDESC (long description) attribute of the image element.

Designing Web content that will be accurately interpreted by this technology can be exigent. A discussion of the challenges and caveats can be found in Asakawa (2005). In common Web-design practice, validation of Web-based applications usually extends to the point where it is determined that the content is visually correct. Speech-output technology requires that the content be syntactically correct (e.g., just because something appears as a bulleted list when viewed in a browser, doesn't mean that it will be interpreted as such by a screen reader).

A mouse is a visually driven device, so mice are not used with screen-reading systems. All input is provided through the keyboard, and focus is given to individual hyperlinks and form objects with the Tab key. The visual cues that normally guide the sighted user as to the requirements of input or the interpretation of output are totally irrelevant in this environment. It is vital, therefore, that all of the visual guides within Web content be supplemented with commensurate textual information so that equivalent aural guides can be provided by the system.

Graphic elements that are meant to provide information content must be coded differently from those that are intended to provide only visual enhancement. The former group should include tagged alternate text that provides as much of the information content as is practical. The latter group should have a null alternate text description (ALT="") to prevent the screen reader from announcing the presence of an "unspecified graphic element" to the user. Chart and graph entities should include a full summary of the content as a linked, plain text description (LONGDESC attribute or "d-link").

With highly interactive applications, such as those involving e-commerce, it is vital that the traditional visual cues be supplemented with equivalent textual information. The disabled individual will be tabbing through and "hearing" the individual items on an interactive Web form rather than viewing the entire form and configuring or filling in the relevant form objects with the aid of a mouse. The overall demands of the application (e.g., which fields are required and which are optional) as well as the semantic of each individual item (e.g., what is the implication of selecting this checkbox?) must be clearly detailed for the screen-reader software.

DESIGNING FOR AT: STANDARDS AND GUIDELINES

Depending on the situation, accessibility of Web content may be legally mandated. In the U.S., the determining factor is whether the site is within the scope of Section 508 of the Rehabilitation Act of 1973. This section requires that information systems utilized by U.S. Government agencies be accessible to people with disabilities. Both in-house-developed and outsourced systems fall under the purview of Section 508. For the first 25 years of its existence the principles of Section 508 were largely unenforceable and ignored. That changed in 1998 with amendments to the act instituted by President Clinton. The 1998 amendments to Section 508 provided technical standards which are unambiguous and enforceable.

The intent of Section 508 is surely noble. The motivation is to provide equality of access to information resources. The expectation is that federal employees who are disabled, as well as disabled members of the public at large, are to have access to federal information services at the same level as their nondisabled counterparts. Many other nations (e.g., Australia, Canada, England, Portugal) have similar legislation in place (Lazar & Greenidge, 2004).

While Section 508 applies to all information technology systems developed or procured by government agencies,

Subsection 1194.22 has arguably been the biggest burden for agencies. This subsection has to do with Web-based, both Internet and intranet, applications and systems. The difficulty surrounding Subsection 1194.22 is understandable in considering that the accommodations legislated by Section 508 must be available to the general public. The agencies responsible for Section 508 compliance have no control over the hardware or software choices or configurations utilized by the public clients of the Web systems that they host.

Subsection 1194.22 includes 16 specific guidelines (labeled "a" through "p") that must be met for full compliance. §1194.22(a), for example, reads as follows. *A text equivalent for every non-text element* [of the Web content] *shall be provided (e.g., via 'alt', 'longdesc', or in element content*). As another example, §1194.22(c) reads *Web pages shall be designed so that all information conveyed with color is also available without color, for example from context or markup*. The full list of guidelines is available at http://www.section508.gov/index.cfm?FuseAction=Content&ID=12#Web.

Often confused with Section 508 is WCAG (Web Content Accessibility Guidelines). This set of guidelines aimed at reducing barriers to accessibility was introduced in 1999 by the World Wide Web Consortium (W3C) as a part of its Web Accessibility Initiative. This W3C initiative commenced in 1997 and its intended purpose is best described by Tim Berners-Lee in the inaugural press release as follows. "The W3C is committed to removing accessibility barriers for all people with disabilities, including the deaf, blind, physically challenged, and cognitive or visually impaired. We plan to work aggressively with government, industry, and community leaders to establish and attain Web accessibility goals" (World Wide Web Consortium, 1997). Unlike Section 508, however, WCAG is not a legal mandate.

WCAG comprises 14 basic guidelines aimed at ensuring accessibility. An example is Guideline 1 which states *Provide equivalent alternatives to auditory and visual content.* Each of the 14 general principles is accompanied by a set (1-10) of numbered *checkpoints* describing how the guideline would be applied in specific application scenario examples. Each checkpoint is assigned a *priority* from 1 to 3. To denote impact on resulting accessibility, priorities 1, 2 and 3 are ascribed the respective tags *must satisfy, should satisfy,* and *may address*. In terms of WCAG conformance, Web content can conform at one of three levels, as shown in Table 1. The full WCAG specification can be found at http://www.w3.org/TR/WAI-WEBCONTENT/.

The motivations behind the two standards, (WCAG and Subsection 1194.22) are similar. That is, to eliminate barriers to accessibility to Web content. Their orientations differ slightly, however, because Section 508 focuses exclusively on disabilities, while WCAG also recognizes environmental and equipment factors such as noisy and poorly-lit surroundings, and hands-free applications. For this and other reasons, full compliance with one standard does not necessarily indicate full compliance with the other. A detailed comparison of the standards is available at http://www.jimthatcher.com/sidebyside.htm#s508View.

Several automated tools to evaluate accessibility and compliance to standards are available. One of the earliest and most recognized free tools is *Bobby* (now called *WebXACT*, http://webxact.watchfire.com/). A full discussion of such automated tools, including their strengths, limitations, and overall efficacy can be found in Ivory, Mankoff, and Le (2003).

Despite the availability of published standards, and of automated tools to evaluate compliance to those standards, accessible content on the Web remains more the exception than the rule. Depending on the type of Web site, violations of principles of accessibility range between 70-98%, except for college and university sites which fare better (Lazar, Dudley-Sponaugle, & Greenidge, 2004; Loiacono et al., 2005). Even in the case of federal and federal-contractor Web sites, those that are mandated under federal law to be Section 508 compliant, only 23% have been found to meet that legal obligation (Loiacono et al., 2005). Perhaps even more discouraging, Web sites have been shown to actually *decline* in accessibility over time, regardless of the category of site (Asakawa, 2005; Hackett, Parmanto, & Zeng, 2003; Lazar & Greenidge, 2006).

Table 1. WCAG conformance requirements

Conformance Level	Requirements
Level AAA	Web content satisfies all checkpoints of Priority 3 and above.
Level AA	Web content satisfies all checkpoints of Priority 2 and above.
Level A	Web content satisfies all checkpoints of Priority 1.

EMBRACING AT: THE BUSINESS JUSTIFICATION

Whether legally mandated or not, at least partial compliance with Section 508, with WCAG, or with both is a responsible business practice. The case for accessible Web design is easy to make on ethical grounds alone. It is difficult to argue that Web content made available to some should not be made available to all, regardless of ability, disability, or situation. Each step toward further compliance represents a potential increase in reach of an organization's Web-based messages and services. An organization's employees also stand to realize advantages of increased accessibility to Internet and intranet based content in the workplace. This becomes especially pertinent as the workforce ages.

As a side benefit, accessible design practices are known to simplify the structure of Web pages and Web sites much as adhering to accepted software development practices and standards leads to improved software design and performance. The end result of both of these efforts is fewer errors and simplified maintenance, leading to reduced cost.

An additional, and often unexpected, benefit of accessibility guideline compliance is that the design principles greatly facilitate accessibility of Web content by devices and technologies which are unrelated to disability. Examples of these technologies are PDAs, handheld computers, Web-enabled phones, automobile-based PCs, audio browsers, and the like. It turns out that the special requirements of these client-side devices are the same as those of most adaptive technologies; specifically, the requirement that the content be independent from display issues. Still another benefit is that the efficacy of the modified Web content is increased in less than perfect work environments such as conditions of poor lighting, or when using older monochrome or LCD screens.

When the physical cuts in the curbs of roadways were federally mandated decades ago to allow wheelchair access, the general population realized unanticipated benefits. These physical curb cuts also facilitated the use of bicycles, roller blades, baby strollers, shopping carts, and skateboards. Similarly, the "electronic curb cuts" can simplify the use of numerous Web-enabled technologies by the population at large.

Where B2C e-commerce is concerned, the disabled population–one of the largest minorities that exists–represents a potential market niche that is largely untapped or undertapped. Despite the heterogeneity with respect to demographic and disability factors, this market segment exhibits numerous features that should be of interest to e-tailers.

Of all adults who use the Internet, disabled adults spend twice as much time online, an additional 10 hours per week, than the nondisabled (Taylor, 2000). This former group is also substantially more likely (48% vs. 27%) to recognize the Internet as factor that "significantly improves the quality of their lives." The difference becomes more pronounced (56% vs. 6%) when considering individuals 65 and older (Taylor, 2000). Slicing this market segment across other demographic factors reveals additional economic enticements. Granted, in almost all cases, home Internet access, as well as general PC usage is lower among disabled individuals compared to the nondisabled. However, the discrepancy diminishes as both income and education rise (U.S. Department of Commerce, 2000). In other words, it is the wealthiest and the most educated of the disabled population who are in the best position to engage in Web-based commerce.

Considering the age factor, which correlates with the incidence of physical impairment and with reliance on technology accommodation, the numbers present a clear message. The U.S. market segment comprising those of age 50 is currently the fastest growing segment; it will increase from the current 38% to 47% by 2020 (Moos, 2006). Households in this age group currently spend twice as much as younger adults and control $750 billion in discretionary income (Moos, 2006). Furthermore, the sharp growth in interest in online banking and electronic shopping by elders is projected to only increase because this group has been shown to be as enthusiastic as their younger counterparts once they get online (Fox, 2004).

The segment of the population that relies on special accommodation appears, therefore, ready and willing to embrace the B2C e-commerce paradigm. They may be ready and willing, but are they *able*? The answer to this question may depend on the degree to which accessibility features are included in commercial Web sites and Web services. Unfortunately, accessibility in retail and service Web sites is as low as 17% (Loiacono & McCoy, 2004).

FUTURE TRENDS

It is difficult to predict what the future holds for Web content accessibility. Based on clear demographic and cultural trends, the need for special technology accommodation will only increase as the population ages and as the Web becomes more engrained in the fabric of our society. In light of these trends, the current level of conformance among federal (23%) and commercial (17%) Web sites is discouraging at best. This situation is exacerbated by the fact that Web systems show a tendency to decline in accessibility over time. As the intricacies of Web content continue to rise (e.g., advanced multimedia formats) we should expect that it will become increasingly difficult to meet the accessibility requirements of all Web users.

On the positive side, the inclusion of accessibility features in familiar software packages and systems is becoming more and more common. For example, Windows XP contains standard accessibility features such as *StickyKeys* and *SoundSensor* that can be easily toggled on and off to

meet the needs of Web users with diverse abilities. IE can also be easily reconfigured through several accessibility options. Furthermore, latest versions of popular Web development systems, for instance *FrontPage* and *Dreamweaver*, contain functionality that assists in development of accessible Web content. Compliance evaluation systems such as *Bobby* (*WebXACT*) are also becoming more powerful and more popular in the Web-development community. These software trends facilitate accessibility from both the user and the developer end.

CONCLUSION

Beyond the legal obligations that exist, arguments for parity of access to Web-based content by individuals with imperfect abilities are easy to make on ethical grounds. Furthermore, there seem to be numerous business advantages related to accessibility conformance of Web systems. There are potential productivity gains from the aging workforce that can be realized through accommodations in Internet and intranet work environments. There are potential performance and maintenance benefits with regard to server-side systems, as well as simplified integration of newer client-side technologies. From the B2C perspective, there is the potential for expanded audience reach and for increased share of an underexploited market niche.

Unfortunately, recent studies have shown that conformance to accessibility standards is sorely lacking on the Web, and that existing Web sites actually *decrease* in accessibility over time. Overall, it appears that little attention is being paid to issues such as Section 508 or WCAG conformance. There is an obvious need for training and awareness of these issues within the Web development community. Web content should be designed from the start with accessibility features in mind, and this awareness should be carried through the entire life of the applications, if we are to protect a significant sector of our society from increasing marginalization.

KEY TERMS

Adaptive/Assistive Technology: Technology that is aimed at providing independence to individuals with disabilities. The terms *adaptive* and *assistive* are often used interchangeably, but there is a fine distinction. Assistive technologies stand on their own, while adaptive technologies provide accessibility to existing mechanisms and systems which might otherwise be inaccessible.

Bobby (WebXACT): The most well-known tool to evaluate Web sites for compliance to Section 508 and WCAG standards. Bobby was launched in 1995, but it was re-implemented as WebXACT in May of 2005. WebXACT remains a free service available at http://webxact.watchfire.com/. Despite the change, it is still often referenced through its original *Bobby* handle.

Digital Divide: The concept that there exist inequities in access to public information and information technologies by certain segments of the population. These segments are defined by such attributes as income, race, education, and disability.

Electronic Curb Cuts: A term referring to adaptive technologies that are aimed at computing and information technologies. The term makes an analogy to the federally mandated removal of curbs at crosswalks to facilitate wheelchair access. Unexpected benefits of such modifications are often called the *curbcut advantage*.

Equality of Access/Equity of Access: The hypothetical ideal situation in which all citizens are afforded full and equal access to public information and information technology, regardless of situation, status, or ability.

Large-Print Access Systems: A type of adaptive technology that is intended to provide screen-based access to persons with impaired vision or with certain cognitive disabilities. These systems are based on enlarging the screen image in some way.

Screen-Reading Systems: Adaptive technologies that are designed to produce the speech output equivalent of text-based information. These systems can be efficacious with Web content only if the content is designed properly.

Section 508: The section of the Rehabilitation Act of 1973 that deals with information technologies and systems. This section requires that all information systems utilized by the U.S. Government agencies be accessible to disabled individuals.

Subsection 1194.22: The portion of Section 508 that covers Web-based (both Internet and intranet) applications. (See *Section 508*).

Universal Design: An approach to designing Web content where the intent is to provide access to the broadest range of clients, regardless of individual abilities, disabilities, circumstances, or environments.

WCAG (Web Content Accessibility Guidelines): A set of design guidelines championed by the World Wide Web Consortium aimed at increasing accessibility to content on the Web. These guidelines consider poor user environments as well as users of varying physical or cognitive abilities.

Developing a Web Service Security Framework

National Cheng-Kung University, Taiwan

INTRODUCTION

Web Service (WS) is an open standard software component that uses *Extensible Markup Language* (XML) functions to access and exchange data via networks in communicating with other WSs. In business transactions, Web Service Description Language (WSDL) is used to describe data and deliver all parameters, return values, and types. However, the convenience of using *WSDL* in business transactions also lets hackers snoop and analyze data easily. In addition, the lack of Web Service standards at present makes the *security* issue even more serious in business transactions using WS. This article proposes a high-level *security* model for the *security* problems of the applications. Unlike other studies in the field, this study is dedicated to provide a total solution consisting of technological, organizational, and managerial aspects when using WS. Therefore, the understanding and development of business behaviors is essential in this study. It first introduces current uses of WS. Then definitions of WS, WS security, and WS policy are reviewed. Finally, a WS security model is proposed and explained in the following examples.

BACKGROUND

The Internet is becoming a global common platform where organizations and individuals communicate with each other to carry out various commercial activities and to provide value-added services (Wang, Huang, Qu, & Xie,, 2004). According to the World Wide Web Consortium (W3C, 2004), Web service means that an application program can be described and invoked, and made use of Uniform Resource Identifier (URI) to distinguish via XML. The *application program interfaces* define ways of contacting and supporting other application programs in order to urge directly through the protocol conforming to the Internet with the information of *XML* form. Web service technology allows users to customize services according to their own needs. This allows businesses to interact more accurately and efficiently with customers, cooperative enterprises, and suppliers.

According to a recent Gartner survey, 10 percent of midsize businesses cited using Web services for some production applications, while 47 percent of midsize stated that they plan to deploy Web services (Browning & Anderson, 2004). Also, Gartner Dataquest predicted that Web services will grow from $56 billion worldwide in 2003 to $283 billion worldwide in 2007 (Varbusiness, 2005). By then, Web services will take hold as a competitive differentiator in business relationships and product innovation (Andrews, 2003; Fensel and Bussler, 2002). Enterprises that want to remain competitive will need to use Web services to provide commonly requested data to their partners (Andrews, 2003) and, therefore, Web service technology will no longer offer a competitive advantage to enterprises. It is necessary for them to become competitive (Wiseth, 2004).

When an enterprise has some basic Web services, the high-level functional demands such as the service *security*, the service composition, and the service semantics will increase, and they are critical to the success of deploying Web services (Wang, et al., 2004). Presently, service-oriented architectures use the Web services to work on the business transaction based on the *Web Service Description Language* (WSDL). During the process of digital data delivery hackers are capable of obtaining the parameters. This data can be decoded and analyzed, which could cause a threat to a business. Communication over Web services is done by using a *Simple Object Access Protocol* (SOAP) that is associated with other programs that are built on *XML*. *SOAP* transfers everything over the HTTP, allowing data to pass through firewalls via a TCP port. This enables information to travel through firewalled ports, but this kind of firewall penetration also adds another *security* concern.

Industry observers have said the biggest obstacle to the wider adoption of Web services has been security concerns (Geer, 2003). Thus, security is critical to the adoption of Web services by enterprises, but, as it stands today, the Web service framework does not meet basic *security* requirements (Wang, et al., 2004). With this in mind, this study attempts to develop and implement a web services *security* model and discuss the essential security problems of this structure.

WEB SERVICE SECURITY FRAMEWORK

Web Service

Web services are a relatively new and emerging technology, they allow enterprises to share application logic and data using the standardized data and messaging formats, namely *XML* and *SOAP*. Web services can be accessed through the Internet and are based on existing communication protocols, such as HTTP. However, a standard definition of Web services has yet to be resolved. According to W3C (2004), "a Web service is a software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-processable format (specifically *WSDL*)." In addition, IBM (n.d.) defines "Web service is a new breed of Web application that is self-contained and self-describing, and which can provide functionality and interoperation ranging from the very basic to the most complicated business and scientific processes." Gartner Group (Natis, 2003) defines Web services as a software module that represents a business function (or a business service) and can be accessed by another application (a client, a server, or another Web service) over public networks using generally available ubiquitous protocols and transports (i.e. SOAP over HTTP).

From the above-mentioned definitions, one can understand that the purpose of the Web services is providing an interoperable interface for application-to-application interaction over public networks. The Internet protocols and standards on which Web Services are based are:

- *Simple Object Access Protocol* (SOAP) that enables communications among Web services.
- Web Services Description Language (WSDL) is the *XML* language that providers use to describe their Web Services.
- Universal Description, Discovery and Integration (UDDI) directories enable brokers to register, categorize, and list Web services and requesters to find them.

In traditional application development, programmers spend a great amount of time to tell an application to find another application, and this connection may require maintenance over the course of its lifetime; again, using human application developers. Web services provide certain secure protection in terms of quality, security, data integrity, and complicated transaction. Table 1 presents the comparison of traditional applications and Web services.

Web Service Security

Security is considered the biggest obstacle to general adoption of Web services (Geer, 2003). Cross-enterprise exchange of information over the Internet is vital but may have *security* implications. *Security* issues over the Internet are important, because the Internet is an insecure and non-trustable public network infrastructure, prone to malicious attacks by professional and amateur intruders (Wang, et al., 2004). According to O'Neill (2002) and O'Neill, White, & Watters, (2003), Web services security challenges are as follows:

- The challenge of *security* based on the end user of a Web Service: In order for users to gain access to a

Table 1. Comparison of traditional applications and Web services

Traditional application	Web services
Centralized	Decentralized
Contained and controlled	Open and unmonitored
Limited, defined user base	Unknown, unlimited user base
Secure (risk minimized)	Exposed (open to random events)
Proprietary	Shared
Fixed, well-defined, compiled	Built dynamically, on-the-fly
Incremental scale based on known demand	Unlimited scale, based on unknown, unpredictable demand
Staged, periodic changes	Continuous, *ad hoc* changes
Implementation technologies are all the same or compatible	Heterogeneous in implementation technologies

(Modify from Ratnasingam, 2002; Yang, 2002)

Web service where logical access control is required, there must be some forms of authentication, such as a username combined with a password, or a digital certificate (secured by a pass phrase) and based on the information to make authorization decisions.

- The challenge of maintaining *security* while routing between multiple Web services: When SOAP message routing between Web services, the requirements for confidentiality can be implemented using SSL between Web services.
- The challenge of abstracting *security* from the underlying network: Web service security not only relies on Web security, but also includes *SOAP* services security, such as *SOAP* messages to be secured between Web services.

In addition, as the incidents of attacks increases, the threats of Web service *security* are emerging. These threats can roughly divide into two parts as follows: (King, 2003; Morrison, 2004; Ratnasingam, 2002; Slewe and Hoogenboom, 2004; Treese, 2002):

- About network *security*:
  1. A shift from generic attacks to more sophisticated and well targeted attacks.
  2. Increasing propagation speed and volume of virus attacks.
  3. Increasing speed of the release new of viruses and attacks after the detection of a *vulnerability.*
  4. Increase in identity or federating identity fraud.
  5. Network eavesdropping.
  6. Unauthorized access.
  7. The *security* of the network in which the runtime is deployed.
- The security of information that is shared between corresponding parties at run time:
  1. Parameter manipulation.
  2. Disclosure of configuration data.

Standards and Technologies in Web Service Technology

When using Web services as the transaction platform in enterprises, the *security* issues will often be put forward and regarded as the credibility that queries the Web services, and influences the development of the Web services. Technology vendors and standards organizations have recognized the risks posed by Web services *security vulnerabilities*. In standards bodies and in various consortia, they are working to formulate new technologies and better practices designed to make Web services more secure. To date, there are numerous standards under development that aim to address a broad range of issues, such as privacy, trust, and reliability of Web services.

- WS-Security
  WS-*Security* was originally designed by VeriSign, Microsoft, and IBM before being submitted to the Organization for the Advancement of Structured Information Standards (OASIS). It provides a way for Web services to attach *security* data to the header of *SOAP* messages, and works with several different security models via *SOAP* extensions.
- *XML* Key Management Specification (XKMS)
  It was originally designed by VeriSign, Microsoft, and Web Methods before being submitted to the W3C organization. XKMS does offer a simplified approach to integrating public key management capabilities with applications.
- *XML* Access Control Markup Language (XACML)
  The XACML was developed by the Organization for the Advancement of Structured Information Standards (OASIS) in 2003. XACML is designed to express access control rules in *XML* format, and integrate seamlessly with SAML and, also, with *XML* Digital Signature.
- Extensible Rights Markup Language (XrML)
  XrML can provide the service about DRM, Metadata, content management, and content transmitting of the digital content.
- Secure Assertion Mark-Up Language (SAML)
  The SAML was developed by OASIS in 2002. SAML defines an *XML* schema that allows trust assertions (*authentication*, authorization, or attribute) representation in XML and request/response protocols to perform *XML authentication*, authorization, and attribute assertion request.
- *XML Encryption* (XML Enc)
  The XML *Encryption* was developed by W3C in 2002. XML *encryption* provides a model for *encryption*, decryption, and representation of full XML documents, single *XML* elements in an XML document, contents of an XML element in an XML document, and arbitrary binary content outside an XML document.
- XML Digital Signature (XML Dig)
  The *XML* Digital Signature was developed by W3C in 2002. It defines syntax and processing rules for representing digital signatures how to digitally sign XML contents and how to represent the resulting information according to an *XML* schema.

Information Security Policy

In an ideal world, configuration, operation, and management of *security* functionality should allow to specify business

Table 2. Security policy and technology trust mechanisms

Security Policy	Technology trust mechanisms
Information Custodianship	Authentication; Authorization
Physical Access Security	Authentication; Authorization
Information Security Administration Functions	Authentication; Authorization
Logon Security	Authentication
Transaction Controls and Database Security	Integrity; Authentication; Content inspection; Confidentiality; Authorization; Non-repudiation
Agency Security Management	Monitoring; Auditing; Exception management
Information Recovery	Backup and recovery procedures
Data Exchange Agreements	Authentication; Authorization
Vendor/Contractor Agreements	Authentication; Authorization
Employee/Agent Responsibilities	Authorization; Exception management (Monitoring and alerting); Authentication
Sensitive information	Authorization; Authentication

oriented terms by non-specialist staff (Kearney, Chapman, Edward, Gifford, & He, 2005). Such tasks should be performable by staffs involved in business operations rather than technical experts. Therefore, the person responsible must be able to lay down rules that are meaningful both to a human being and to the Web service management software. Such rules are known as policy (Kearney, et al., 2004). Web services *security* provides developers, application architects, and security professionals the need to build *security* policies and strategies from the ground up in a Web Services environment.

According to Panko's (2004) definition, the *security* policies specify at a broad level what should be done in terms of security. In addition, Rees, Bandyopadhyay, & Spafford, (2003) defines that the *security* policies are generally high-level, technology neutral, and concern risks and set directions and procedures. The *security* policy should be applied to all in existence and future technology infrastructures including the provision of management standards for information departments and non-information departments in enterprises to follow.

Table 2, summarized from literature and cases, shows how a *security* policy can be implemented by applying technology trust mechanisms (Natoli, 1997). By doing so, it is expected to increase the enterprise *security* when using Web services to communicate with each other.

Web Service Security Model

To provide a comprehensive model of *security* functions and components for Web services, the integration of currently available processes and technologies with the evolving *security* requirements of future applications is required. It demands unifying concepts requiring solutions to both technological (secure messaging) and business processes (policy, risk, and trust). It also requires coordinated efforts by platform vendors, application developers, and network and infrastructure providers and customers. Therefore, we suggest that the development of Web services *security* model categorizes into three aspects: organization, technology, and management (see Figure 1). *Security* capabilities of Web services in this model are: authorization, confidentiality, *authentication*, integrity, content inspection, and *encryption*.

The security model shown in figure 2 details how to secure critical components such as Web services, application servers, and networks.

The model includes three parts: external, Web Service *Security* Integration (WSSI), and internal. External application, Web service, or user can request/response business internal Web services or application servers via firewall. Management console can set enterprise *security* policies to re-evaluate whether the enterprise's *security* policy can satisfy business requirements in the future technology infrastructures. In addition, *authentication*, authorization, confidentiality, content inspection, *encryption*, routing, and integrity mechanisms need to protect messages and transactions, including how to implement and communicate those mechanisms using

Figure 1. Development of Web service security model

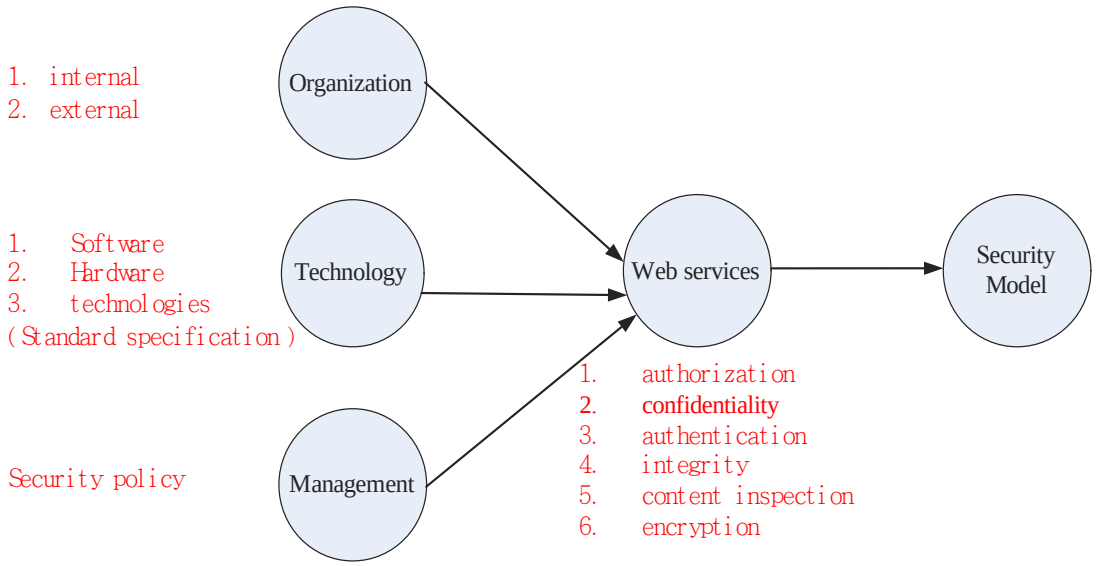

Figure 2. Web service security model

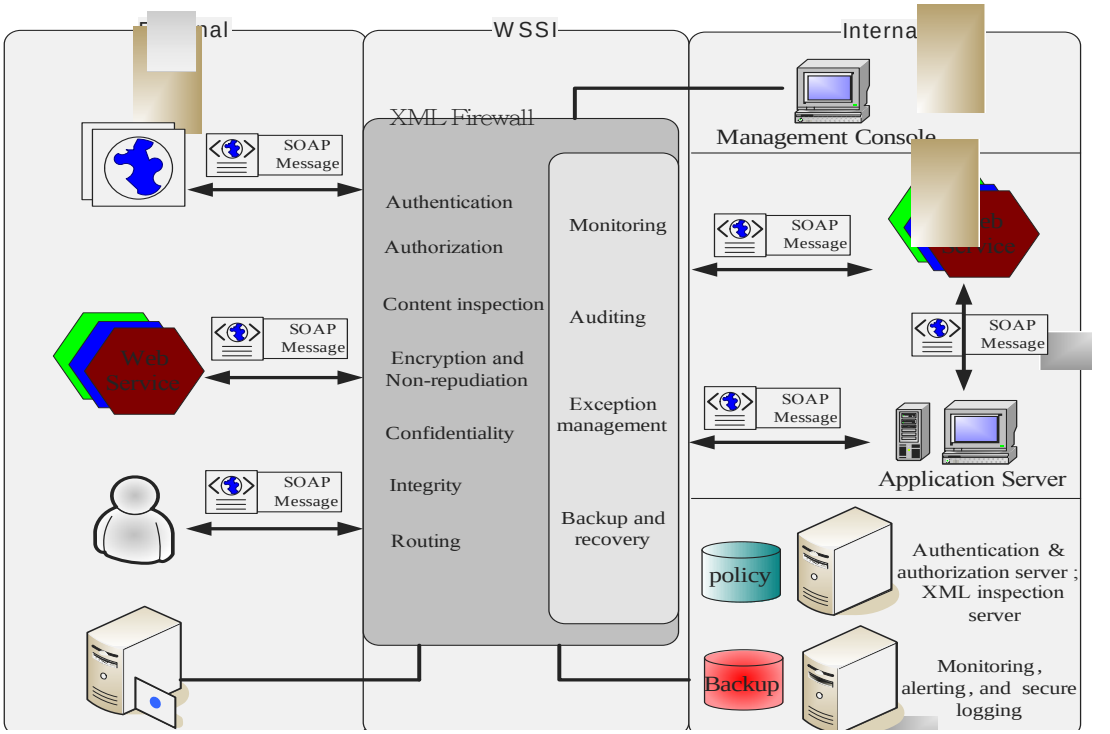

WS-Security, *XML Encryption*, *XML* Signature, SAML, WS-Routing, and XACML. The importance of auditing, monitoring, and exception management is also covered to ensure that data access and system execution are accurate, and data backup can protect data from irreparable loss or damage and reduce enterprise's risks.

FUTURE TRENDS

Web services are becoming a very serious part of development for businesses, which is why Web service *security* plays such an important role. The *security* infrastructure for Web services is growing rapidly due to the demand for privacy of users; sensitive information of users should be protected by *security* policies and a strong security system. The goal for this field of research is to provide a safer environment for users so that this service can be used without the worries of data leakage.

This calls for a significant amount of research that needs to be done in the Web services *security*, such as authorization and *authentication* in heterogeneous environments. For instance, understanding and analyzing similarities of distributed applications design would help to design more secure Web services applications.

CONCLUSION

Security requires all parties and systems to work in show to build a good protection, thus, secure Web services entail a macro solution. This paper suggests a high level solution for the security problems of the application to business-to-business behavior. We discussed the essential security problems of this structure, and then laid out solutions to the currently faced problems. The study also discussed the different platforms and policies of Web services security; however, further understanding of the many kinds of *security* infrastructures is suggested. The suggested *security* model shows that security policies and technology trust mechanisms are working successfully to prevent improper accesses and protect their assets. These security issues are a very important subject in the business-to-business communication sector due to possibility of great losses if data leakage exists.

KEY TERMS

B2B (Business-to-Business): Refers to one business communicating with or selling to another.

HTTP (HyperText Transfer Protocol): Protocol used to transfer hypertext requests and information between servers and browsers.

Port: A number from 0 through 1023 used to identify a network service on an IP network.

Security: Freedom from risk or danger; safety.

Security Policy: A security policy is a generic document that outlines rules for computer network access. It determines how policies are laid out and some of the basic architecture of the company security environment.

TCP (Transmission Control Protocol): TCP ensures that all data arrive accurately and 100% intact at the other end.

Web Service: An open standard software component that uses XML functions to access and exchange data via networks to communicate with other Web Services.

Web Service Description Language (WSDL): Used to describe data and deliver all parameters, return values, and types.

INTRODUCTION

As with any new program, the chance of failure runs high and distance education, in comparison with the longevity of traditional education, is considered relatively new. Still, distance education appears to be here to stay. In fact, a 2000 market survey found that over 94% of all colleges were either offering or planning to offer distance education courses (Twigg, 2001). With this much interest and popularity, the need for policies to regulate distance education program practices should be recognized by all participating institutions of higher education (Czubaj, 2001). While students appear to be more focused on the conveniences that distance education provides, universities are more attentive to the need for offering a valid learning alternative. Higher education enrollments have shown upward movement and this has, to a degree, been attributed to the adult learners' interest in, and availability of, distance education (Boettcher, as cited by Worley, 2000). Change in the enrollment demographics and the offering of distance education programs stimulates the need for new decisions by academic administrators for quality and accreditation purposes (Shea, Motiwalla, & Lewis, 2001; Tricker, Rangecroft, Long, & Gilroy, 2001).

One of the first steps toward ensuring success of distance education programs is identifying the requirements of all those involved. Student needs are to receive a quality education; faculty needs are to have at their disposal (and to use) the knowledge and means to provide this education; and institution needs are to assess that students receive a quality education and to provide faculty with the resources for student educational needs to be met. One of the problems that could harm distance learning or prevent it from being all that it can be is the lack of a good evaluation system. The focus of this article will be to identify and describe, from the literature, the components of an effective evaluation system. Armed with this information, administrators will be able to make better program decisions.

BACKGROUND

The need for information in any decision-making process is crucial. The newness of distance education makes the need for related information even more critical. One of the most popular methods for amassing information in higher educational settings is by performing evaluations. According to Patton (1997), education has a long history of using evaluations. Users of this data have their own purposes in mind. Students are seeking affirmation that the course contains relevant content, the instructor teaches effectively, and the course will help them reach their long-term goals (McKeachie, 1996; Spencer & Schmelkin, 2003; Willis, 1993). Faculty will have access to feedback that can help guide them in their teaching. Job performance reviews can be gleaned from either an administrator or student evaluation of faculty (Algozzine et al., 2004; Chen & Hoshower, 1998; Halpern & Hakel, 2003; McKeachie, 1996; Spencer & Schmelkin, 2002; Willis, 1993). Critical to institutional administrators is the collection of information that relates to whether or not institutional strategic goals are being accomplished. Decisions as to the potential development of a distance program (Willis, 1993) and changes to support programs (i.e., bookstore, tutoring, etc.) that support this program can be made. Academic administrators use evaluation data as one means to judge teaching performance (Emery, Kramer, & Tian, 2003; Neumann, 2000; Willis, 1993). Whether appropriate or not, decisions on tenure and promotion are frequently based on this information (Algozzine et al., 2004; Chen & Hoshower, 1998; Halpern & Hakel, 2003; McKeachie, 1996; Spencer & Schmelkin, 2002; Willis, 1993). Regardless of the reason for information collection, quality information can be gathered only with the use of a quality instrument. Reliability and validity of the information is always in the forefront of concerns when conducting an evaluation (Scanlan, 2003; Griffin, Coates, McInnis, & James, 2003; Marshall, 2000; Regalbuto, 1999; Achtemeier, Morris, & Finnegan, 2003). To fur-

ther perpetuate this problem, unless faculty believe in the validity of the information collected, change is not likely to occur (Reid & Johnston, 1999); unless students believe their responses will provide a reward, less-than-valid response may be supplied (Chen & Hoshower, 1998). Differences associated between distance and traditional courses can hinder the desired outcome of validity, emphasizing the evidence that an alternate evaluation instrument is required. Despite the distinctiveness of distance education, many universities continue to use traditional course student evaluation instruments to evaluate distance learning courses (Achtemeier et al., 2003). To increase the reliability and validity of evaluation data, an evaluation instrument designed to represent distance education uniqueness would be required (Henckell, 2007). At the very least, alterations or amendments are required to take a well-designed traditional evaluation instrument and make it valid for evaluating distance education courses (Holcomb, King, & Brown, 2004; Shuey, 2002; Willis, 1993). A system contains parts that, when placed together, represent and share a relationship to the whole or what Marshall (2000) describes as a model. As with traditional courses, student evaluations are a vital part of the system for assessing distance education programs. Information collected from student evaluations should not stand alone. Administrative reviews are also necessary to provide a more accurate picture of performance. With each type of evaluation, there is the need to review the components of the evaluation process and what can positively or negatively affect these events. With the recommendations provided in this article, changes can be made to perfect the components used in an evaluation system. Improvements to current evaluation systems will hopefully lead to a greater buy-in of the system by students, faculty, and administrators.

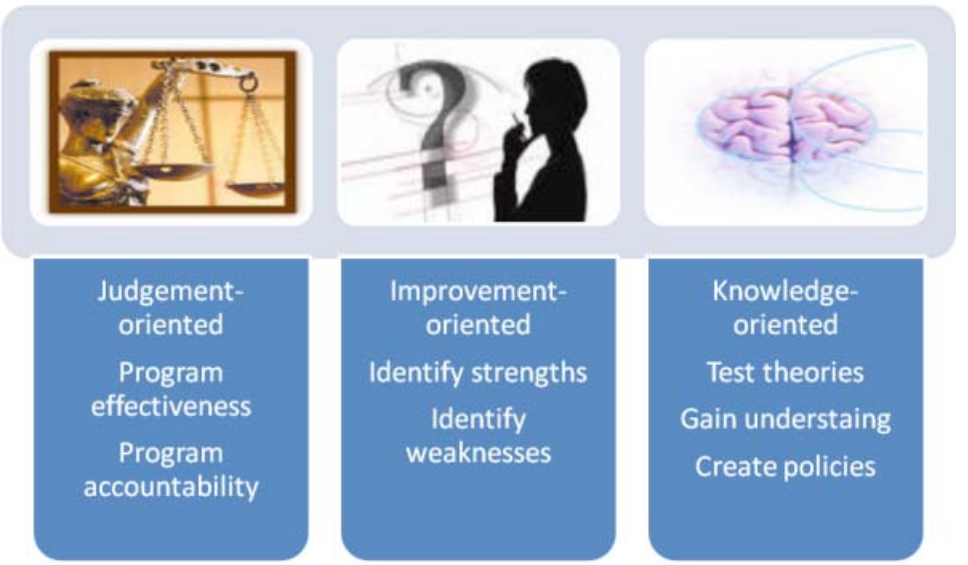
COMPONENTS OF A COMPREHENSIVE DISTANCE EDUCATION EVALUATION SYSTEM

Involved in the building of an evaluation system is an evaluation plan. This plan must recognize purposes and rationale of an evaluation and identify how, what, and when to evaluate (Henckell, 2007). Evaluation methods, styles, and strategies can then be determined (Robson, 2000). University administrators, academic administrators, faculty, and students are the four parties that should be included in all evaluation systems of distance education courses (Willis, 1993).

How to Evaluate

First and foremost, the purpose of the evaluation must be identified in order to know the right information for decision making will be present. The cynosure of an evaluation, according to Patton (1997), is its intended use. Data gathered

Figure 1. Intended use



from the process can be utilized to relinquish judgments, expedite improvements, and create knowledge. Patton's judgment-oriented evaluation could be used to focus on program effectiveness and accountability. His second evaluation type, improvement oriented, could be used to enhance programs by identifying strengths and weaknesses. Both of these evaluation types required that a decision or action follow the use of these instruments. In contrast, the intent of the third evaluation type is to simply increase knowledge. Uses of the knowledge-oriented evaluation include testing theories, gaining understanding, or creating policies. For representation of these intended uses, see Figure 1. Regardless of which type of evaluation is used, if the collection of valid information fails to be used, one has to question the value of the exercise.

When and What to Evaluate

Society has held a high regard of universities for years; the public, in more recent times, has demanded more accountability (Sutherland, 2000). Evaluations are one of the main methods used to prove courses are being monitored and institutional standards are maintained. Two of the most frequent evaluation activities are the end-of-course student evaluation and an evaluation conducted by an academic administrator. As part of the evaluation process, Benigno and Trentin (2000) recommend that students enrolled in a distance education course complete a pre-course survey. This procedure would allow instructors to discover distinct characteristics of the student such as previous experience with distance education, the student's learning environment that may adversely affect the student, and technology skills. Vrasidas, Zembylas, and Chamberlain (2003) agreed with Benigno and Trentin but suggested also assessing student perceptions and attitudes of online courses. In addition to evaluating the students prior to course activity, three other evaluations have been recommended to take place throughout the course. During the later part of the second or third week, it is thought that students should have had enough course experiences to be able to provide valid information on the course, instructor, and medium (Henckell, 2007). What is crucial about conducting the evaluation during this time is collecting data prior to the course drop deadline. This may be the only opportunity to gather information regarding issues that forced the students to drop the course. Evaluation results are possibly skewed if information is provided by only the successful students (Phipps & Merisotis, 1999). While this early evaluation can aid in improving teaching, mid-semester evaluations also work toward this purpose. At mid-semester, more detailed and useful information is available (Laverie, 2002). Using this timeline allows time for the instructor to make improvements, benefiting the currently enrolled students. As practice has demonstrated, the third evaluation time recommended is slated for the end of the course. An overall impression can be provided during this time, but the downside is that the timing is not very favorable for accurate responses. Most students are extremely overwhelmed at this time and not in the best frame of mind or attitude to respond in a manner that may provide an authentic picture of course experiences. By conducting and combining the results of mid- and end-semester evaluations, a more valid representation of the course will transpire. To prove or refute student evaluation responses, another source for information should be sought, and academic administrators, using the right tools and processes, should be able to meet this need. Academic administrators experience a more difficult time evaluating faculty teaching distance education courses. Faculty evaluations generally require a visit to the classroom for observations and the writing of an evaluation report that sometimes includes results from scores on faculty presentation skills, professionalism, material coverage, media usage, and general comments (Tobin, 2004). Challenges for evaluating courses at a distance must be surmounted. Questions administrators must now seek answers to during the distance education evaluation process include:

1. How is a classroom visit to occur if the course is asynchronous?
2. What preparations are needed to review class discussions?
3. How can the evaluator ascertain the classroom discussion quality and the instructor's involvement?
4. How can the instructor's demeanor be evaluated?
5. Where, how often, and what should constitute a visit in the course Web site?
6. Is more multimedia required for the online instruction?
7. And most importantly, how can one evaluate an online course when one has never experienced the process? (Tobin, p. 76, as cited by Henckell, 2007)

Regalbuto (1999) also provided valuable and pertinent questions for use by academic administrators when assessing distance education. He suggested:

1. Was innovation present in the teaching style?
2. Was the learning competence equal or superior to that of a traditional classroom?
3. Were the students engaged in the material?
4. Were there interactions between professors and their students, and between the students themselves?
5. Was technical support readily available?
6. For online programs that are more extensive, such as entire degree programs, are the signs of academic maturity present?

Administrators who have never experienced the online process have a responsibility to immerse themselves in distance education literature. To get a true understanding of distance courses, administrators should go one step further and audit the type of distance education course they will be responsible for evaluating. Communication plays a very important role in distance education. As to how to evaluate asynchronous type courses, reviewing communications that occur between students and faculty can provide valuable clues as to the events and activities that occurred during the course, as well as how well the events and activities were received. Communication can also provide information as to the instructor's demeanor, whether students appeared to be engaged in the material, and whether or not academic maturity was present. Course materials, as well as lesson plans, can be reviewed in response to whether innovation was present in the teaching style or more multimedia should be required. Comments by the students regarding this subject would also assist in this determination. Special elements present in distance education courses require that the traditional course evaluation system be altered in order to prevent the loss of valuable information. The recommended evaluation of items known to affect student success are listed as (Benigno & Trentin, 2000):

"(a) individual characteristics; (b) level of participation; (c) collaborative and content message analysis; (d) interpersonal communication; (e) available support resources (i.e., bookstore, technology, registrar, etc.); (f) reaction to the methodological approach (as opposed to seeking judgment as to whether the student thought it was a correct instructional method); (g) usefulness of the learning material (as opposed to seeking judgment as to whether the student thought it was the correct learning material); (h) learning environment (i.e., local, virtual, social, etc.); (i) communication through technological means; and (j) value placed on the course as opposed to value placed on traditional learning." (as cited by Henckell, 2007, p. 70)

FUTURE TRENDS

Distance education grew rapidly after technology advancements (Spooner et al., 1999; Worley, 2000; Miller & King, 2003; Holcomb et al., 2004), and it has been envisioned that distance education will continue to experience growth (Allen & Seaman, 2004; Phipps & Merisotis, 1999). With such rapid growth, there has been little time devoted to creating policies to ensure quality programs. Now that programs are established, issues are becoming apparent and more universities are taking the time to create policies that will make the programs stronger. The development and use of an evaluation system is one policy, but others are needed. Future research is needed to identify what policies are being developed and the negative or positive effect of these policies on the programs, once in place. Evaluations serve a variety of purposes, and when the information collected is acted upon, students, faculty, academic administrators, institutional administrators, and distance education programs benefit. One of the most desired results of conducting evaluations is for course and content improvement. Research is needed on whether or not change is occurring based on evaluation results and methods employed by administrators to ensure that the evaluation results are being used.

CONCLUSION

Applied research has shown distinguishable differences between traditional and distance education courses that warrant the development of similar, yet separate, evaluation systems. In order for an evaluation system to meet its intended use, those involved must believe in the system. More than an end-of-course evaluation is needed to meet the challenges and uniqueness of distance education. The development of a distance learning evaluation system or, at a minimum, the revamping of the traditional system is warranted. Information provided in this article can be used to assist the reader in building a more comprehensive evaluation system that will, in turn, help improve distance education programs.

KEY TERMS

Applied Research: Research efforts that seek findings that can be used directly to make practical decisions about or improvements in programs and practices to bring about change with more immediacy (Schein, as cited by Bogdan & Biklen, 1998).

Distance Education: Education or training courses delivered to remote (off-campus) sites via audio, video (live or prerecorded), or computer technologies, including both synchronous (i.e., simultaneous) and asynchronous (i.e., not simultaneous instruction) (Distance Education, 2003).

Evaluation: The systematic determination of merit, worth, and significance of some object (Stufflebeam, as cited by Fowler, 2000).

Evaluation System: A devised system that outlines in a plan what, when, and how courses are to be assessed (Benigno & Trentin, 2000; Robson, 2000).

Improvement-Oriented Evaluation: Formative evaluation directed toward improving what is evaluated (Patton, 1997).

Judgment-Oriented Evaluation: Summative evaluation in which judgments are made on value or worth (Patton, 1997).

Knowledge-Oriented Evaluation: Evaluation used to test theories, gain a better understanding, and create policies (Patton, 1997).

Policy: "Policy as a chain of decisions stretching from the statehouse to the classroom is a by-product of [many] games and relationships; no one is responsible for the whole thing" (Firestone, as cited by Fowler, 2000).

Student Evaluations: Forms specifically designed to measure observed teaching styles or behaviors (Wright & Neil, as cited by Chen & Hoshower, 1998). Student evaluations are typically administered at the end of the course (Algozzine et al., 2004; Neumann, 2000).

Traditional Course: Course with no online technology used; content is delivered in writing or orally (Allen & Seaman, 2004).

Developing the Enterprise Architect Perspective

Brian H. Cameron
The Pennsylvania State University, USA

INTRODUCTION

Enterprise systems design, implementation, and integration are focal points for business and information technology. Businesses must change processes, environments, and technologies as organizations strive to become more integrated and break down traditional silos of information systems and responsibility. These challenges require a new type of technical professional: one with the training and perspective of an enterprise architect with general technical expertise as well as business strategy and planning skills. Some college and university programs have risen to this challenge in recent years, and the joint ACM/Association for Information Systems Task Force developed the MSIS curriculum model to establish the fundamentals of enterprise information systems in response to the increasing demand for university-trained graduates in an information economy (Gorgone, Gray, & Feinstein, 2000). Recently, the Association for Open Group Enterprise Architects called for industry and academia to work together to craft new enterprise systems curricula that are relevant to today's global business environment and developed from the perspective of an enterprise architect.

Today's globally competitive environment requires technical professionals to move beyond technical expertise and contribute to the strategy and development of dynamic IT systems that are able to support changing business objectives. To be prepared to meet such expectations, IT students must have broad experience in the design, implementation, and integration of such systems. This education is typically offered in a layered fashion, teaching students about databases, networks, and applications in different courses devoted to single topics (Nickerson, 2006). While this method allows universities to assign faculty with specific expertise to particular courses, it does not adequately prepare students for the work environment of the enterprise architect, where all of these different layers must be combined to support and align with business strategy. Students trained in a specific, narrow layer may fail to anticipate certain trends or requirements, such as a database designer overlooking the need for remote replication (Nickerson).

To meet this need, many information technology programs are incorporating enterprise systems curricula for senior students. These courses are often referred to as "capstones" in the curriculum, and must focus on a wide variety of educational goals including understanding the enterprise as a whole, understanding how technology can provide a competitive advantage, learning to design complex integrated systems, learning concepts underlying technical systems integration, learning how to assess the requirements of an integrated system, and learning how enterprise architecture design is practiced as a profession.

BACKGROUND

Enterprise architecture education is particularly important when trying to meet current business objectives. Several prestigious consulting groups, including IBM and Forrester, have noted a major shift in most technology-centric businesses since 2005 toward service-oriented architectures (SOAs; Boyle & Strong, 2006; Seethamraju, 2007). An SOA is the practice of sequestering the core business functions into independent services that typically do not change frequently. These services can then be combined to create composite applications that can be easily reconfigured to meet the changing needs of the organization. This new paradigm in enterprise systems development and integration highlights the demand for enterprise architects who can understand and align business goals with a technical strategy and architecture capable of supporting current and future needs. SOA does not represent the entire scope of responsibilities of the enterprise architect—it is simply one method of the overall goal of aligning the strategic vision of the business with its information technology infrastructure (Cannon, Klein, Koste, & Magal, 2004; Davis, 2004; Mulder, Lidtke, & Stokes, 1997).

In spring 2007, the Information Technology Association of America (ITAA) identified the need to double the number of graduates in science, technology, engineering, and math over the next 10 years to maintain U.S. information technology competitiveness. Specifically, ITAA (2007) identified "a commitment to the use of information technology to solve real customer problems now and in the future" as a primary goal of the U.S. education system—higher education in

particular. The organization is committed to enhancing IT education through better understanding of the IT workforce, and frequent assessment of the IT needs of industry.

The lack of well-educated IT workers is further emphasized when considering recent surveys predicting significant shortages in IT workers on the horizon. Despite the off-shoring of certain technology jobs, a large number of organizations in the United States are currently deficient in properly trained IT workers. A survey of Washington Trade Group members (over 14,000 companies) indicated that 36% of member companies had open technology jobs: *open* meaning the position has been posted and unfilled for more than 3 months (Barrett, 2007). The most common explanation for the open positions among executives interviewed is a lack of business literacy. In other words, applicants for the position are not sufficiently well rounded in business and technology. Most of these unfilled positions are for an employee who can interact with various groups within the organization, manage technology projects, analyze business needs and translate those needs into a technical solution, and become an effective bridge between functional business units and the technologists. In short, thousands of U.S. companies are in need of employees with the background, skills, and perspective attributed to the enterprise architect.

To meet the needs established by industry, information technology curricula must produce well-rounded students who have a broad enterprise-wide understanding of a variety of IT concepts from databases to networks, to data storage and management. IT firms are looking for employees who can engage the organization at a high level, define comprehensive requirements for large projects, design solutions, and be able to easily develop expertise in multiple areas of the company (Marshall & Roadknight, 2001; Sanders, 2004). This is no small task, and it necessitates a significant restructuring of many of the IT curricula in place today.

CHALLENGES TO ENTERPRISE SYSTEMS CURRICULA

Meeting the educational needs of enterprise-systems-related courses is difficult enough, but faculty and administrators in higher education are also plagued with paperwork and committees when attempting to implement new courses, content tracks, and areas of study. More significantly, university faculty are faced with a variety of concerns when attempting to produce and promote new curricular changes. On top of the challenge of mastering new content, many universities have an arduous approval process in place for any new class, making the task of linking a new course to an existing curriculum even more difficult (Helps, 2006). Most significant of all, the delivery of pedagogically sound content specific to information technology is problematic. Students must be prepared to engage rapidly developing equipment and practices by the completion of a degree, but ready access to equipment and content to meet these needs is extremely difficult. Universities cannot afford to adopt equipment at the same rate large companies are able to, making it difficult to offer a course on a topic like enterprise systems integration that will remain relevant and up to date (Davis, 2004; Prigge, 2005; Tompsett, 2005).

Beyond the challenge of specific courses, the landscape of enterprise information systems instruction in higher education covers a wide variety of interpretations. With no parent organization to make decisions about what is appropriate content for an information technology curriculum, individual colleges and universities are freely creating very disparate curricula. A 2005 survey of IT programs in colleges and universities around the United States showed that while many institutions placed unique emphasis on different aspects of information technology, all offered courses on networking, database construction and management, and software applications (including operating systems; Helps, 2006). Each of these parent topics in IT could easily be a curriculum of its own.

With such wide ground to cover with respect to content areas in information technology, capstone courses within the discipline are extremely challenging. Student preparation entering into these courses is often widely varied. These courses often take the form of an enterprise systems integration topic, or some other closely related topic (Suchan, Blair, Fairfax, Goda, Huggins, & Lemanski, 2006; Tetard & Patokorpi, 2005). It is at this point in an educational program that students have developed a broad-enough skill set to begin understanding the relationships between different areas of IT to one another and to the enterprise as a whole.

These capstone classes are often an ideal situation for academic-industry partnerships (Courte & Bishop-Clark, 2005; Turk-Bicakci & Brint, 2005). A few universities attempt to begin industry partnerships early in the academic program, but according to Courte and Bishop-Clark, partnerships involving more senior students tend to have higher rates of return (industry partners are interested in repeating the experience the following year) and more often lead to internships and job placements. Pedagogically, this industry interest in advanced students offers an opportunity to put students in situations that expose them to current technologies and problems within an industry setting.

The traditional method of teaching enterprise-systems-related topics at the college level would almost certainly involve the use of case studies to articulate relationships between technologies and practices. These case studies are beneficial to a student because they offer significant context to a real-life problem and afford the student an insider perspective on the subject. While this seems ideal, case studies cannot be written at the rate at which industry moves forward, rendering a specific case study more meaningless and outdated each semester. Industry engagement allows students

to work on projects designed with cooperating companies. Students receive the most hands-on training possible with relevant contexts and scenarios (Cameron, Knight, & Semmer, 2005; Harman, 2001).

THE PILLARS OF INFORMATION TECHNOLOGY

Helps' (2006) survey of information technology curriculum content identified three major areas of focus for most institutions: networking, databases, and applications. Presumably, a fully comprehensive education would offer a student significant training in all three areas. These areas map reasonably to industry definitions of information technology architecture as laid out by the five pillars of the modern IT architectural components suggested by EMC Corporation (Van Sickle et al., 2007), but not completely. Van Sickle et al.'s five pillars include databases, networking, software applications, operating systems (which many universities and colleges include under the umbrella of applications), and storage.

Van Sickle et al. (2007) argue that storage is a fifth pillar in the modern enterprise systems architecture that higher education has, for the most part, missed in curricular designs. The reasons for this lack of appreciation for the importance of this topic in modern IT and MIS (management information system) curricula are many, but mainly stem from a general lack of appreciation for the importance of storage-related topics in the modern corporate technology architecture. Storage as a topical area of study encompasses a wide range of concepts, topics, and issues including technologies and protocols, the evaluation of technical options based on business requirements, architectural design, systems management and governance, performance considerations, information management, data recovery, security, and emerging issues and technologies.

Furthermore, in modern enterprise architecture, each of the five pillars is interrelated with other pillars of IT. The enterprise architect cannot consider one pillar without at least some consideration of the other pillars. For example, databases require an expertise of their own, but some degree of expertise in networking allows a database administrator to better plan a database through knowledge of how users will access it. Likewise, expertise in storage allows the database administrator to better utilize resources by understanding the storage environment where the database resides. Network specialists can improve throughput with some expertise in storage technologies and through knowledge of the storage demands and capabilities of existing systems. Storage experts can customize their systems for better performance with expertise in the databases and applications stored on these systems.

This partial mapping shows that higher education is generally on the right track with IT education, but is often not doing a complete job. Several pillars of IT are commonplace in information technology curricula (databases, applications, networking), but these are often taught within their own curricular tracks or simply as independent courses of varying complexity, with universities expecting that a student will take lower level courses in each topic and then choose a specific pillar (for example, networking) to specialize in through advanced coursework.

The enterprise systems architect must be well versed in all of the pillars of IT, and higher education must develop curricula that foster this perspective in students (Catanio, 2005; McGann, Frost, Matta, & Huang, 2007). This means creating a curriculum to support comprehensive courses on enterprise systems design, implementation, and integration that teaches students to build systems encompassing networking, storage, databases, and applications (including operating systems or a lower level course specifically on operating systems) all in the context of alignment with business objectives and corporate strategy.

IMPORTANCE OF THE STORAGE PILLAR

While storage spending in industry (and in higher education, for that matter) continues to skyrocket, with respect to both spending and information production and retention (Gantz, 2007; Sun, 2005; "VUB Bank Improves Storage Performance," 2006), colleges and universities lag woefully behind in curriculum implementation. This can be due to several factors including the rapidly changing landscape of the storage industry (making it difficult to keep up with in an academic setting), an absence of instructional materials on the subject, or a lack of appreciation on the part of faculty of the importance of the topic in industry today. At the time of this writing, there is a plethora of practitioner-focused articles on storage-related topics, but no adequate textbooks or other instructional materials commercially available. Companies are forced to train storage professionals on the job rather than being able to hire university graduates with relevant knowledge and skills ("SNIA Announces Storage Networking Courses," 2005; Van Sickle et al., 2007).

In the mid to late 1990s, when universities began deciphering what content would be appropriate for an information technology curriculum, industry spending was predominantly on network equipment and software applications (McDonald, Rickman, McDonald, Heeler, & Hawley, 2001). This was quickly followed by interest in databases (Lynch, Carbone, Arnott, & Jamieson, 2002), and the early information technology curricula were framed. It has been a decade since those content areas were selected for IT in higher education, and most universities still hold tightly to them today. Industry definitions of core competencies for information technologists have evolved in that time. While

many universities have begun teaching operating systems from an experiential standpoint or as part of their application content, storage remains relatively ignored.

The primary problem with the disregard for storage is that the topic remains critical to enterprise systems education whether curricula support it or not. As a result of the absence of storage courses in higher education, enterprise architects must either go into the workforce with no understanding of storage (and thus, significantly unprepared to meet a growing industry need), or enterprise systems integration instructors must abandon weeks of their course to cover storage—thereby undermining the students' training in the integration of the five pillars of information technology.

Storage is of significant importance to industry because the value of information (and the virtual space it consumes) continues to climb. We have moved on from bookkeeping and asset-management tasks to business-to-business multimedia, video on demand, and voice and data integration. The number of e-mail messages alone has grown from 9.7 billion per day in 2000 to more than 35 billion messages per day in 2007. Within those e-mails we embed a variety of media and file types, forcing a focus on information sharing rather than server-centric data storage. Material has to be shared via storage networking environments to meet current information needs ("Information Lifecycle Management," 2006; Mesabi Group, 2006]. In addition, the increased storage and information management demands related to the Health Insurance Portability and Accountability Act (HIPAA), Sarbanes-Oxley, and other government-mandated regulations have created an enormous demand for enterprise storage and information management solutions.

To meet growing storage needs, the industry has introduced a selection of storage solution alternatives, each addressing specific data storage and management needs (Duplessie, 2006). Direct attached storage (DAS) systems attach storage drives directly to servers, network attached storage (NAS) environments are made up of specialized servers dedicated to storage, storage area networks (SANs) are highly scalable and allow hosts to implement their own storage file systems, and content addressable storage (CAS) systems are mechanisms for storing and retrieving information based on content rather than location. Because the storage needs of all organizations are growing exponentially today, huge investments are made each year in storage-related hardware, software, and skilled employees to design and navigate through these complex enterprise solutions.

CHALLENGES OF TEACHING STORAGE

The rapidly increasing need for storage professionals calls for an innovative capstone component in information technology education, drawing together the many aspects of storage technology and linking them to core information technology concepts. Students must be able to design, build, and manage storage architectures, as well as strategically plan for an organization's storage and information management needs.

Understanding the landscape of storage requires a broad skill set. Storage is not simply hard drives with data on them. The design and development of storage technologies require understanding technologies from legacy systems to emerging technologies, including knowledge management, disaster recovery, data replication, and application-aware resource management, as well as the business needs that storage networking addresses. Clearly, storage is a complex topic that highlights the relationships between each of Van Sickle et al.'s (2007) five pillars of IT: While each is unique, they go hand in hand, such as storage and networking, or storage and databases, and so forth.

As important as how storage courses are taught is when they are taught. Storage is one of the five pillars of information technology, and universities would do well to treat it as such. Courses and modules on enterprise storage-related topics throughout an educational curriculum are needed today in order to properly develop the enterprise architect demanded by industry ("SNIA Announces Storage Networking Courses," 2005). The implication of adding storage to the existing curriculum is significant. Additional classes on any topic are always a challenge for a solid curriculum as it usually means other classes must be dropped or modified to make space in the overall credit load. Capstone courses, such as systems integration, must also be changed to model the realistic expectations of a systems integration professional in industry. An integration architect must plan and coordinate all aspects of the information architecture for an organization, which includes storage as an independent item of consideration. Information storage architecture is a unique pillar of IT because it has unique requirements and attributes related to but not found in the other more traditional pillars. Likewise, a capstone enterprise systems integration course should seek to bring all five pillars of IT together for students, making distinct courses in networking, databases, applications, operating systems, and storage prerequisites for such a capstone course.

FUTURE TRENDS

Given the clear demand for graduates with the perspective of an enterprise architect in industry today and for the foreseeable future, and the rapidly growing demands for storage over that same time period, enterprise systems curricula clearly need to make adjustments to accommodate courses on enterprise systems integration as well as redesigning or creating necessary supporting courses.

Enterprise systems curricula must reflect comprehensive, broad education in relevant topics to prepare students for occupations in IT. This means introductory courses on networking, databases, applications, and storage, necessitating a minimum of four independent courses. Students will also require training on organizations and business processes, project management, and systems design. At an advanced level, enterprise systems curricula will need courses specific to enterprise integration (people, processes, and technology), teaching students to connect in relevant, meaningful ways what they have learned in the supporting courses.

CORPORATIONS LEADING THE CHARGE FOR STORAGE EDUCATION

The need for storage education has been publicized for several years (Morgenstern, 2003; Ruddlesden, 2005; Trelwyn, 2004). With virtually no institutions of higher education hearing the call, corporations have begun leading the charge for storage education. Hewlett-Packard and McData are among industry leaders actively encouraging colleges and universities to include storage education in their curriculum (Trelwyn). Professional organizations, such as the Storage Networking Industry Association (SNIA), are also encouraging storage education, offering course requirement suggestions and certifications.

EMC Corporation has recently launched the Academic Alliance Program (Van Sickle et al., 2007) to partner in a variety of ways with academia. The company is teaming up with university faculty to determine how to best create courses to educate students in storage-related topics within the context of a larger curriculum in information technology or related areas. The company also offers course content for storage education, as well as simulation materials and a current industry perspective on storage. To date, EMC is the only corporation stepping up in such an organized manner to work with academia to address the industry need for the inclusion of storage and information management topics and courses in IT, MIS, and other technology curricula.

CONCLUSION

With the clear importance of the enterprise architect's perspective in industry, and the subsequent increase in demand for skilled enterprise systems graduates, colleges and universities wishing to remain competitive in their educational offerings will have to make significant overhauls to their IT curriculum to accommodate these demands. Despite the difficulty of incorporating a complement of foundational courses in the five areas that comprise the modern enterprise IT architecture, IT and MIS curricula must strive to meet the increasing demand for employees who can address information systems and technologies at an organization-wide level. With IT budgets increasingly being spent on storage-related projects and components, a competitive educational institution must offer foundational education in all of the five areas suggested by Van Sickle et al. (2007).

While the challenges to implementing new curricula are significant, and the development of storage-specific courses is especially difficult due to the lack of instructional materials, academic partnerships with industry can help a college or university make significant progress toward completely supporting enterprise systems education. In addition to the creation of appropriate, relevant instructional content, these alliances also afford students industry engagements that are both highly effective for learning and helpful in ensuring skill sets that will help information technology students be better prepared for the business environment they will face upon graduation.

KEY TERMS

Enterprise Architect: An enterprise architect (EA) takes a company's business strategy and defines an IT systems architecture to support that strategy.

Enterprise Architecture: Enterprise architecture is a comprehensive framework used to manage and align an organization's business processes, IT software and hardware, local and wide area networks, people, operations, and projects with the organization's overall strategy.

Enterprise Systems Integration: It is a discipline that combines processes and procedures from systems engineering, systems management, and product development for the purpose of developing large-scale, complex systems that involve hardware and software and may be based on existing or legacy systems coupled with totally new requirements to add significant functionality.

Information Technology: IT includes all matters concerned with the furtherance of computer science and technology and with the design, development, installation, and implementation of information systems and applications. An information technology architecture is an integrated framework for acquiring and evolving IT to achieve strategic goals.

Sarbanes-Oxley (SOX): Administered by the Securities and Exchange Commission (SEC) in 2002, SOX regulates corporate financial records and provides penalties for their abuse. It defines the type of records that must be recorded and for how long. It also deals with falsification of data.

Service-Oriented Architecture: A service-oriented architecture is essentially a collection of services. These services communicate with each other. The communication can involve either simple data passing or it could involve two or more services coordinating some activity. Some means of connecting services to each other is needed.

Storage Networking: It is the practice of creating, installing, administering, or using networks whose primary purpose is the transfer of data between computer systems and storage elements and among storage elements.

Developing Trust in Virtual Teams

Niki Panteli
University of Bath, UK

INTRODUCTION

During the last few years, there has been an increasing acknowledgment of the importance of trust in business interactions within the management and organizational literatures (e.g., Kramer & Tyler, 1996; Mayer, Davis, & Schorman, 1995; Rousseau, Sitkin, Burt, & Camerer, 1999). Trust, as a positive and confident expectation in the behavior of another party (Cook & Wall, 1980; Currall & Judge, 1995), enables cooperation and becomes the means for complexity reduction, even in situations where individuals must act under uncertainty with ambiguous and incomplete information. Therefore, it is not surprising that in the current age of global and digital economy and virtuality (Shepherd, 2004), there has been an overwhelming interest in trust. Motivated by the need to better understand trust in the digital era, this paper views the case of global virtual teams in commercial business organizations.

BACKGROUND

Trust has received significant recognition as a phenomenon worthy of detailed study in organizational and management studies (Dirks & Ferrin, 2001). In organizations, individuals must often act under uncertainty with ambiguous and incomplete information. This lack of explicit knowledge introduces risk and thus the requirement for trust. Accordingly, trust is defined as the willingness of a party to be vulnerable to the actions of another party (Mayer et al., 1995) based on a state of a positive, confident, though subjective, expectation regarding the behavior of somebody or something in a situation that entails risk to the trusting party (Baba, 1999; Cook & Wall, 1980; Currall & Judge, 1995).

Numerous scholars agree that trust is highly beneficial for the functioning of organizations. Trust "is at the heart of knowledge exchange" (Davenport & Prusak, 1998, p.35). High levels of trust are also key to effective communication (Dodgson, 1993) as they "improve the quality of dialogue and discussions … [that] facilitate the sharing of … knowledge" (Ichijo, von Krogh, & Nonaka, 2000, p.200), and committed relationships (ibid). The centrality of trust is further accentuated by its absence: "mistrust ... makes success harder to attain" (Kanter, 1994, p.105) as it weakens relationships, increases dependence on less information, compromises rational and unprejudiced analysis and exploration, and undermines learning (Luhmann, 1979). Furthermore, it has been recognized that if trust is not prominent, this may lead to dissatisfaction, absenteeism, and even intention to quit (Cunningham & MacGregor, 2000). At the inter-organizational level, trust also plays a vital role since it is found to affect the degree of cooperation among participating parties (Grabowski & Roberts, 1998; Newell & Swan, 2000). This is particularly important for virtual organizations. The business motivation for virtual arrangements is the potential for increased value-added and competitive advantage from the enhanced knowledge stock and core competencies, which are deemed to accrue to such networks (Alavi &Leidner, 2001).

Clearly, there is little dispute over the significance of trust in the organizational literature. However, there seems to be little agreement on how trust is developed and maintained in both the traditional and the virtual organizational literature.

In the traditional literature on trust where face-to-face communication is the norm, trust develops as the degree of familiarity with other people increases; i.e., the more we get to know others, the more likely it is that we trust them (Lewicki & Bunker, 1995,1996). Lewicki and Bunker (1996) take the view that trust varies over time and takes on a different character at the various stages (early, developing, and mature stages) of a relationship, as we not only begin to feel more comfortable with other people as we spend more time with them, but also as our knowledge of their integrity and competence improves. Based on this view, Lewicki and Bunker (1996) suggest three categories of trust, each corresponding to a different stage of the relationship:

- Calculus-Based Trust, the type of trust that is grounded in the rewards to be derived from pursuing and preserving the relationship or in the fear of punishment for violating trust within the relationship;
- Knowledge-Based Trust that assumes that the more information one has about others, the more able one is to predict their actions; and
- Identification-Based Trust, the type of trust that is characterized by mutual understanding among all parties to the point that each can effectively act for the other.

These types of trust are "linked in a sequential iteration in which the achievements of trust at one level enables the development of trust at the next level" (p. 119).

Familiarity with other people has also been identified as an important antecedent of trust development in virtual teams. According to Handy (1995), for trust to develop in virtual environments there is a need for constant face-to-face communication. As he puts it: "paradoxically, the more virtual an organization becomes, the more its people need to meet in person" (Handy, 1995, p.46). This view has also been reinforced by Lipnack and Stamps (1997, p.226): "if you can drop by someone's office, see first-hand examples of prior work, and talk with other colleagues, you can more easily evaluate their proficiency." Researchers have already argued that the lack of proximity impersonalizes trust (Nandhakumar, 1999), while the virtual context of a geographically dispersed workforce may constrain or even impede rich information exchange[1] since communication becomes highly computer-mediated (Davenport & Pearlson, 1998). It follows, therefore, that trust based on familiarity with other individuals could not be easily developed in virtual settings.

In the following section, the challenges of developing trust in a virtual team setting are discussed by drawing upon the findings of existing empirical research.

Trust and Virtual Teams: Empirical Findings

While trust has been identified as a key feature for the success of virtual interactions, empirical research in this area has remained limited. Jarvenpaa and Leidner (1999) have conducted one of the most detailed research projects into studies on trust and virtual teams thus far. Their eight-week study of 75 teams of university students, each consisting of four to six members, highlighted significant differences in the behaviors and strategies between high- and low-trust teams and supported the existence of swift trust; this type of trust presumes that roles are clear and that each team member has a good understanding of others' roles and responsibilities (Meyerson, Weick, & Kramer, 1996).

However, trust is not always swift. Tucker and Panteli (2003) have illustrated the significance of shared goals and power in influencing trust development; these factors were not identified in the context of university settings as the tasks are often well-articulated in advance while power differentials, which could influence the degree of inter-dependence among members, are not significant in the case of university students. In business environments, however, power differentials prevail. Power, defined as the capability of one party to exert an influence on another to act in a prescribed manner, is often a function of both dependence and the use of that dependence as leverage (Rassingham, 1999). Indeed, power is an important contextual factor that affects trust (Hart & Saunders, 1997) in that it suggests the existence of a unilateral dependency or an imbalanced relationship (Allen, Colligan, Finnie, & Kern, 2000).

Accordingly, within a business environment where conflict and power differentials prevail, building trust is not always a swift process. Instead, it is found that the process of jointly constructing team goals holds significant value as it may provide the "glue" to hold team members together long enough to enable trust development.

Shared goals are and should be a key characteristic of virtual teams. They could provide a means to developing a common sense of identity for team members that can be of particular benefit to those global virtual teams who meet infrequently or perhaps not at all. These benefits include the establishment of a foundation upon which to build trust and minimize the use of coercive power in pursuit of a collaborative and productive relationship. However, the study finds that even though shared goals are important for the success of virtual teams, these should not be taken for granted. Indeed, goals may not be shared either because they do not exist at all, or because team members have not become aware of them, have their own priorities, or share different interpretations of the team's role. Furthermore, this study has also shown that the construction of shared goals is often not a one-off activity, but rather it is a process that requires the ongoing participation of all parties involved. Though this could be a time-consuming, iterative, and difficult process, these findings allow us to argue that it is far better to invest in it and as up front in the project as possible than deal with the vicious, destructive, downward spirals that result from team members with conflicting goals and poor levels of trust.

In considering power within virtual teams, there is an increasing recognition in the literature that knowledge is indeed power and that teams are often formed to create knowledge through combination and exchange. Within these teams, the team member with power at any given time is the one with the most relevant knowledge at that time. Tucker and Panteli (2003) found that in high-trust teams power differentials do not disappear; rather, power shifts from one member to another throughout the life cycle of a project depending on the stage and requirement of each stage.

Further to the issues of shared goals and power, Tucker and Panteli (2003) found support for the need for face-to-face interaction. However, the opportunities to meet face-to-face have been severely limited by economic pressures and, more recently, terrorist attacks. Under these circumstances, those virtual teams that work well tend to undertake regular communications via synchronous, "live" computer-mediated communication (CMC) such as the telephone and videoconferencing systems. Participants confirmed that synchronous media offered more feedback and therefore facilitated understanding more effectively than asynchronous technologies such as voicemail and e-

mail. The use of asynchronous technologies was, however, regularly used for documenting and recording agreements and providing brief, simple updates to work progress. The teams that worked well also included a social and fun element in their interactions that appeared to help in creating a stronger shared social context.

Table 1 details the common features and behaviors observed within the global virtual teams studied in Tucker and Panteli (2003, p.91).

FUTURE TRENDS

The increasing pressure to perform in a short period of time with unfamiliar people and within a computer-mediated environment makes it imperative to study not only the type of trust but also how trust is formed and developed in a virtual team context.

It is readily acknowledged that what has been attempted here is only an exploration of contingencies to provide a better understanding of trust within the virtual team environment. There is no doubt that this is only the beginning of our understanding of trust in a virtual context.

Virtual interactions, however, exist at multiple levels—between individuals, individuals and organizations, and between organizations. Nandhakumar, Paneli, Powell, and Vidgen (2004, p.79) have introduced a digital era interaction (DEI) matrix to support exploration of trust relationships at these different levels.

The digital era interaction (DEI) matrix in Figure 1 indicates areas where digital era developments might be expected with consequent implications for trust. It views trust in two dimensions allowing an exploration of its nature in organization-to-organization settings, organization-to-individual and individual-to-organization interactions, and at an individual-to-individual level. In this paper, trust at the individual-to-individual level (and, more specifically, employee-to-employee) was explored. Thus, although the individual-to-organization (I2O) quadrant is currently the least developed of the four, it may prove to be an interesting sector in the longer term. Consumer-to-Business (C2B) is another growing area that allows consumers to organize themselves and use their stronger bargaining power to obtain a better price. As it was put: "The matrix is not exhaustive (for example, it does not include E2C, employee to consumer), but it does cater for the principal electronic relationships that currently exist and highlights ones that will be significant in the future" (p.79).

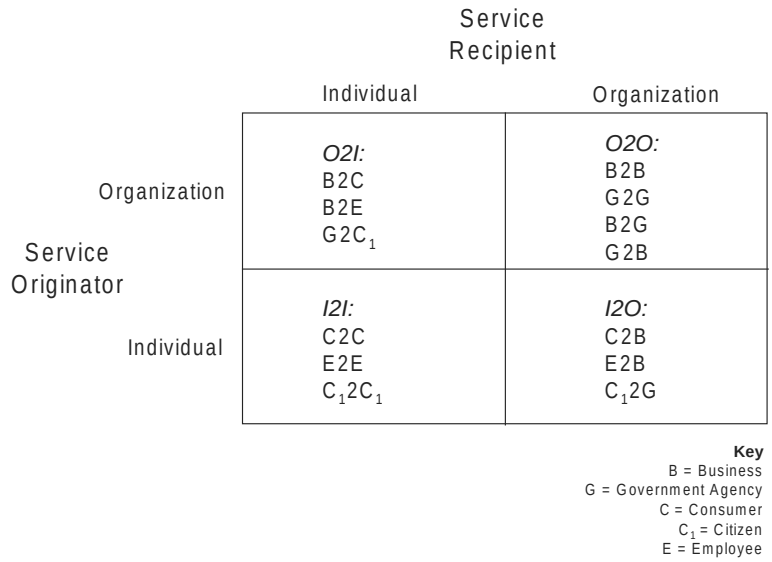
CONCLUSION

This paper reinforces arguments in the existing literature on the significance and complexity of trust dynamics in building effective virtual teams. It defined trust and outlined its central role in virtual interactions while also identifying some of the challenges involved in developing trust in the digital era, arguing that trust is necessary but not sufficient for promoting effective, collaborative virtual interactions using empirical findings. The paper illustrates the significance of shared goals and power in influencing trust development. It has also become apparent that while the agreement of shared goals provides a mobilizing force for the members of global virtual teams, the process of developing these goals holds significant value in terms of the exchange of information, learning, improving understanding, and an opportunity to

Table 1. Differences between high-trust and low-trust global virtual teams

High-Trust Global Virtual Teams	***Low-Trust Global Virtual Teams***
Factors related to Shared Goals: *Awareness of shared goals *Take time to build shared goals *Open debate for shared goals up front *Team-based goals have primacy	**Factors related to Shared Goals:** *Lack of awareness of shared goals *Lack of shared goals *Opinions of others not considered *Individual goals take primacy
Factors related to Power: *Availability of facilitators *Facilitators focus on win-win *Recognition of knowledge as power *Recognition that power moves; power in many places *Power differentials are minimized	**Factors related to Power:** *Power battles *Coercion *Misunderstandings and conflict of interests *Use of positional power *Perception of 'I have Power'
Communication: *Face-to-face where possible *Regular synchronous CMC *Social interaction	**Communication:** *Asynchronous CMC * Time difference matters *Little or no social interest

Figure 1. Digital era interactions (DEI)



demonstrate trustworthiness. Repositioning trust in this way increases our chances of making sense of complex virtual, computer-mediated situations, and puts us in closer touch with the challenges of developing trust. In doing so, the paper carries forward an important debate in the digital era.

KEY TERMS

Computer-Mediated Communication: Communication that is facilitated using information technologies such as email, videoconferencing, teleconferencing.

Power: The ability to influence others.

Power Differentials: The existence of imbalanced power relationships.

Shared Goals: Goals that articulate what the teams stand for and their shared vision.

Social Interactions: A chain of interrelated messages that include a social and fun element and contribute to increasing familiarity among participants.

Trust: A state of a positive, confident though subjective expectation regarding the behavior of somebody or something in a situation that entails risk to the trusting party.

Virtual Teams: A group of geographically dispersed individuals who work on a joint project or common task and communicate electronically.

ENDNOTE

[1] This view corresponds to the media richness theory that argues that electronic media are lean (Daft & Lengel, 1986).

Diffusion of E-Learning as an Educational Innovation

Petek Askar
Hacettepe University, Turkey

Ugur Halici
Middle East Technical University, Turkey

INTRODUCTION

Most of the discussions related to education are about technological innovations. Indeed as Rogers (1995) stated, we often use the word "innovation" and "technology" as synonyms. Technology is regarded as an agent of change in educational settings, and a quick analysis of the educational projects all over the world shows us that it is not possible to define a future vision of education without technology, especially e-learning, which brings two important concepts together: technology and learning. Therefore as a form of distance learning, e-learning has become a major instructional force in the world.

Besides the technological developments, the last two decades have brought a tremendous increase in knowledge in education, particularly in learning. The emerging views of learning which should be taken into consideration for every learning environment could be stated as follows: personalized, flexible, and coherent (learning is connected to real-life issues); not bounded by physical, geographic, or temporal space; rich in information and learning experiences for all learners; committed to increasing different intelligences and learning styles; interconnected and collaborative; fostering interorganizational linkages; engaged in dialogue with community members; accountable to the learner to provide adaptive instructional environments (Marshall, 1997).

WWW is an environment that fits the new paradigm of learning and facilitates "e-learning" which faces a challenge of diffusion. Diffusion is defined by Rogers (1995) as the process by which an innovation is communicated through certain channels over time among the members of a social system. Therefore the adoption of WWW as a learning environment is influenced by the following set of factors: 1) the individuals' perception of the attributes of e-learning, 2) the nature of the communication channels, 3) the nature of the social system, and 4) the extent of the change agents' efforts in the e-learning. These are the variables that affect the diffusion of e-learning in the schools and countries.

E-LEARNING AND INSTRUCTIONAL DESIGN

E-learning not only opens up new ways of learning and teaching, but also leads to a new way of thinking and organizing learning content. Collaborations among different stakeholders cause new standards for design of knowledge on the Internet. In traditional computer-based instruction, content comes in units called courses. However a new paradigm for designing instruction, grounded in the object-oriented notion of computer science, is called "learning objects."

Learning object is defined by the Learning Technology Standards Committee (2002) of the Institute of Electrical and Electronics (IEEE) as any entity, digital or non-digital, that can be used, re-used, or referenced during technology-supported learning. The features of learning objects are self-contained, interactive, reusable, and tagged with metadata. By the use of learning objects, one can learn just enough, just in time, and just for them. Learning objects can be considered a movement within the field of e-learning, one aimed at the componentization of learning resources, with a view to reusability (Duchastel, 2004).

The idea of educational software as a package is becoming outdated and making way for learning objects as a new way of designing instructional materials. In designing learning objects, the studies on multiple representation of knowledge become important since people have different learning styles and strategies. The associations between these two constructs are the main focus of the new instructional design principles. Therefore, the development of learning objects and the way of creating teaching units are well suited for what we call the Information Age.

A representation of knowledge could be decomposed into its parts, where the parts are far from arbitrary. Then they can be used and reused in a great variety of combinations, like a child's set of building blocks. Every combination is meaningful and serves as an instructional whole. Holland (1995) compares building blocks to the features of the human face. The common building blocks are: hair, forehead, eyebrows, eyes, and so on. Any combination is different and may never appear twice. This analogy could be true of

e-learning platforms, where learning objects are put together to make up a meaningful whole, which we call instructional materials.

The five fundamental components of instructional design process are learners, content, objectives, methods, and assessment. Hence, for a systematic instructional design of a subject matter, the basic steps are: learner characteristic identification, task analysis, objectives, content sequencing, instructional strategies, message design, and instructional delivery and evaluation.

The awareness of learner differences with respect to entry competencies, learning styles and strategies, motivation, and interest are critical. However it is difficult to accomplish this task by using ongoing approaches. Indeed, new technologies, if used properly, enable us to make the lessons more individualized. The Learning Objects Metadata Working Group (IEEE, 2002) stated its goal as: to enable computer agents to automatically and dynamically compose personalized lessons for an individual learner. This leads a paradigm shift to approaches to instructional design. As Wiley (2001) stated, a problem arose when people began to actually consider what it meant for a computer to "automatically and dynamically compose personalized lessons." It seems that the idea of learning objects is challenging, but opens to new concepts, strategies, and research areas in the instructional design process.

E-LEARNING AND SCHOOL MANAGEMENT

For most of the last two decades, technology has been implemented in schools, and its potential to change the educational systems has been argued for. There are tremendous efforts to encourage the integration of computers and Internet into schools. However, in one of the diffusion studies conducted by Askar and Usluel (2001), two paths to the adoption of computers are presented. One path is related to the use of technology in the school management system; the other one is related to the use of technology in the teaching and learning process. For many reasons the rate of adoption of computers in management applications is quicker than the learning-teaching applications. Indeed the concerns related to use of computers in the teaching-learning process are still at the awareness stage. On the other hand, the need for using computers and the Internet for management purposes is more relevant and seems more convenient for the current school system.

Educators assert that the central purpose of school management systems should be to improve instructional program quality. In light of this idea, a typical configuration of a Web-based school management system designed—taking this idea into consideration—includes administration, assessment, and communication. The features are: student enrollment, attendance, registration, test scores, grades and other record-keeping tasks, formative and summative evaluation, and feedback to parents and teachers about student learning and performance. In addition, new online management systems include item- banking capability for adaptive testing and online learning modules.

E-LEARNING AND THE COMMUNITY

The modern world requires individuals and communities to be able to continually develop and utilize different skills and knowledge. There is growing consensus among OECD countries that modern economies cannot afford a significant number of uneducated people (OECD, 2000). However, education systems throughout the world are ill equipped to address individual and community learning needs. The existing school system is not flexible for those who for some reason left school early.

Distance education is a recognized solution all over the world for bridging the learning and education divide between the educated and poorly educated. It gives people the opportunity to continue their formal education. Despite the initial concerns that distance education might be lower in quality than traditional method of schooling, many forms of distance education are gaining acceptance (Belanger & Jordan, 2000). Therefore distance education is receiving positive attention from governments as a solution to the educational problem mentioned above.

Also, the trend towards lifelong learning is universal. The transformations taking place in all societies require an increasing participation of individuals, an ability to innovate and solve problems, and a capacity to learn and go on learning (Mayor, 1994). Moreover, the term "open learning" is used to lower barriers that stand in the way of individuals and communities wishing to engage in different learning opportunities.

One of the solutions for the above mentioned problems is learning centers, which are flexible learning organizations and which serve the learning needs of the individuals and communities. A school that is well equipped and organized could be opened during non-traditional school hours. Therefore, schools as learning centers can be critical resources to meet the growing need for distance education students and other community members. However, in highly centralized education systems, it is very difficult to organize schools for those other than the registered students. The rules and regulations for conventional school become real barriers for open learning environments.

FUTURE TRENDS IN TECHNOLOGY

While adopting the current technology for enhancing teaching and learning, advances in micro- and nano-technology push the limits of miniaturization, and of minimizing the costs and power of microelectronic components and microsystems. Explorations of alternative materials are expected to allow organic flexible materials for displays, sensors, and actuators so that they can be placed anywhere and can take any shape. Furthermore it is expected that not only PCs, but also all our surroundings, will be interfaced. Instead of only " writing and reading" in human-computer interaction, all senses are to be used intuitively. Information search will be context-based instead of "word " based. Mobile and wireless devices will be used not only for voice transfer, but also for full multimedia (IST WP, 2002)

As information and communication technologies change, open systems and services are to be developed in support of ubiquitous, experiential and contextualized learning, and virtual collaborative learning communities improving the efficiency and cost-effectiveness of learning for individuals and organizations, independent of time, place, and pace. Next-generation learning solutions are expected to combine cognitive and knowledge-based approaches, with new media having intelligence, virtual and augmented reality, virtual presence, and simulation (ISTC, 2001).

CONCLUSION

Our current educational system is highly resistant to change. Making a client-based change rather than a technological based one will be the most important innovation to accomplish for the educational change. While technology is pushing the limits of e-learning environments, special care should be taken in educational and organizational frameworks. The stakeholders of the systems are students, teachers, principals, learners, and community. Their attitudes, needs, and expectations from e-learning are important issues for the change process. The innovation adoption variables of relative advantage, compatibility, visibility, ease of use, results demonstrability, and triability should be considered by school administrators seeking to increase the rate of adoption of e-learning within their organization (Jebeile & Reeve, 2003).

Complexity is another issue to be considered. Fullan (1991) defines complexity as the difficulty and extent of change required of the individuals responsible for implementation. Therefore, there should be an emphasis on simplifying the process of e-learning, while moving from approaches based on knowledge transfer to systems based on the dynamic construction and user-friendly exchange of knowledge between learners, teachers, and learning communities.

The educational community, as the end user of e-learning systems, should be given the opportunity of observing and trying the e-learning systems. Awareness or being informed about the innovation is the key factor for changing the negative attitudes or beliefs. It is known that if people see the implementation and results of innovation, they are more likely to adopt them for their usage. Unfortunately, the benefits of e-learning are not well known and well recognized by all relevant stakeholders. Therefore, a comprehensive and systematic awareness campaign is needed to speed up the rate of adoption.

KEY TERMS

Diffusion: The process by which an innovation is communicated through certain channels over time among the members of a social system.

Distance Education: A type of formal education in which the majority of the instruction, which is transmitted through technology, occurs when student and instructor are not in the same place.

Innovation: An idea, practice, or object that is perceived as new by an individual or other unit of adoption.

Instructional Design: The systematic process of translating general principles of learning and instruction into plans for instruction and learning.

Learning Object: Any entity, digital or non-digital, that can be used, re-used, or referenced during technology-supported learning.

Learning Styles: The ways in which a person takes in and processes information and experiences.

Rate of Adoption: The relative speed with which an innovation is adopted by members of a social system.

A Diffusion-Based Investigation into the Use of Lotus Domino Discussion Databases

Virginia Ilie
University of Kansas, USA

Craig Van Slyke
Saint Louis University, USA

Hao Lou
Ohio University, USA

John Day
Ohio University, USA

INTRODUCTION

Some information and communication technologies (ICT) that support groups have become tightly engrained in the fabric of organizational life, but others have not been as widely adopted (Orlikowski, 1993). This is true of both businesses and educational institutions. For example, many professors and students regularly interact through e-mail. In contrast, groupware systems are not as widely used.

In this article, we present research that uses diffusion of innovation (DOI) theory (Rogers, 1995) as the lens through which to study factors that impact intentions to use a groupware application in a higher education setting. This research investigates the following research question: *Are adopters' perceptions of the characteristics of groupware technology related to their intentions to use the technology?*

Organizations are increasingly making use of ICT to enable distance learning for their employees and, in some cases, customers (Dick, Case, Ruhlman, Van Slyke, & Winston, 2006). Furthermore, numerous academic institutions are implementing and supporting collaborative technologies to support student learning. For instance, Cordon, Anaya, Gonzalez, and Pinzon (2007) report on implementation of a virtual learning center to support learning of 4,000 students in Spain. Leung and Li (2006) describe efforts to create an e-learning environment in Hong Kong. High student dropout rates and low student satisfaction with e-learning remain major drawbacks in such implementations. Despite the presence of online discussion boards, sometimes students feel that there is little interaction in Web-based learning (Chatterjea, 2004). Avoiding failure in distance learning efforts requires better understanding of e-learners and their perception of ICT-based learning technologies.

BACKGROUND

Groupware technology is designed to facilitate the work of groups. This technology may be used to communicate, cooperate, coordinate, solve problems, compete, or negotiate. While traditional technologies such as the telephone qualify as groupware, the term is ordinarily used to refer to a specific class of technologies relying on modern computer networks, such as e-mail, newsgroups, videophones, or chat.

Figure 1. Groupware classification

	Same Time "Synchronous"	**Different Time** "Asynchronous"
Same Place "Co-Located"	Group decision support systems, voting, presentation support	Shared computers
Different Place "Distance"	Videophones, chat	Discussions, e-mail, workflow

Groupware technologies are typically categorized along two primary dimensions, time and place (Johansen, 1988), as shown in Figure 1. In this study, we investigate Lotus Domino discussion database (DDB), an asynchronous groupware product designed to be used by users "any time and any place."

The DDB is one of the Lotus Notes groupware applications made available to Web browsers via the Domino HTTP server technology. One may think of a DDB as an informal meeting place where the members of a workgroup can share ideas and comments. Like a physical meeting, each member of the workgroup "listens" to what others have to say, and can voice his or her own opinion.

Users have the ability to simply browse through discussion topics and responses contributed by others. This is particularly useful for new workgroup members who need to become oriented to important issues regarding the group. The history of any discussion is preserved in the discussion database and is presented as a discussion thread. Figure 2 illustrates a threaded discussion.

In a threaded discussion, users can either respond to an existing discussion thread or create a new discussion thread by posting a new topic. Posted items can also be edited and deleted by the author. Among the most important benefits of such groupware systems is to extend learning beyond the classroom (Day, Lou, & Van Slyke, 2004). Discussion databases can expand learning between students and faculty, and between students themselves by encouraging interaction and reflection on a topic.

An additional benefit comes from the fact that online interactive discussions may promote higher-order learning. For example, online debates often require synthesis of knowledge, which represents higher-order learning (Hazzari, 2004). In asynchronous online discussions, students have more time to reflect and synthesize their knowledge; there is less time pressure to respond quickly than there would be in a classroom setting. In addition, higher levels of certain cognitive processes may occur with online learning than with traditional classroom interactions (Heckman & Annabi, 2006).

MAIN FOCUS OF THE CHAPTER

DOI theory serves as the theoretical basis for this study. DOI theory is concerned with how the use of an innovation spreads throughout a social system (Mahajan, Mueller, & Bass, 1990). Diffusion theory has been applied to a wide range of technologies, including information and communication technologies such as groupware.

An often studied area related to innovation adoption is the impact of adopters' perceptions of the characteristics of an innovation on its adoption (Gatignon & Robertson, 1985; Lancaster & Taylor, 1986; Rogers, 1995). It is important to note that it is the potential adopters' *perceptions* of these characteristics rather than an expert's objective assessment of how an innovation rates on these characteristics

Figure 2. Discussion thread in a Domino discussion database

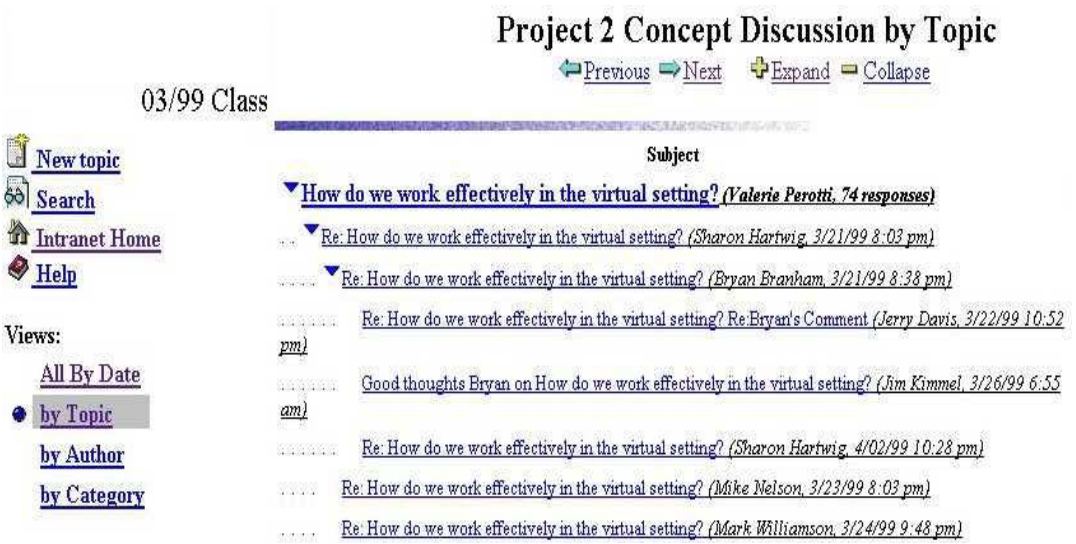

Table 1. Perceived innovation characteristics

Characteristic	Definition	Conceptual References	Empirical References
Relative Advantage	Degree to which an innovation is seen as being superior to its predecessor	Rogers, 1995	Van Slyke, Belanger, & Comunale, 2004
Complexity	Degree to which an innovation is seen by the potential adopter as being relatively difficult to use and understand	Rogers, 1995	Cooper & Zmud 1990; Teo, Tan, & Wei, 1995; Van Slyke et al., 2004
Compatibility	Degree to which an innovation is seen to be compatible with existing values, beliefs, experiences, and needs of adopters	Rogers, 1995	Taylor & Todd, 1995; Van Slyke et al., 2004
Trialability	Based on adopters' perceptions of the degree to which an innovation can be used on a trial basis before confirmation of the adoption must occur	Rogers, 1995	Teo et al., 1995; Chong & Pervan, 2007
Result Demonstrability	Degree to which the results of using an innovation are perceived to be tangible	Moore & Benbasat, 1991	Ilie, Van Slyke, Green, & Lou, 2005
Visibility	The perception of the actual visibility of the innovation itself as opposed to the visibility of outputs	Moore & Benbasat, 1991	Agarwal & Prasad, 1997; Ilie et al., 2005
Voluntariness	Degree to which use of an innovation is perceived as being of freewill	Moore & Benbasat, 1991	Agarwal & Prasad, 1997; Van Slyke, Dick, & Case, 2005; Anderson, Schwager, & Kerns, 2006

that impacts the diffusion rate (Lancaster & Taylor, 1986; Rogers, 1995).

Rogers (1995) lists five perceived characteristics of an innovation that can help explain its adoption: (1) relative advantage, (2) compatibility, (3) complexity, (4) trialability, and (5) observability. Other constructs of interest to this study include voluntariness, result demonstrability, and visibility. Table 1 provides definitions for the innovation characteristics included in this study along with references for both conceptual and empirical studies related to each construct.

The research model derived from the relationships between intention to use and each of the factors discussed in this section is shown in Figure 3. Intention to use DDB is the dependent variable of interest. The expected direction of each relationship is indicated on the corresponding path.

A series of testable hypotheses can be developed from the research model and the operationalizations of the constructs of interest. These are shown below.

H1: Student perceptions of the characteristics of DDB technology are related to their intention to use the technology.

Several sub-hypotheses can be derived from H1, all of which are similar in wording. H1n shows the general form for each hypothesis. Table 2 shows the hypothesis number, scale of interest, and hypothesized relationship direction for each sub-hypothesis.

H1n: Student perceptions of the X characteristic of DDB technology as measured by the X scale are positively/negatively related to their intention to use the technology.

In order to test the research model, a voluntary survey was administered to business students at a major Midwestern university. Only students enrolled in a course where Domino

Figure 3. Research model

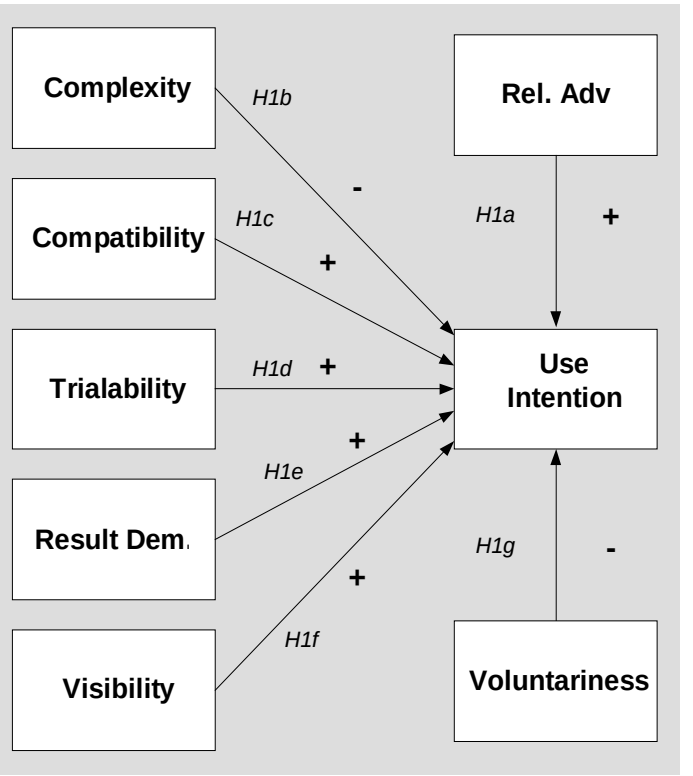

Table 2. Hypotheses

Hypothesis	Characteristic (X)	Direction
H1a	Relative Advantage	Positive
H1b	Complexity	Negative
H1c	Compatibility	Positive
H1d	Trialability	Positive
H1e	Result Demonstrability	Positive
H1f	Visibility	Positive
H1g	Voluntariness	Negative

Table 3. Sample characteristics (descriptive)

Characteristic	Median	Mean	Std. Dev.
Age	*22.5*	*25.9*	*7.28*
Work experience	*3.0*	*5.5*	*7.19*
Computer experience	*8.0*	*8.5*	*4.13*

Table 4. Sample characteristics (frequencies)

Characteristic	Frequency
Gender	
- Female	98
- Male	88
Class	
- Sophomore	4
- Junior	41
- Senior	139
- Graduate	2
Prior E-Mail Use	172
Prior Web Use	172
Prior Word Processor Use	164

was made available to the students as part of the course were included. A total of 186 surveys were completed. Tables 3 and 4 summarize the respondents' characteristics.

Measures

Most items for the measurement instrument were adapted from an instrument developed and validated by Moore and Benbasat (1991). Items were measured using a seven-point Likert-type scale. Cronbach's (1970) alpha values ranged from 0.77 to 0.96, indicating acceptable levels of reliability. The scales were further validated by performing a series of factor analyses, with one analysis performed for each scale. In all cases, the analysis indicated that the scale items associated with a given construct loaded on a single factor, indicating that each set of scale items measures a single construct. Factor loadings were all acceptably high.

Regression analysis was used to test the hypotheses. The data met the assumptions underlying the use of regression. An initial regression analysis revealed that no demographic variables were significant predictors of use intentions. Therefore none of the covariates were included in the final model.

The model variables were then analyzed, resulting in the following regression equation:

$$UI = 0.375 + 0.383RA + 0.335CP - 0.170CX + 0.012TR + 0.207RD - 0.027VI + 0.044VO$$

The F statistic for this equation is significant, indicating that the overall model is significant ($F = 36.313$, 7/178 df, $\alpha < .001$). The adjusted R^2 value for the model is 0.656, indicating that model can account for 65.6% of the sample variation in intention to use.

Next, the significance of individual terms were analyzed. These results are shown in Table 5.

FUTURE TRENDS

As new technologies and methods continue to emerge, there are a number of trends that warrant watching. The proliferation of mobile devices may impact the way in which education is conducted. Today's students seem tethered to their iPods and mobile phones. As the displays and input technologies on these devices improve, it may become possible to leverage their popularity by allowing students to use them for learning-oriented interaction. This would truly make learning anytime, anyplace. Our results indicate that designers of such systems and change agents interested in promoting their use should pay particular attention to promoting the relative advantage of these systems. Further, pointing out how the mobile, ubiquitous nature of such systems fits well with students' lives may improve compatibility beliefs, leading to greater adoption.

Table 5. Hypotheses test results

Construct	Hypothesis	Significance	Support
Relative Advantage (RA)	H1a	< 0.001	Supported
Complexity (CX)	H1b	0.035	Supported
Compatibility (CP)	H1c	< 0.001	Supported
Trialability (TR)	H1d	0.824	Not supported
Result Demonstrability (RD)	H1e	0.014	Supported
Visibility (VI)	H1f	0.601	Not supported
Voluntariness (VO)	H1g	0.475	Not supported

Students are not a homogeneous group, however. While younger users are accustomed to communicating through mobile devices, the same may not be true of non-traditional learners. Non-traditional learners are increasingly seeking new degrees and continuing education, so it is unwise to ignore their perceptions, especially since non-traditional students may hold favorable perceptions of distance learning (Stafford & Lindsey, 2007). In the future, it will become increasingly important to understand how to use ICT to meet the needs of diverse learner groups.

Because of this need, in the future it will be important to enable agile learning systems that can easily adapt to students' needs and preferences (Chatterjea, 2004). Such adaptation will positively impact perceptions of relative advantage and compatibility. We are already seeing the emergence of such systems, such as that reported by Leung and Li (2006), who use profiling methods to deploy personalized course materials.

CONCLUSION

ICT supporting "outside the classroom" interaction holds great potential for facilitating both traditional and distance learning. Our research shows that students' perceptions of these technologies are critical to their acceptance, which seems to agree with similar studies (e.g., Rentroia-Bonito, Jorge, & Ghaoui, 2006). Mandating use may lead to compliance through superficial use, but faithful use may be highly dependent on students' perceptions of relative advantage and compatibility. Open-ended comments from survey participants seem to support this thinking. Students pointed out a number of advantages to DDB, such as more frequent and timely instructor feedback and the ability to submit assignments online. Also, students pointed out that DDB facilitated easy communication among team members, another advantage of DDB.

Students also made comments related to compatibility. Recent research indicates that there must be congruence between technology that supports learning and the student's conception of the "best way to learn" (Hornik, Johnson, & Wu, 2007). Interestingly, students who had good working conditions at home (such as high-speed Internet access and a quiet workspace) were used to working at home and found DDB to be more compatible than those without suitable home conditions. Preferred communication style also seemed to be important to compatibility beliefs. Several students mentioned that DDB allowed them to interact, even though they were reluctant to speak up in class. In contrast, others said they preferred interacting personally. It is important to realize that students are not "one size fits all," so flexibility in a learning environment is important (Leung & Li, 2006; Chatterja, 2004).

While technology is a very useful tool and should be used in the classroom, both designers and faculty users should not forget the "human touch" (Lee, Tan, & Goh, 2004). In other words, according to Lee et al. (2004), IT tools are only effective when they reinforce good teaching!

KEY TERMS

Compatibility: Degree to which an innovation is seen to be compatible with existing values, beliefs, experiences, and needs of adopters.

Complexity: Degree to which an innovation is seen by the potential adopter as being relatively difficult to use and understand.

Diffusion of Innovations: How the use of a new idea, product, or technology spreads throughout a social system.

Discussion Database: An asynchronous groupware product designed to be used by users "anytime and anyplace." The product allows threaded discussions among members of a group.

Groupware: Information and communication technologies designed to facilitate the activities of cooperative workgroups.

Relative Advantage: Degree to which an innovation is seen as being superior to its predecessor.

Result Demonstrability: Degree to which the results of using an innovation are perceived to be tangible.

Voluntariness: Degree to which use of an innovation is perceived as being of freewill.

Digital Asset Management Concepts

Ramesh Subramanian
Quinnipiac University, USA

INTRODUCTION TO DIGITAL ASSET MANAGEMENT

"DAM. Looks like something you might say if you couldn't find a photograph you needed for a front-page story. But DAM—digital asset management—is actually designed to preempt such frustrated outbursts. In an age when oodles of media, including print, images, video and audio, are stored in computers rather than file cabinets, newspapers and other groups need a way to organize, manipulate and share those media quickly and easily." (Grimes, 1998)

Dramatic changes have occurred on the corporate front in the last few years, as more and more businesses have started to conduct commerce on the Internet. New business concepts and products are being developed on a daily basis. The accent is on speed, and changes occur quickly – daily, hourly or even minute-to-minute. Two major facets of these changes are:

1. Large amounts of data are created and stored in digitized forms in organizations, and
2. New "digital products" are created.

As more and more information is created in electronic form, organizations are faced with the following problems:

- The volume of digital data has become cumbersome to manage and reuse (Sharples, 1999).
- Organizations have struggled to reduce cycle time, maintain brand consistency, and coordinate cross-media publishing as well as one-to-one marketing efforts.
- The number of digital assets that an organization may manage has exploded.
- Gistics, a California-based research firm that has studied media asset management for several years, estimates that approximately 30% of all media assets in organizations are misplaced, and then reworked or duplicated.

A 2001 Frost and Sullivan market indicator report by Subha Vivek forecasts tremendous future growth in the U.S. digital media management market (Vivek, 2001). The three market segments that will be affected represent the capture, storage and access, and distribution of digital media, respectively.

The promise of digital asset management has attracted a lot of commercial enterprises and software research laboratories, and several products have been introduced commercially in the last few years. However, due to the "newness" of the field, there is not much academic research literature in the field. A good source of academic thought in this field can be found in the online proceedings of the Annenberg DAM Conference, held at the Annenberg School of Communication, University of Southern California in 1998 (Annenberg DAM Conference, 1998).

BACKGROUND: DIGITAL ASSET MANAGEMENT (DAM) CONCEPTS

This section is adapted from our earlier paper on the subject (Subramanian & Yen, 2002).

A. Definition

A *digital asset* is any asset that exists in a digitized form, and is of intrinsic or commercial value to an organization. *Digital asset management* can be defined as a set of processes that facilitate the search, retrieval, and storage of digital assets from an archive.

B. Basic Features of DAM

The basic features of any DAM system include: storage, search and retrieval, and "thumbnail browsing" (Rosenblatt, 1998). A good DAM system will also include the ability to perform object check-in and check-out.

Other desirable features include:

- Integration of the DAM system with content creation applications on the desktop.
- Enterprise features, that is, features that are necessary for a digital media management system to be useful in a large-scale deployment at a large media company (i.e., an industrial strength, scalable database).
- The ability of a DAM system to have a user interface that can function in a cross-platform environment (e.g., the Java language from Sun Microsystems, and the development of XML technology).

- The ability to extend the functionality of the DAM system through programming interfaces.

C. What are the basic differences between DAMs and standard data management systems?

One might argue that DAMs are not much different from currently available database management systems that facilitate the search, retrieval, and storage of data. However, DAMs are different in their potential to address four key problems that pertain to the creation, storage, search and dissemination of multi-media data. According to Hilton (Hilton, 2003), those four issues are:

1. Asset mining: New and sophisticated methods for mining multidimensional, multi-media data stores, which can result in the creation of dynamic, "on-demand" digital products
2. Automation: Automated classification and retrieval systems
3. Managing intellectual property (and associated security issues)
4. Engagement: New GUIs and other data manipulation methods as well as collaboration tools

Somani, Choi and Kleewein distinguish traditional data management systems from "content management systems" that handle digital assets, communications and content such as documents, intellectual property, rich media, e-mail and Web data, and discuss the differences between the two types of systems in the following areas (Somani et al., 2002):

1. Data federation to provide in-place access to existing data
2. An expressive data model that accommodates data from very disparate sources
3. Search over metadata and data

Somani et al. then propose an architecture for integrating the two, that is, data and content management systems. A detailed discussion of the architecture is beyond the scope of this article.

DAM SYSTEM ARCHITECTURE

Figure 1 uses a three-tiered architecture of the generic DAM system architecture to show the process followed during an asset creator's session and a client's query session.

In the *asset creation flow*, the Asset Creator creates an asset, which could be in any digital format, and provides the asset and its associated information to the Asset manager. The Asset manager converts the information associated with the asset into an XML metadata format, builds the appropriate data type definitions, and passes the information and the asset to the Metadata manager. The Metadata manager manages the organization of the Metadata Store, which is a database containing meta information on the assets. Appropriate links between the metadata and the actual assets are created and maintained here. The Metadata Store contains information about the digital assets, typically in an XML DTD format. The assets are passed by the Metadata manager to the File manager, which is responsible for the check-in and check-out of the assets into and out of the Digital Asset Store, which is a combination of file systems and databases.

In the *query processing flow*, the Client asks a query. The Query processor parses the query and sends the user information as well as the parsed query to the Metadata manager, which maintains the metadata for the assets. The metadata include not only information about the asset but also information on who is allowed to access the asset. After this information is retrieved from the Metadata store, a message is sent back to the Query processor by the Metadata manager. The message passed may either be a refusal to access the asset, or an affirmation that the requested asset is being retrieved.

The metadata component acts as a store, search, retrieve and security tool, managed by the Metadata manager.

ADDITIONAL ARCHITECTURAL DETAILS

A. An Open and Distributed Architecture

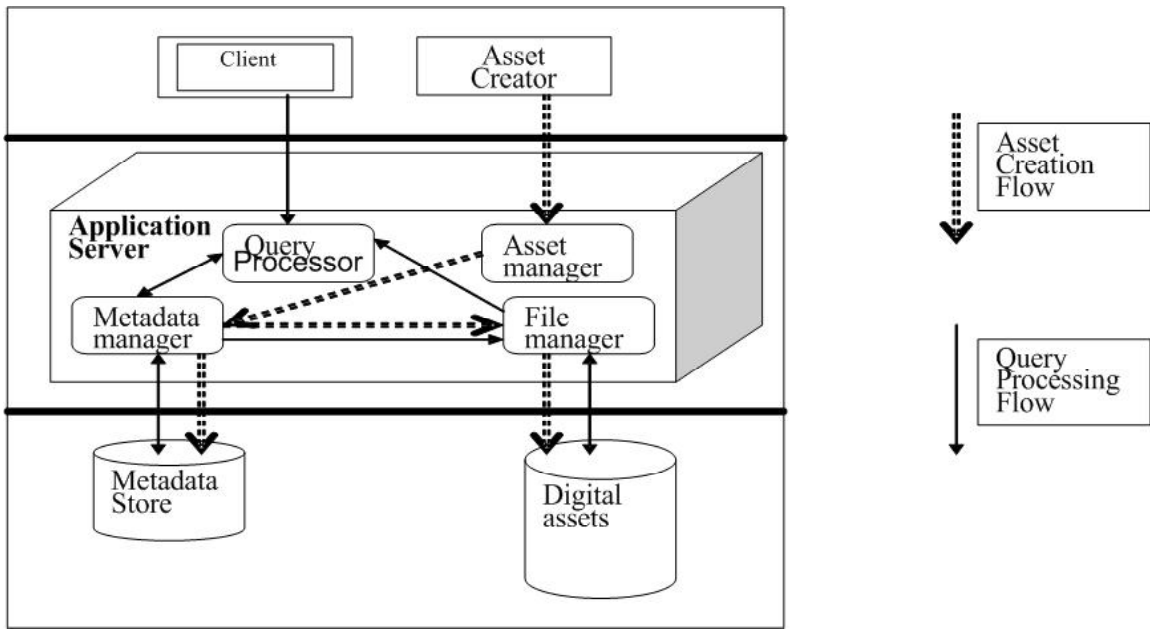
The key to any digital asset management system is to create an open and distributed architecture. A well designed DAM system first should provide the ability for people to take an asset, repository or archive and be able to customize it into their environment and extend it to their existing system and other new systems. The architecture should allow for the following features:

1. Scaling
2. User Interface and Custom Interface
3. File Management and Asset Association
4. Platform Independence and Transportability

B. Representation and Identification of Digital Assets

1. Representation Issues and Addressable Unit: The three categories of digital asset representation issues are:

Figure 1. Architecture for DAM system



Production Workflow, Creative Workflow, and the Addressable Unit (Romer, 1998). Production workflow is the ability for metadata to be added throughout the life cycle of digital asset handling (captioning, or cataloging), with appropriate knowledge management capabilities to establish standardization and consistency. Production workflows often deal with known items. Creative workflows are more discovery-oriented, hence more volatile and browse intensive. This workflow is characterized by the need to do many interactive searches and temporarily store candidate assets until a final decision can be made. A good DAM system must allow the designer or user to leverage this valuable production knowledge to help search for what one is looking for, by defining appropriate addressable units within a particular digital asset such as a digital video movie.

2. Identification Issues and Metadata Creation: Organizations are becoming increasingly aware that library science techniques need to be a very integral part of the process of identifying digital assets. DAM systems need to have a very sophisticated metadata model that will store and classify property information, details, names and descriptions, and anything else that the user defines and can be put on top of his/her digital assets. One promising method for classifying digital assets is through the use of "controlled vocabulary". This technique addresses how the hierarchical key words work, so that one can take a system, like the key word structure from the Library of Congress, and apply it to assets inside one's database.

C. Searching Digital Assets

1. "Top Down" Approach: Usually provides specialized searching routines that recognize the properties of the objects being searched. It is also referred to as "Content-based analysis". Image understanding and pattern recognition are all technologies that automatically process images based upon certain inherent properties of the image itself. Some examples are the color, texture and shape recognition systems from Virage (*http://www.virage.com*) or IBM's QBIC application (Faloutsos et al., 1994; Flickner et al., 1995). "Search extenders" facilitate content-based searching of digital files (e.g., content base searching of textural images). Bulldog's Search Extender™ technology allows the search mechanism to recognize the properties of various file types and implement specialized searching routines. They allow users to do context searching, such as finding the name "Bulldog" very close to information about Sun Microsystems inside the database. Equivalent search extender technology exists for images, video and audio.

2. "Bottom Up" Approach: A method is to design image representation schemes that will match the goals of the search process used for retrieval. The search subsystem was designed with decision support in mind.

TAXONOMY OF DAM SYSTEMS

We have categorized the DAM systems based on two criteria. The first criterion is based on how many people DAM systems need to serve, the price range and their complexity level. In this criterion, DAM can be divided into three categories (Rosenblatt, 1998):

1. The Enterprise category, to give an organization the capabilities to be scalable and with industrial strength. It typically costs in the millions of dollars.
2. The Mid-range category, where the system is purpose-built for a specific asset management purpose. They typically cost in the one hundred to five hundred thousand dollar range.
3. The Low-end category, for basic, low-end solutions that are useful for small installations. These systems cost typically cost around $50K. These are systems that just have basic features, and they run on work group class servers.

The second criterion we use is based on several representative functions of the DAM.

1. The Image Cataloging Feature: With image cataloging feature, systems capture low-resolution thumbnails.
2. The Object Repository Feature: With object repository feature, systems can capture not only thumbnails and metadata, but also high-resolution media files.
3. Content Management Back End for Web Sites Feature: This provides service/editorial environment with content management for the Web. The content can be in different file formats, such as text, graphics, multimedia, XML, and SGML documents.
4. Intelligent Cataloguing and Indexing Feature: This intelligent cataloguing and indexing feature has Web-based interface with intelligent navigation tools, allowing the user to search and organize images, video, audio and text documents easier and more efficiently.

PROTECTION AND DISTRIBUTION ISSUES OF DIGITAL ASSETS

Digital Assets Protection

The rapid growth of multimedia manipulation tools and the wide availability of network access lead to the convenience of digital data processing, delivery and storage. Powerful digital facilities can produce a large amount of perfect digital asset copies in a short period of time. The advanced compression technology also contributes to make the digital content compacted into a small data stream to facilitate transmission. These advantages benefit content users, definitely to raise concerns from content creators and content owners if the intellectual property right cannot be enforced successfully (Su et al., 1999). This is especially true in the present time, which has seen the rapid proliferation of peer-to-peer online file sharing systems such as Napster and Kazaa (Subramanian & Goodman, 2003). Yet, it has been noted by several researchers that senior corporate executives rarely pay a whole lot of attention to computer security and the security of digital assets. Austin and Darby discuss the types of threats that a company is apt to face and propose eight processes, ranging from deciding how much protection each asset receives, to insisting on secure software, to rehearsing a response to a security breach (Austin & Darby, 2003). We discuss the subject of digital assets protection from three different viewpoints, that is, legal, technical and non-technical means to ensure protection of digital assets:

1. Legal Methods: Patents, Copyrights, and Trademarks:
   A patent is a grant of exclusive right that is given by the government to anybody who files an application for patent protection. It confers upon the applicant the right to exclude everyone else from making, using or selling that patented invention. The term of protection offered by a patent is shorter than that of a copyright by a good deal. The term of protection for a patent is generally 20 years from filing throughout the world. Under the U.S. patent system, that protection is available for any invention. Anything that can be conceived of by humans and put into practice in a useful way that is new and novel can be subject to patent protection. This includes any creation of a human's mind, such as drugs, pharmaceuticals, computer software, inventions, processes, methods of manufacture, chemical compounds, electronic devices, and so forth.
   A copyright protects an original work of authorship. The term of protection for a copyright under the U.S. law is "life of the author and fifty years for the case of a work made in the course of employment by an employee working for an employer". Under certain conditions, the protection period for the latter case could be 75 years from publication or 100 years from creation, whichever expires first. There is a proposal currently in the U.S. Congress to extend the term of copyright protection by an additional 20 years, to bring it up to the level that is guaranteed in the European Union.
   A trademark is a right that attaches to a marking used to identify goods and commerce. It helps serve as a

guarantee of the source of those goods for consumers, so you know where they come from and you may have expectation as to the quality associated with that mark. Trademarks may be registered with the USPTO; they may also be registered with state authorities. Many states have their own trademark registries. Trademarks can also arise by the operation of common wall.

Copyright laws can be separated into the Anglo-American and the European copyright laws. The Anglo-American laws are followed by America, Great Britain and other British colonies. They adopt a pragmatic, market-oriented approach towards copyrights. On the other hand, under European laws, the copyright is seen as a basic fundamental human right. The economic incentives that it provides are secondary to insuring the protection of someone's personality.

2. Technical Methods for Intellectual Property Protection: Encryption and watermarking are the two most important digital assets content protection techniques. Encryption protects the content from anyone without the proper decryption key. There are two types of encryption existing: symmetric (secret-key) mechanism and asymmetric (public-key) mechanism. Symmetric mechanism uses the same security key to "lock" and scramble a digital file and to recover a bit-exact copy of the original content at the destination. Asymmetric encryption employs dual keys. The sender encrypts the digital with the recipient's public key, and the recipient decrypts it with his or her private key (Cravotta, 1999). Watermarking, on the other hand, further protects the content by embedding an imperceptible signal directly into the content for ownership declaration, play control or authentication (Su et al., 1999).
3. Non-technical methods for intellectual property protection: "This has to do with our providing products at a value above and beyond that provided by those who would pirate our products" (Griffin, 1998).

Digital Assets Distribution

In order to manage the asset owner and the user, the owner of a digital asset must be able to determine the usage scenarios that are appropriate for the asset. The scenarios are summarized by the notion of placement, size, duration, and extent. License management refers to the legal terms and conditions that apply to the specific usage scenario.

CONCLUSION AND FUTURE DIRECTIONS

In the era of e-commerce, digital asset management is emerging as a very hot topic of study for both practitioners as well as researchers. In this article we discuss different concepts and issues of DAM, which include but are not limited to the components and architecture of DAM systems, its basic and desirable features, the taxonomy of DAM systems, and protection and distribution sub-systems of DAM. There are several open issues for research in DAM. A list of these issues includes but is not limited to modeling the storage and organization of digital assets, the digital assets valuation, pricing, rights and licensing models, and methodologies for optimal search and retrieval of digital assets. In a future study, we plan to address some of these open issues.

KEY TERMS

Addressable Unit: A specific unit within a particular digital asset such as a digital video movie.

Asset Creator: Anyone who creates an asset, which could be in any digital format, and provides the asset and its associated information to the asset manager.

Asset Manager: The asset manager converts the information associated with the asset into an XML metadata format, builds the appropriate data type definitions, and passes the information and the asset to the metadata manager.

Creative Workflow: These are more discovery-oriented, hence more volatile and browse intensive. This workflow is characterized by the need to do many interactive searches and temporarily store candidate assets until a final decision can be made.

Digital Asset: A digital asset is any asset that exists in a digitized form, and is of intrinsic or commercial value to an organization.

Digital Asset Management (DAM): Digital asset management can be defined as a set of processes that facilitate the search, retrieval, and storage of digital assets from an archive.

Digital Asset Store: A combination of file systems and databases.

Metadata Manager: The metadata manager manages the organization of the metadata store, which is a database containing meta information on the assets.

Metadata Store: The metadata store contains information about the digital assets, typically in an XML DTD format.

Production Workflow: It is the ability for metadata to be added throughout the life cycle of digital asset handling (captioning, or cataloging), with appropriate knowledge management capabilities to establish standardization and consistency. Production workflows often deal with known items.

Search Extenders: Methods that facilitate content-based searching of digital files.

From Digital Divides to Digital Inequalities

Francesco Amoretti
University of Salerno, Italy

Clementina Casula
University of Cagliari, Italy

INTRODUCTION

Concerns about inequalities deriving from the penetration of new information and communication technologies (ICTs) have only recently become a widely debated issue in industrial societies. Until the 1980s the diffusion of ICT was mainly considered a matter of technological innovation regarding selected fields and limited territorial areas (such as the military and academic centers in the U.S.). Gradually, scholars started to point to the rise of an *information society* based on the production of information as the crucial resource to manage coordination and control of increasingly interconnected organizational systems (Masuda, 1981; Beniger, 1986; Toffler, 1990). The expression offered an alternative to the otherwise negative definitions used by scholars since the 1970s to identify changes occurring in Western democratic societies ('post-capitalism', 'post-industrialism', 'post-materialism', etc.) (Touraine, 1969; Bell, 1973).

The debate over the information society, enthusiastically greeted by some authors (Negroponte, 1995) and critically observed by others (Castells, 1996, 2001; May, 2002; Mattelart, 2003), witnessed since the mid-1990s widespread success in public and political debates (Thomas, 1996). In front of the fast and capillary diffusion of ICTs virtually to all sectors of private and public life, most Western countries' governments and international organizations have inserted within their policy agendas a reference to the unavoidability, if not desirability, of a radical shift to the new information age. The rhetoric accompanying those discourses often presents the expansion of the ICT sector—and especially the Internet—as offering citizens returns at both the individual and collective level, in the form of greater access to goods and services, increased levels of social and civic participation, and wider economic and working opportunities for all. Presented as a crucial means to participate in the new global information society, ICTs become recognized as a resource that should be fairly distributed among citizens, albeit on the basis of different arguments (ranging from social equity to economic efficiency or global development concerns), often leading to opposite conclusions on the scope for redistributive interventions (Strover, 2003; Selwyn, 2007).

BACKGROUND

The first framing of the issue of digital inequalities was in terms of a *digital divide* indicating the distance between the 'haves' and the 'have nots' in access to ICTs, mainly with reference to the Internet (NTIA, 1999). At the territorial level the analysis focused on the wide gap existing between most industrialized and Third World countries in access to ICTs (*global digital divide*), although it was also applied at the sub-national level (with reference to the disadvantages of peripheral or rural areas): in both cases existing gaps were mainly explained with reference to the unequal spatial distribution of socio-economic wealth between centers and peripheries. The measurement of *social digital divides* (i.e., gaps between the different social groups) was mainly considered within countries, because of the peculiarities of different socio-institutional contexts.

The widely registered existence of unequal access to ICTs was differently interpreted. We can draw an ideal type, analytically distinguishing three positions on the debate, ranging from a more to a less optimistic view, and consequently drawing an increasingly active role for policy intervention: (a) ICT diffusion may particularly favor disadvantaged groups; (b) ICT distribution becomes increasingly even with their diffusion; and (c) ICT diffusion follows and reinforces existing inequalities.

The first position holds an optimistic view both in terms of equal access to ICTs and the opportunities that free market developments in the ICT sector may offer in terms of redressing inequalities actually structuring societies at different levels. An example of this position can be found in the so-called *leap-frog hypothesis,* referring to the fact that poor countries investing in the latest ICTs may develop into an information society skipping some of the difficult stages (in terms of political, economic, and social problems) faced by developed countries that heavily invested in older information technology (Butler, 1999; James, 2001). Another example is offered by those arguments stressing the *death of distance* created by ICTs, in terms of improving the quality of life, particularly for disadvantaged individuals or communities in terms of offering new services (empowering inhabitants of peripheral or disadvantaged areas, women having to reconcile work and family) and enhancing civic participation (the *mobilization hypothesis* refers to the role of ICTs in helping

citizens actually marginalized from their political system to get informed, organize, or engage in public life).

The second position interprets the diffusion of ICTs as following a 'natural path', already undertaken by other mass media (telephone, radio, TV). Initially access to the new technology is restricted to an *élite*, with a large divide between the 'haves' and the 'have-nots', but with time its increasing penetration within society progressively reduces gaps. The *normalization thesis* is based on the idea that a series of factors linked with the development of technology (increasingly lower costs, user-friendly access, differentiated contents) will create a saturation in the market allowing 'have-not' groups to access innovation. From this view, the role played by processes of liberalization of the ICT sector, reducing the digital divide due to increased competition in the telecommunication market, is often praised (OECD, 2001; Dutta & Mia, 2007). However a limited contribution to governmental action is also allowed as far as it enhances this path, through policy measures aiming to facilitate the development of the ICT sector (infrastructure building, facilitated connections in schools and other public institutions, introduction of digital alphabetization in education programs) and market liberalization (regulatory actions to grant free competition).

The third position, identifiable with the *stratification thesis,* argues that there is a strong positive relation between distribution of access to ICTs and the main social inequalities related to different variables: economic wealth, education, gender, location, age, and ethnicity (Norris, 2001). This perspective revives the *knowledge gaps model* (Tichenor, Donohue, & Olien, 1970), in that it argues that the segments of population with the higher socio-economic status tend to have easier access to ICTs, and thus to knowledge, than those with a lower status and that, with time, this increases distance between the two groups. From this perspective governmental action will be fundamental in devising policies to reduce digital divides, specifically targeted for disadvantaged groups (for instance with specific services for SMEs or rural communities, or vocational training courses for women or the elderly). The inclusion of the 'digital divide' issue in the policy agendas of most Western governments during the 1990s has also been related to the wider emphasis on social inclusion legitimized by 'New-Left' governments at that time in power in the wealthiest countries (Selwyn, 2004).

THE INCREASING COMPLEXITY OF DIGITAL INEQUALITIES STUDIES

The differences between the positions enounced reveal an increasingly rich and complex picture of the debate on inequalities and ICTs, as their diffusion further develops and a body of data and literature goes more thoroughly into the matter (Van Dijk & Hacker, 2003).

The first position has the merit of having emphasized the relevance of investing in innovation, information, and knowledge as crucial sectors for a development considered not only in terms of growth, but also as a fairer distribution of resources at the global and social level. In so doing, it builds upon initial enthusiasm on the potentials of ICT, considered as an intrinsic democratic medium because of the logic of its networked structure, leading to a reduction in social differences and space-time coordinates. However the rhetoric over the democratic potential of the rising information age must be tempered by the reality that its effects are benefiting a limited part of the world's population (OECD, 2001; Norris, 2001). Findings also suggest that the countries with strongly developed information societies are those that invested heavily in early communications infrastructures and reaped economic benefits that propelled them forward in development (Howard, 2007).

The fact that the age curves usually show increasing access of younger generations to ICTs, due to the lowering of diffusion costs of the technology and the growing digital alphabetization of societies, has been interpreted as a confirmation of the 'normalization thesis' (Moschella & Atkinson, 1998). The thesis, arguing that the diffusion of technologies is followed by spillover effects and positive externalities, builds on the analogy with the case of radio and television. However, while the abilities needed to use the 'old media' are quite intuitive, they are more demanding in the case of ICTs. To avoid falling in a technological determinism fallacy, the study of digital inequalities also must consider how, beyond access, the use of ICTs relates to the different social groups and institutional contexts considered (Wilson, Wallin, & Reiser, 2003; Carter Ching, Basham, & Jang, 2005).

The third position contributed to the identification of a plurality of digital divides related with social inequalities, showing that they need to be considered from a multidimensional perspective (Bertot, 2003). However, its reference to an idea of 'strong media' has as its main drawback the assignment of a relatively passive role to social actors, which does not allow acknowledgment of the relevance of exceptions (as in the case of gender divides, the movement of *cyberfeminism* or data relative to women's overtaking in some countries; Plant, 1996; Tsaliki, 2001). Those difficulties seem to be related to the main limits of the initial framing of the debate on inequalities and ICTs. On the one hand id the reference only to 'access' to ICTs, considering information as something physical that one can easily accumulate or redistribute, as in the mathematical model of communication (Shannon & Weaver ,1949). On the other hand is the consideration of inequalities only in terms of 'haves' and 'have nots', referring to an ideal concept of 'simple equality' as a distributive condition inadequate to address the issue of inequality with reference to a plurality of social spheres (Walzer, 1983).

These critiques have prompted researchers to broaden the frame defining the issue inequalities and ICTs. This has been pursued, on the one hand, by considering the evolution of information and communication technologies as a collective and shared process embedded within different socio-institutional contexts; and on the other hand, by defining the issue of inequalities related to ICTs not as a social problem in itself, but when determined by the distribution of other material or immaterial resources. From this wider perspective research has addressed the issue of the many origins and consequences of differences in ICTs, not only in terms of access but also with reference to use, emphasizing how it is affected by a variety of factors such as level of autonomy, adequate cognitive and linguistic skills, and social network support. At their turn, those factors are related to individual characteristics (motivation, age, gender, race, IQ), the specific arenas of social interaction (family, school, labor market), and the wider socio-institutional and political context (location, presence of a cosmopolitan culture, openness of political regime, public investments in R&D), offering actors both incentives and constraints defined by contexts of opportunities as well as patterns of social inequalities (DiMaggio & Hargittai, 2001; Katz & Rice, 2002; De Haan, 2004; Milner, 2006).

The widening of the theoretical frame defining the issue of inequalities and ICTs has already provided new, interesting insights from empirical research on the topic, although contributions are usually limited in their scope, and investigate practices and use, focusing on case studies or using specific research designs. Studies on the relation between ICTs and democracy have shown how public policies defined within the discursive framework of 'e-democracy' are later translated in actions more interested in containing the decline of popular consensus than in launching a process of democratic reform (Amoretti, 2006) or in favoring the diffusion of alternative sources of information (Kalathil & Boas, 2003). Other evidence suggests that, even in front of closing 'digital divides' in the case of access to ICTs, the analysis of differences in the practices linked to the use of ICTs reveals a relation with material, cognitive, and social resources (De Haan, 2004). For instance, gender divides in the use of ICTs have been related to the 'symbolic violence' inbred in technology practices in different social spheres (school, household, work) linked to naturalized male-dominated cultures (Casula & Mongili, 2006). Thus, forms of 'cyber-phobia', sometimes preventing women or the elderly to use computers, might also be read as processes of self-exclusion responding to an already defined social hierarchy. The accumulation of advantages following the acquisition of digital resources (following the so-called *Matthew effect*) is thus reconsidered as part of a complex social process, rather than a separate trend, where resources related to ICTs (the 'digital capital') also interlink with other (economic, cultural, social) resources identified as crucial to the creation of social stratification in contemporary society (Bourdieu, 1979; Coleman, 1990). This also explains the relevance given by some authors to the availability for the individual of social networks, which can help him or her in gradually overcoming fears in access to ICTs, diversifying their use and solving technical problems (DiMaggio, Hargittai, Celeste, & Shafer, 2003; Sartori, 2006).

Developments within the academic debate on the issue of digital inequalities have been followed by modest changes in the political discourse, still bound to the 'digital divide' formulation. This has to do with the fact that the increasing complexities of the debate (offering alternative views, definitions, and datasets discouraging the achievement of definitive answers and 'one best way' prescriptions) do not easily combine with the 'political-electoral-cycle' logic, driving politicians to consensus-building rhetoric and short-term outcome actions.

FUTURE TRENDS

To date, research on ICTs and inequalities has mostly concentrated on access to the Internet and possession of computers; as partly anticipated, this approach is increasingly deemed as in need of further elaboration. Along with recent developments in the 'multimedia' sector, the field of analysis should be revised and broadened also with reference to the medium itself. In this regard particularly promising for future research seems the case of mobile phones, both because of their increasing integration of different services and their wide diffusion crossing social stratification.

The shift of the debate from the issue of access to that of use of ICTs, as well as the recognition of their 'embeddedness' in different socio-institutional contexts, suggests that further efforts are needed to tackle digital inequalities. Differently from the policies promoting access, focused on the provision of equal access for all, those for use do not aim to equalize behavior but rather to regulate new problematic areas related to the use of ICTs according to democratic values. In this regard, for instance, new instruments are actually being devised in most democratic countries in order to update the protection of rights (such as that to privacy, freedom of speech, intellectual property), or to define different forms of preventing, controlling, and fighting against the illegal uses of ICTs (from fraudulent commercial practices to paedo-pornography or terrorism).

CONCLUSION

Until recently, concerns over digital inequalities have been mainly addressed in the public debate in terms of the existence of a 'digital divide', identifying unequal distributions of individual access to ICTs. However, developments of research in the field have shown both the existence of a plurality of

digital divides, typically related to social stratification, and the closing up of others as technologies diffuse or due to specific policy action. The latest contributions further enriched the debate, shifting the analysis of inequalities from access to use of ICTs, considering the factors that both at the individual and socio-institutional level may affect the possibility of exerting an aware and proper utilization. In this respect, the role of governments becomes relevant not only in favoring investments relative to the ICT sector, but mostly in devising new instruments regulating the field of ICTs to protect citizens' rights and enabling them to benefit from their use. Because of its shifting nature and increasing complexity, the issue of digital inequalities seems bound in the next future to constant empirical investigations and theoretical redefinitions.

KEY TERMS

Cyberfeminism: Feminist movement interpreting the evolution of cybernetics as allowing the development of a culture in which inequalities are eradicated and traditional gender relations and stereotypes are defied (for instance, through the experimentation with gender identities or the creation of sisterhood networks on the Internet), empowering women and marking a shift away from their traditional symbolic representation as technologically ignorant.

Information Society: Expression used by scholars since the 1970s, but gaining popularity 20 years later, identifying in the expansion and ubiquity of information and communication technologies in contemporary societies the rise of a new age centered on information and thus influenced by the network morphology (along which information flows) in the organization of time and space as well as other social spheres, from the local to the global level.

Knowledge Gaps Thesis: The position arguing that, in the penetration of mass media within a social system, the segments of a population with higher socioeconomic status will retrieve information faster than those with a lower socioeconomic status; as a result of this positive feedback, with time the knowledge gap between the two social segments will increase rather than decrease. Originally applied to the diffusion of the TV, it has recently been revived by the *stratification thesis* in the case of ICTs.

Leap-Frog Hypothesis: An optimistic view of the potential of information and communication technologies (ICTs) in enhancing a fairer global development, referring to the fact that poor countries investing in the latest ICTs may develop into an *information society,* skipping some of the difficult stages (in terms of political, economic, social problems) faced by the more developed countries that heavily invested in older ICTs.

Matthew Effect: An expression introduced by sociologist R. Merton (with reference to the Evangelist's sentence "unto everyone that hath shall be given") to indicate a process of social accumulation, and lately also applied to the debate on inequalities and ICTs. Refers to a mechanisms of accumulation of advantages, in science as in other occupational spheres, when certain individuals or groups repeatedly receive resources and rewards, enriching them at an accelerating rate and leading in the medium-long term to stratification and élite formation.

Mobilization Hypothesis: An optimistic view fn the potential of information and communication technologies (ICTs) in terms of enhancing social and political inclusion, which tends to consider ICTs as an intrinsically 'democratic' means that may help citizens actually marginalized from their political system to get informed, organize, or engage in public life.

Normalization Thesis: The position arguing that inequalities in access to information and communication technologies are mainly linked to a first stage of penetration of the technology—the normal path—but gradually decreasing in the later stages when the technology is adopted widely across society because it becomes cheaper, easier, and more effective; in contrast to the *stratification thesis,* this view posits an optimistic scenario where also less privileged social groups can fully participate in the *information society.*

Stratification Thesis: The position arguing that inequalities in access to information and communication technologies are mainly linked to the relatively stable hierarchies positioning individuals and groups within a social system, allowing some of them more privileged position than others. In contrast to the *normalization thesis,* this position takes back the *knowledge gaps* stance, stressing the crucial role of information as a source of power in contemporary society to explain access to information as a new source of social, economic, and political differentiation.

Digital Game-Based Learning in Higher Education

Sauman Chu
University of Minnesota, USA

INTRODUCTION

Since the 1970s, computer games have become more and more a part of our culture. For the past 20-30 years, some studies have shown that certain aspects of computer games may have potential benefits in a learning environment. For example, games may increase motivation, collaboration and competition, as well as provide an effective inquiry-based framework (Squire, 2002). With the extreme success of the gaming industry in recent years, the potential for using computer games as a teaching tool in higher education is being increasingly explored. Game-based learning has been used in the military, medicine, and physical education quite successfully. However, the rules and guidelines of incorporating digital game-based learning into education are still quite open and exploration of possibilities is greatly encouraged.

BACKGROUND

To understand the concept of a digital game, and be able to create a game, one must understand the components of a game. In other words, what are the elements that comprise a game?

Definition of a Game

Salen and Zimmerman's Rule of Play: Game Design Fundamental (2004) provides a comprehensive discussion of the definition of a game. The book reviews and compares eight different models of game definition by David Parlett, a game historian; Clark Abt, also a game historian; Johann Huizinga, an Anthropologist; Roger Caillois, a Sociologist; Bernard Sutis, a Philosopher; Chris Crawford, a computer game designer; Greg Costikyan, a game designer and writer; and Elliot Avedon and Brian Sutton-Smith, both scholars of play and games. Each of these scholars/professionals provides his own framework of the elements that comprise a game. These elements can be defined and grouped into 15 categories: (1) proceeds according to rules that limit players; (2) conflict or contest; (3) goal/outcome-oriented; (4) an activity, process or event; (5) involves decision-making; (6) not serious and absorbing; (7) not associated with material gain; (8) outside ordinary life; (9) creates special social groups; (10) voluntary based; (11) uncertain quality; (12) make-believe or representational; (13) inefficient; (14) resources and tokens; and (15) a form of art.

Based on their analysis, Salen and Zimmerman provide their own definition of a game: "A game is a system in which players engage in an artificial conflict, defined by rules, that results in a quantifiable outcome. The key elements of this definition are the fact that a game is a system, players interact with the system; a game is an instance of conflict, the conflict in games is artificial, rules limit player behavior and define the game, and every game has a quantifiable outcome or goal" (Salen & Zimmerman, 2004, p. 83). Therefore, one can assume that digital games should include these components, and that digital games are like every other kind of game.

Definition of Digital Game

The major characteristic of a digital game that differs from other games is that the game itself is composed of computer hardware and software. According to Salen and Zimmerman (2004), there are four characteristics that summarize the qualities and capabilities of digital games: immediate but narrow interactivity, manipulation of information, automated complex system, and networked communication.

1. **Immediate but Narrow Interactivity:** One of the common elements of a digital game is that it can offer immediate and interactive feedback. However, the interaction that the player can have with a computer is quite narrow. For instance, one's interaction with a home computer is usually restricted by using a mouse, keyboard, screen, and speakers.
2. **Manipulation of Information:** Digital games are usually filled with various kinds of visual information such as text, images, video, audio, as well as 2D and 3D animations. Besides this visual information, digital games are also capable of handling internal logic, player interactivity, or even hiding the information and only revealing it under certain circumstances.
3. **Automated complex system:** Digital games can automate complicated procedures that are created to facilitate the play process. In most nondigital game environments, a player's direct input is necessary in

order to move the game forward. In a digital game, however, the program can automate these procedures without direct input from a player.

4. **Networked Communication:** Digital games can facilitate communication between players. For example, players can use e-mail, text chat, and audio communication that are digitally mediated. The major advantage of this form of communication is that it offers (the players) the ability to communicate over long distances, and to share a complex social space with many other participants.

The Relationship of Digital Game and Learning

Learning is powerful when it is personally meaningful, experiential, social, and epistemological (Shaffer, Squire, Halverson, & Gee, 2005). The focus of leaning is the interconnection between tools, resources, activities, and works that are composed in a particular learning environment. From a constructivist perspective of learning, knowledge is constructed when learners play an active role in the learning process by exploring, manipulating, and interacting within the learning environment. This reflects that learners have more control in the learning process, and that the environment must provide the structure to foster learners (Dickey, 2006).

The virtual worlds that are created by digital games are what make video games a powerful learning environment. In a virtual world, words and symbols are grounded in contexts; things and objects co-exist and correlate to each other. Through the experience of playing or the process of problem solving, learners can understand complex concepts by connecting abstract ideas with real problems. Games then integrate knowing and doing (Shaffer et al., 2005). In addition, games provide a goal-oriented environment that encourages the player to understand and solve problems through the provided tools. Therefore, the focus of gaming is reaching goals and solving problems, rather than simply learning facts and information.

Gee (2005) stated that the domain of knowledge is composed of ways of doing, being and seeing. Pivec, Dziabenko, and Schinnerl (2004) suggested that computer games can support and facilitate the learning process by providing a variety of presentations, and creating opportunities to apply knowledge within a virtual world. Playing games requires deep thought and complex problem solving skills (Gee, 2004). In the game environment, learners are encouraged to combine knowledge from different areas, and choose a solution. Learners are required to make decisions at certain points in a game in order to proceed, and they can experiment with how the outcome of a game may change based on their decisions. Games are simulations with a goal-oriented structure in which the learner has a definite objective and desired outcome. Salen and Zimmerman (2004) suggested that what makes games so appealing is that they give users meaningful choices.

Stoney and Oliver (1998) suggested eight attributes of an interactive multimedia leaning environment that affect the motivation and engagement for adult learners: immersion, reflection, play and flow, collaboration, learner control, curiosity, fantasy, and challenge. There seems to be a close relationship between playing and learning. Rieber (1996) indicated that play is an important part of a child's psychological, social, and intellectual development because play is motivating, and it involves make-believe thinking. Digital games allow players to think, talk, and act in new ways in which they take on representational or make-believe roles that are otherwise unattainable to them (Shaffer et al., 2005). In addition, computer games enhance learning through visualization and experimentation. Visualization has tremendous value in computer games because it is the main cognitive strategy for discovery and problem solving.

COMPUTER GAMES IN HIGHER EDUCATION

The Roles of Digital Game in Education

"Games and education, education and games, learning, play, theory, whatever the permutation, whatever the words, this is a deeply popular topic, almost a movement if some hierophants are to be believed" (Sefton-Green, 2005, p.441). The current learning generation is the key influence on this game movement. Microsoft's investment in MIT for the project, the education arcade, demonstrates a commitment to developing and researching games and education.

Digital game-based learning has been introduced in various educational settings for the purpose of creating a more engaging environment for the learners or so called "computer natives." The learning generation today is extremely game literate (Dekanter, 2004). David (1997) found an increasing demand from learners for greater interactivity in learning materials. A complex level of interactivity is required to stimulate learners' engagement. Squire (2005) stated that e-learning educators, in particular, spend a significant amount of time building learning environments from games. The question is not whether educators should use games to support learning, but how educators can use games more effectively as educational tools.

The integration of technology into the classroom allows educators to explore new technology-mediated spaces and environments for teaching and learning. The challenge in education is how to form a learning environment that can take advantage of the power and potential of the virtual world. Most educational games are not grounded in learning theory

and they lack underlying research (Shaffer et al., 2005). As Dickey (2006) suggested, new models and methods must be explored and used in order to create effective digital learning materials that will enhance learners' engagement and motivation.

Exploration of the potential uses for digital games in education should not be seen as a failure of the educational system. Nor should it create an expectation that gaming is the ultimate solution for students' learning issues. The purpose of analyzing the theory and conceptual framework of computer games is to examine possibilities for enhancing students' learning abilities. Robertson (2002) indicated that computer games have enormous educational potential if they are used responsibly and appropriately. Computer games are not intended to replace traditional teaching methods, but rather, to provide an additional method for transferring knowledge to others.

Research on Digital Game-based Learning

Lawson (2003) suggested that an adult social play gaming approach could help landscape architecture students obtain key knowledge and skills for land-use decision making. A study conducted by Amory, Naicker, Vincent, and Adams (1999) identified the type of game that was most appropriate for their teaching environment at a college level, and investigated game elements that students found useful within various types of games. Results showed that students rated logic, memory, visualization, and problem solving as the most essential game elements. Adventure games were the most highly preferred type of game. Students also indicated that sounds, graphics, story lines, and the use of technology are important motivators. Numerous memory retention studies have shown that game-based learning has better outcomes, and students are very much in favor of learning from interactive games (Pivec et al., 2004).

Another study conducted by Mann, Eidelson, Fukuchi, Nissman, Robertson, and Jardines (2002) used an interactive game-based learning module related to breast problems for training medical school students in surgery education. The game was created as a problem-based learning experience in which students were required to collect needed information to solve problems. The overall mean test scores among 32 student participants increased after the participants played the module. Participants also agreed that the game approach was helpful for imparting knowledge about breast disease.

Early research indicated that games intrinsically motivate users due to the presence of challenges, fantasy, curiosity, novelty, and complexity (Malone, 1981). In other words, although some games might not be educational, they are at least motivating. Squire (2005) suggested that future studies on educational games should examine how different players experience different games, as well as the relationship between those experiences and learning.

Problems of Digital Game-Based Learning

Edutainment software is defined as the combination of electronic games and the goal of achieving an educational purpose. Okan (2003) suggested that this approach has a long-term harmful effect to learners because it creates an expectation that learning should always be colorful and fun, and that the acquisition of knowledge cannot be a serious endeavor. He argues that education is concerned with the development of cognitive structures, and that technology is only a medium. However, the edutainment approach suggests that if students are not enjoying themselves, they are not learning. Therefore, if learning feels difficult, it is viewed as an obstacle to overcome. This trivializes the learning process.

Okan (2003) also addresses that the fact that currently, most attention is on how to use games as a tool for increasing students' motivation and engagement within the learning context. However, no attention has been paid to the fundamental issue of the impact of games on bringing about a change in the definition of learning. There is limited academic literature that explores the benefits of game-based learning. In fact, there is little existing theory in game design even though game technology is advancing (Smith & Mann, 2002). Druckman (1995) stated that game-based learning is not a superior learning method, because although games enhance motivation, and increase students' interest in the subject matter, it is very unclear as to whether games are an effective teaching method.

A further suggestion by Okan pointed out that animation is only beneficial for learning if the learner engages in active cognitive processing. Further research needs to be conducted on the effectiveness of using animation within the learning environment; such research should be based on well supported cognitive theory.

FUTURE TRENDS

There are potential subject areas where game-based learning could be explored. Specifically, these areas include (1) game-based learning to assist people with learning disabilities, (2) game-based learning for younger children, (3) computer games that deal with social and cultural issues, and (4) how games assist the learning of foreign languages. Future studies to examine the potential for applying computer games in education should be grounded in learning theory. Usability testing should also be done to provide necessary data that will ultimately help to develop guidelines for the

development of educational games. Most recently conducted studies have focused on investigating and measuring how much information students have learned from using computer games. More studies could be conducted to examine what subject matter or disciplines would benefit substantially from applying computer games as a teaching method.

CONCLUSION

Recent research studies and writings address the advantages and benefits of using a computer game model as a teaching strategy. Positive outcomes have been discovered, and students' learning responses to this approach are certainly encouraging. Game-based learning in higher education will be an important teaching and research focus in years to come. The MacArthur Foundation initiated its 5-year funding program (total of $50 million dollars) in 2006 to support projects that examine digital media and learning. Several proposals that have been funded by the MacArthur Foundation are related to computer game-based learning (MacArthur Foundation, 2006). With this new wave of using gaming technology as a teaching approach, it is my hope that significant issues such as gender-bias and cultural stereotyping in commercial computer game designs will be discussed and addressed.

KEY TERMS

Animation: An illusion of movement that is created through a rapid display of a sequence of drawings which shows a continuous action.

Constructive Learning: Constructivism describes learners as active participants in knowledge acquisition. Learners engage in knowledge restructuring, manipulation, re-invention and experimentation. Understanding is constructed by the learner. Therefore, knowledge becomes meaningful and permanent.

Digital/Computer Natives: Refers to individuals who grew up with direct access to digital media such as computers, cell phones, and electronic games. Electronic media is part of this group's culture, and they are native speakers of the digital language.

Digital Immigrants: Refers to individuals who have needed to adapt to the digital environment after they were born. Examples include individuals who have needed to learn about the Internet or e-mail later on in their lives.

Edutainment: Edutainment is a type of entertainment which provides information that is both educational and entertaining at the same time.

Game-Based Learning: Game-based learning includes elements of competition, engagement, and immediate reward. Players should receive immediate feedback—for example, scoring—when a goal is accomplished. A game-based learning environment allows students to compete with one another or work collaboratively; it provides a level of challenge that motivates students' learning; and it provides a storyline that will help students engage in activities.

Usability Testing: Usability testing is a way of measuring and observing the degree to which people are able to use a product for its intended purpose. Usability testing is done in a controlled environment, and the objective is to discover errors in the product and identify areas that need improvement.

Digital Identity in Current Networks

Kumbesan Sandrasegaran
University of Technology, Sydney, Australia

Xiaoan Huang
University of Technology, Sydney, Australia

INTRODUCTION

The daily activities of humans and business are increasingly depending on the usage of (digital) identity for interaction with other parties and for accessing resources. Current networks use a number of digital-identity management schemes. For example, in the public switched telephone network (PSTN), a telephone number is simply used as the digital identity of a user. Most of the digital-identity management schemes are effective only within their networks and have limited support for interoperability. In the hybrid network environment of next-generation networks (NGNs), new digital-identity management models are expected to be proposed for digital-identity management.

The rest of the chapter is focused on the introduction of digital identity, the digital-identity schemes used in current telecommunication networks, and the future trends.

BACKGROUND

What is Digital Identity?

We define the identity of an individual as the set of information known about that person. With the development and widespread use of digital technologies, humans have been able to communicate with each other without being physically present. Digital identity is the means that an entity (another human or machine) can use to identify a user in a digital world. The aim of digital identity is to create the same level of confidence and trust that a face-to-face transaction would generate. Some selected definitions for digital identity are as follows.

Digital ID World ("What is Digital Identity?" 2003):

"A Digital Identity is the representation of a human identity that is used in a distributed network interaction with other machines or people. The purpose of the Digital Identity is to restore the ease and security human transactions once had, when we all knew each other and did business face-to-face, to a machine environment where we are often meeting each other for the first time as we enter into transactions over vast distances."

Field Elliot (2002)

"A Digital Identity is an assurance by one end of a digital conversation (such as a Web Services transaction) that the other end of the conversation is being conducted on behalf of a specific human, company, or other entity."

Composition of Digital Identity

Digital identity is comprised of two basic elements: the actual identity of the entity (something that can be observed by human senses), and the credentials or what are used to prove the identities. Credentials can take the following forms (Reed, 2002).

- **Something that the entity knows:** An example is a password or any piece of knowledge that the entity knows.
- **Something the entity has or possesses:** An example would be a magnetic swipe card used for entry into a room, elevator, or so forth.
- **Something the entity is:** Examples of parts of an entity include fingerprints and eye scans. These attributes are the most difficult to copy or impersonate.

Profile

A profile consists of data needed to provide services to a user once his or her identity has been verified. A user profile could include what an entity can do, what he or she has subscribed to, and so on. Profiles are important to digital identity as they represent records and other data about users that can be stored external to the actual entity itself.

Usage of Digital Identity

Authentication

One of the important uses of digital identity is authentication, where an entity must prove digitally that it is the entity that it claims to be ("What is Digital Identity?" 2003). It is at this stage that the credentials of digital identity are used.

The simplest form of authentication is the use of a user name and a corresponding password.

Authorisation

Once an entity is authenticated, a digital identity is used to determine what that entity can do. This is where the profile of a digital identity is required. For example, while both an administrator and a user are authenticated to use a computer, the actions that each may do with that resource are determined by the authorisation.

Accounting

Accounting involves the recording and logging of entities and their activities within the context of a particular organisation, Web site, and so forth. Effective accounting processes enable an organisation to track unauthorised access when it does occur.

DIGITAL IDENTITY IN CURRENT NETWORKS

Digital Identity in Mobile Networks

One of the evolution paths of mobile networks is from the global system for mobile communications (GSM) to general packet radio service (GPRS), and to the universal mobile telecommunication system (UMTS). Figure 1 shows the architectures of the GSM, GPRS, and UMTS networks. In GSM/GPRS, users connect to the mobile core networks via the base-station subsystem. The mobile switching centre (MSC) and visitor location register (VLR) in the core network are the main entities used for the CS domain. The serving GPRS support node (SGSN) and gateway GPRS support node (GGSN) are the main entities used for the PS domain. In UMTS, the new radio network controller (RNC) takes charge of connecting users with the SGSN or MSC and VLR. A number of RNCs form the UMTS terrestrial radio access network (UTRAN).

Digital-Identity Composition in Mobile Networks

There are three broad aspects of digital-identity composition in mobile networks.

Identity and Communication Management

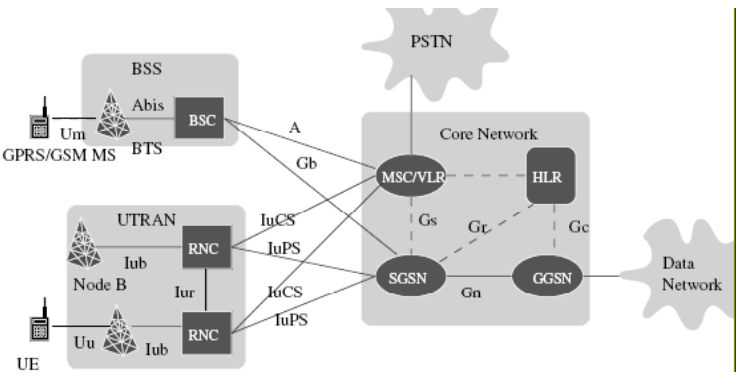
In identity and communication management, each subscriber has to be uniquely identified. The unique addressing codes are described below (Kaaranen, 2001).

- **International Mobile Subscriber Identity (IMSI)**
  It is a unique and confidential identity for the mobile subscriber (MS) and is the same in GSM, GPRS, and UMTS. The structure of IMSI is shown below (Pandya, 1997):

  IMSI = MCC + MNC + MSIN,

  where
  MCC = mobile country code (3 digits),
  MNC = mobile network code (2 digits),
  and
  MSIN = mobile subscriber identity number (normally 10 digits).
- **Mobile Subscriber International ISDN (Integrated Services Digital Network) Number (MSISDN)**
  The MSISDN is used for service separation. A subscriber may have several services provisioned and

Figure 1. GSM, GPRS, and UMTS network architectures (Lin & Chlamtac, 2001)



activated with only one IMSI. The MSISDN consists of three parts:

MSISDN = CC + NDC + SN,

where
CC = country code (one to three digits),
NDC = national destination code (one to three digits), and
SN = subscriber number.

- **Temporary Mobile Subscriber Identity (TMSI)**
  Due to security reasons, it is very important that the IMSI is always transferred in ciphered mode during signaling across the air interface so as to protect the digital identity of the user. For this purpose, the GSM system uses a 4-byte TMSI number.
- **International Mobile Equipment Identity (IMEI)**
  IMEI is a number uniquely identifying the user's mobile equipment hardware. The network may ask the user equipment (UE) to identify itself with an IMEI number either in the context of every transaction or occasionally as defined by the network operator (Kaaranen, 2001).
- **Mobile Subscriber Roaming Number (MSRN)**
  The MSRN is a number used for call routing purposes in the mobile terminated call.
- **Packet Temporary Mobile Subscriber Identity (P-TMSI)**
  The P-TMSI is a temporary identity used in the PS domain for the same purpose as TMSI in the CS domain. The P-TMSI is a set of random-format numbers consisting of 32 bits and has limited validity in terms of time and area. The P-TMSI is allocated by the SGSN.
- **P-TMSI Signature**
  The P-TMSI signature, which may be sent to the MS by the SGSN, consists of three octets. It can be used to prove that the corresponding P-TMSI returned by the MS is the one allocated by the SGSN.
- **Temporary Logic Link Identity (TLLI)**
  The TLLI is derived from the P-TMSI received in the MS. It is used to identify a mobile user on the radio path.
- **Access Point Name (APN)**
  The APN is used to identify the GGSN in the PS domain. It will be translated into an IP (Internet protocol) address of the GGSN for roaming purposes.

Mobility Management

One of the important functions of a mobile network is to keep track of the approximate location of a mobile user for the purpose of routing incoming calls. The following identities are used for mobility management.

- **Cell Global Identity (CGI)**
  To globally separate cells from each other, the CGI is used:

  CGI = MCC +MNC + LAC + CI (cell identity).

  The CGI value consists of the country of the network (MCC), the network within the country (MNC), the location area in the network, and finally the cell number within the network.
- **Location Area Identity (LAI)**
  The location area is used in the circuit-switched domain. It consists of a group of cells. The minimum is one cell and the maximum is all the cells under one VLR. An LAI is used to uniquely identify an LA.
- **Routing Area Identity (RAI)**
  An RA is very similar to the LA. An RA is the area where the MS may move without performing a routing area update. The reason why these two definitions coexist is to cater to the possibility that an MS can have either circuit or packet connection.
- **UTRAN Registration Area Identity (URAI)**
  For mobility management in 3G (third generation) UMTS, the URA is introduced. As a subscriber moves into the geographical range of an RNC serving area, the subscriber is allocated into the serving URA and the information in the network databases has to be updated (Third-Generation Partnership Project [3GPP], 2005).

Security Identity

In GSM, the identification key (Ki) is used for authentication purposes. The Ki is allocated at the subscription time together with the IMSI. It is confidential and never transmitted over the network (Bates, 2001).

In UMTS, the authentication mechanism uses a master key K. This is a permanent, secret private key with a length of 128 bits that is never transferred outside of the USIM and AuC (Kaaranen, 2001; 3GPP, 2004).

Digital Identity Storage in Mobile Networks

- **Subscriber Identity Module (SIM)**
  The SIM card represents the main hardware used for identification purposes in GSM. It contains authentication algorithms and the application protocol of GSM, and also the subscription and user-specific data (Vedder, 2001). In UMTS, the SIM card has been developed to use the universal subscriber identity module (USIM).

- **Home Subscriber Sever (HSS)**
  The HSS is the main entity in which permanent subscriber information is stored. The HSS contains the following information about the subscriber for the purposes of authentication, authorisation, location information, naming and addressing resolution, and so forth (3GPP, 2005).
  - Identification, numbering, and addressing information of the user
  - User security information for authentication and authorisation
  - User profile information
  - User location information at the intersystem level
- **Home Location Register (HLR)**
  The HLR can be seen as a subset of the HSS. It contains permanent data of the subscribers. One subscriber can be in only one HLR.
- **Authentication Centre (AuC)**
  The AuC contains parameters (e.g., secret keys, the cipher key, etc.) that the VLR uses for security activities. The AuC has only one associated HLR and communicates only with it (Bates, 2001).
- **VLR**
  The VLR database contains temporary copies of the active subscribers who have performed a location update in its coverage area. The identity information includes the user's IMSI, TMSI, MSISDN, MSRN, old LAI, and so on. The VLR also contains supplementary service parameters from the HLR specific to a mobile subscriber.
- **Equipment Identity Register (EIR)**
  The EIR maintains the security information about the mobile equipment hardware, which is the IMEI.
- **SGSN**
  The SGSN stores subscriber data required for a number of functions such as mobility management, packet data transfer, and so forth. The information includes the IMSI, subscription information, P-TMSI, location information, and so on.
- **GGSN**
  The GGSN stores subscriber data received from the HLR and the SGSN. The data are needed to handle originating and terminating packet data transfer.

Digital-Identity Usage in Mobile Networks

Security

The usage of digital identity for security is mainly in the authentication procedures. The algorithm A3 and the identity of Ki that corresponds to the IMSI are used for authentication in GSM (3GPP, 2000). In UMTS, the possibility of an attacker setting up a phony network has been removed by means of a mutual or two-way authentication procedure.

Mobility Management

When the old and new location areas are different, the MS initiates a location area update procedure to inform the network in the CS domain; this is typical in GSM. The user's TMSI and the LAI are used in the procedure (3GPP, 2000). In the PS domain, when the old and new routing areas are different, the MS initiates a routing area update procedure. The routing area update is typical in GPRS. The P-TMSI of the user and the RAI are used for this purpose. There are both a location area update and a routing area update in UMTS (3GPP, 2002).

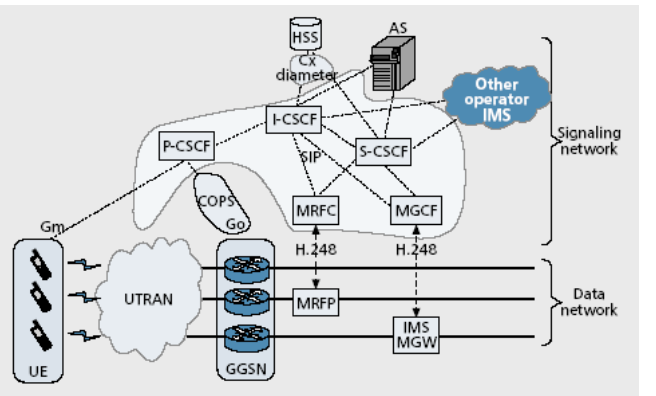
Internet Protocol Multimedia Subsystem (IMS)

IMS is the emerging subsystem of UMTS for providing users with IP multimedia services. The architecture of IMS is shown in Figure 2.

The IMS architecture is organised in two networks: the control network and the transport network. The main element in the control network is the call session control function (CSCF). It is responsible for session control, and AAA and charging support. There are three types of CSCF in IMS: a serving CSCF (S-CSCF), a proxy CSCF (P-CSCF), and an interrogating CSCF (I-CSCF).

The S-CSCF is located in the home network of the MS. The session control of multimedia services is handled by the S-CSCF. In addition, it is responsible for authenticating

Figure 2. Architecture of the IMS (Marquez, Rodriguez, Valladares, de Miguel, & Galindo, 2005)



the users by communicating with the HSS/AuC. A P-CSCF acts on behalf of a roaming mobile terminal in the visited IMS. It is responsible for redirecting the messages of a UE to the home network. An I-CSCF is a firewall for the messages coming into a home network. It is also responsible for selecting an S-CSCF in the home network for the UE (Marquez et al., 2005).

Composition of Digital Identity in IMS

- **IP Multimedia Private Identity (IMPI)**
  The IMPI is a unique global identity for the IMS user. It has similar functions as the IMSI in GSM. During registration, the initial request of the user should contain the user's IMPI. Each IP multimedia service identity module (ISIM) stores one IMPI. The S-CSCF and HSS store the user's IMPI during registration (3GPP, 2005).
- **IP Multimedia Public Identity (IMPU)**
  The IMS user will also be allocated one or more IMPUs by the home network operator. Other parties can know the subscriber by its IMPUs. One ISIM has one or more IMPUs (3GPP, 2005).

Usage of Digital Identity in IMS

P-CSCF Discovery

The UE needs to discover the P-CSCF no matter if the user is in the home network or roaming in a visited network. After receiving both the domain name and IP address of a P-CSCF, the UE may initiate communication with the IMS.

Registration Procedure

After discovering the corresponding P-CSCF, the user can initiate the registration procedure of the IMS. The user's IMPI is used for registration purposes (Yi-Bing, Ming-Feng, Meng-Ta, & Lin-Yi, 2005).

Digital Identity in WLAN

In IEEE (Institute of Electrical and Electronics Engineers) 802.11, the wireless local area network (WLAN) systems primarily focus on the physical and link layers and have limited mobility when compared to mobile networks. Therefore, the digital identities in WLAN are not as complex as in mobile networks. No specific mechanisms have been defined for the IP layer and above layers. The format of digital identities in these layers varies and depends on the specific protocol being used.

The WLAN architecture shown below has several stations (STAs) that are connected to access points (APs). The APs are interconnected to form a local network or are connected to external fixed networks. The stations and APs that are within the same radio coverage form a basic service set (BSS), which is the basic building block of a WLAN. A collection of BSSs can form a single network called an extended service set (ESS).

Digital-Identity Format in WLAN

In WLAN, the media access control (MAC) address is normally adopted to identify some entities of WLAN, for example, the AP or BSS. The receiver's or transmitter's MAC address can also be used as the digital identity.

Figure 3. The IEEE 802.11 architecture (Yan, 1998)

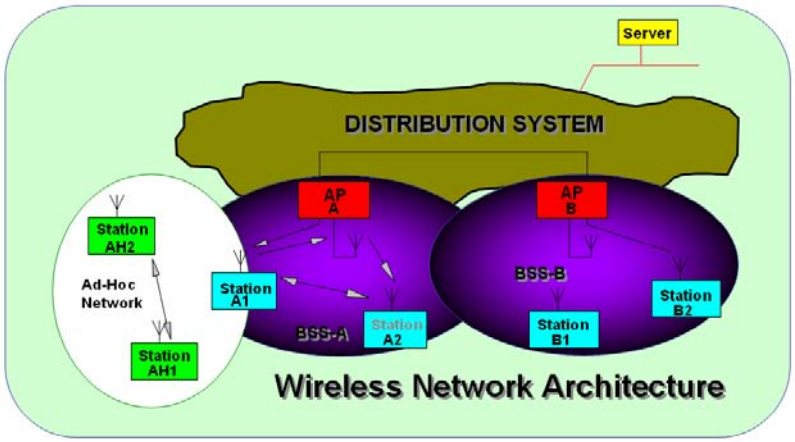


Figure 4. Format of the SSID information element

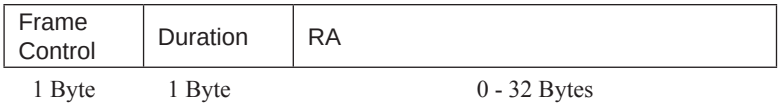

SSID

The service set identifier (SSID) can be up to 32 bytes in length, and if the length is 0, the SSID is a broadcast SSID.

In IEEE 802.11, the SSID is used to identify all entities of a WLAN or ESS.

Usage of Digital Identity in WLAN

Authentication

In IEEE 802.11 specifications, there are two basic mechanisms for the authentication of WLAN clients: open authentication and shared-key authentication. The WEP key is used as the client's identity.

Open authentication relies on the preconfigured WEP key on the client and the AP. If the keys mismatch, the clients are not allowed to communicate.

Shared-key authentication is more robust by using a challenge. If the AP can retrieve the original challenge that was previously sent by decrypting the frame from the client, the identity of the client is validated (Roshan & Leary, 2004).

In addition, MAC-address authentication is also supported by many vendors.

Encryption

Data encryption mechanisms are based on cipher algorithms (Roshan & Leary, 2004). IEEE 802.11 provides the encryption of data by using the WEP algorithm.

Mobility Management

Generally, the mobility management solutions of WLAN can be classified into the following two categories.

- Layer 2 solutions (link-layer solutions)
- Layer 3 solutions (network-layer solutions)

In Layer 2, scanning is employed by wireless clients to find a suitable AP by identifying the SSID. Besides the AP discovery mechanisms, the roaming process of Layer 2 mobility management mainly relies on the registering and updating of the client's MAC address in the APs (Roshan & Leary, 2004).

In IEEE 802.11 WLAN, the client must perform Layer 2 roaming before it can use Layer 3 roaming. The roaming between different domains can be enabled by network-layer solutions, such as mobile IP (MIP). MIP is a protocol for accommodating node mobility within the Internet. It enables nodes to change their points of attachment to the Internet without changing their IP addresses (Perkins, 2002).

Digital Identity in PSTN

Identities in PSTN are much simpler compared to mobile networks. The wireline network in PSTN and dedicated loop to a user makes it naturally more secure than mobile networks, which use the air interface. Furthermore, the fixed nature of PSTN users results in far less mobility management functionality than in mobile networks.

PSTN has several characteristics relevant to digital identity.

1. Simplified identity: The amount of user information that needs to be sent and stored for a PSTN is minimal.
2. Security concerns: The simplicity of PSTN, as well as its dependence on wiring, makes it less susceptible to security breaches.
3. Simple technology: It is difficult to introduce new services or increase the variety of data types that PSTN can support. Therefore, simple identity is sufficient to be used in PSTN.

Digital-Identity Format in PSTN

The phone numbers used in PSTN can be considered as simple digital identities. They are referenced according to area (national, state or province, household).

ITU-T International Numbering Plan

The numbering format was defined in the ITU-T Recommendation E.164 and has the following three parts.

- Country code
- National destination code
- Subscriber number

The CC is also referred to as the international access code. It is comprised of one to three digits. The world number zones are defined in the first digit.

The length of the NDC and the SN can vary according to the needs of the country, but should not exceed 15 digits.

Digital identity in mobile communications (e.g., GSM, GPRS, UMTS, and IMS) has been designed carefully to provide users with anonymity, security, and mobility. Consequently, it has become more complex than digital identity in other networks. Due to the advanced nature of digital identity in mobile networks, it is expected that most of this digital identity's features will be retained in NGN.

FUTURE TRENDS

Trends in mobility, security, and convergence are driving the current telecommunications networks toward a single all-IP-based network, which is referred to as NGN. All of the traditional telecommunication networks and the emerging networks will be integrated and become a single NGN in the near future. Users should have ubiquitous access to multiple services anywhere and anytime (ITU-T, 2004). In the hybrid network environment of NGN, digital-identity information needs to be exchanged across different network technologies. However, most of the digital-identity management schemes used in current networks are effective only within their networks and have limited support for interoperability. For example, the identities used in one network cannot be used in others or the interconnection between them causes a lot of errors or latency. Therefore, new digital-identity management models have to be proposed for digital-identity management in NGN.

CONCLUSION

In this article, we have defined the concept of digital identity and described the basic usage of it in authentication, authorisation, accounting, and so forth. Thereafter, the digital identities that are used in current networks including wireless cellular networks (such as GSM, GPRS, UMTS, and IMS), WLAN, and PSTN have been introduced. The composition, storage, and usage of the digital identities in these networks are analyzed and compared. Some of the advanced features of digital identity in current networks will be retained in NGN. However, new digital-identity management models are required to meet the requirements of digital identity in NGN.

KEY TERMS

Accounting: It involves the recording and logging of entities and their activities within the context of a particular organisation, Web site, and so forth. Effective accounting processes enable an organisation to track unauthorised access when it does occur.

Authentication: It is the process where an entity must prove digitally that it is the entity that it claims to be.

Authorisation: It is the process that is used to determine what an entity can do once the entity is authenticated.

Credentials: They are objects that people use to prove their identities in an authentication process.

Digital Identity: It is the means that an entity (another human or machine) can use to identify a user in a digital world. The aim of digital identity is to create the same level of confidence and trust that a face-to-face transaction would generate.

NGN: A single all-IP-based network that integrates the current telecommunications networks. Users of NGN should have ubiquitous access to multiple services anywhere and anytime.

Profile: It consists of data needed to provide services to users once their identities have been verified. A user profile could include what an entity can do, what it has subscribed to, and so on.

Digital Knowledge Management Artifacts and the Growing Digital Divide: A New Research Agenda

Ioannis Tarnanas

Vassilios Kikis
Kozani University of Applied Science, Greece

INTRODUCTION

That portion of the Internet known as the World Wide Web has been riding an exponential growth curve since 1994 (Network Wizards, 1999; Rutkowski, 1998), coinciding with the introduction of NCSA's graphically based software interface Mosaic for "browsing" the World Wide Web (Hoffman, Novak, & Chatterjee 1995). Currently, over 43 million hosts are connected to the Internet worldwide (Network Wizards, 1999). In terms of individual users, somewhere between 40 to 80 million adults (eStats, 1999) in the United States alone have access to around 800 million unique pages of content (Lawrence & Giles, 1999), globally distributed on arguably one of the most important communication innovations in history.

Yet even as the Internet races ambitiously toward critical mass, some social scientists have begun to examine carefully the policy implications of *current* demographic patterns of Internet access and usage (Hoffman & Novak, 1998; Hoffman, Kalsbeek, & Novak, 1996; Hoffman, Novak, & Venkatesh, 1997; Katz & Aspden, 1997; Wilhelm, 1998). Looming large is the concern that the Internet may not scale *economically* (Keller, 1996), leading to what Lloyd Morrisett, the former president of the Markle Foundation, has called a "digital divide" between the information "haves" and "have-nots." For example, although almost 70% of the schools in this country have at least one computer connected to the Internet, less than 15% of classrooms have Internet access (Harmon, 1997). Not surprisingly, access is not distributed randomly, but correlated strongly with income and education (Coley, Cradler, & Engel 1997). A recent study of Internet use among college freshman (Sax, Astin, Korn, & Mahoney 1998) found that nearly 83% of all new college students report using the Internet for school work, and almost two-thirds use e-mail to communicate. Yet, closer examination suggests a disturbing disparity in access. While 90.2% of private college freshman use the Internet for research, only 77.6% of students entering public black colleges report doing so. Similarly, although 80.1% of private college freshman use e-mail regularly, only 41.4% of students attending black public colleges do.

Further, although numerous studies (e.g., CyberAtlas, 1999; Maraganore & Morrisette, 1998) suggest that the gender gap in Internet use appears to be closing over time and that Internet users are increasingly coming from the ranks of those with lower education and income (Pew Research Center, 1998), the perception persists that the gap for race is not decreasing (Abrams, 1997).

We now raise a series of points for further discussion. We believe these issues represent the most pressing unanswered questions concerning access and the impact of the digital divide on the emerging digital economy. This article is intended to stimulate discussion among scholars and policymakers interested in how differences in Internet access and use among different segments in our society affect their ability to participate and reap the rewards of that participation in the emerging digital economy. In summary, we have reviewed the most recent research investigating the relationship of race to Internet access and usage over time. Our objective is twofold: (1) to stimulate an informed discussion among scholars and policymakers interested in the issue of diversity on the Internet, and 2) to propose a research agenda that can address the many questions raised by this and related research.

BACKGROUND

Laugksch (1999) pointed out that scientific literacy has become an internationally well-recognized educational slogan, buzzword, catchphrase, and contemporary educational goal. The same applies to the case of the digital divide. Courtright and Robbin (2001) contend that "the metaphor of the digital divide" has become part of the national discourse of the United States, an abstract symbol that condenses public concerns about social inequality and evokes hopes for solutions related to the use of information technology. In addition, "the digital divide is a potent resource whose symbolic properties and communicative power have activated a wide array of participants in the policy debates about how to create a more just society."

According to Hoffman (2001; cf. Arquette, 2001), the term *digital divide* was first used by Lloyd Morrisett who vaguely conceived of a divide between the information-haves and have-nots. However, the divide herein mainly is a gap of PC penetration in the early days of the Apple II in 1980 (Arquette, 2001). The term then grasped the public's attention with the issuance of the first National Telecommunications and Information Administration (NTIA) survey on Internet adoption and use in the United States in 1994 with the catchy title, *Falling Through the Net.* Since then, numerous articles, either popular or academic, on this issue have been published. According to a convenient sample of newspapers, journal articles, newswires, and similar mass media sources in the Lexis-Nexis database from January 1999 to December 2000 (Arquette, 2001), the increasing rate of digital divide-related articles hits almost 3,000%.

In developing countries, the digital divide is receiving similar social saliency. A quick search with the keywords "digital divide" in one of Greece's leading news Web sites *Daily Online* (*www.in.gr*), shows that at least 500 articles somehow related to this term are available. In July 2001, a high-level forum on public understanding of information technology with the special topic of "Pay Attention to the Digital Divide" was held in Greece. A wide range of representatives, including governmental officials, information technology (IT) experts, educators, social scientists, and media practitioners, presented their viewpoints and comments on this issue. The digital divide has been incorporated into daily conversational discourse.

Ironically, while the term *digital divide* has frequently appeared in varied contexts, including academic writings, both the connotative and denotative meanings of it are confusingly incoherent. The presence of other similarly prevalent terminologies, such as digital equality, information equality, e-development, network readiness, and so forth, add confusion. People seem to debate on the issue without a shared understanding of what is meant by the digital divide. As Arquette (2001) contends, the entire researcher community is plagued by a lack of definitional clarity of the concepts such as digital divide: "Each researcher assumes other researchers use the same definitional frameworks for these terms while in fact there is no such shared meaning in nomenclature" (p. 3).

While the comment of Arquette (2001) mainly refers to the phenomenon in the English-speaking world, the use of its minority counterpart of the term *digital divide* is also in a similar situation. For example, among more than 30 articles collected by the book *Pay Attention to the Digital Divide in Developing Countries* (Leng, 2002), no consistent conceptual definition is available across the writings. While some are talking about the Internet penetration divide among different social groups categorized by age, occupation, and educational level, others refer to the concept as an uneven development of e-infrastructure among different areas or nations. So, whenever the term digital divide is confronted, the following question can always be raised: *In terms of what*?

This article intends to introduce a new approach of operationalizing the digital divide from the perspective of developing countries. We first briefly review different definitional perspectives of the term *digital divide.* Then a detailed introduction of the National Informatization Quotient (NIQ) is presented which will be employed as the operational definition of the informatization level of a region. Finally we will investigate the geographical digital divide in developing countries in terms of NIQ.

CONCEPTUAL REVIEW

Conceptual definition involves verbal descriptions of the essential properties that are to be included in the intended meaning of a concept. In research practice, it often involves specifying the essential dimensions of a concept (McLeod & Pan, 2002, p. 62). On the other hand, o*perational definition* involves procedures by which a concept is to be observed, measured, or manipulated. It details the rules, specific steps, equipment, instruments, and scales involved in measuring a concept (p. 65). In this section, we will briefly review the multiple conceptions around digital divide.

Digital divide is a fresh term not unfamiliar to communication scholars (Zhu, 2002). As early as 1970, a theory called *knowledge gap* (Tichenor, Donohue, & Olien, 1970) was developed which was one of the most active inquiry fields thereafter in communication studies. The supposition of knowledge gap mainly concerns the different knowledge possession through mass media by social groups with varied social-economic status. In the 1980s, with the development of information and communication technologies (ICTs), especially with the wide application of PCs in diverse contexts, a divide between the information-haves and have-nots was sensitively observed and warned (Compaine, 2001). Since the early 1990s, digital divide has gradually become a convenient label, or more precisely, a metaphor (Courtright & Robbin, 2001), in describing the inequality of possessing and using ICTs, especially the Internet connectedness.

The first group of definitions varies on the concrete referents of what 'digital' means. In a narrow sense of the definition, digital divide particularly referred to the inequality of Internet access and use among different social groups or localities. The U.S. Department of Commerce's (1995, 2001) *Falling Through the Net* reports represent the most influential version of the stream. Zhu (2002) also takes Internet penetration as the sole indicator of what 'digital' means in his construction of the digital divide index (DDI), while taking age, sex, education, and occupation collectively as the categorizing factors. In short, in this stream of definitions, digital divide is operationalized to Internet

access/penetration divide categorized by demographics and social status factors.

However, to many people, the term *digital* means a wide range of ICTs other than the Internet. Arquette (2001) labeled it as the concept *fit disjuncture* in the studies of digital divide — that is, to measure global digital equality in terms of teledensity or Internet penetration. Employing the so-called Information Intelligence Quotient (IIQ) analytical framework, he uses ICT infrastructure rather than a single ICT, such as the Internet or telephony, as the subject of the "digital."

A second clue of conceptualizing the digital divide basically focuses on the meaning of "divide." Many different analytical perspectives on this concern are available. Jackel (2001) exemplifies some of these:

- A macro-level-comparison of the so-called First and Third world or a comparison of rich and poor countries;
- a comparison of differences in modern societies according to the level of integration in the labor market;
- a comparison of differences in modern societies according to education groups, gender, and age — that is, more general a comparison of generations;
- a specification of differences in modern societies according to communication skills;
- a comparison of different diffusion curves as a result of differing demands.

As can be seen, the dimensions identified by these perspectives are noticeably diverse.

Synthesizing the prior research on digital divide, Arquette (2001) proposed an organizational framework based on three dimensions of digital divide: ICS infrastructure, access, and use. ICS infrastructure refers to the technophysical means by which voice, audio, video, and/or data communication circulates. The operationalization of the dimension involves the specification of 16 indicators, including telephony penetration (wire line and wireless), Internet hosts, and costs of calls. The second dimension is ICS access, which focuses on the ability of persons interested in using the infrastructure (regardless of that infrastructure quality or quantity) to gain access to the infrastructure. Nineteen indicators are developed to operationalize the dimension.

The third dimension of digital divide that Arquette (2001) specifies is ICS use. Use-based conceptualizations of digital divide are conceived in terms of how people employ the technologies. Another 19 indicators are developed to measure the situation of this dimension of digital divide. In summary, IIQ is an aggregate meta-analytic framework for assessing the state of digital divide among different nations or regions.

A notable point implied by the IIQ is its consideration of the dimension of ICT use. In fact, 'access is not enough' is becoming a recognizable consensus (e.g., Blau, 2002; Jackel, 2001; Nagaraj, 2002). In other words, merely connecting people and computers will not bridge the digital divide (Blau, 2002), and there's digital discrimination among the information haves, too (Nagaraj, 2002). Jackel (2002) labels the divide among ICT haves as the second level of "divide."

NIQ is a composite index comprising 20 indicators in six dimensions. It is the operational definition of the National Informatization Level (NIL). In the remaining part of the article, the digital divide is discussed in terms of this NIL, which is operationally defined as NIQ. The six dimensions of NIQ are:

1. **The development and application of information resources (IR):** The indicators under this umbrella term include *radio and TV broadcasting hour/per 1,000 people, bandwidth per person, telephone use frequency per person,* and *total capacity of Internet database.*
2. **Information network construction (IN):** There are four components in this dimension, including *total length of long distance cable, microwave channels, total number of satellite stations,* and *number of telephone lines per 100 people.*
3. **The application of information technologies (IT):** The indicators for this dimension include *number of cable TV stations per 1,000 people, number of Internet users per one million people, number of computers per 1,000 people, number of TV sets per 100 people, e-commerce trade volume,* and *proportion of investment in the information industry by enterprises to the total fixed investment.*
4. **Information industry development (II):** There are two indicators designed to reflect the situation of this dimension: *added value contributed by the information industry to the total GDP* and *contributions made by the information industry to the total GDP increase.*
5. **Human resources of informatization (HR):** There are two indicators for this dimension: *proportion of university graduates per 1,000 people* and *information index which refers to the proportion of expenditure other than fundamental consumption to the total expenditure.*
6. **The environment for informatization development (EI):** Two indicators are designed to measure the situation of the dimension: *proportion of expenses for research and development of the information industry to the country's total budget in R&D* and *proportion of investment on the infrastructural development of the information industry to the country's total investment in capital construction.*

Compared to other index used to reflect the digital divide or ICT development in a country or region, NIQ has several characteristics:

1. It is a multi-dimensional composite index. Therefore, NIQ is a comprehensive reflection of the state informatization level rather than the development of some particular ITs.
2. As for its application in assessing digital divide, the divide it evaluates is a geographical divide rather than informatization divide among different social groups or divides defined by other factors.
3. The index covers a wide range of the aspects regarding the informatization development. Particularly, NIQ emphasizes the importance of information industry in its structure of dimensions. The proportion of indicators related to information industry is notably high, which reflects the fact that NIQ will be a guideline for the promotion and adoption of IT in developing countries.

DEVELOPING A RESEARCH AGENDA

We now raise a series of points for further discussion. We believe these issues represent the most pressing unanswered questions concerning access and the impact of the digital divide on the emerging digital economy.

Computers in the Home

While previous research has shown that inequalities in Internet access in schools persist (Educational Testing Service, 1997; Sax et al., 1998), the research reviewed here suggests that inequalities in Internet access at home may be even more problematic. The role of access to the Internet at home needs to be much more clearly understood (Abrams, 1997). Caucasians are more likely to have access to the Internet and to have ever used the Web than minorities, and these gaps appear to be *increasing* over time. Probing deeply, we have discovered that among recent Web users, who by definition have access, the gaps in Web use have been *decreasing* over time. Over time, there appear to be no or only slight differences between caucasians and minorities in how recently they had used the Web, how frequently, or in their length of time online. Gaps in general Web access and use between different minorities and caucasians appear to be driven by whether or not there is a computer present in the home. Access to a personal computer, whether at home, work, school, or somewhere else, is important because it is currently the dominant mechanism by which individuals can access the Internet. We believe that access translates into usage. Overall, individuals who own a home computer are much more likely than others to use the Web. This suggests that programs that encourage home computer ownership (e.g., Roberts 1997) and the adoption of inexpensive devices that enable Internet access over the television should be aggressively pursued, especially for minorities.

Morrisette (1999) forecasted that by the year 2003, over half of all households in the United States would have access to the Internet, but that PC penetration could stall at 60% of households. Research is necessary to understand what motivates individual-level adoption of home computers and related technologies, as well as Internet adoption, both within and outside the home. Additionally, research is required to understand the long-term impact of home computer ownership on Internet access and use. Katz and Aspden (1997) investigated the role of social and work networks in introducing people to the Internet. The dominant three ways people were originally introduced to the Internet were (1) taught by friends or family, (2) learned at work, and (3) self-taught. Formal coursework was the *least* often mentioned way people were introduced to the Internet. Long-term Internet users were most likely to have learned at work; for recent Internet users, friends/family and self-taught were equally important. These results reinforce the importance of the presence of a computer at home, or the opportunity to access the Web from locations other than the home, in stimulating Web use.

Insight into the importance of reducing this gap in Web use between caucasians and African-Americans is provided by Anderson and Melchior's (1995) discussion of *information redlining.* Information redlining signifies the relegation of minorities into situations where satisfying their information needs is weighed against their economic and social worth. From the minority point of view, this is both an access issue and a form of discrimination. The new technologies of information are not simply tools of private communication as a telephone is or tools of entertainment as a television is; they provide direct access to information sources that are essential in making social choices and keeping track of developments not only in the world at large, but also within their immediate neighborhoods. Unless the neighborhoods are properly served, there is no way out of information redlining for most of these disadvantaged groups. Research on this topic is warranted.

There are also interesting differences in media use between caucasians and minorities that also deserve further probing. For example, although the rate of home PC ownership among minorities is flat or even decreasing, the rates of cable and satellite dish penetration are increasing dramatically for minorities. At a minimum, these results suggest that minorities may make better immediate prospects than caucasians for Internet access through cable modems and satellite technology.

Web Use Outside of the Home

In addition to gaps in home computer ownership, the implications of differential Internet access at locations outside the home, including school, the workplace, and other locations, needs to be clearly understood. Research suggests that additional access points stimulate usage. Further research is necessary to understand the impact of multiple access points on Web use, particularly for individuals who have no access at home. Public-private initiatives such as Bell Atlantic's efforts in Union City and Bill Gates's announcement of a $200 million gift to provide library access to the Internet are a step in the right direction (Abrams, 1997). It has also been noted that "community networks and public access terminals offer great potential for minority communities" (Sheppard, 1997). Further, the recent rollout of e-rate funds (Schools and Libraries Corporation, 1998) provides a significant opportunity for researchers to understand the factors important in stimulating Web usage among those least likely to have access.

School Web Use

The role of Web access in the schools, compared to other locations, needs to be clearly understood. Students enjoy the highest levels of Internet access and Web use, especially when there are computers in their households. However, caucasian students are still more likely than minority students to have access and to use the Internet, and these gaps persist over time. Indeed, our findings closely parallel statistics comparing student Internet use at private universities and minority public colleges (Sax et al., 1998). As a recent report by the Educational Testing Service (1997) makes clear:

- "There are major differences among schools in their access to different kinds of educational technology."
- "Students attending poor and high-minority schools have less access to most types of technology than students attending other schools."
- "It will cost about $15 billion, approximately $300 per student, to make all the our schools 'technology rich'."

This is five times what we currently spend on technology, but only 5% of total education spending. Anderson and Melchior (1995) cited lack of proper education as an important barrier to technology access and adoption. Access to technology does not make much sense unless people are properly educated in using the technologies. Our data do not speak to the quality of the hardware/network connections or the quality of information technology education that is provided by school.

Differences in Search Behavior

Reasons for the gap between different minorities and caucasians in Web search behavior need to be clearly understood. Such differences could have important implications for the ultimate success of commercial efforts online. Caucasian Web users are more likely to report searching for product- or service-related information than minorities. One possibility is that despite sites such as NetNoir and Black Entertainment Television, general purpose search agents may not be perceived as an effective way to locate Web content that is compelling to minority users (New Media Week, 1997). This suggests the development of search engines and portals targeted to the interests of racial/ethnic groups.

Shopping Behavior

There appear to be no differences between different minorities and caucasians in the incidence of Web shopping. Is this because race does not matter for "lead users" who are most likely to shop, or is this because commercial Web content better targets racial and ethnic groups than does non-commercial Web content? Previous research (Novak, Hoffman, & Yung, 1999) suggests that more skill is required to shop online than to search. However, as noted above, caucasians are more likely to search for information online than are minorities. More generally, consumer behavior in the commercial Web environment is complex and only weakly understood. Further research is needed to explore fully the differences in consumer behavior on the Web and their implications for commercialization.

Multicultural Content

Studies investigating the extent of multicultural content on the Web are needed. Another possibility for the gap between different minorities and caucasians in Web search behavior is that there is insufficient content of interest to different minorities. *Interactive Daily* (1997) claimed that "while there are about 10 million sites on the Web, there are fewer than 500 sites targeted" to different minorities. However, others have commented on the multicultural diversity of the Web. Skriloff (1997) reported, "There are thousands of Web sites with content to appeal to other ethnic groups. Many of these sites are ready-for-prime time with high quality content, graphics, and strategic purpose."

Community Building

Are there different cultural identities for different parts of cyberspace? Schement (1997) notes that by the year 2020, major U.S. cities such as Los Angeles, Chicago, and New

York will have increasingly divergent ethnic profiles and will take on distinctive cultural identities. An important question is whether there are divergent ethnic profiles for areas of cyberspace. While the questions in the three IDSs do not allow us to directly address this issue, our analyses provide some preliminary evidence of divergent ethnic profiles for various Web usage situations. For example, minorities appear to be more likely to use the Web at school and at other locations, and in some cases are more likely to use the Web at work. How much of this is driven by the lack of a PC in the home and how much by other factors we have yet to hypothesize and investigate?

In addition to facilitating community building at the global level, the Web also facilitates neighborhood-level community building. Schwartz (1996) discusses how the Internet can be used as a vehicle for empowering communities. Anderson and Melchior (1995) raise the issue of the ways in which telecommunications can be used to strengthen communities. Thus, we should expect to find neighborhood Web sites emerging as an important aspect of cyberspace, and that these Web sites will parallel the ethnic profiles of the corresponding physical communities.

Income and Education

Income matters, but only after a certain point. Household income explains race differences in Internet access, use, home computer ownership, and PC access at work. In terms of overall access and use, higher household income positively affects access to a computer. But at lower incomes, gaps in access and use between caucasians and minorities existed and were increasing. Research is necessary to determine the efforts most likely to be effective to ensure access for lower-income people, especially minorities. The situation is different with education. As with income, increasing levels of education positively influence access, Web use, PC ownership, and PC access at work. However, caucasians are still more likely than minorities to have access to and use the Internet, and own a home computer, and these gaps persist even after controlling for educational differences.

Tags to Allow a Higher Degree of Social Networking

Since the later half of 2004, the communities on the Internet have embraced a practice of manually tagging content with metadata, which produced a phenomenon described as folksonomies (Mathes, 2004). Until now, metadata has been known as an element attributed to librarians and information architects to manage large pools of data such as collections of books, archives, and so forth. Now, however, metadata has become rather trendy in organizing personal digital information and artifacts by using simple keywords without hierarchies. Whereas in the domain of information architecture and retrieval, the artifacts stored in databases and information systems are usually described with conventional metadata according to a standard with controlled vocabularies and taxonomies, the new trend of folksonomies allowed users and user communities to describe and classify digital artifacts by using the keywords that they felt were suitable — hence the term *folksonomy,* a combination of folk and taxonomy. These keywords, called tags, are now commonly used by many applications for organizing and tagging pictures, bookmarks (URL), blog entries, Web feeds, and other digital content items on the Internet.

Social Content and Social Context

A plethora of recent online tools use tags for the above listed reasons. One main purpose of these tools is to allow people to organize their personal knowledge artifacts (content), whereas the networking and interlinking of people through networks gives us the context where this takes place. The terms *social content* and *social context* are used by social networking specialist Stowe Boyd (2004). By social content, he means any information that people create about themselves to share with others such as preferences, postin gs, or manifests of relationships (e.g., self-proclaimed such as *Friend of a Friend*, *www.foaf project.org*). This could be extended to contain all the digital artifacts that people create both for formal and informal learning.

On the other hand, social context centers on a person's heterogeneous social networks; people are known to have a variety of networks, some being through their social lives, whereas others might be based on interests in professional lives, in hobbies, and such. How to capitalize on this multitude of networks and contacts for the purpose of facilitating social networking is a challenge for current applications. Creating social protocols as we experience them in real life does not translate easily to a form of a software application. Social context in this article has been extended to explain how the tools and applications listed below facilitate the creation of networks trying to imitate the reallife social protocols that users have.

Tools for Knowledge Artifacts and Social Networking

The following is a short summary of some current applications that fall into the category of tools for creation of knowledge artifacts and social networking. They are explained briefly by using the terms *social content* and *social context* as explained above. Blogs and other end user authoring tools are not mentioned in this list, as they are outside the scope of this article. A good reference on the subject can be found by Downes (2005).

Rojo.com (www.rojo.com)

Short description: RSS feed reading and discovery with commenting and sharing though keywords and established groups.

Social content: RSS feeds: find, track, read, and share feeds through tags.

Social context: Allows setting up groups, also sharing through tags. Recommends links though Rojo.

43 Things (*www.43things.com*)

Short description: A site that provides an area where people can write their goals, become inspired by others, and share their process, as well as learn from others how to achieve goals.

Social content: Lists of life goals, desired things to achieve, and places that people plan and wish to visit. Also "have done this" and user profile.

Social context: Connections are built between people who have listed similar aims or desires in order to have a peer group to support one another. Connections can also be made between people who want to achieve some goal and the ones who have already done that in order to give guidance and support.

360° Yahoo! (360.yahoo.com)

Short description: Yahoo!'s service for blogging and networking, allows sharing all types of artifacts, also the ones on external services, with public or restricted groups.

Social content: Own profile, blog, photos, local review s, friends, music, lists of favorite books, movies, music, TV shows, and groups. A personalized page collects different artifacts either from Yahoo! Services or external ones.

Social context: Groups (private, friends, friends of a friend, etc.) can be created and categorized, and artifacts can be shared with groups through Web feeds, notifications on a messenger, and so forth.

The policy implication needs to be carefully considered. To ensure the participation of all people in the information revolution, it is critical to improve the educational and social networking opportunities for minorities. How this might best be achieved is an open research question.

CONCLUSION

The consequences to civil society of the digital divide in Internet use are expected to be severe (Beaupre & Brand-Williams, 1997). Just as Liebling (1960) observed for the freedom of the press, the Internet may provide for equal economic opportunity and democratic communication, but only for those with access. The united world economy may also be at risk if a significant segment of our society, lacking equal access to the Internet, wants the technological skills to keep national firms competitive.

Personal knowledge management in the context of the digital divide is probably an issue that is less discussed nowadays, but one that will gain more public interest as learning management systems and eportfolios are rolled out in education on a wider scope. Being able to organize one's own knowledge as the information revolution progresses — to create personal repositories of knowledge artifacts, and to enhance and enforce new ways of learning through social networks — will be one of the future challenges (classify, link, share, recommend, distribute). New efforts should be put into researching the importance of personal knowledge management in the context of decreasing the digital divide and its potential for enhancing social aspects of bridging the digital divide with ICTs. It could be predicted that social software as described in this chapter plays a major role, even driving the development.

The broad policy implications for these findings should not be overlooked. By identifying those who are truly in need, policymakers can prudently and efficiently target support to these information disadvantaged. Only when this point is reached can *all* those who desire to access online services possibly be accommodated. However, connectivity to all such households will not occur instantaneously; rather, there is a pivotal role to be assumed in the new electronic age by the traditional providers of information access for the general public — the public schools and libraries. These and other "community access centers" can provide, at least during an interim period, a means for electronic access to all those who might not otherwise have such access. Policy prescriptions that include public "safety nets" would complement the long-term strategy of hooking up all those households that want to be connected to the online services.

KEY TERMS

Artifacts: Tools to manage one's personal knowledge artifacts by categorizing them using novel approaches such as tags and ratings, but also more conventional forms of metadata.

Digital Divide: A gap between the information "haves" and "have-nots."

Folksonomy: A combination of folk and taxonomy.

Knowledge Gap: The different knowledge possession through mass media by social groups with varied social-economic status.

Personal Knowledge Management: Storing personal information online, for example favorite recipes, which allow people not only to access them from any computer connected to the Internet, but also arrange them using personally meaningful keywords.

Social Networking: A phenomenon described as a community consisting of a collection of individuals and the linkages among them.

Digital Literacy and the Position of the End-User

INTRODUCTION

As an educational setting, the traditional classroom fails to meet the learner's need for suitable skills to learn with educational software. The development of digital learning skills in school curricula challenges designers of educational software. A useful starting point of research in this domain is the study of literacy, both in its traditional and new forms (Tyner, 1998). It is a powerful background for research on the interaction of learners with educational software platforms. A "platfom" is a particular software package, designed for educational use.

BACKGROUND

Both in school and society, the skill to comprehend and handle printed course materials is essential. Literacy has since long been a vital skill for functioning adequately in an industrial society (see e.g. Marvin, 1984).

An Emerging Plural Notion of Literacy

The International Adult Literacy Survey (IALS) describes literacy as a broad range of information processing skills in relation to written or printed language. Traditional literacy is defined as follows (OECD, 1997, p. 2):

"Using printed and written information to function in society,to achieve one's goal and to develop one's knowledge and potential."

However, traditional literacy is increasingly evolving into a new, plural literacy that refers to making sense of meaningful content in more complex and technological environments (Erstad, 1998). The growing importance of images and of communication technologies has a cultural backlash that even transforms the nature of literacy. Gee (1990) opened up so-called "New Literacy Studies" (NLS). He defends a socio-cultural approach of literacy (p. 153):

"Literacy is the mastery of, or fluent control over, secondary discourse."

While primary discourse pertains to infant face-to-face interaction of children with trusted figures (parents, family, and others), secondary discourse develops through contact with public life and its social and cultural conventions. Secondary literacy is in itself a plural concept: a multitude of social institutions and commitments to public life invade an adult's life and are as many "literacies" to master. As Walter (1999, p. 34) points out:

"The existence of multiple literacies, none more valid than the next, but each specific to a culturally-defined community."

According to this plural notion of literacy, literacy can be neither neutral nor universal, since all literacy includes social and cultural conventions that shape a particular type of "literacy". Visual literacy, for instance, complements traditional literacy and claims a unique position in today's school curriculum. Debes (1969) first mentioned "visual literacy". According to visual literacy, a specific "image" language supports communication. In traditional language, words support verbal communication. Visual literacy may not only be a means of communication, but also a way of thinking (Hortin, 1983). Thinking visually, then, means the ability to think and learn in terms of images. And children's acquisition of skills to work effectively and efficiently with educational software has to underpin this recent position of a new and full interpretation of literacy.

Undoubtedly, it is of prime importance to analyse the nature of skills necessary to take full advantage of today's learning opportunities. In a visual oriented culture the acquisition of new reading and writing skills is indispensable, e.g. the analysis and composition of images. Indeed, literacy supposes an active intervention in a social and cultural context. Avgernou and Ericson (1997) define visual literacy as a group of skills that make it possible for an individual to understand and use visuals for intentional communication with others. This concerns different target groups, for instance primary school pupils or even impaired children.

During the last decade, a wide array of "literacies" relating to information and communication technologies (ICT) surfaced: media literacy (Hobbs, 1998; Potter, 1998), electronic literacy (Maylath, 1993), multimedia literacy (Kellner, 1998), computer literacy (Guthrie & Richardson, 1995; Peha, 1995), and digital literacy (Gilster, 1997). This evolution accompanies the expansion of IT to ICT. Indeed, communication is now a central feature of technological environments, clearly depending on both "traditional" and "new" literacies (Plowman & Stephen, 2003):

"(...) the flexible and sustainable mastery of a repertoire of practices with the texts of traditional and new communication technologies via spoken language, print and multimedia."

The overarching notion "information literacy" denotes the ability to access, retrieve, manage, and use information relevant to an identified need for information (Kuhltau, cit. in Campbell, 1994). Originally, information literacy was limited in scope to computer information. The progress of computer sciences and, more generally, the use of ICT in a wide array of domains broadened its meaning into library skills, computer skills, thinking skills, and critical reading skills.

Media literacy pertains to communication through and critical analysis of a diversity of media; it is the end user's ability to navigate both effectively and efficiently and to keep track of position in electronic media, while "criss-crossing the landscape" (Spiro, R. J., Feltovich, R. L., Jacobson, M. J., & Coulson, R. L., 1991). Gilster (1997, p. 1) defines digital literacy as follows:

"(…) the ability to understand and use information in multiple format from a wide range of sources when it is presented via computers."

Computer literacy is the ability to integrate information and build a personal knowledge base. Both electronic literacy (e-mail reading skills) and multimedia literacy (technical multimedia skills) are building blocks of more general "computer" literacy. Electronic and multimedia literacy explain, for instance, the comprehension of hypertext.

When comparing different "literacies", two observations are important. First, critical analysis, interpretation, and processing of information are attributed to media literacy and digital literacy. The processing and integration of information (computer literacy) and technical skills (electronic and multimedia literacy) have to be critically evaluated by computer users. Secondly, without the notion of traditional and visual literacy, none of the newer forms of literacy can be understood. Indeed, media and digital literacy acquire meaning for users through similar basic mechanisms as traditional and visual literacy. Literacy education elucidates implicit messages, ideological content or even idiosyncratic intentions designers may embed in software packages. On the other hand, the study of ICT related literacies informs software designers of problems encountered by learners with educational software platforms. Traditional issues are accessibility of information and user interface design.

Current Research Questions

The "literacies" debate is a theoretical starting point. Empirically, the detection of specific skills that explain interaction with educational software -digital literacy- is a first research path. These skills have to be integrated in the school curriculum and are treated as abilities underlying new "literacies". Before any application of theoretical insights, a primary research question has to pertain to the relationship between "operational skills" (searching, clicking, and/or dragging screen and user interface objects) and content comprehension in educational software. Is retrieval of information influenced by the mastery of operational skills?

Moreover, information can be represented through text, visualization, or talk. Does the integration of these different symbol systems in educational software alter the typical linear end-user interaction with the computer screen interface? The most common pattern of software use is sequencing interface screen after interface screen in a so-called linear fashion. Clicking hotspots and exploring additional in-depth layers of screens, providing e.g. background information, are seldom spontaneous actions. This type of research question addresses conditions that facilitate "switching content" in -for instance- an educational software package fitted out with hotspots and hyperlinks. The content of an educational platform can for example be organized in an adventure game with hyperlinks, combined with an illustrated encyclopaedia supporting the game with textual and verbal background information. A related question points to the relationship between switching content and retrieving or remembering information afterwards. Is switching detrimental to retrieval of information or does it on the contrary support memory?

Research with 3rd and 4th graders using a multimedia comic strip about World War II (see Utsi & Lowyck, 2002) revealed end-users to anticipate crucial events: they look for objects in the interface screens that most probably will play a crucial role in the next few screens. Mere reactions to audio-visual events in interface screens steadily fade, while searching, clicking, and/or dragging objects become increasingly well-considered throughout the user-interface interaction. Throughout the process, visual literacy gradually changes from superficial use of visual cues to deeper comprehension of educational content. Thus, visual literacy is an essential condition for meeting the educational goals. Multimedia literacy skills are effortlessly acquired on the spot: clicking and dragging objects pose no problem. When first confronted with a new educational software platform, visual literacy seems narrowed to multimedia skills, like

clicking and dragging, but gradually visual literacy opens up again to more thoughtful, content driven interaction with all the platform's trimmings.

FUTURE TRENDS

Future studies in this research field can make use of the cognitive load model of Kalyuga, Chandler, and Sweller (2000), who suggest a trade-off effect between text and visual cues. Cognitive load can be defined as the amount of mental resources necessary for information processing. High cognitive load requires the end-user to spend extra memory resources to deal with new incoming information. Accordingly, text and visual cues compete for attention of users since the cognitive span of learners is limited, while effort needed for both task completion -clicking one's way through the platform's interface screens- and content comprehension requires maximum investment of cognitive resources and attention (see also Kirschner, 2002). The trade-off of text and visual cues (Utsi & Lowyck, 2002) yields a clear distinction between low performing pupils clinging to visual cues and the ones who use the full range of novel experiences and skills offered in the educational platform.

Processing and integrating information from different sources is a digital and "computer" (Guthrie & Richardson, 1995; Peha, 1995) literacy skill that may acquire its place in school curricula in due time. Recent and future studies can provide input for implementing research findings with regard to digital literacy in educational software. Like any other type of ICT, educational multimedia runs through a cycle of design, development, and implementation. The shift, in the strip story mentioned above, from the user's shallow reactions to visual stimuli toward anticipation of events is a leading theme. This anticipation can be triggered by visual cues or by story line comprehension. Pupils seem to encounter difficulties to cope with the different layers of multimedia information: text, pictures, motion, music, and sound. They hardly break up the linear nature of the "storyline": background information is scarcely accessed. A core concern while designing, developing, and implementing educational media is the trade-off of textual and visual information in educational multimedia, hampering the break up of linear content material. Textual and visual symbol systems compete for the attention of learners, involved in learning with educational software.

Designers of educational software need to try and ease the integration of text and visuals. Throughout the realization of educational software, care should be taken that the precise role of hyperlinks and hotspots is clear to the user. Indeed, available cognitive span is highly occupied by an educational platform using different symbol systems, such as textual and visual information. The end user's decision to access an additional content layer in the platform needs to be an informed decision. If the learner does not know where a hyperlink or a hotspot will lead to, he may neglect to select the hyperlink, because he is not aware of the relevance of this information for the task at hand. The type and relevance of information hyperlinks and hotspots can be realized through embedded, formal features (for instance glowing or blinking) that signal the information value of a hyperlink or hotspot.

Furthermore, educational software platforms presenting information and exercises in a rousing setting, for instance in an adventure game context, need to ensure that a balanced arch of task tension is built up throughout the platform. Task tension is the "track" of the learner to reach intermediary goals that eventually lead to a successful mastery of an assignment. Regularly, the learner has to be attended to the end goal, for example retrieving a tool for repairing a space ship. This tool has to turn up visually from time to time or nearing it may be signalled by a characteristic sound. Ideally, this arch of task tension implies a series of pauses: moments for the learner to relax and explore course content from another point of view, for instance through the access of background information. Ultimately, tension is discharged in a culminating accomplishment of the assignment or end goal. Pauses can be created through opening up rigid linear progress from one content element or exercise to another and/or and through filling in the "gaps" with interesting, but distracting information or modest tasks. In an educational adventure game, for instance a journey through outer space, a simple, but distracting lottery game can be integrated, without any relevance for the end goal of the adventure game: retrieving a tool for repairing a space ship. Educational material that is presented in a serial, linear fashion without consideration of the limited processing capacities of young learners is doomed to be incompletely and thus inadequately processed.

Information sticks better when the end user's attention is triggered by repeating screen elements that suggest an optimal route across specific content elements offered at a learner's initial level. The design, development, and implementation of educational ICT need to balance the signalling function of visual cues, routing pupils' clicking behaviour, and the effort of learners to look for content, relevant for reaching goals. In educational software, this can for instance be achieved via a "road map", lending learners a hand in orienting themselves on the way to their goal. Small screen elements cue the learner's attention and break up the linear character of traditional course material, if presented in a low task tension context.

CONCLUSION

Digital literacy is a baseline set of skills for successfully coping with a complex, often technological world, holding multiple media messages. In line with traditional reading

and writing training, digital literate learners may also cope successfully with new ways of communicating. Digital literacy comprises technical computer skills (searching, clicking, and/or dragging) and visual cue awareness that triggers reading and deepened understanding of information. Support of the user-platform interaction needs to be embedded in the design, development, and implementation of educational software platforms. This interaction is more than merely user-friendly, but it is challenging the in-depth understanding of the information at hand. Cognitive load is an important constraint for unconcerned use of educational software. Apart from hampering processing and transferring information to memory, cognitive load undermines spontaneous exploration across content layers. The linear nature of most actual course material can be broken up by the users' inquisitiveness, but only if they decide to do so and if actions to switch to parallel content layers in an educational software platform do not imply a cognitive burden. The integration of visuals and other media types, text and sound, has to be well-considered. Consistent appearance and use of hyperlinks and hotspots, an arch of tension with some moments to pause, and repeating screen elements are important in designing an appealing and effective educational software platform.

KEY TERMS

Children: Tutees, enrolled in primary school.

Cognitive Load: Amount of mental resources necessary for information processing.

Educational Software: Software packages, supporting specific goals in the education of target groups, e.g. primary school tutees or impaired children.

End-User: Tutee, working with dedicated educational software packages.

Impaired Learners: learners, hampered by physical of psychological deficiencies.

Instructional Design: Lay-out of an optimal integration of educational content and interface lay out of end-user software.

Learning: Cognitive processing and integration of new educational content, if possible induced through exercises or games.

Literacy: Operational and cognitive skills, necessary to work effectively and efficiently with educational software.

INTRODUCTION

Following the success and wide adoption of the European Digital Video Broadcasting for Terrestrial (DVB-T) standard for digital terrestrial television, numerous coordinated research efforts on digital broadcast technology resulted in the recent standardization of Digital Video Broadcasting for Handeld Devices (DVB-H). The new specification aims at defining the physical and link-layer level of a digital broadcast network for Internet protocol (IP) datacasting services. At its core, DVB-H is based on DVB-T but it is more oriented in mobile and stationary reception by handheld devices. This article attempts a brief though thorough overview of the new technology, its technical aspects, and its new application perspectives.

BACKGROUND

During the mid-1990s, the MPEG-2 Transport Stream (TS) (International Organization for Standardization [ISO], 1996) was accepted worldwide as baseband format for digital television networks. Its structure allows the transmission of encoded digital video and audio streams, along with IP data, organized in a statistical Time Division Multiplex (TDM). The need for an efficient physical layer arose, which would deliver the MPEG-2 TS to the end-user terminals via the "difficult" terrestrial channel.

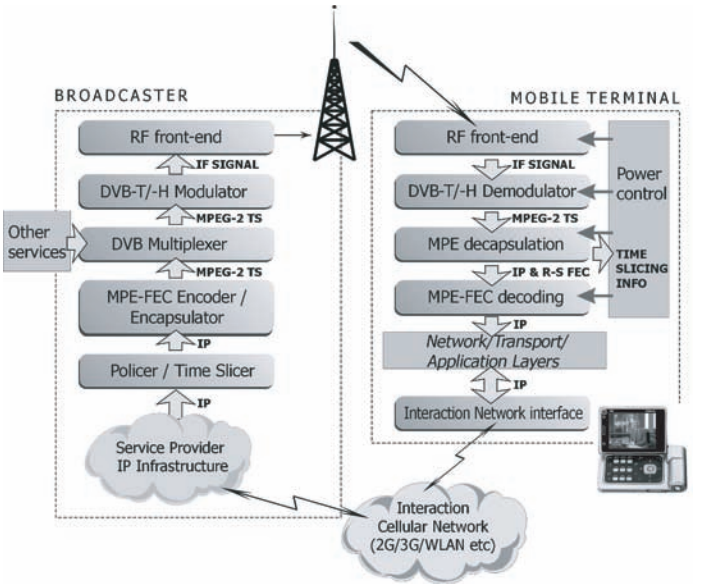
Several research efforts have been conducted around the world to optimize the physical layer for terrestrial digital television (DTV). North America adopted the ATSC A/53 system, developed by the Advanced Television Systems Committee (ATSC) in 1995, based on 8-VSB modulation. In Japan, the Association of Radio Industries and Businesses developed in 1998 the Integrated Services Digital Broadcasting-Terrestrial (ISDB-T) specification for the same purpose.

In Europe, DVB-T was standardized by the European Telecommunications Standards Institute (ETSI) in 1997 as a transmission system designed and optimized for terrestrial DTV configurations. Although it was initially designed for stationary use, DVB-T also presented an outstanding performance in mobile reception (Stare, 1998), where it outclassed ATSC (Wu, Pliszka, et al., 2000). To further support the perspective of mobile DTV, ETSI introduced in 2004 the DVB-H specification (*Digital Video Broadcasting (DVB); Transmission System for Handheld terminals (DVB-H),* 2004). DVB-H substantially comprises of a set of extensions to DVB-T which are oriented to handheld use. DVB-H inherits all the benefits of its predecessor and adds new, mobile-oriented features, focusing on IP datacasting and including better mobility and handover support, adaptive per-service error protection and power saving capabilities. At present, DVB-H is the dominant open standard in its field, and compliant systems are being deployed around the world, including Europe, the United States, and China. A strong competitor of DVB-H is Terrestrial Digital Multimedia Broadcasting (T-DMB), a standard developed in Korea and Japan, based on the European Digital Audio Broadcasting (DAB). A third player in the field of handheld DTV is Media Forward Link Only (MediaFLO), a U.S. proprietary technology developed by Qualcomm, which is gaining ground in North America.

The ETSI specification defines DVB-H as a "broadcast transmission system for datagrams." Like DVB-T, it specifies the physical and link layers, along with the service information. A DVB-H-compliant broadcast platform consists substantially of a DVB-T chain, including all the enhancements introduced by the new specification (Figure 1). Since a broadcast platform has no native support for interactivity, an IP-based cellular infrastructure (like WLAN, 2G/3G) can be employed complementarily to enable for fully interactive applications.

It must be clarified that most of the innovative features of DVB-H, as explained in the next section, are implemented on the link layer and do not affect the DVB-T physical layer. This allows the new technology to inherit all the benefits

Figure 1. Block diagram of a DVB-H system



of its predecessor, including flexible transmission schemes providing from 5 up to 32Mbps of capacity, excellent multi-path performance, due to the use of OFDM (Orthogonal Frequency Division Multiplexing), use of TV bands UHF using 8 MHz channels, and SFN-based operation.

In order to use the link-layer features of DVB-H, it is assumed that the useful payload to be conveyed consists of IP-datagrams (or other network layer datagrams) which are transmitted within the MPEG-2 TS, encapsulated according to the Multi Protocol Encapsulation (MPE) protocol. With this assumption, DVB-H becomes a totally IP-oriented system and does not support native MPEG-2 audiovisual streams. It is however feasible (although not recommended), that DVB-H services can coexist with traditional, DVB-T, MPEG-2-based DTV programs within the same multiplex.

DVB-H TECHNICAL INNOVATIONS AND APPLICATION PERSPECTIVES

The new features of DVB-H were introduced taking into consideration three principal issues in mobile use: (1) handover/mobility, (2) varying signal reception conditions, and (3) limited battery time. DVB-H innovations can be summarized as follows:

DVB-H innovations at physical layer (extensions to DVB-T)

- **4K FFT Mode:** Native DVB-T operates at two modes (8K and 2K), referring to the number of carriers within the OFDM spectrum. 8K mode (6817 carriers) provides a longer symbol period, having a very good performance in large Single Frequency Networks (SFNs) due to better tolerance in long echoes. However, it is unsuitable for fast-moving receivers, since it is very vulnerable to Doppler shift, having relatively small intercarrier spacing. On the other hand, 2K mode (1705 carriers) provides improved Doppler performance but its behavior in SFN networks is poor. DVB-H introduces the 4K mode (3409 carriers) as a trade-off, combining good mobile reception with acceptable performance in small and medium SFNs.
- **Additional TPS Signalling:** Transmission Parameter Signalling (TPS) bits within the OFDM symbol carry additional DVB-H related information to enhance and speed up service discovery. TPS also carries cell-specific information, which assists the handover procedure in mobile receivers.
- **In-depth Symbol Interleaver:** The DVB-T symbol interleaver requires a certain buffer size both in the transmitter and the receiver. When switching from 8K mode to 4K or 2K, the buffer required for the process falls to ½ and ¼ respectively, since the size of the symbol (in bits) also decreases. DVB-H exploits the unused buffer by increasing the interleaving depth by a factor of 2 (4K) and 4 (2K), thus increasing tolerance to impulse interference.

DVB-H innovations at link layer

- **Time Slicing:** A basic issue in handheld operation is the limited battery time. This issue is of particular importance in terrestrial DVB reception, where the receiver/demodulator/demultiplexing/decapsulation chain consumes typically 1W. The time slicing fea-

ture of DVB-H aims at reducing the average power consumption by allowing the terminal to know when to expect data and to switch off the receiving chain when not needed (i.e., when the transmitted data are of no interest to the specific receiver). At the broadcaster, prior to encapsulation, IP data belonging to a certain stream are organized in TDM bursts. During encapsulation, each IP section is tagged with a "delta-t" value, which informs the receiver about the time interval until the next burst. This information allows the receiver to switch off until the next burst of data arrives (Figure 2). Practically, the duration of one burst is in the range of several hundred milliseconds, whereas the powersave time may amount to several seconds. A typical power saving up to 90% is expected, whereas this figure depends on the number and the bit rate of the IP services that the terminal is "listening" to.

- **Multi Protocol Encapsulation-Forward Error Correction(MPE-FEC):** DVB-T includes two layers of error-protection coding, namely a transport-level Reed-Solomon and an inner convolutional coder. These methods protect the transport stream as a whole and have been proven to be very effective. DVB-H introduces an additional FEC layer, prior to encapsulation, which can be applied on a per-stream basis. The MPE-FEC method organizes the IP datagrams in a table, column-by-column, and then protects each row of the table with a Reed-Solomon overhead, as shown in Figure 3. IP datagrams are then separately encapsulated and transmitted from the FEC data. The latter can be discarded by FEC-ignorant receivers, thus making the method backwards compatible. Puncturing, applied on the useful data or the FEC overhead, can result in either stronger or weaker coding, respectively. MPE-FEC allows the broadcaster to apply a different level or protection on each broadcast IP service, depending either on the importance of the service, and/or on the reception conditions of the terminal(s) to which the service is targeted. Intensive testing of DVB-H, which was carried out by DVB member companies in autumn of 2004, showed that the use of MPE-FEC can result in a coding gain of some 7 dB over DVB-T (Kornfeld & Reimers, 2005).

The efficiency and flexibility of DVB-T, enhanced with the new, mobile-oriented features of DVB-H, open virtually innumerable application perspectives for the digital broadcasting market. Validation efforts include services based on anywhere-anytime access, with portable devices and mobile terminals in cars, trains, and other transportation media with very high success. The report of the validation phase is extensively presented in *Digital Video Broadcasting (DVB); Transmission to Handheld Terminals (DVB-H) Validation Task Force Report* (2005).

Very promising service scenarios are expected via the synergy between digital broadcasting and cellular networks (Rauch & Kelleler, 2001; Xu, Tonjes, 2000). Hybrid DVB-H/cellular handheld terminals are soon to appear in the market (Figure 4). At the moment, as the official DVB-H site reports (The DVB Project Office, 2006) 33 companies worldwide

Figure 2. The principle of time slicing

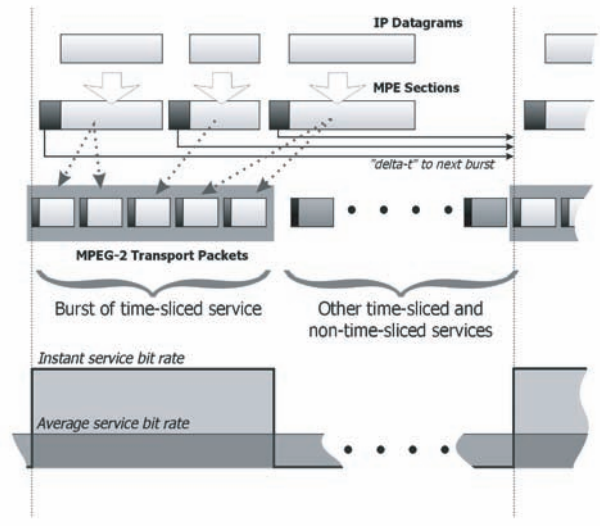


Figure 3. IP data protection via MPE-FEC

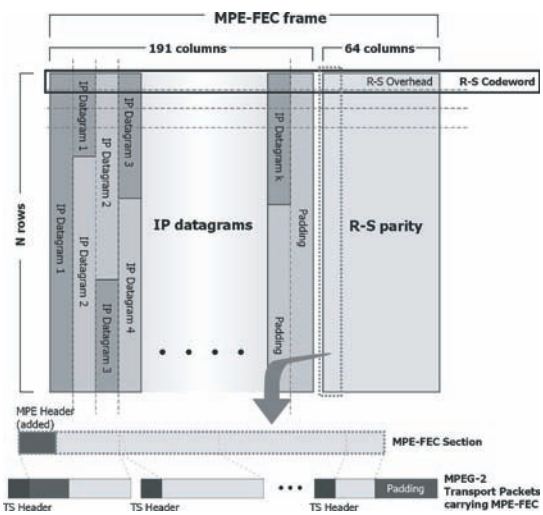

Figure 4. Experimental hybrid DVB-H/cellular handheld terminal

are finalizing their DVB-H receivers and 42 manufacturers have DVB-H headends commercially available.

Service scenarios which can exploit the capabilities of the new broadcast technology can be discriminated according to the degree of interactivity they require: *Noninteractive* (broadcast) applications are unidirectional, as data are broadcast to the terminals, allowing only for local pseudo interactivity between the user and the terminal. Applications with *low interactivity* include the occasional transmission of small blocks of data back to the broadcaster, via the interaction cellular network (e.g., Tele-voting via SMS or IP). *Fully interactive* applications require a constant, bidirectional, asymmetric flow of data between the broadcaster and the terminal.

Future use cases of DVB-H include, but are not limited to, the following scenarios:

- **Digital Television Broadcasting:** DVB is the fundamental use of every DVB platform. The innovation introduced by DVB-H is that DTV programs are no longer limited to MPEG-2 encoding, but are conveyed over IP using state-of-the-art encoding protocols, like MPEG-4 or H.264/AVC. Early DVB-H tests of video streams encoded at these formats showed that a pleasant viewing experience can be achieved on a handheld device at common intermediate format (CIF) resolution using a rate of around 300 kbps. This means that a 10 Mbps downlink can accommodate more than 30 simultaneous programs. Moreover, the use of MPE-FEC gives the broadcaster the potential to prioritize the various DTV programs, assigning a different degree of error protection to each of them. Small hard disks or flash memory modules incorporated in the DVB-H terminals can be employed to add video recording capabilities.
- **Scrambled DTV Transmission:** Currently, DVB platforms utilize transport-oriented proprietary conditional access (CA) methods for scrambling pay-TV content. In DVB-H, where video streams are conveyed over IP, security mechanisms can be elevated to the network layer. All state-of-the-art authentication and security mechanisms designed for IP networks can be used for encrypting data, including IPsec, and multicast key management.
- **Push/caching of DTV Content (News, Weather Forecast, Sports Flash, etc.):** "Idle" DVB-H terminals can work in the background to receive broadcast multimedia content and store it locally. The user can then access the content and view it off-line, whenever appropriate. For example, a citizen going to work may use the handheld terminal when waiting for the bus to view the latest news, or a traveler can watch a cached movie during travel. This feature can be employed at no operating cost for the broadcaster as no bandwidth-per-user is required. Indeed, broadcast platforms like DVB-H are extremely cost- and spectrum-efficient when the same content is to be distributed to a large target group. This is not the case with 3G-based TV streaming, which is very expensive since additional bandwidth must be allocated for every user joining the service.
- **Message Alerts:** A multicast-based alert service can enable users to stay informed about events of their interests such as a "breaking news" event, a goal which was scored, or an unusual stock fluctuation. A text message can be accompanied with audiovisual content. Since the common downlink is used for all customers, this service can also be provided at no cost.
- **Enhanced Interactivity DTV Programs:** The foundation of all DVB-H services over IP and the use of an interaction channel via a cellular network allows for new, truly interactive mobile DTV services, including televoting, e-shopping, participation in quiz shows, questionnaire filling, via the easy-to-use handheld devices, all over IP. The built-in cameras of hybrid terminals can also enable the real-time transmission of pictures/sound/video to the broadcaster, thus enabling a fully interactive television. The *mobile active viewer* scenario envisages that the citizens act as journalists, by providing live feeds—when needed—to the broadcasters, giving instant, on-site news coverage.
- **Push/Caching of Web Content:** A broadcaster may decide to allocate a portion of the DVB-H bandwidth for multicasting popular Web content to an unlimited number of terminals for time-shifted, off-line use, as Stare (2002) suggests. Such content may include electronic newspapers, traffic reports, stock quotes, or entertainment guides. Given that the memory capacity

of the handheld terminals is constantly increasing, it is possible for the broadcaster to allocate, for example, 2 Mbps for this type of service, providing the customers with a complete Web site of 300 pages (assuming an average page size of 50 Kbytes) at their hands after only 1 minute of transmission! The users are unaware of the caching procedure and are experiencing a very high *virtual bandwidth* as they access the content offline. Time slicing can be employed along with proper service information to enable the terminal to save memory and precious battery time by caching only the information in which the user is interested in.

- **Full On-Demand Access to Data and Multimedia Content:** If the content in which the user is interested in is neither broadcast nor cached, the hybrid cellular-broadcast topology can be used to retrieve the data on demand. By sending the requests/acknowledgments via the cellular network and receiving the data via the DVB downlink (hybrid asymmetric access), several Mbps of download rate can be achieved (Gardikis, Kormentzas, Xilouris, Koumaras, & Kourtis, 2005). An interesting approach is that of the load sharing between the broadcast and the cellular network: When many users request the same block of information, the delivery is performed over DVB-H so that all users benefit from the common downlink. If there are only a few requests, the data is delivered to each user via the cellular network. In the latter case, the download rate can be much lower, but the wasting of the DVB capacity is avoided (Cosmas, Itegaki, Cruickshank, 2003).
- **DVB-H Service Continuity Using the Cellular Interaction Network:** In the case that the user roams outside the DVB-H coverage area, a tight broadcast/cellular synergy could enable for the continuity of the DTV service by routing it exclusively via the cellular network at lower quality and, presumably, at higher cost.
- **Emergency Systems:** In the case of a widespread emergency situation (e.g., a natural disaster or a massive terrorist attack), where cellular networks usually collapse, DVB-H can realize a low-cost and always-on backup broadcast system. A centralized authority can use a DVB-H transmitter to broadcast encrypted or unencrypted material with high error protection to ambulances, police cars, and so forth.

FUTURE TRENDS

In order for all the aforementioned services, along with many more to come, can be deployed in a uniform basis across different countries, a lot of standardization effort is to be devoted in the near future regarding the architecture and software issues of DVB-H platforms. Towards this direction, the DVB Convergence of Broadcasting and Mobile Services (CBMS) working group has set an initial framework for use cases and services of DVB-H (*IP Datacast over DVB-H: Use Cases and Services,* 2005a). The same group is also responsible for specifying the video and audio formats, the Electronic Service Guide (ESG), and the content protection aspects of the DVB-H standard. It has also provided guidelines for the ESG information flow, defined interfaces among the various network entities and illustrated the way the components in IP Datacast over DVB-H work together (*IP Datacast over DVB-H: Architecture*, 2005b).

There is also a lot of work to be done in the migration of the state-of-the-art features of IP into the world of DVB. The transfer of the benefits of IPv6 in a DVB-H platform can result in a unified architecture for providing dynamic addressing, mobility/handover support, and increased security.

CONCLUSION

This article outlined the innovative features of the DVB-H technology and demonstrated how they can be exploited via numerous service scenarios, tailored to suit the capabilities of a hybrid broadcast/cellular network. The enhancements introduced by DVB-H, combined with the efficiency of the DVB-T-based physical layer and the synergy with an IP-based cellular network for interaction, opens innumerable application perspectives to this new digital broadcasting system. By offering high data rates, very good mobile performance, flexibility, and interactivity, DVB-H brings the dream of *mobile broadband access* much closer to realization.

KEY TERMS

Digital Video Broadcasting (DVB): A family of standards specifying technology for the global delivery of digital television and data services. The DVB project is an industry-led consortium committed to the standardization process.

European Telecommunications Standards Institute (ETSI): An independent organization, whose aim is to produce telecommunications standards for European and global use. Among ETSI achievements is the deployment of the DVB family of standards.

FFT Mode: The modulation mode which refers to the number of orthogonal subcarriers within an OFDM frame. DVB-T employs two FFT modes (8K, 2K), while DVB-H adds a 4K mode.

MPEG4/H.264: State-of-the-art protocols for digital video compression. They can achieve remarkable video quality even at bit rates of a few hundreds of Kbps.

Multi Protocol Encapsulation (MPE): An adaptation protocol which undertakes the framing and fragmentation of IP datagrams to be injected in MPEG-2 Transport Packets so that they can be conveyed over a DVB platform.

TDM Burst: A block of contiguous data which belongs to the same IP stream and is transmitted within a DVB-H Time Slice.

Ultra High Frequency (UHF): The frequency band between 300 MHz and 3 GHz. The TV-dedicated part of UHF (470-806 MHz) is divided into 8-MHz channels.

Digital Watermarking Techniques

INTRODUCTION

In recent years, services on the Internet have greatly improved and are more reliable than before. However, the easy downloads and duplications on the Internet have created a rush of illicit reproductions. Undoubtedly, the rights of ownership are violated and vulnerable to the predators that stalk the Internet. Therefore, protection against these illegal acts has become a mind-boggling issue.

Previously, artists and publishers painstakingly signed or marked their products to prevent illegal use. However with the invention of digital products, protecting rightful ownership has become difficult. Currently, there are two schemes to protect data on the Internet. The first scheme is the traditional **cryptography** where the important data or secret is to be encrypted by a special process before being transmitted on the Internet. This scheme requires much computational process and time to encrypt or decrypt. On the other hand, the second scheme is **steganography** where the important message or secret is hidden in the digital media. The hidden data is not perceptible by the **human visual system** (**HVS**). The digital **watermarking** technique is an application of **steganography** (Chang, Huang, & Chen, 2000; Chen, Chang, & Huang 2001). In order to safeguard copyrights and rightful ownerships, a representative logo or watermark could be hidden in the image or media that is to be protected. The hidden data can be recovered and used as proof of rightful ownership.

The **watermarking** schemes can be grouped into three kinds, largely, dependent on its application. They use the fragile watermark, semi-fragile watermark, and robust watermark, respectively (Fabien, Ross, & Markus, 1999). Fragile watermarks are easily corrupted when the watermarked image is compressed or tampered with. Semi-fragile watermarks can sustain attacks from normal image processing, but are not robust against malicious tampering. Fragile and semi-fragile watermarks are restricted in its use for image authentication and integrity attestation (Fridrich,2002; Fridrich, Memon, & Goljan, 2000). For the **robust watermarking**, it is always applied in ownership verification and copyright protection (Fridrich, Baldoza, & Simard, 1998; Huang, Wang, & Pan, 2002; Lu, Xu, & Sun, 2005; Solanki, Jacobsoen, Madhow, Manjunath, & Chandrasekaran, 2004). Some basic conditions must be followed: (1) Invisibility: the watermarked image must look similar to its original and any difference invisible to the **human visual system**. (2) Undetectable: the watermark embedded in the image must not be easily detectable by computing processes or statistical methods. (3) Safety: watermark is encrypted and if accessed by a hacker; cannot be removed or tampered with. (4) Robustness: the watermark is able to withstand normal and/or illegal manipulations, such as compression, blurring, sharpening, cropping, rotations and more. The retrieved watermark is perceptible even after these processes. (5) Independence: the watermark can be retrieved without the original image. Last but not the least, (6) Efficiency: the watermarked image should not require large storage and must also allow for a comparable-sized watermark to be hidden in the media.

The proposed method is a **VQ-based watermark** technique that depends on the structure of a **tree growth** for grouping the codebook. The scheme is robust. That is, the watermark is irremovable and also can withstand normal compression process, tampering by compression or other malicious attacks. After these attacks, the watermark must be recovered with comparable perceptibility and useful in providing proof of rightful ownerships.

BACKGROUND

The **watermarking** schemes are classified into the methods of the **spatial domain** and the **frequency domain**, respectively (Chang, Huang, & Chen, 2000; Chen, Chang, & Huang, 2001; Zhao, Campisi, & Kundur, 2004). To hide a watermark in the **frequency domain**, an image has to be transformed from a **spatial domain** into its **frequency domain**. This scheme requires many computations and time to embed/retrieve the watermarks. Meanwhile in the **spatial domain**, the watermark can be directly embedded into the pixels values. The algorithms for embedding and recovering are simple. Traditionally, the scheme involves hiding the watermark bits in the **least significant bits** (**LSB**). More literature on the **LSB** technique can be found in Chan and Cheng (2004) and Chang, Hsiao, and Chan (2003). This scheme is not robust. The watermark is easily corrupted after compression.

VQ-Based Watermarking

VQ is a low bit-rate image compression technique. It is simple and easy to encode and decode. Suppose an original image I is partitioned into small non-overlapped blocks with $m \times m$ pixels. Each block contains m^2 pixels. Before **VQ** encoding, block vectors are trained dispersedly and uniformly from several images. The trained set of the block vectors is called codebook. Each block vector in the codebook is called a codeword. In the **VQ** encoding phase, the codeword closest to the encoded block is chosen and stored as an index value in a table. The procedure is repeated for all the blocks in the image. In **VQ** decoding, indexes from the index table will be used to find the corresponding codeword in the codebook and to recover the image (Chang, Huang, & Chen, 2000; Poggi & Ragozini, 2001; Wu & Shih, 2004).

VQ-based watermarking is an effective **steganography** scheme in **spatial domain** and several algorithms have been proposed in different literatures (Wu & Chang, 2004; Huang, Wang, & Pan, 2002). Many of them rely on modifying codewords to achieve the purpose of watermark embedding. But it makes more distortion of images. Lu et al. (2005) used another scheme in illustrated as follows:

1. Input an image X with size $M \times N$, watermark W with size $M_W \times N_W$.
2. In **VQ** encoding process, X is divided into vectors x's with size

   $$\frac{M}{M_W} \times \frac{N}{N_W},$$

   then find the closest to encoded block vectors from the codebook, yield and record index $y(m, n)$ to table Y. Equation is shown as follows:

   $$Y = VQ(X),\ y(m, n) = VQ(x(m, n). \quad (1)$$

3. Compute the variances of $y(m, n)$ of Y after **VQ** encoding vectors by this equation.

   $$\sigma^2(m,n) = \left(\frac{1}{9}\sum_{i=m-1}^{m+1}\sum_{j=n-1}^{n+1} y^2(i,j)\right) - \left(\frac{1}{9}\sum_{i=m-1}^{m+1}\sum_{j=n-1}^{n+1} y(i,j)\right)^2. \quad (2)$$

   And obtain polarites P:

   $$P = \bigcup_{m=0}^{(M/M_W)-1}\ \bigcup_{n=0}^{(N/N_W)-1} p(m,n), \text{ where}$$

   $$p(m,n) = \begin{cases} 1, & if\ \sigma^2(m,n) \geq Threshold \\ 0, & otherwise. \end{cases} \quad (3)$$

   W_P will be the watermark W reordered by random function with $key1$.

   $$key2 = W_p \oplus P \quad (4)$$

   After the **VQ** decoding, the reconstructed image and the secret key will be the protection of the original image.

In Lu et al. (2005), the authors also point to the problems of the algorithm: (1) The watermarks are not really embedded into the image. A secret key is only produced by composing the **VQ** index table and watermark messages, so users can retrieve the watermark from the original image where no other watermark had been embedded in it. (2) If the codebook is public then the user can also embed another watermark in the watermarked image without any modification.

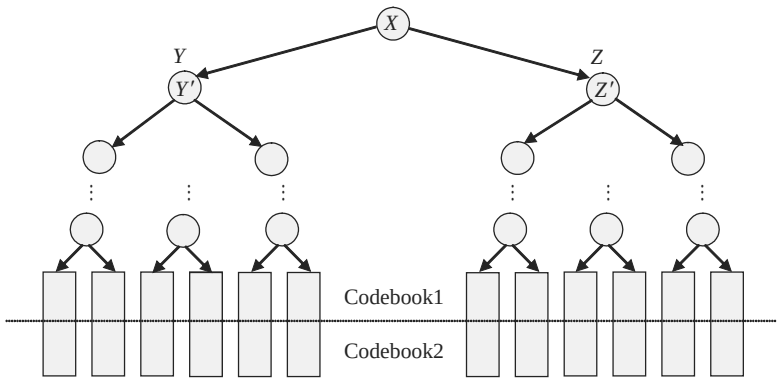
THE PROPOSED SCHEME

The proposed method in this article embeds the watermark bit stream into the **VQ** encoding codes directly without modifying the **VQ** codewords anymore. Meanwhile, the watermarked image quality is controlled by **VQ** compression technique. We can use the existing codebook or produce a new one. In the next section, we demonstrate the proposed codewords grouping method by applying the tree growing structure. The proposed watermark embedding and retrieving processes are illustrated in the following sections.

Grouping Codewords by Proposed Tree Growing Structure

The scheme for grouping the codewords is based on a tree growing structure. First, codewords from a codebook are classified into groups by tree growing structure as described in Algorithm 1. Assume $X(x_1, x_2, ..., x_{m \times m})$, the centroid of the codebook, is the root of tree. Let $Y(y_1, y_2, ..., y_{m \times m})$ and $Z(z_1, z_2, ..., z_{m \times m})$ individually be two nodes of two branches such that $y_i = x_i + k$, $z_i = x_i - k$ and k is a constant. Let each codword belong to the nearest branch node and separate all the codewords into two groups. Computation is repeated to the new centroids Y' and Z', and let Y' and Z' be the new nodes in the sub-tree which will grow the same way as before until members of each sub-tree are equal or less than 2. Each group of codewords should be close to each other and their members are distributed to subcodebook 1 and subcodebook 2. The
steps are described in detail in Algorithm 1.

Figure 1. Grouping codewords by tree growing structure



Algorithm 1: Grouping Codewords by Tree Growing Structure

Input: A codebook C containing codewords $c_1, c_2, ..., c_n$.

Output: A new codebook C' contains 2 subcodebooks C_0 and C_1.

Step 1: Compute the centroid of the codebook, and present it as $X(x_1, x_2, ..., x_{m\times m})$. Also, let X be the root of the tree.

Step 2: Use $X(x_1, x_2, ..., x_{m\times m})$ to grow two vectors Y, Z and satisfy $y_i = x_i + k$, for each $y_i \in Y$, if $y_i > 255$ then $y_i = 255$; $z_i = x_i - k$, for each $z_i \in Z$, if $z_i < 0$ then $z_i = 0$.

Step 3: Classify the vectors belonging to the nearest vectors of the Y and Z groups, and obtain the new centroids Y' and Z'.

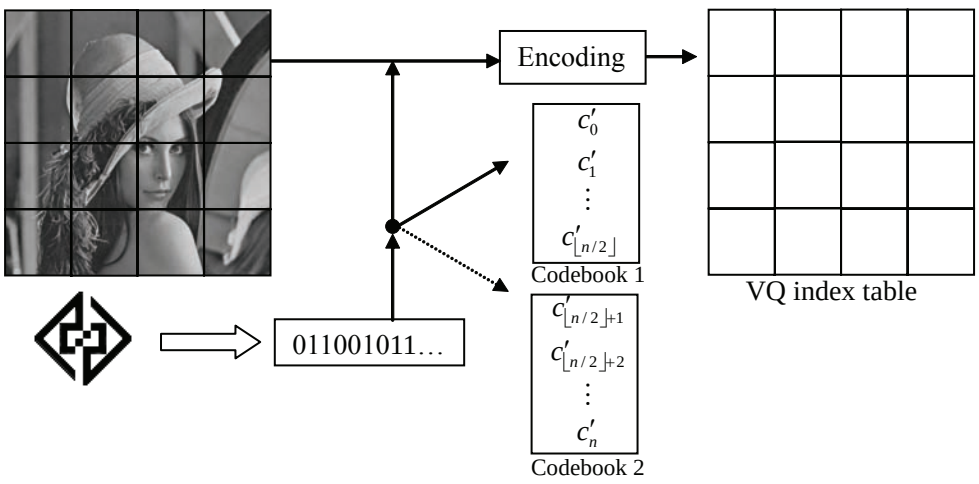
Step 4: Let Y' and Z' be the new root of each sub-tree and repeat **Step 2** and **Step 3** until each group member is equal or less than 2 and very close to each other.

Step 5: Partition the two closest vectors of each group into subcodebook 1 and subcodebook 2. Reindex the two sucodeboks $C_0 = (c'_0, c'_1, \cdots, c'_{\lfloor n/2 \rfloor})$ and $C_1 = (c'_{\lfloor n/2 \rfloor+1}, c'_{\lfloor n/2 \rfloor+2}, \cdots, c'_n)$

Embedding the Watermark

First, the watermark is transformed into a bit stream and let watermark $W = b_1 b_2 ... b_k$. During **VQ** compression, the original image is partitioned into $m\times m$ pixels blocks. The encoding order is then decided randomly to increase the

Figure 2. Embedding a watermark during VQ encoding



security of the embedding watermark. When encoding the first block, and embedding b_1, the closest codeword located in the binary tree is searched from one of the two subcodebooks according to the value of b_1. If the value of b_1 is "0" then search the codeword from C_0. Otherwise, if b_1 is "1" then search the codeword from C_1. The index is then stored into the index table. The process is repeated for the rest of the blocks until all the watermark bits are embedded.

Retrieving the Watermark

When the copyright of an image is in doubt, the embedded watermark can be retrieved and used as proof of its origin. In the retrieval process, the image is read from the index table by the random order using the same seed used in the embedding process. The values "0" or "1" are retrieved for the watermark, *W*, based on whether the index value is smller than $\lfloor n/2 \rfloor$ or otherwise. After all of the watermark bits are retrieved and the watermark is recovered to its original form, the recovered watermark will be used to proof the image's rightful ownership.

EXPERIMENTAL RESULTS

In the experiment, the original image is a grayscale 512×512 image "Lena" as shown in Figure 4(a). The watermark is a black and white 64×64 image as shown in Figure 4(b). Using the proposed **tree growth** scheme, Figure 4(c) shows the watermarked image with PSNR 31.22 dB. By visual

Figure 3. Retrieving watermark during VQ decoding

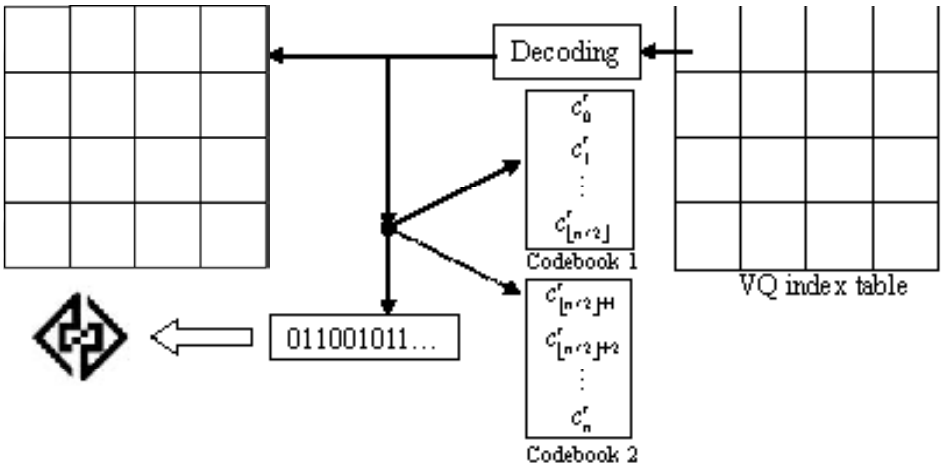


Figure 4. Hiding a watermark in Lena

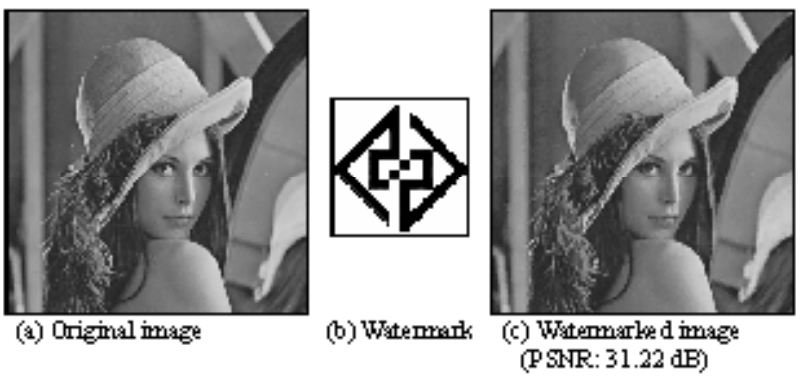

Figure 5. Retrieved watermark with correct bit rate 100%

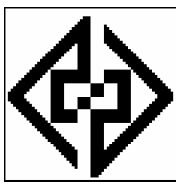

perception, the watermarked image is similar to its original in Figure 4(a). This means that **tree growth** based hiding did not distort the image.

The retrieved watermark is as shown in Figure 5. Its correct bit rate is 100%, that is, the retrieved watermark is the same as the original watermark in Figure 4(b).

The watermarked images are processed by normal and/or illegal manipulations, such as cropping (shown in Figure 6), blurring (shown in Figure 7), sharpening (shown in Figure 8) and resizing (shown in Figure 9), respectively. The retrieved watermark is perceptible even after these processes. The percentages of retrieved watermarks with correct bit rate are shown in Table 1.

In order to show the **robustness** of the **watermarking** technique, we also do similar experiments using the same watermark and the same size of codebook with 4096 codewords as Lu et al. (2005). The comparative results from the experiments are shown in Table 1. We apply the normalized hamming similarity (NHS) to compute the effectiveness of the twoschemes.

$$NHS = 1 - \frac{H(W, W')}{A_W \times B_W}, \tag{5}$$

where W is defined as a watermark, and W' is the retrieved watermark from the watermarked image that might be tampered.

Comparing with the scheme of Lu et al. (2005), the proposed method can resist against various temper. Some results are better than Lu et al. (2005) and some are not, as shown in the results from the experiments. However, the key point in our method is that the watermark is robustly embedded in the image. A hacker cannot remove the watermark except to destroy the image. The watermarked image could be sent directly on the Internet and does need not an extra key at all. The algorithm and codebook can also be open to the public and the watermark will still be safe. In Lu et al.'s (2005) method, the watermark is not embedded in the image. It only produces a secret key composed of the **VQ** index table and watermark message. The image has to be sent with the secret key. It goes without saying that there would exist two problems. They are: 1) users can retrieve the watermark from the original image without any watermark embedded in it; 2) if the codebook is public then the user can also embed another watermark in the watermarked image without any modification.

Figure 6. The watermarked images are under cropping attacks

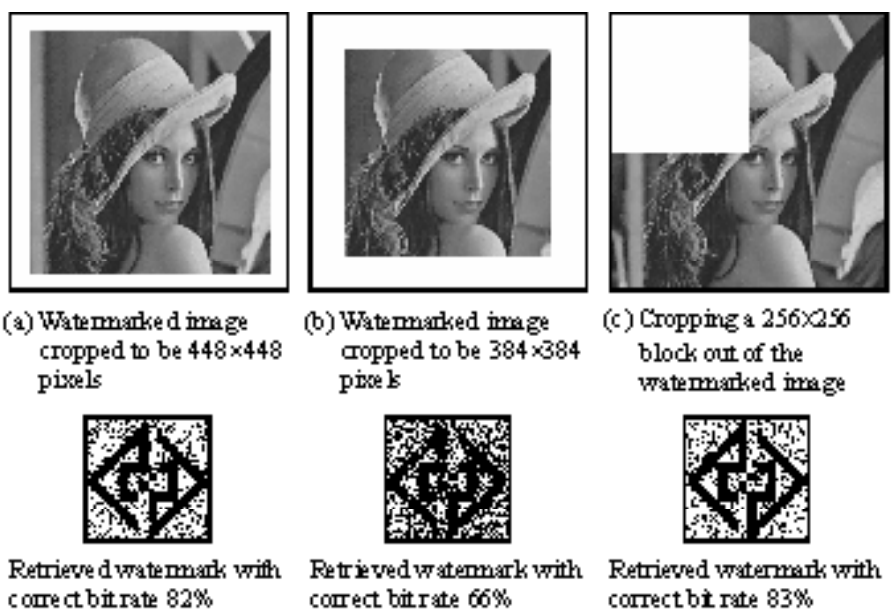

Figure 7. The watermarked images are manipulated by different blurring times

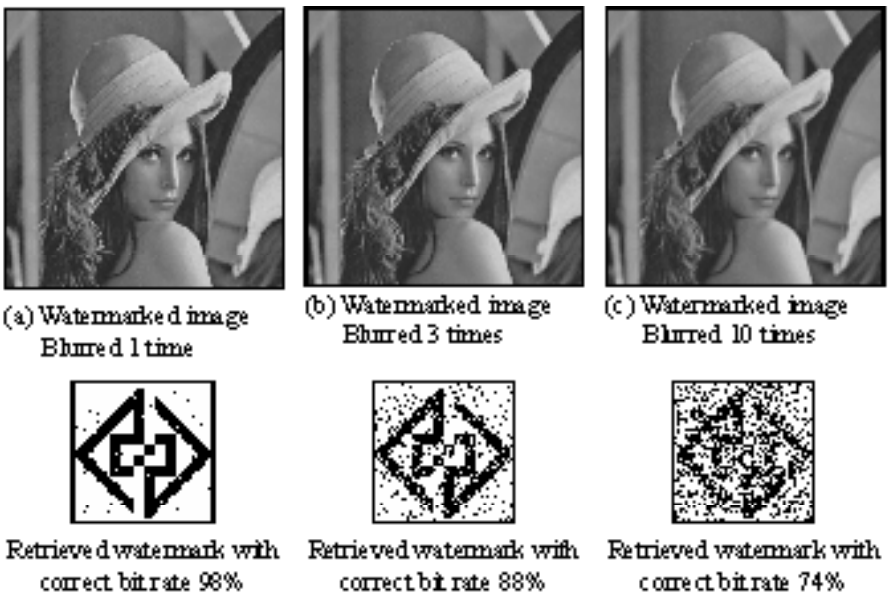

Figure 8. The watermarked image is manipulated by sharpening

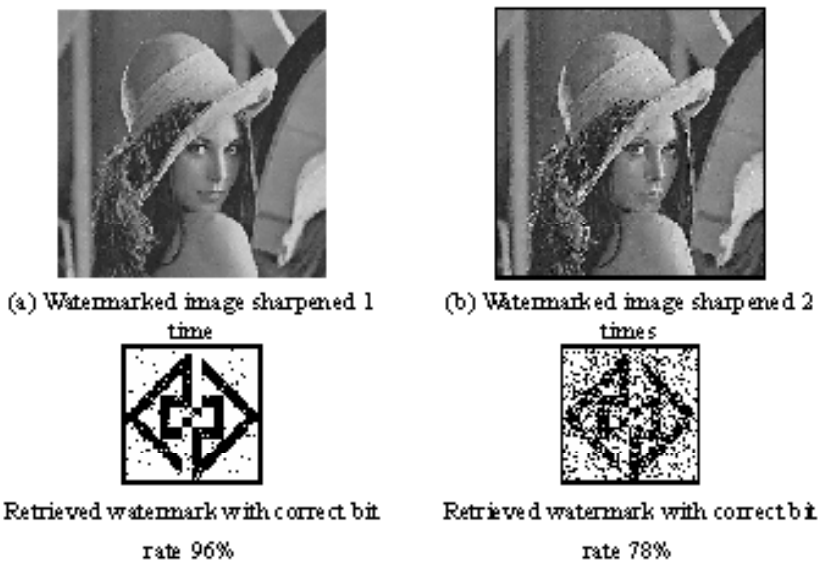

Figure 9. The watermarked images are manipulated by resizing

Table 1. Results for the experiment

Operations	Lu et al.'s method	The proposed method
VQ compression using codebook with 4096 codeword and producing VQ recovered watermarked image (PSNR in dB)	33.74 dB	35.215 dB
Cropping a 256×256 block out of the watermarked image (NHS)	0.887	0.894
Watermarked image blurring (NHS)	0.954	0.973
Watermarked image sharpening (NHS)	-	0.957
Watermarked image contrasting (NHS)	0.926	0.760
Watermarked image brightening (NHS)	0.71	0.747
Watermarked image resized to 256×256 (NHS)	-	0.924
Watermarked image resized to 1024×1024 (NHS)	-	1.000

FUTURE TRENDS

The performance of the proposed **watermarking** technique is stable and reliable in dealing with the ownership disputes of digital media. The capacity for hiding can be further enhanced if the codewords are classified into more groups

CONCLUSION

The proposed method embeds a watermark into an image during **VQ** encoding. The watermark can be retrieved during decoding back correctly. The requirement for space storage is low since **VQ** compression is used. Furthermore, very little computation is needed and time is saved. The proposed method is efficient, robust, and can be used to safeguard rightful ownership. The hidden watermark is safe and not easily detectable by computing processes or statistical methods. Since the watermark is randomly embedded by a secret key, illegal users will have a difficult time hacking even if the watermark algorithm is known. As proven in the experimental results, the watermarked image has a high PSNR of 31.22 dB, is not distorted, and the hidden watermark is confined to invisibility. The retrieval process does not require the original image and the retrieved watermark can be used to prove the rightful ownership of an image.

KEY TERMS

Image Compression: An image is compressed by VQ compression or other compression techniques to maintain a smaller sized image that requires less storage and, at the same, maintains a perceptible undistorted appearance when in decompressed mode.

Robustness: Refers to sustainability in an image that is not easily distorted by normal or malicious manipulations.

Steganography: Associated to a data hiding technique for hiding an important message or secret data into digital

media. The hidden data is not visible, and the image with the hidden data is called a stego-image.

Tree Growing Structure: The codebook for an image is trained based on the structure of a **tree growth**. Training starts from the root of the tree that grows into two branches and two for each branch and multiple off. The centroid at each node is computed until the tree grows to a certain level where the codewords are the closest that would give the maximal trained codebook.

Vector Quantization: A scheme for image compression that maps blocks of the image to a codebook and its index table.

Watermark: A digital logo, mark, symbol, or data stream that is hidden in an image by a **watermarking** technique to protect the rightful ownership of a media data.

Watermarked Image: An image that has one or more hidden watermarks.

Distance Education Initiatives Apart from the PC

José Juan Pazos-Arias
University of Vigo, Spain

Martín López-Nores
University of Vigo, Spain

INTRODUCTION

Developed countries have long been interested in distance education. This interest is growing due to the advance toward a global economy, because education is commonly regarded as the best way to maintain a region's competitiveness. Thus, we have recently witnessed a great development of *e-learning* (taken as a synonym for Web-based learning, or learning through an Internet-enabled computer) to the point that using the Internet to deliver educational material has practically displaced the early initiatives based on postal mail, radio, or television.

The initial evolution of the Internet led to envisaging a massive adoption of e-learning solutions. However, as proved by data from Internet World Stats (http://www.internetworldstats.com), the penetration of the Internet in homes has been rather limited (around 35% in Europe and 67% in the USA), so it follows that the penetration of e-learning has been limited too. This is indeed one consequence of the so-called *digital divide*, that is, the separation between people who make frequent use of the information technologies and those who have no access to them or, even having access, lack the necessary knowledge to use them.

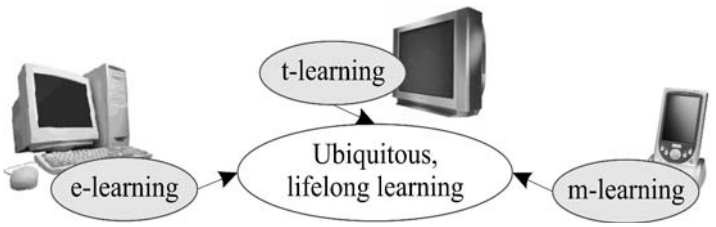
A divide in the access to technology can lead to inequalities in the access to knowledge and education, posing risks of social exclusion. To prevent that, public administrations have launched large-scale initiatives, like the *World Summit on the Information Society* and the *i2010 plan*, that aim at making technology available to everyone, at anytime and from anywhere. As a cornerstone, these initiatives promote the development of access platforms different from the PC, with special interest in harnessing the interactive features of devices that have attained greater penetration in society. This includes the new digital TV set-top boxes, which bear the term *t-learning*, and the modern mobile devices (e.g., mobile telephones and media players), which set the foundations for *m-learning*. The vision, as represented in Figure 1, is that the information technologies, combined with suitable pedagogical and andragogical approaches, will enable a scenario of ubiquitous and lifelong learning, freeing people from time and place constraints, and offering flexible learning opportunities to individuals and groups.

This article describes technical, methodological, and educational issues that make t-learning and m-learning substantially different from previous works on e-learning. We also review developments in both areas to finally discuss problems that may be the subject of much research in the near future.

BACKGROUND

Next, we discuss the evolution of the motivations and scopes of t-learning and m-learning. It will be seen that many pieces

Figure 1. Convergence of approaches to distance learning



of work have had disparate views of the learning paradigms that should be pursued over the new technological media.

Motivations and Scope of T-Learning

Television has been present in nearly every home for decades, getting to be so familiar that everyone feels comfortable using it. Thus, it may become an entry point to the information society, especially for the social sectors that are more reluctant to have contact with technology. Actually, the idea of using the television for educational purposes dates back to the 1950s, but its potential to disseminate knowledge remained underexploited. However, the advent of interactive Digital TV (IDTV) by the late 1990s opened an unprecedented range of possibilities, which made Lytras, Lougos, Chozos, and Pouloudi (2002) predict that "the possibility of broadcasting data and interactive applications jointly with the audiovisual contents will have far-reaching implications in education." T-learning then arose as an approach to exploiting the advances in IDTV technologies to deliver interactive applications that would promote learning and problem solving by requiring active involvement from the viewers (Zhao, 2002).

At first, there were discrepancies regarding the very conception of t-learning, with two opposite perspectives.

- On the one hand, some authors (Russell et al., 2004) argued for simply providing an interface to the same e-learning services running on the Internet, porting existing solutions to a new execution platform (the IDTV set-top box).
- On the other hand, as noticed in Pazos-Arias et al. (2006), most of the experiences launched up to 2005 merely consisted of adding interaction capabilities to the TV programs, promoting the concept of "edutainment" (education and entertainment).

The first approach has been practically abandoned for neglecting various IDTV-specific features that advise against making t-learning a direct translation of the models devised for e-learning (Lekakos & Chorianopoulos, 2006). First, there are technical factors like the limited interactivity achievable with a remote control, the reduced amount of text that can be readable on a TV screen, or the low computing power of a set-top box. Furthermore, it is clear that many potential IDTV users have a lower level of predisposition to learn new technologies than Internet users. Finally, the many years of analogue TV have consolidated a passive attitude from the users, plus a conception of television as an entertainment medium. Thereby, as claimed by the second approach, it is now accepted that an effective t-learning strategy should lean on entertainment to lure people into education, and deliver interactive applications that guide the users through audio and video contents (Chorianopoulos & Lekakos, 2007; Trindade, do Vale, & Pedroso, 2006). Notwithstanding, the kind of edutainment envisaged at first has evolved into two distinct philosophies in the design of t-learning services, which may be seen as the reverse of one another.

- By *pure edutainment* (meaning education that entertains), we now refer to educational services whose central axis is a TV program, enhanced with interactive learning elements that furnish pedagogical added value.
- The term *entercation* (entertainment that educates) refers to educational services designed around an interactive learning element that is supplemented with audiovisual material for the sake of amusement.

In sum, we can delimit the scope of t-learning halfway between the mere entertainment provided by the TV programs and the formalities of e-learning. Interactivity provides a major advantage with regard to the traditional TV programs because it makes the learning experience more engaging, for example, by letting the user influence the presentation of contents, evaluate his or her knowledge through assessment tests, participate in competitions synchronized with TV shows either individually or as representative of a group (Sperring & Strandvall, 2006), and so forth.

Motivations and History of M-Learning

Grounded on the requirement to have the learners in front of the PC, the e-learning models cannot meet the requirements of the modern lifestyle. M-learning arose to embrace the initiatives that harness the educational possibilities of mobile devices that have attained massive penetration in society, like mobile telephones, media players, and PDAs (personal digital assistants). The vision is common that mobile computing will enable the greatest level of time and space flexibility, together with unprecedented possibilities to adapt to individual learners' needs. However, this idea has borne disparate realizations.

The first m-learning developments focused on providing access through mobile telephones to existing e-learning platforms using technologies like wireless application protocol (WAP) to browse hypermedia and short messaging system (SMS) to deliver textual notifications (Garner, Francis, & Wales, 2002), and using specialized navigators and e-mail (Savill-Smith & Kent, 2003). In general, there were no attempts to think of m-learning as a distinctive approach, and research focused on technical issues like delivering content over wireless networks (Vedula & Han, 2003), adapting content and interfaces to make the same courses accessible through different devices (Bandelloni and Paternò, 2004), or maintaining the learning activities during periods of disconnection (Trifonova & Ronchetti, 2005).

In a posterior stage, many claims arose from the educational community to develop m-learning more from the

pedagogical and andragogical perspective, with a focus on exploiting the highly fragmented attention of users on the move. This philosophy led to guidelines on how to create and organize content (Vavoula, 2004): structuring content in short learning modules (from 30 seconds to 10 minutes), supporting nonlinear follow-ups, and so on. Within these guidelines, we witnessed a proliferation of experiments that assessed m-learning in a variety of contexts (Kukulska-Hulme & Traxler, 2005), and its scope grew to embrace both formal and informal, intentional and unintentional learning activities: accessing academic courses as above (Alexander, 2004), downloading localized information during museum visits (Papadimitriou, Komis, Tselios, & Avouris, 2006), and taking pictures to aid retention of knowledge from a seminar or surgical operation (Parks & Dransfield, 2006), among others. Accordingly, the notion of learning was broadened to include "the needs that emerge when one strives to overcome any problem in everyday activity," and the range of devices for m-learning was once and for all extended from just mobile phones to "any device that is small, autonomous and unobtrusive enough to accompany us in every moment in everyday life, and that can be used for some form of learning: digital cameras, smart phones, MP3 players, etc" (Trifonova & Ronchetti, 2005). This enumeration should now be expanded to leave place for ongoing advances in wearable computers.

As the major distinctive feature of m-learning, many authors are working on mechanisms to provide contextualized learning experiences, i.e., to take into account where the user is and what he/she is doing in order to recommend the best suited educational activity. In this regard, we can cite studies to manage context using geographical positioning (Ogata, 2006) and radio-frequency identifiers (Baggetun & Wasson, 2006). Also, terms like *adaptivity* and *context awareness* already appear regularly in the m-learning literature, but there is yet little evidence that m-learning applications harness these capabilities or fulfill novel pedagogical aspirations.

THE CURRENT SCENARIO OF DISTANCE LEARNING

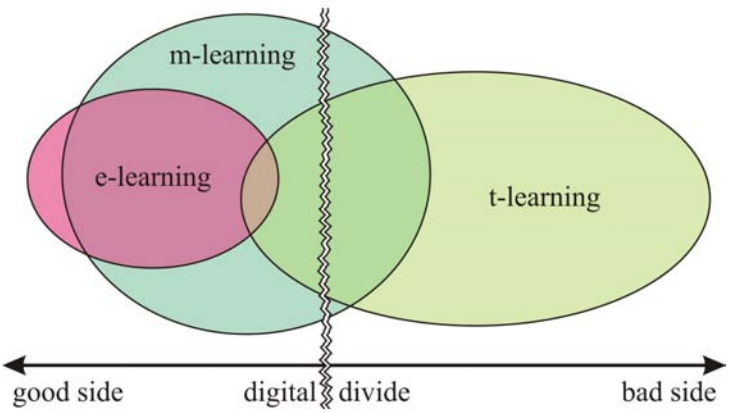
The works cited in the preceding section, together with many others in literature, already provide sufficient practical feedback to consolidate the scopes of both t-learning and m-learning with regard to e-learning. The relations can be represented as in Figure 2.

To begin with, it is noticeable that e-learning is mostly circumscribed so as to enhance the training of people on the good side of the digital divide since it is mostly sustained by (a) companies looking for a quick and affordable way to keep employees educated on the latest developments in their fields, and (b) universities offering certificate programs via the Internet. Accordingly, e-learning has consolidated as a suitable approach for formal and intentional educational settings, targeting people who engage purposefully in well-defined methodologies to achieve certain curricula. The role played by these learners is active, promoting the design of user-driven interaction schemes wherein the applications respond to the users' actions.

Due to the usage models linked to the PC, e-learning is unsuitable for informal and accidental types of learning, which may be defined as:

the process whereby individuals, often in an unintended or unexpected manner, acquire attitudes, skills and knowledge from daily experience and the educative influences and resources in their environment, from family and neighbors, from work and play, from the market place, the library and the mass media. (Conner, 2005)

Figure 2. The relative scopes of e-learning, t-learning, and m-learning



This definition supposedly applies to over 75% of adult learning, and obviously to an even greater share in children (Organization for Economic Cooperation and Development [OECD], 2006). T-learning is called to fill this huge gap, especially targeting the people who have not been involved with formal or semiformal education for many years, and those who have a poor technological background. Interactions in this case are predominantly *media driven* to let the users take part in a reduced number of decisions. Nevertheless, t-learning is also available for people on the good side of the divide, who may select a formal or informal learning option depending on their interests in individual topics.

Finally, m-learning may be regarded as a medium to provide increased learning opportunities to people with a solid technological background, plus the so-called *digital natives*, that is, people who have grown up accustomed to using electronic widgets (Prensky, 2001). Targeting this audience, m-learning covers the wide spectrum of applications in distance education opened by the latest pilots and trials, to such an extent that it could be perceived as a superset of e-learning. The only e-learning services that fall out of the scope of m-learning are those for which the educational material cannot be adequately perceived and/or handled with a mobile device due to limitations in screen size and/or input facilities. Undoubtedly, though, the most distinctive feature of m-learning lies within its possibilities to furnish a *context-driven* approach to interactivity, capable of adapting the learning experiences to the user's evolving attention, skills, knowledge, and location.

Having said that, the goal of achieving convergence of the three distance learning paradigms (as depicted in Figure 1) is still hampered by incompatibilities among the different technologies employed for learning management tasks: student monitoring, content description, organization and retrieval, and so forth. The reason is that the efforts in the standardization of distance learning have been mostly focused on e-learning. However, recent studies have shown that many solutions originally devised for e-learning, specifically, those bundled in the *sharable content object reference model* (SCORM) (ADL, 2004), can be successfully applied to t-learning and m-learning as well, requiring minor adaptations or extensions to cater for their peculiarities (Low, 2007; Pazos-Arias et al., 2006). These works reveal that it is possible to build a full-featured and consistent whole reusing existing solutions.

FUTURE TRENDS

One of the topics that will presumably be the subject of much research in the following years is that of *personalization*, aimed at enabling learning experiences suited to the interests, needs, and capabilities of the different users. The SCORM standards, together with domain-specific norms, provide the foundations to develop intelligent tutoring systems that match the descriptions of the educational resources available, records of TV watching habits, learning histories, and so on to discover the most suitable educational resources for each individual. In this regard, as suggested by Blanco-Fernández, Pazos-Arias, Gil-Solla, Ramos-Cabrer, & López-Nores (2007), *semantic reasoning* techniques have the potential to deliver the most engaging and effective experiences, but their application in this area is still incipient. The same happens with research on the automatic assembly of services tailored to users' interests, which aims at boosting reusability to lower the costs of producing educational material. Finally, closely related to personalization, there are still more open problems than working solutions in adapting the learning experiences to the user's context and changing attention. This issue is mostly linked to m-learning, but also touches t-learning to a remarkable extent, for example, to differentiate when the user is watching TV alone or accompanied, or to change the learning material offered as the user zaps different channels. Advances in these topics require contributions from such fields as electronics, artificial intelligence, software engineering, human-computer interaction, and even human physiology to bring distance learning progressively closer to emerging areas like *ambient intelligence* (Remagnino, Foresti, & Ellis, 2005) and *ubiquitous computing* (van't Hooft & Swan, 2006).

CONCLUSION

During the last decade, we have witnessed a great development of e-learning solutions, taken as a synonym for learning through an Internet-enabled personal computer. However, there is growing evidence that e-learning fails to reach sizable social sectors, especially people who are reluctant to have contact with the new technologies and those who have not been involved with educational activities for many years. To narrow the effects of the digital divide, the research community is devoting significant effort to develop alternative learning platforms that solve the accessibility, usability, and availability limitations of the PC. The bet is placed on exploiting the interactive features of digital TV receivers and the modern mobile devices. We have seen that these initiatives serve to fill in different gaps left uncovered by e-learning, and that, overall, the goal of making learning opportunities available at any time, from any place and for everyone is progressively becoming a reality.

KEY TERMS

Context-Driven Interaction: It is an approach to the design of interactive services that adapts their content and functionality to users' evolving context, including attention, interests, needs, and location.

Digital Learning Divide: This is a social phenomenon caused by inequalities in the access to knowledge and education that arise from familiarity with the information and communication technologies.

Edutainment: It is a pedagogical and andragogical orientation based on developing services around entertaining material, enhanced with learning elements that furnish educational added value.

Entercation: It is a pedagogical and andragogical orientation based on developing services around a learning element that is supplemented with audiovisual material for the sake of amusement.

Media-Driven Interaction: This is an approach to the design of interactive services that caters for passive consumption habits, letting the applications guide the users through audiovisual contents.

M-Learning: M-learning is a distance learning approach based on delivering interactive and possibly contextualized educational material to mobile devices.

T-Learning: T-learning is a distance learning approach based on accessing interactive educational material of a predominantly audiovisual nature, primarily within the home and using devices that bear usage habits similar to those of watching television.

Distance Education Teaching Methods in Childcare Management

Andreas Wiesner-Steiner
Berlin School of Economics, Germany

Heike Wiesner
Berlin School of Economics, Germany

Petra Luck
Liverpool Hope University, UK

INTRODUCTION

The cultural and technical history of e-learning scenarios can be traced back to traditional forms of distance studies, CD-Rom learning programmes, audio-programmes or educational TV. But other than these forerunners, two closely related myths often shape policy towards ICT and education: the irresistible power of globalisation and the determining effect of technology. Both views present the success of e-learning throughout the education system as inevitable. The space left for practitioners in higher education is either to embrace the new media or to watch its inevitable unfolding. In this paper we take a critical stance towards that perspective and suggest that the shape and learning effect of new media in higher education is contested and evolves in communities of practice. No technologies are neutral and it is more appropriate to speak of economic, technological and societal features as interactively fostering the importance of e-learning through *distributed actions* (Rammert, 2002). From such a perspective, e-learning is perceived as a co-product of didactically and technically situated features (Wiesner-Steiner, Wiesner, & Schelhowe, 2006) that foster and enable but don`t determine human learning through the use of digital technologies. Main characteristics are:

- Interactive and multimedial design of content
- Learning via digital networks
- Netbased communication

The EU-Leonardo-project "European Enhancement of Early Years Management Skills—EEEYMS" (http://www.eeeyms.org/) was intended to enhance employability of people employed in the Early Years Childcare management sector by providing access to a high level qualification in line with the emerging industry requirements. This was achieved by developing distance learning materials available via the World Wide Web and other forms of media including CD-Rom`s, specific to the employment area which is also aligned to a degree pathway, and will be available within Europe. It was further achieved by the creation of a European network association for childcare to ensure sustainability after the project is complete. EEEYMS provides an accredited route for the attainment of a relevant degree level qualification for careers and managers within the childcare sector, and assist in attracting suitable people into this employment sector to meet the childcare demand over the next 10 years. With ODL materials, the project enhances employment opportunities and career status for a still predominantly female workforce. Research suggests that the increased status and professionalisation obtained through the availability of a high level qualification will make the industry more attractive to male employees. EEEYMS thus provided higher level qualification to people disadvantaged in the labour market and those who faced discrimination in accessing training due to disability, geographical location or family commitments. The use of ICT systems was thus thought to enhance knowledge and learning experience *and* the employability factors, as the knowledge will be directly transferable to the work environment.

The primary target group was that of childcare professionals actively working in the sector or entering this profession, where a niche in the market exists for a relevant specific degree award. EEEYMS thus wanted to attract more women into managerial positions, while encouraging more men to enter the profession by providing a credible award.

Because empirical evidence on the increase of e-learning-efficiency is both difficult and important, external evaluation of the EEEYMS e-learning modules via surveys has been an integral part of the entire project. The aim here was to include a more objective, independent feedback at every stage of the programme. According to the projects aims, the evaluation was conducted following the principle of gender mainstreaming (Wiesner, Kamphans, Schelhowe, Metz-Göckel, Zorn, Drag, Peter, & Schottmüller, 2004) and considering intercultural inclusion-aspects (Zorn & Wiesner-Steiner, 2006).

The article is divided into three main sections. After introducing the use of VLE and a problem based learning

approach, we discuss the effects of group work, the use of technology and the main learning experiences. As a result we come up with an overview of critical sociotechnical issues of distance learning materials.

BACKGROUND

In the development of e-learning for the early years sector through the EEEYMS partnership these key issues emerged: the importance of the use of a suitable VLE in delivering the learning programme, the use of problem-based learning (PBL) to enhance student motivation through collaboration, the need of IT skills development and the role of context as it relates to student success.

The VLE in use is Granada's "Learnwise". This VLE has as one of its technical features collaborative "forums" in which participants take part in asynchronous discussion in small teams and work on specific management and education problems The partnership decided that these forums would provide a prime vehicle for student support through "encouraging active learning", shifting from didactic to "facilitative teaching" or "building online communities" (Armitage, Brown, & Jenkins, 2001)

The stated aim of the EEEYMS project is that early years practitioners will develop knowledge and understanding of the educational and management issues pertinent to their sector, and that they will also develop the requisite skills to critically analyse, evaluate and apply this knowledge. As professional knowledge requires functioning knowledge that can be put to work immediately, most module designers for EEEYMS choose to adopt a "problem-based learning" approach.

Problem based learning simulates everyday learning and problem solving. Knowledge is acquired in a working context and is put back to use in that context. The learning and assessment on the programme will be aligned (Biggs, 1999) to learners everyday work experiences. Participants learn the skills for seeking out the required knowledge when the occasion arises during the process. They are motivated immediately by the interaction with a 'real' problem and are active early in the process.

Although on-line participants face time constraints as working practitioners and as parents with family responsibilities, the use of media-communicated communication has been used to build successful collaborative learning. As Salmon (2000) asserts, the Internet can change concepts of space and time: "*Working and learning with others who happen to live in a particular locale may become less important than finding shared professional and personal interests in online environment" (p. 492).*

The EEEYMS project aimed to provide learning opportunities at degree level, so that practitioners can develop the requisite skills to critically analyse, evaluate and apply knowledge. A large body of literature support the motivational aspects of collaboration on learning (Johnson & Johnson, 1989; Sharan & Shaulov, 1990). Wenger (1999) also offers a perspective on learning that emphasises social learning processes within *communities of practice* where individuals engage in the negotiation of meaning and the mutual construction of knowledge. The EEEYMS participants often refer to this "community of practice" when expressing the relevance of the tasks to the everyday practice.

The issue of gender was also pertinent as with the exception of one male EEEYMS participant, all others were female. For example, a study by Kirkup and von Prumm (1990) comparing the experiences of women adult distance learners in Germany and the UK points to a pattern of preference for shared learning.

This type of social-technical interaction, learning and decision making is expected in the workplace today and this approach should ultimately therefore promote a desire for and ability to partake in 'life long learning'.

Meisalo, Lavonen, and Juuti (2005) also emphasise the importance of Web based community formation for off-campus participants in their study of primary teachers taking a science education course. Dron (2005) in his paper on the construction of e-learning environments to cater for the needs of diverse learners utilises Michael Moore's theory of transactional analysis. For Moore (1980), distance is a pedagogical more than a physical phenomenon, and transactional distance measures the amount and nature of dialogue. Transactional distance is said to be low when there is a lot of dialogue between learners and teacher, but where transactional distance is high, teachers often provide a highly structured learning experience. The use of PBL appears to ensure that student autonomy flourishes and dialogue is high not only between student and teacher, but also student and student.

This importance of web based community and the need to maintain a low transactional distance through constant dialogue appears to be a critical outcome of the EEEYMS project. Donohue (2002) analyses the challenges of teaching the target group for EEEYMS online, as the Early Years sector is characterised by "low tech/ high touch". While many Early Years Managers and Practitioners might only have little involvement with high tech equipment such as computers in their work place settings, much of their practice is concerned with managing relationships with colleagues, children and families. Donohue (2002) suggests the use of learning approaches aiding the building of a community of practitioners such as collaborative knowledge construction and group work. The evaluation results discussed now show that it has successfully utilised learning approaches to mirror that "high touch."

PARTICIPANT EXPERIENCES WITH GROUP WORK AND E-LEARINNG TECHNOLOGY

In our view, interlinking the scopes of didactics, evaluation and technology can help to increase the user's (long dated) commitment to e-learning modules. If electronic learning tools are perceived as "didactical actors" that not only bear their own action potential but influence and redirect participants belief systems and agency (Wiesner-Steiner, Wiesner & Schelhowe, 2006), new relations between learners and *didactical technology* come into focus. The results of the external evaluation thus mark important "passage points" for technical *and* didactical implementations of e- learning modules.

Methodically we used semi-standardized questionnaires that consist of a combination of closed yet multiple choice questions and open questions that leave room for participants to explain their more subjective learning experiences. Interpretation was done by means of the content analysis (Gläser & Laudel, 2004; Mayring, 2000).

GENERAL PARTICIPANT EXPERIENCES

Asking for general experiences, we could identify three points:

- Time management, intensity of tasks, and work amount mark the most difficult aspects.
- Although quite challenging, the modules "were well designed" and "offered something for everybody"—learning outcomes were met throughout all the modules.
- Group work and tutors play a crucial and positive role in all modules.

GROUP WORK

Throughout our evaluation of EEEYMS, the overall importance of group work in a VLE became evident. Group work activities are not just a work form among others. For e-learning modules, they proved to be the work form par excellence! Group work was not only generally important, it does enhance group commitments in virtual communities. Two of the most stunning *social* remarks about electronic group work thus stated: *"Without group work I don`t think I would have managed the course."* (...) *"I feel as if I know my group members better without having the physical get-togethers than in previous studies."* Accordingly, students also pointed to the advantage of a shared workload, especially for part-time students or people who have to work full time and have a family life. They also mentioned that informal phone and e-mail contacts have been used in group work more often than informal chat rooms. Moreover, they found that e-learning group work offers different perspectives on an issue, allowing for a more holistic image and approach of the tasks. The relevance of group work can be summed up as follows:

- Electronic group work needs blended learning with face-to-face meetings at the beginning, "everybody had a face".
- Being part of the same group in different modules helps for getting used to different learning styles.
- Changing groups can constrain learning processes.

Both the combination of face-to-face with electronic group communication and the importance of group continuity mark important points for the appropriation of different learning styles and the development of social commitment. Didactically applied, they can improve the general learning experiences mentioned previously.

Although most EEEYMS students agree that group work plays a very important role in e-learning modules, they also addressed some risks:

- "The team leader's position is sometimes confusing because of individual's different aims—sometimes ignoring other needs."
- "You have to monitor yourself all the time in order to try to avoid communication misunderstandings."

Group members have to learn to work in a team. But as we know from everyday life and work practices, teams can be organized in more hierarchical or more symmetrical ways, depending on the members and social dynamics of a certain group as well as on the specific tasks and contexts. Within e-learning environments, students have to organize their group work mostly on their own. Moreover, they have to deal with social aspects like leadership and communication. Participants also found that group work is helpful not only for dealing with certain tasks but to navigate through both the technical and learning requirements of a module. Due to that, group work also functions as a method to downsize the drop-out quote in two directions—dropping out because of difficult (social) tasks or dropping out because of technical problems. But do the online students use the communication offers given by Learnwise? Studies in the area of e-learning and knowledge management systems conclude that communication offers are not used very often if they are not designed in a didactically carefully fashion. This is clearly perceived by EEEYMS participants as one of the most positive aspects of the e-learning modules. Thus group work—experienced as a new way of collaborative learning and in combination

with team support by tutors—was perceived as *the* most positive aspect. Nonetheless, group work proved both important and challenging, creating mutual dependencies as well as commitments. It is important to note that both aspects can be perceived as very positive, depending on the student's experiences with team support and technical support.

Group work was also useful in cases when technology did not work as expected, trying to solve or bypass technical problems as a group. Because group work also works in informal, non-electronic ways, an important point stressed by the students is the unique form of electronic group work. Electronic group work is seen as a learning process in itself, requiring both commitment and easily accessible technology. In sum, the importance of electronic group work for learning processes was highlighted for all Hope modules, not the least because group work and electronic learning tools build learning communities and communities of practice (Lave & Wenger, 1991). We thus recommend that the concept of technically mediated group work should mark one of the central aspects for future e-learning modules and should be integrated into didactical approaches.

TECHNOLOGY

In accordance with the role of group work, we also evaluated the role of technology in e-learning environments:

- Electronic systems are great as long as they are running.
- E-sources where sometimes difficult to find and time consuming.
- Forums and chat rooms for group work were useful for communication among group members and contacts with tutors.
- Online sources were most useful in combination with supplementary materials (CD-Rom), group work and tutorial help.
- Tutors play an important role as they mediate between the requirements, technical possibilities and social dynamics of the e-learning modules.
- Tutors were given excellent credits, have been responsible "even at simple questions", accessible most of the time and (often) replied promptly.

For EEEYMS participants, websites and journals became high-rated whereas library resources seem to be "out". Nonetheless, in terms of provided materials the students often felt that hard-copy handouts gave more safety than other material. This has to do with technical problems that are perceived as very time-consuming, i.e. access-problems that occurred while trying to use e-journals, informal chat rooms with slow responding action or Web links with passwords (with the exception of tutor-directed Web links). CD-ROMs and module handbooks thus became important when access to those materials failed. Moreover, they were also important in the modules`introductory phases. In addition, the role of the tutor became quite important in cases when technology failed, forcing tutors to organize a new or alternative learning environment. The facilitation and encouragement of electronic communication by tutors marks another important evaluation point. We thus recommend that for future e-learning modules, tutors should be especially trained in supporting online communities and group activities.

LEARNING

Not only did EEEYMS participants learn something new, but they became able to translate their new knowledge into their own professional contexts. In addition, the following features of their collective learning experiences point to the close interplay between didactical, social and technical e-learning issues:

- Discovering the unique style of e-learning;
- Discovering group work as a learning experience;
- Learning of IT skills and time management;
- Discovering the advantages of problem based learning;
- Discovering the possibility to study while working and being "old age";
- Discovering the possibility to choose one's own learning time (look at resources, listen to CD lectures, etc.);
- Discovering many ways to act towards the same aims;
- Discovering appropriate and comprehensive modules for day care managers";
- Discovering excellent experiences in communicating and learning with colleagues from different countries; and
- Discovering that children have the same basic demands and affairs in spite of cultural differences.

FUTURE TRENDS

In summary, e-learning is clearly perceived as a new type of learning. Nonetheless, we might only use 20% of the possibilities of e-learning. To some extent, that mirrors the development of television where at the beginning the actors did act like actors in a stage play and were not aware of the new technology and its influence on their performance. The same thing could be true for e-learning, when virtual group work and electronic learning tools are offered and mediated in a didactically careful fashion, creating new forms of lifelong learning. As our informants mentioned, this process can be initiated and improved by

Table 1. A summary of critical issues for future distance learning materials

• Time management, intensity of tasks and social context (work amount, family) create learning problems. • Integration of working duties and job related perspectives into the content of teaching and into the structure of e-learning modules is important (e-learning adds the load to daily work!). • Interaction between didactical and technological issues within sociotechnical support: tutors and group work play a crucial role in e-learning-modules as they mediate between the requirements, technical possibilities/problems and social dynamics of the e-learning modules. • Electronic group work needs to be discovered as a learning experience of its own. • Group work bears risks and opportunities, is at the same time socially challenging and creates new learning experiences. • Intercultural aspects are linked to technical aspects: Time differences, quality of technology at hand and language barriers (academic language) can create communication problems between participants from different countries. • Online-sources are most useful in combination with supplementary materials (CD-Rom) and group work.

- Strengthening of group commitments;
- Clarification of submission procedures;
- Research guidance;
- Obligatory contributions to the forums and chat rooms;
- Language diversity;
- Less academic language;
- Small weekly activities with one large assignment at the end of a module; and
- Reflections on different professional backgrounds and qualification levels.

CONCLUSION

Observing participant experiences with group e-learning technology, group work, and learning itself sharpens the view on how the shape and learning effects of new media in higher education is contested and evolves in communities of practice. Due to that, we assessed e-learning as a mixture of didactically and technically situated and mediated features. Carefully applied, these features foster and enable human learning. Although successfully evaluated for the EEEYMS case, distance and e-learning technologies are not free of risks and controversies. In this respect, Table 1 summarized important issues of distance learning materials, issues that are at the same time technical, didactical and social. Throughout these issues, participants clearly articulated how working in groups "kept them going". The availability of synchronous and asynchronous communication tools utilised by the e-learning cohort, has supported that desire or preference for shared learning, without the many barriers perceived by "regular" learning.

KEY TERMS

E-Learning: Electronically supported learning; all kinds of learning with the use of digital media for the presentation or distribution of learning materials and/or the support of communication.

Gender: Refers to the social gender role or the social gender qualities; everything that is typically assiociated with men and women within a certain culture.

Gender Mainstreaming: Refers to the political idea of gender equality on all levels of society.

ODL: Open distance learning.

Sociotechnical: Emerging from management and economic research as well as from the sociology of science and technology, the term refers to the mutial dependency and intertwining of social and technical features within companies, production systems or social systems at large.

VLE: Virtual learning environment.

Category: IT Education

Distance Learning Overview

Linda D. Grooms
Regent University, USA

INTRODUCTION

The knowledge explosion, the increased complexity of human life, and the ubiquitous nature of technology coupled with the globalization of the marketplace herald the need to embrace the most effective methods and formats of teaching and learning. Currently providing powerful educational opportunities, the science and technology of distance learning continues to multiply at unprecedented rates. Where just a short time ago traveling from village to village verbally disseminating knowledge was the only process of training those at a distance, today many eagerly embrace the rapidly expanding synchronous and asynchronous delivery systems of the 21st century. So what exactly is distance learning?

In very simplistic terms, distance learning is just that: learning that occurs at a distance (Rumble & Keegan, 1982; Shale, 1990; Shale & Garrison, 1990) or that which is characterized by a separation in proximity and/or time (Holmberg, 1974, 1977, 1981; Kaye, 1981, 1982, 1988; D. J. Keegan, 1980; McIsaac & Gunawardena, 1996; M. Moore, 1983; M. G. Moore, 1973, 1980, 1989a, 1989b, 1990; Ohler, 1991; Sewart, 1981; Wedemeyer, 1971). In his 1986 theory of transactional distance, Michael Moore (Moore & Kearsley, 1996) defined distance not only in terms of place and time, but also in terms of structure and dialogue between the learner and the instructor. In this theory, distance becomes more pedagogical than geographical. As structure increases, so does distance. As dialogue increases, distance declines, thus accentuating the need for interaction in the distance learning environment. Saba (1998) furthered this concept, concluding,

the dynamic and systemic study of distance education has made "distance" irrelevant, and has made mediated communication and construction of knowledge the relevant issue.... So the proper question is not whether distance education is comparable to a hypothetical "traditional," or face-to-face instruction, but if there is enough interaction between the learner and the instructor for the learner to find meaning and develop new knowledge. (p. 5)

To facilitate greater interaction in the geographically and/or organizationally dispersed distance environment, today, individuals most often use some form of technology to overcome the barrier of separation, affording institutional and learner opportunity to transcend intra- and inter-organizational boundaries, time, and even culture. By definition, the paradigm of distance learning revolutionizes the traditional environment (Martz & Reddy, 2005); however, even with this change, learning, which involves some manner of interaction with content, instructor, and/or peers, remains at the core of the educational process.

Although imperative in both environments, these three types of interaction seem to be at the hub of the ongoing traditional-vs.-distance argument. Traditionalists often fear that with anything other than face-to-face instruction, interaction somehow will decrease, thus making learning less effective, when in reality, numerous studies have revealed no significant difference in the learning outcomes between traditional and distance courses (Russell, 1999). In fact, distance courses have been found to "match conventional on-campus, face-to-face courses in both rigor and quality of outcomes" (Pittman, 1997, p. 42). Despite these findings, critics still abound.

Two distinguishing characteristics of the nontraditional environment—individualized learning and flexibility—often arouse suspicion and caution among traditionalists (Grooms, 2000). Many are convinced that with any form of study outside the confines of the typical brick and mortar, "every vestige of intellectual rigor [will] disappear into oblivion....[These skeptics interpret] individualized learning as individualized isolation, especially from faculty, and they look on flexibility as no more than a synonym for escape from regulation and responsibility" (Gould, 1972, p. 9). Inherently, they fear loss of interaction.

In contrast, with their introduction of equivalency theory, Simonson, Schlosser, and Hanson (1999) accentuated the concept of equivalency as "central to the widespread acceptance of distance education" (p. 72), thus supporting Keegan's (1989) call for parity in quality, quantity, and status. Furthermore, recognizing the need to bring integrity and prestige to the field, Shale and Garrison (1990) suggested building a framework based not on isolation but upon interdependence, which would imply that distance learning would merely become an alternative method for delivering traditional content. This begs the question of how distance learning has evolved.

BACKGROUND

As previously mentioned, distance learning has been with us in one form or another virtually since the creation of time.

For years, itinerant teachers traveled from village to village verbally disseminating information to those hungry for knowledge; however, the invention of Guttenberg's printing press in 1440 made possible serious distribution of learning to larger numbers of people.

Capitalizing on this broader use of print media, correspondence study became a popular form of distance education, the first record of which was in 1728 when Caleb Philipps advertised the introduction of shorthand (Battenberg as cited in Baath, 1980; & Holmberg, 1986). Often conjuring thoughts of isolation and autonomy, this record of instruction mirrored those images. In fact, in this account, there was no mention of interaction of any type other than what was inherent with the content.

Over a hundred years later in his 1833 Swedish advertisement, although not directly stated, Meuller's offer to study composition seems to be the first to imply some form of exchange between the student and teacher. More definitively, in 1840, the most acknowledged root of distance learning explicitly employing learner-instructor interaction began in the United Kingdom. Using passages from the Bible, Isaac Pitman taught shorthand (Baath, 1980; Holmberg, 1974; Kaye, 1988; Rumble, 1986), but this time, once learners transcribed these passages, they were returned for correspondence with the teacher via the penny post, thus some call it postal teaching (Dewal, 1988).

As evidenced in these early days of pure correspondence education, any offered guidance transpired through some form of dispatched communication such as the mail (Wedemeyer, 1971), and student contact, even with the instructor, was not necessarily encouraged. This is clearly seen in Keegan's (1980) classic article "On Defining Distance Education," where he documented that in its strictest sense, pure correspondence study advocates specified that "students enrol [sic] with them because they 'want to be left alone'" (p. 31).

As distance learning evolved, learner-instructor interaction became increasingly important, thus catapulting the first of two paradigm shifts. While many recognized the significantly positive impact of the distance learning interactive component (Cookson, 1989; Grooms, 2000, 2003; Robinson, 1981), others such as Daniel and Marquis (1979) accentuated the importance of getting the right independence-interaction mixture. Further stressing this need for learner-instructor interaction, Holmberg (1982) directly confronted the pure correspondence model when he concluded that "any postgraduate distance study must have a truly communicative character if more is meant than merely providing reading lists and odd comments on students' work" (p. 259).

Print remained the primary mode of distance learning until the 1920s and '30s when the introduction of radio broadcasts soon followed by television and satellite delivery systems initiated the labor pains for the birth of the current online technological revolution. Prior to the advent of the World Wide Web (WWW) in the early 1990s, interaction continued to transpire primarily between the learner and content, with occasional interaction between the learner and the instructor through such means as telephone and videoconferencing. The second paradigm shift was on the horizon.

THE CURRENT STATE OF AFFAIRS

To be embraced, any new mode or method of education must do more than merely emulate the status quo. The virtual environment of the 21st century claims to do just that. While offering flexibility from traditional proximity and time constraints (Barnes & Greller, 1994; Harasim, 1990; Hiltz & Johnson, 1990; Kaye, 1989; M. Moore, 1983), computer-mediated communication (CMC) (Harasim, 1993; Kaye, 1989; McIsaac & Gunawardena, 1996) serves as an excellent participation equalizer. Coupled with unprecedented technological advances (Graham, Allen, & Ure, 2005; Osguthorpe & Graham, 2003), the line between traditional face-to-face learning and that which occurs at a distance becomes increasingly blurred.

While multiple studies have indicated there is no significant difference between distance and traditional learning effectiveness, the geographical dispersion of people, shifting market conditions, and rapid technological changes continue to compel transformation in the way we do business both in the marketplace and in the halls of academe. Promising to deliver increased access, quality, and efficiency of learning in an ever-growing competitive market (Benoit, Benoit, Milyo, & Hansen, 2006), the technology of higher education alters teaching and learning (Kapitzke, 2000) and thus instructor and student roles (Stadtlander, 1998).

Learning is no longer dispatched through print or even audio or video, but rather it is now mediated through synchronous (interactive/real time) or asynchronous (delayed interaction) means. Regardless of technology's sophistication, the most critical consideration must always be to align the task, the delivery method, and the delivery format.

Distance Learning Delivery Methods

Almost 150 years following the advent of postal teaching and the first record of any form of learner-instructor interaction, Linda Harasim (1989), a pioneer in the online classroom, clearly differentiated three delivery methods that she believed distinguished traditional, distance, and online education: *one-to-many*, as in the traditional lecture method when one instructor addresses many students; *one-to-one*, as in the tutorial method; and *many-to-many*, a collaborative process with students learning from each other, with or without an instructor. In the first method, learners are mere passive recipients of knowledge and information, whereas in the latter two, they are actively involved in the learning

process. A clear shift in the role of the instructor transpires from information dispenser to one who facilitates an environment where knowledge "emerges from active dialogue among those who seek to understand and apply concepts and techniques" (Hiltz, 1990, p. 135).

Although the traditional face-to-face environment is time-place dependent, it allows for the implementation of all three delivery methods contingent upon the instructional task. In contrast, the distance and online environments are time-place independent and mediated, facilitating flexibility and reflective response; however, in like manner they also align method with context. When appropriate, distance learning uses the *one-to-one* (e.g., print media such as programmed instruction) or *one-to-many* (e.g., audio and video teaching) methods, while online classes additionally employ the *many-to-many* concept, which forces the second paradigm shift: the need for peer interaction.

Distance Learning Delivery Formats

Distance learning formats typically corral into four arenas: print, audio, video, or digital, with all serving as viable options. Apart from media or technology differences, communication within these formats can either be one-way with the learner taking a passive role or two-way with the learner interacting with either the instructor or peers.

Today, using syllabi, texts, and instructor notes, the medium of print remains a significant component in distance learning, while telephones and audio conferencing permeate our 21st century culture. Although video technology also engulfs our society, the rapid proliferation of the Internet has provided a plethora of learning opportunities, both synchronous and asynchronous, through such means as instant messaging and white boards, or through e-mail and threaded discussions. Regardless of the format, learning remains the ultimate goal. Table 1 delineates some of the various formats at our disposal.

More recently, many educational institutions have turned to a blended learning approach, combining some form of the traditional with the digital. Osguthorpe and Graham (2003) summarize this approach very well:

Those who use blended approaches base their pedagogy on the assumption that there are inherent benefits in face-to-face interaction (both among learners and between learner and instructor) as well as understanding that there are some inherent advantages to using online methods in their teaching. Thus the aim of those using blended learning approaches is to find a harmonious balance between online access to knowledge and face-to-face interaction. The balance…will vary for every course [based upon the] instructional goals, student characteristics, instructor background, and online resources….No two courses will be exactly the same….[The goal] is to ensure that the blend involves the strengths of each type of learning environment and none of the weaknesses. (p. 228)

Citing three typical reasons for using a blended approach—more effective pedagogy, increased convenience and access, and increased cost effectiveness (Graham et al., 2005)—it is easy to see why progressively more institutions are entertaining the thought of implementing such a format.

Further blurring the line between traditional and distance learning, the blending and convergence of technologies continue to increase the fluidity and ubiquity of education. Today, learners already have almost instant access to a plethora of information via the Internet. With Webcams and microphones, they can freely see and talk with instructors and peers, maintaining the dialogue heralded earlier as necessary for effective distance learning. With handheld computers, learners—no longer desk- or library-bound—can travel freely around the globe without ever missing a class. With the future in mind, McCain and Jukes (2001) posited, "at a certain point, the boundaries between reality and virtual reality will collapse because of the increased sophistication and transparency of these powerful, fused technologies" (p. 60). So, where do we go from here?

FUTURE TRENDS

In a 1965 *Electronics* magazine article, Gordon Moore, cofounder and CEO of Intel, the world's largest silicon chip manufacturing company, predicted that the number of components on the integrated circuit board would double every 12 to 18 months. While this timeframe was amended in 1975 to every 24 months (Kanellos, 2005), it has been accurate in excess of 40 years. At present, what has become known as Moore's Law shows no signs of slowing down, although in a 2000 interview with *Time* magazine, Moore did acknowledge that at some point in the next two or three generations, this exponential rate of growth would perhaps slow down to doubling every 5 years. Even then, we are quite a distance from reaching the apex of technological discovery, which history reveals directly affects distance learning.

Negroponte (1995) poignantly prophesied, "Distance means less and less in the digital world. In fact, an Internet user is utterly oblivious to it. On the Internet, distance often seems to function in reverse" (p. 178). Supporting this prediction, science and technology have triggered physical distance to become truly irrelevant. So, what does the future hold? Where will distance learning be in 5, 10, or even 20 years from now? Some would postulate that we are only limited by our imaginations.

Table 1. Distance learning delivery formats

MEDIA	PASSIVE One-Way	INTERACTIVE Two-Way	
		Synchronous Real Time	**Asynchronous** Delayed
PRINT	Texts Syllabi Instructor notes Study guides Workbooks Fax		
AUDIO	Radio Audiotape CD-Rom Voice mail	Telephone Audio conferencing with or without a bridge	
VIDEO	Videotape DVD Film Cable, broadcast, and digital television (one-way audio and video)	Satellite videoconferencing (two-way audio and one-way video) Microwave television conferencing Digital videoconferencing (two-way audio and video) Internet videoconferencing	
DIGITAL	CAI (computer-assisted instruction), using the computer as a self-contained teaching machine CD-Rom Streaming video Blogging Linklogging Moblogging Photologging Vlogging Weblogging Podcasting Phonecasting Vodcasting	Chat rooms Shared white boards Instant messaging	CMI (computer-mediated instruction) E-mail Bulletin boards (threaded discussions, newsgroups) Listservs Wikis Web-based instruction (e.g., Web CT, Blackboard)

CONCLUSION

Whether one views distance as geographical or pedagogical, as the above suggests, the technological explosion of the 21st century provides unprecedented opportunity to render distance virtually irrelevant. If Moore's Law holds fast and technology continues to double every 18 to 24 months, the exponential growth of distance learning will continue to catapult educators into uncharted territory. The question remains: Will there still be a place for the staunch traditionalists or will education be so radically transformed that traditional education is hardly recognizable? Regardless of the media (print, audio, video, or digital), method (*one-to-many*, *one-to-one*, or *many-to-many*), or format (passive or interactive), interactive learning continues to remain at the core of the distance educational process.

KEY TERMS

Correspondence Learning: A form of distance learning using dispatched or one-way interaction.

Equivalency: Distance learning that possesses equality with learning experienced in the face-to-face venue.

Face-to-Face Learning: Learning that is time-place dependent.

***Many-to-Many*:** A collaborative process with students learning from each other with or without an instructor.

***One-to-Many*:** The lecture method; one instructor to many learners.

***One-to-One*:** The tutorial method; one instructor to one learner.

Time-Place Dependent: Education that transpires in the same location at the same time.

Time-Place Independent: Learning that does not rely on proximity or time.

Traditional Study: Face-to-face learning.

Distributed Construction through Participatory Design

Panayiotis Zaphiris

Giorgos Zacharia
MIT, USA

INTRODUCTION

This article presents an empirical study of an online learning community that collaborates with the course design team under the Participatory Design methodology. The different phases of this methodology were implemented using a four-stage participatory design process (Zaphiris & Zacharia, 2001):

1) building bridges with the intended users,
2) mapping user needs and suggestions to the system,
3) developing a prototype, and
4) integrating feedback and continuing the iteration.

We took advantage of the online and distributed nature of the student community to asynchronously design, implement, and study the course. We carried out the participatory design methodology by following the Distributed Constructionism pedagogical theory. During the different phases of the design process, we measured the student participation and the changes in their behavior when new design elements were introduced. We conclude that the most important element of this course was our discussion board, which helped us to promote student collaboration and the identification of the key community users who can participate productively in Participation Design activities.

There are three main sections to this article. After defining the key terminology, our Participatory Design approach is presented and its linkage to the Distributed Constructionism pedagogical theory specified. The article ends with ideas for future research and a set of conclusions.

BACKGROUND

Participatory Design

Participatory design (PD) refers to a design approach that focuses on the intended user of the service or product, and advocates the active involvement of users throughout the design process. PD is often termed as the "Scandinavian Challenge" (Bjerknes, Ehn & Kyng, 1987), since it was researchers from Scandinavian countries who pioneered its use in information systems development (Blomberg & Henderson, 1990; Bodker, Gronbaek & Kyng, 1993; Ehn, 1988).

User involvement is seen as critical both because users are the experts in the work practices supported by these technologies and because users ultimately will be the ones creating new practices in response to new technologies (Ellis, Jankowski & Jasper, 1998).

Blomberg and Henderson (1990) characterize the PD approach as advocating three tenets:

- The goal is to improve the quality of life, rather than demonstrate the capability of technology.
- The orientation is collaborative and cooperative rather than patriarchal.
- The process is iterative since PD values interactive evaluation to gather and integrate feedback from intended users.

By involving the users in the design process, the designers also gain knowledge of the work context, so that the new technology explicitly incorporates the values, history, and context of the work system (Ehn, 1988). The users take part in the entire design, implementation, and decision-making processes. Their involvement ensures that their activities are taken into account. Also by participating in the design, the users have a sense of "ownership" (Brown & Duguid,

2000), and the final system will have an increased user acceptance.

Distributed Constructionism

Simply put, Constructionism can be thought of as "learning-by-making" (Papert, 1991). It is both a theory of learning and a strategy for education (Papert, 1993). It focuses on the construction of a system rather than the information that will be used. The theory views computer networks as a new medium for construction, not as an information distribution channel. By embedding construction activities within a community, new ways for students to learn arise (Papert, 1993). Based on Piaget's constructivist theories, people don't get ideas, they make them. Learning is an active process where people construct knowledge from their experiences (Resnick, 1996).

Distributed Constructionism (Resnick, 1996) extends the Constructionism theory (Papert, 1991, 1993) to knowledge-building communities, where the online learning community (instead of one student) collaboratively constructs knowledge artifacts (Resnick, 1996). Distributed Constructionism asserts that "a particularly effective way for knowledge-building communities to form and grow is through collaborative activities that involve not just the exchange of information but the design and construction of meaningful artifacts" (Resnick, 1996). The three major activities of DC, within the context of an online learning community, are (Resnick, 1996):

- *Discussing Constructions:* Students discuss their constructions during the design, implementation, evaluation, and reiteration phases.
- *Sharing Constructions:* Web-based systems allow students to share their constructions and make them part of the shared knowledge.
- *Collaborating on Constructions:* The community can use online communication to collaborate on the design and development of the knowledge artifacts.
- *Distributed Constructionism:* Was enhanced among the users of the system, due to the iterative structure of our Participatory Design approach. Both the learning experience of the users and the content and functionality of the course itself were enhanced by the knowledge artifacts that were contributed to the course.

DESIGN APPROACH AND COURSE EVOLUTION

In this section, a case study applying the theories presented in the previous section is described.

Our focus has been to design an online learning community around a Computer Aided Language Learning (CALL) course. We believe that online interaction and community would increase users' motivation, commitment, and satisfaction with the online course. The Participatory Design methodology blends nicely with our goal. In particular, involving users during system development is thought to lead to greater user commitment, acceptance, usage, and satisfaction with the system (Baroudi, Olson & Ives, 1986).

In the design phase of the online course, we implemented PD as a four-step process (Ellis et al., 1998).

1) Building Bridges with the Intended Users

This step opened lines of communication between intended users and the development team. Specifically, this step involved the initialization of a multidisciplinary development team, identifying key groups of end users, and creating new methods of communication with users.

The development team in this project came out of the Kypros-Net (2002) group. Through their involvement in Cyprus and Greece related projects, they had longstanding relations with the intended user community.

The intended users have been especially people of the Greek Diaspora, travelers to Cyprus and Greece, and other Greek-speaking areas, and people who are generally interested in the Greek culture and language or languages in general. In our case, bridges with the intended users were build through our years of work at providing information about Cyprus through the Web pages of Kypros-Net, which primarily attracts the same user population as our intended Greek language online course.

2) Mapping User Needs and Suggestions to the System

Our conceptual design model has been "to design an effective online Greek language course that can build and sustain an online learning community of students." Based on the questions and inquiries we received from our users, we tried to match their needs (they wanted an easy-to-follow, both elementary and advanced course that they could attend at their own pace) with our conceptual design model.

3) Developing a Prototype

The project consists of 105 audio files, which were originally recorded as Radio lessons in Modern Greek for English speakers in the 1960s. The lessons were retrieved from the archives of the Cyprus Broadcasting Corporation, digitized in Real Audio 5.0 format, and published online through the course. Although, an optional textbook accompanied the original radio lessons, the online lessons were designed as a complete standalone course. We used several tools to assist students with the lessons, including an online Eng-

lish-Greek-English dictionary, a Greek spell checker, and a Web-based discussion board. The discussion boards served as the foundation for creating a community of online students and enhanced the learning experience with Distributed Constructionism.

4) Integrating Feedback and Continuing the Cycle

Feedback from our users and suggestions are continuously incorporated into our design through a series of additions and corrections. For example, we were asked to add an online notes section and to encode some files again because they were corrupted.

An important element in the participatory design methodology is the direct involvement of the users in all stages of the design process. We kept the users involved by participating in the discussion boards, and sharing with them design and development plans for the course.

The students of the audio courses included people with no knowledge of Greek language, bilingual members of the Greek Diaspora, as well as high-school professors of non-Greek language. These students created an open online community whose collaboration has boosted the learning experience of the whole community. The Web-based discussion board has proven to be the most constructive tool for the students' learning experience and the main source of feedback for the maintainers of the project. The experiences shared on the discussion board included tricks and tips on how to record the audio files, installation of Greek fonts, learning methodologies, and questions about the Greek language itself that arise from the lessons. The experienced users (some of them were retired teachers of foreign languages) had taken a lead role in the vast majority of the threads on the discussion board, answering most of the questions and encouraging the beginners to study the lessons further. They have also become the communication interface between the maintainers of the project and the community's requests.

At some point, the users started exchanging, through e-mail, written notes taken by the experienced users. They also used the discussion board to announce the availability of their personal notes. This behavior suggests that we must provide (and we did) the users with the capability to post their notes on the project's site.

The students had initiated Distributed Constructionism themselves. The course designers only provided technical support to facilitate the students' construction activities.

Discussing the Constructions

The course designers offered to provide publishing access to the online course to whomever wanted to contribute their material. Five users asked to be given access. Consequently, the five users, along with the two course designers, constituted the Participatory Design team. The PD team solicited contributions from the user community. The users suggested that they should transcribe the audio lessons, and compile verb lists, vocabulary lists, and grammatical notes for each lesson.

Sharing the Constructions

All the user contributions were shared in the common area of the online course. The user members of the PD team regularly posted notices on the discussion board about new material for the course. Also, other less active users chose to offer contributions for the course, by posting on the discussion board, rather than contacting the PD team. In their study on student involvement in designing an online foreign language course, Zaphiris and Zacharia (2002) state that the discussion board proved to be the most constructive tool for the students' learning experience and the main source of feedback for the maintainers of the project.

Collaborating on the Constructions

The user members of the PD team did not include any native speakers of Greek. They were all learning the language through the online course, and at that stage, they primarily depended on the audio lessons. In order to ensure the quality of the new material before publishing them on the course Web site, the user members of the PD team implemented a peer review process. A group of seven users, which included the five central user PD team members, reviewed and corrected all the material before posting them on the Web site. Each of the seven users offered to transcribe a number of the 105 audio lessons, and two of them also offered to provide verb and vocabulary lists. However, all materials were posted in a private area first, reviewed by the seven user members of the PD team, and posted on the Web site, when the five PD users were satisfied with the quality. Then the two PD course designers, who were both native Greek speakers, would go over the already published material and make sure it was correct. Most of the mistakes we had to correct were spelling mistakes, and we rarely had to correct grammatical mistakes.

Two months after the Distributed Constructionism effort started, students of the audio lessons managed to transcribe 81 out of the 105 lessons, correct them through the peer review process among themselves, and post them on the project's Web site. Six months later, the students had transcribed and peer reviewed all 105 lessons.

The knowledge constructed attracted significant user attention. The access to the audio lessons, the language tools, and the total access of the message board and the notes pages all kept increasing exponentially (Zaphiris & Zacharia, 2001). However, once we allowed our users to publish their own notes, there was a dramatic shift of traffic from the message board to the notes pages. In our view this is due to the fact

that the users did not need to visit the discussion board any more to find out where other users had posted their notes. All the content was already aggregated and organized in a central location.

The course's popularity is apparent from the fact that the course currently has more than 25,000 registered students who actively participate in an online community that evolved around the course.

FUTURE TRENDS

Future work on this specific project will focus on a non-virtual, face-to-face participatory design team. Like the previous PD team, key stakeholders (teachers of Greek in the Diaspora, students, administrators, and designers) will work together, participating and interacting throughout the whole iterative design process. They will once again collaborate on the content and functionality development, peer review, and publish content contributions.

We believe that by encouraging the active involvement of the users, the product developed will be more enjoyable, more usable, and most importantly, more catered to their specific needs and requirements.

Also we anticipate that the expected benefit of this face-to-face PD team versus the virtual PD team will be that everyone involved will feel more like a team and have a stronger relationship with each other. Since the PD team will be a face-to-face one, communication will be better and there will be fewer misunderstandings or misinterpretations, and finally the collaboration results should be more immediate, and the final product more usable and acceptable by all the stakeholders.

From our analysis of existing literature, we observed that there is a need for additional research in areas like ethnography in participatory design and the application of our proposed methodology to new domains. As new delivery e-learning technologies are constantly emerging, research into Distributed Constructionism with the latest technology also remains important. Finally, evaluations of case studies of PD and DC will be very useful to case-specific applications of the theories.

CONCLUSION

By facilitating Distributed Constructionism in the iteration phase of a Participatory Design methodology, we enhanced the learning experience in our Web-based training. A questionnaire evaluation (Zaphiris & Zacharia, 2001) shows that the end system received high usability ratings from the users. Therefore, Distributed Constructionism enhanced the learning experience of both the PD team and the more passive users.

The students who participated actively in the design of the course also played a central role in the discussion board, answering other students' language questions, helping students to overcome technical problems, and helping them to find other resources to enhance their learning of the Greek language. These observations are with agreement the underlying goals of Participatory Design, which was an integral part of the development of this specific course.

Furthermore, the results of the analysis of the user questionnaire and the server logs shows that the final product (the course) meets—to a very large extent—the expectations and needs of the whole user population of this specific course. We believe that the direct involvement of the users in the development of the course helped in designing a more usable course that enhanced the learning of our users, and provided them with an enjoyable and rewarding experience.

Distributed Geospatial Processing Services

Carlos Granell
Universitat Jaume I, Spain

Laura Díaz
Universitat Jaume I, Spain

Michael Gould
Universitat Jaume I, Spain

INTRODUCTION

The development of geographic information systems (GISs) has been highly influenced by the overall progress of information technology (IT). These systems evolved from monolithic systems to become personal desktop GISs, with all or most data held locally, and then evolved to the Internet GIS paradigm in the form of Web services (Peng & Tsou, 2001). The highly distributed Web services model is such that geospatial data are loosely coupled with the underlying systems used to create and handle them, and geospatial processing functionalities are made available as remote, interoperable, discoverable geospatial services.

In recent years the software industry has moved from tightly coupled application architectures such as CORBA (Common Object Request Broker Architecture—Vinoski, 1997) toward service-oriented architectures (SOAs) based on a network of interoperable, well-described services accessible via Web protocols. This has led to *de facto* standards for delivery of services such as Web Service Description Language (WSDL) to describe the functionality of a service, Simple Object Access Protocol (SOAP) to encapsulate Web service messages, and Universal Description, Discovery, and Integration (UDDI) to register and provide access to service offerings. Adoption of this Web services technology as an option to monolithic GISs is an emerging trend to provide distributed geospatial access, visualization, and processing. The GIS approach to SOA-based applications is perhaps best represented by the spatial data infrastructure (SDI) paradigm, in which standardized interfaces are the key to allowing geographic services to communicate with each other in an interoperable manner. This article focuses on standard interfaces and also on current implementations of geospatial data processing over the Web, commonly used in SDI environments. We also mention several challenges yet to be met, such as those concerned with semantics, discovery, and chaining of geospatial processing services and also with the extension of geospatial processing capabilities to the SOA world.

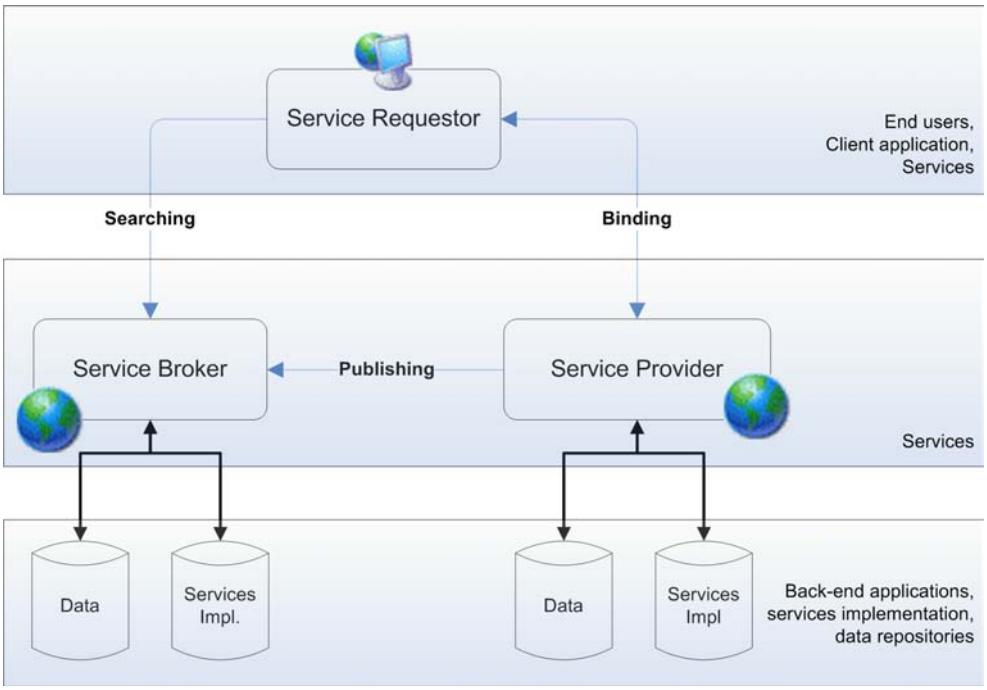
BACKGROUND

Service-Oriented Architecture

A Web service is an executable program available on the Internet. Services are the basic units for creating distributed applications in the context of SOAs. As Papazoglou (2008) stated, SOA is an architectural style to design service-centric applications relying on published and discoverable interfaces. Web services are, by definition, loosely coupled (independent units) and are well described (interface description contains functional properties), thereby promoting one of the goals of SOA: enabling interoperability or the ability of software components to interact with minimal knowledge of the underlying structure of other components (Sheth, 1999). Interoperability is achieved by using standard interfaces (SOA does not focus on the concrete implementations of components) and also by decomposing an application's functionality into modular and flexible services. Such building-block services can be published, discovered, aggregated, reused, and invoked using standard protocols and specifications, independently of the specific technology used to create each component. Essentially SOA introduces a new philosophy for building a pyramid of distributed applications where Web services can be published, discovered, and bound together to create more complex value-added services (Alameh, 2003; Lemmens et al., 2006).

Figure 1 illustrates some of the roles and operations in SOA-based applications. There are three different main SOA roles: service provider, service requestor, and service broker. Each SOA role interacts with others utilizing three basic operations: publication, search, and binding. The service provider publishes service descriptions to the service broker. The service requester searches the required services by querying the service broker and then consumes (binds to) them. Note that often the role of service requester is assigned both to end users (and client applications) and to other services. The latter makes use of two key mechanisms in SOA: service reuse and service chaining to create new,

Figure 1. Roles and operations in SOA



complex, value-added services from simpler, discoverable services. In this sense, services can play the role of service requestor and service provider.

The OWS Service Framework

Within the GIS community, the Open Geospatial Consortium (OGC)—an international industry consortium created in 1994 to develop consensus-based open standards and specifications to support the exchange, sharing, and processing of geospatial data—has adopted a general set of interfaces for a wide range of geospatial Web services (ISO 19119, 2005). Table 1 lists a sample of key OGC Web Services (OWS) categorized as defined in ISO 19119.

These OWS services fall into five categories as follows:

- *Application services* are client-side applications that provide an entry point for end users to find and access geospatial data and services. Among the notable

Table 1. Examples of OGC Web Services

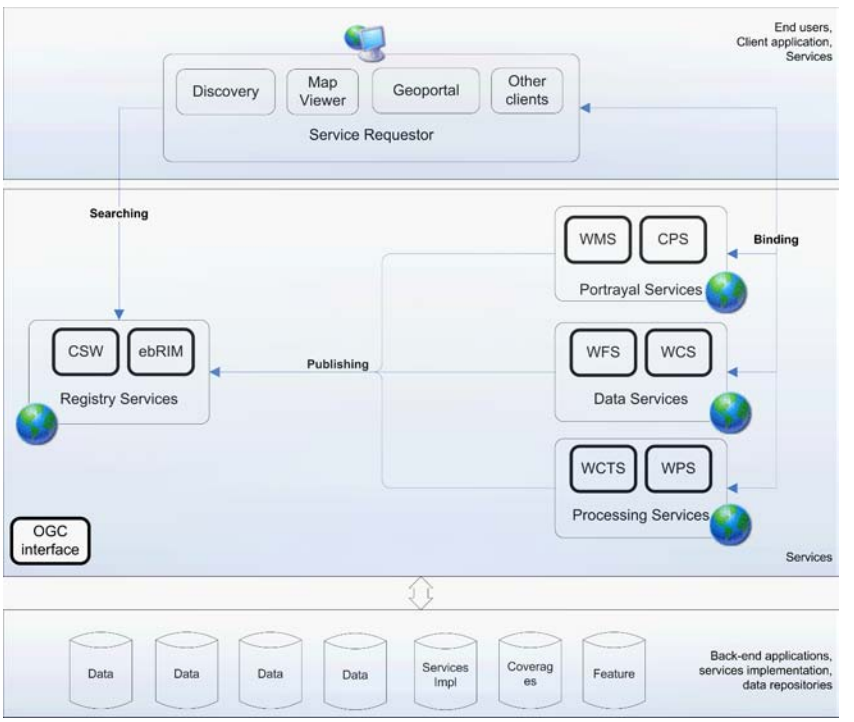
Service Category	Service Name
Application Services	Discovery Application Services Map Viewer Application Services Sensor Web Application Services Geoportal (one-stop portal)
Registry Services	Catalog Service (CSW)
Data Services	Web Feature Service (WFS) Web Coverage Service (WCS)
Portrayal Services	Web Map Service (WMS) Coverage Portrayal Service (CPS)
Processing Services	Web Coordinate Transformation Service (WCTS) Geocoder Services Gazetteer Services Route Determination Services Web Processing Services (WPS)

examples of application services are geoportals (Bernard, Kanellopoulos, Annoni, & Smits, 2005), which in turn may integrate other client-side application services such as discovery services and map viewers. Examples of geoportals may be found at *http://www.geodata.gov and http://geoportal.jrc.it/*.

- *Registry services* (often called catalog services) are a special kind of service that offers end users a common mechanism to register, search, and access discoverable geospatial data and services.
- *Data services* are the basic geospatial services that serve geospatial data to application services. Examples of data services include the Web Feature Service (WFS), which filters and retrieves vector format representations of geospatial features and feature collections encoded in Geographic Markup Language (GML) (Cox, Daisay, Lake, Portele, & Whiteside, 2002), and the Web Coverage Service (WCS), which provides access to client-specific continuous coverage or image datasets.
- *Portrayal services* may be also considered a specialized data service that produce rendered data such as portrayed maps, perspective views of terrain, annotated images, and so on. Examples are the Web Map Service (WMS) that dynamically produces spatially referenced maps of client-specified criteria from one or more geographic datasets, returning the map views in well-known image or graphics formats.
- *Processing services* essentially transform geospatial data to produce new data or actionable information. Examples are the Web Coordinate Transformation Service (WCTS), which transforms the geographic coordinates of feature (map) or coverage (imagery) data from one coordinate reference system (CRS) to another; and the Gazetteer Service, which provides location geometries for specified geographic names. In order to help standardize access and binding to processing services, the OGC created the Web Processing Service (WPS) specification (Schut, 2007), which describes the interfaces needed in order to offer generic geospatial processing services over the Internet, as described in the following section.

Spatial data infrastructures (SDIs) were designed to share existing geospatial data (most held by the public sector) and make them widely accessible and available at the lowest possible cost, where and when they are needed (Granell, Gould, Manso, & Bernabé, 2008). An SDI can be thought of as a network of interoperable Web services to facilitate basic geospatial data (e.g., a digital topographic map) and customized information (e.g., a daily forest fire risk map) and services. Figure 2 summarizes the conceptual

Figure 2. The OWS Service Framework (adapted from Percival, 2003; Yang & Tao, 2006)



SDI architecture that may be interpreted as a traditional three-tier client-middleware-server model, where GIS applications (clients) seek geospatial data content (servers) that are discovered and then possibly transformed or processed by intermediary services (middleware) before results are presented back to the client tier. The presentation layer in Figure 2 includes the application services, whereas the middleware layer contains data services, registry services, portrayal services, and processing services.

Beyond the three-tier model, however, under the SOA perspective, the previous SDI architecture also may be interpreted using the Web services 'publish-find-bind' triangle model (Papazoglou, 2008), as shown in Figure 1. In this context, the OGC proposed the OWS Service Framework (OFS) as the common set of interfaces required for enterprise-wide interoperability within and beyond the GIS community (see Figure 2). Following this framework, geospatial data content (and service) offers are published to registry services, which are later queried to discover (find) the data or services, and finally the client application binds to (consumes or executes) them. In this sense, the adoption of a common geographical data model expressed in GML and standardized OGC specifications constitutes one ingredient to achieve geospatial data integration and interoperability in the wider sense (Díaz, Granell, & Gould, 2008a). The next section will focus on OGC specifications for geospatial (Web) processing services.

DISTRIBUTED GEOSPATIAL PROCESSING SERVICES

Although OGC has already proposed specifications under the processing services category (see Table 1), these are devoted primarily to performing specific and well-defined processing functions. A substantial leap ahead in the domain of processing services was the recently released OGC Web Processing Service (WPS) specification (Schut, 2007), which was designed to encapsulate generic geoprocessing operations over the Internet. The WPS specification allows any piece of geospatial processing code to be published and accessed as if it were a common OWS service (WMS, WFS, etc.). This section focuses on this new specification and describes some emerging open source frameworks that support the implementation of distributed geospatial processing services as defined by the OGC WPS.

OGC Web Processing Service Interface

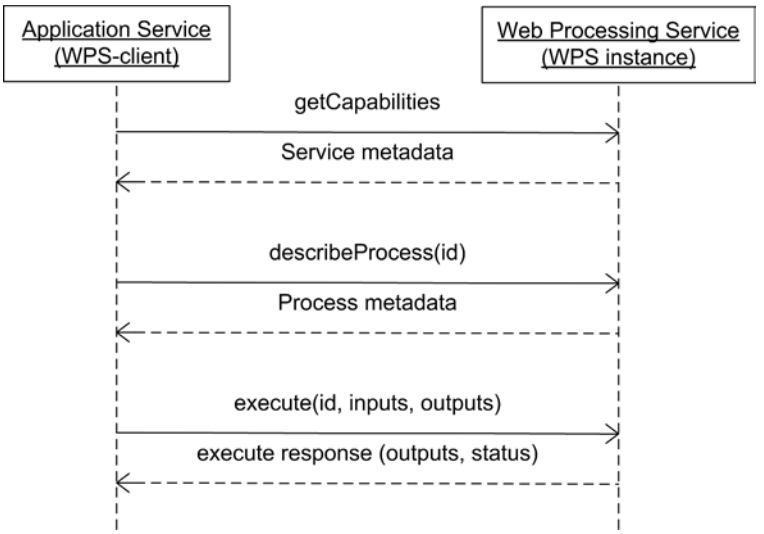
OGC WPS specification provides the service interface definitions to specify a wide range of geospatial processing tasks as geospatial Web services in order to distribute over the Internet many of the functionalities (computation, analysis, etc.) common in today's desktop GIS applications. Geospatial processing services can be considered as being similar to collections of operations in a software component library in the sense of preexisting components that deliver some concrete functionality. The main difference is that WPS can be accessed remotely and can be reused in many different scenarios. This can be achieved by creating accessible libraries of geospatial processing algorithms under the appearance of geospatial Web service chains (Alameh, 2003; Lemmens et al., 2006).

The OGC WPS provides access to calculations or models that operate on spatially referenced data. The data required by the service can be available locally or delivered across a network using data exchange standards such as GML or Geolinked Data Access Service (GDAS). The calculation can be as simple as subtracting one set of spatially referenced numbers from another (e.g., determining the difference in influenza cases between two different seasons) or as complicated as a global climate change model. While most OGC specifications and standards are devoted to geospatial data abstraction, access, and integration, the OGC WPS specification is focused on geospatial data processing of heterogeneous data sources. The main steps in this process are to identify the spatially referenced data required by the calculation, initiate the calculation, and manage the output from the calculation so that it can be accessed by the client. The OGC WPS specification is targeted at both vector and raster data processing.

The basic operational unit of the OGC WPS is the notion of process—a geospatial operation with inputs and outputs of a defined type. This means that a given WPS instance (a concrete WPS service running) may offer one or various operations (or processes) as normal Web services do. Figure 3 shows how a WPS client communicates with a WPS instance, issuing three types of requests. A request can be sent to the WPS instance via HTTP GET with parameters provided as Key-Value Pairs (KVP) or via HTTP POST, with parameters supplied in a XML document. These three types of requests are:

- *getCapabilities:* First, a WPS instance receives a KVP getCapabilities request (which is common for all OWS services) and simply responds with an XML document, containing metadata such as server provider, contact information, general description, and a list of contained geoprocessing operations (processes) offered by the queried WPS instance.
- *describeProcess:* A WPS client selects a process identifier from the getCapabilities response and performs a describeProcess request, either as a KVP or as an XML document. The WPS instance responds with an XML document containing needed information for the solicited process, such as input and output parameter

Figure 3. Synchronous interaction between a WPS-compliant client and a WPS service instance



names and types, so that the WPS client may later build the execute request.

- *Execute:* The WPS client eventually requests the execution of a geospatial operation, with all required input data by invoking the execute method as an XML document request. The WPS instance then runs the operation and returns the results, informing also of its status.

Implementations

This section summarizes some relevant and interesting open source frameworks that currently support one or both available versions (0.4 or 1.0) of the OGC WPS specification.

Cepický and Becchi (2007) introduce the *Python Web Processing Service* (PyWPS), an open source python framework that implements the OGC WPS specification version 0.4.0 (*http://pywps.wald.intevation.org/*). PyWPS includes native support for GRASS (Geographic Supported Analysis Support System, *http://grass.itc.it*) GIS, as well as with the R Project for Statistical Computing (*http://www.r-project.org/*). GRASS GIS is a well-known, powerful GIS tool for geospatial data management and analysis, image processing, graphics/maps production, geospatial modeling, and visualization, while the R Project is a free software environment developed for statistical computing. It is important to highlight that PyWPS allows developers to make native connections to both GRASS GIS and R Project commands, wrapping (or encapsulating) them as contained processes in a given WPS service. This capability fosters the proliferation of distributed geospatial processing services in new domains (environmental, hydrological, etc.) in which distributed geospatial processing services previously were not so easily implemented.

The *Tigris WPSint* implementation (*http://wpsint.tigris.org/*) is an open source Java plug-in for Spring—a Java framework for developing Web applications—to support the OGC WPS version 0.4. This implementation was initially developed by Peter Schut and colleagues during an OGC Interoperability Experiment in order to define initial interfaces and XML schemas for geospatial geoprocessing services, leading then to the first release of the OGC WPS specification in 2005. Contrary to PyWPS, the Tigris WPSint implementation has recently added support for SOAP and WSDL, key Web service components. This feature helps to converge SOA-based services and OGC-based services because both kinds of services may be combined to build heterogeneous service chains since both are described using the same service interface (WSDL).

The *52N Web Processing Service* (52N WPS) is an open source Java framework developed by the 52 North Open Source Initiative (*http://www.52north.org*) that enables the deployment of WPS services. It features a pluggable and extensible architecture for processes and data encodings based on the notions of repositories, which provide dynamic access to the embedded functionality of the WPS already registered in the framework (Foerster, 2006). The current release provides the first attempt to support both the GRASS GIS framework and the WSDL specification. In this sense, the 52N WPS follows the path chosen by PyWPS and Tigris WPSint to support GRASS GIS commands and WSDL/SOAP interfaces respectively, reinforcing the idea that both characteristics are crucial for a widespread use of distributed geospatial processing services in SOA contexts. The benefit of 52N WPS implementation is that it integrates

both capabilities, although they are not (yet) as mature as in the previous two implementations.

The *Deegree* project (*http://www.deegree.org*) is an open source Java framework that implements the OGC WPS as well as traditional OGC services such as WMS, WFS, WCS, and so on. The benefit of Deegree is that it provides the most extensive implementation of OGC standards; however, unfortunately, their WPS implementation seems less mature when compared with the previous WPS implementations. Examples of WPS services using the Deegree project have been reported by Kiehle (2006).

FUTURE TRENDS

The OGC WPS services have been tested in different contexts (Friis-Christensen, Lutz, Ostländer, & Bernard, 2007; Foerster & Shäffer, 2007; Díaz et al., 2008b), illustrating that it is possible to combine several geospatial processing services for accessing, processing, and visualizing data within an SDI. However, many open issues remain regarding the structure and use of the OGC WPS specification itself (Michael & Ames 2007). Other technical and architectural design limitations that constraint the usability, flexibility, and scalability of applications based on distributed geospatial processing services also remain (Friis-Christensen et al., 2007).

One of the most essential problems in implementing distributed geospatial processing services is the overall service chain performance when distributed data sources are involved. This is the case when large processing tasks are performed over the network, because of network bandwidth, data transportation, and data validation. Historically a critical factor of distributed processing has been the network capability or network bandwidth. As GIS resources (inputs and outputs) are by nature large data files, the network bandwidth will always be a limiting factor for successfully distributed geospatial processing. Apart from the bandwidth factor, data transportation and validation (parsing of geospatial data used for the processes) may dramatically increase the response time to users as well. Friis-Christiensen et al. (2007) propose the use of asynchronous messaging to address time-consuming requests. In asynchronous messaging the WPS instance does not return immediately the process results, but rather it responds some time later in a different communication session. This means that the WPS client would not be waiting while the WPS instance is processing a request, but instead it would monitor the process and retrieve the results once the WPS instance has either finished or reported a failure; this essentially means processing results off-line.

Finally other open and challenging issues are enumerated that need further research:

- semantically enriching the descriptions of geospatial processing services by means of geo-ontologies and semantic descriptions that will help to clarify meanings when searching and combining geospatial processing services;
- creating alternative architecture designs and methodologies for chaining geospatial processing services, including in mobile computing contexts;
- creating a mechanism for improving discovery of geospatial processing services;
- using transactional processes;
- improving security; and
- introducing performance and novel techniques for overcoming data transportation issues.

CONCLUSION

The future scenario for geospatial Web services may not ever reach a wholly automated service chaining for a set of self-describing geospatial Web services; however in the near term, semi-automated solutions will emerge to assist users in solving geographical problems with remote services. The geospatial Web services listed in Table 1 mainly deal with the delivery of data instead of advanced processing which is performed online. More heterogeneous, complex geospatial processing services will need to be specified in order to distribute functionalities common in desktop GISs and frameworks such as GRASS GIS and Project R, and make them available over the Internet. The first steps towards distributed, advanced geospatial processing services online are outlined by the recently published OGC Web Processing Service (Schut, 2007), which provides interface specifications to enable geospatial Web services to support a wide range of geospatial processing operations, by creating accessible libraries of geospatial processing algorithms under the appearance of geospatial Web services.

Future research efforts in distributed geospatial processing services should involve new mechanisms for enhancing description and discovery of geospatial processing services, as well as new methodologies for improving composition of geospatial processing services in mobile contexts.

KEY TERMS

Geography Markup Language (GML): An XML grammar defined by OGC to express geographical features. To help users and developers to structure and facilitate the creation of GML-based application, GML provides *GML profiles* that are XML schemas that extend the very GML specification in a modular fashion. A GML profile is a GML subset for a concrete context or application, but without the need for the full GML grammar, simplifying thus the adoption of GML and facilitating its rapid usage. Some common examples of GML profiles that have been published are *Point Profile,* for applications with point geometric data, and *GML Simple Features Profile,* supporting vector feature requests and responses, as in the case of a WFS.

Geospatial Processing Service: Similar to operations in a software library in the sense that these services are preexisting software components that deliver any geospatial processing functionality over the Internet.

ISO/TC211: ISO Technical Committee 211 in Geographic Information/Geomatics is in charge of establishing a set of standards for digital geographic information concerning objects or phenomena that are directly or indirectly associated with a location relative to the earth.

Open Geospatial Consortium (OGC): An international industry consortium participating in a consensus process to develop publicly available interface specifications. OGC members include government agencies, commercial companies, and university research groups.

Service: Functionality provided by a service provider through interfaces (paraphrased from ISO 19119).

Service Broker: Publishes service descriptions and is queried by the service requestor in order to discover suitable services that meet requestor needs.

Service Metadata: Metadata describing the operations and geographic information available at a particular instance of a service (paraphrased from ISO 19119).

Service Provider: Provides software applications as Web services, creating functional descriptions and making them available in public registries.

Service Requestor: Requires certain requirements and needs that are fulfilled by one or more Web services available over the Internet.

Distributed Systems for Virtual Museums

INTRODUCTION

The Internet has meant a social revolution, changing forever the way we communicate and how we access to the information. The growing expansion of technology and the development of easier applications have given as a result the high level of popularity achieved by Internet related services, especially the World Wide Web. Using a hypertext system, Web users can select and read in their computers information from all around the world, with no other requirement than an Internet connection and a browser. For a long time, the information available on the Internet has been a series of written texts and 2D pictures (i.e., static information). This sort of information suited many publications, but it was highly unsatisfactory for others, like those related to objects of art, where real volume and interactivity with the user, are of great importance. Here, the possibility of including 3D information in Web pages makes real sense.

As we become an increasingly visual society, a way to maintain heritage is to adapt museums to new times. The possibility of not only visiting and knowing the museums nearby but also enabling anybody to visit the building from their homes could be enabled. This would imply the incorporation of the virtual reality (Kim, 2005; Vince, 2004), although today only a few museums allow this kind of visit via Internet. In virtual reality, human actions and experiences that interact with the real world are emulated although, obviously, with some limitations. With virtual reality, the user could walk, examine, and interact with the environment, in contrast to traditional media like television that present excellent graphics but lack interactivity. Although this is not a new idea, it is achieving a wider expression due to the availability of software standards like VRML and X3D. VRML, virtual reality modeling language (Carey, Bell, & Marrin, 1997) is a widespread language for the description of 3D scenes and WWW hyperlinks (an analogy of the HTML for virtual reality). X3D, Extensible 3D (Web3D Consortium, 2004) is the successor of VRML, it is intended to be the universal interchange format for integrated 3D graphics and multimedia. VRML/X3D are, perhaps, most interesting to Internet users eager to discover new interesting sites on the Internet, and for the people that use it like a hobby, but those could also allow us to see a 3D artifact from any angle and perspective, to turn it in any way, manipulate it (Lepouras & Vassilakis, 2005; Petridis et al., 2005)—something totally forbidden in a real museum.

This work deals with the design of a system, which allows this interactive Web access to works of art in 3D, as a step in a research project dealing with the design and implementation of a virtual and interactive museum in 3D on the Web. Also, all the associated information like history, architectural data, archaeological data, and culture will be available at the click of a mouse.

BACKGROUND

Several museums around the world are already committed to a strong Web presence and many others will adopt one very soon. Dynamic museum leaders understood that the increasing number of internauts requires special attention from museums: Internet—and CD-ROM's—represent new media that will challenge museum communication strategies.

According to Proença, Brito Ramalho, and Regalo (1998):

Two distinct Web approaches are being adopted by the museums. Some regard their presence on the Web as another way to publicize the museum and to promote their activities; others use the Web as a powerful resource to achieve their purposes: to conserve, to study and to display.

The most common attitude is to consider the Web as a simple sum of the different kinds of information already in use by museums—especially printed information—but gathered in a global structured way. These data include a museum description and a list of activities and collections, where a typical Web page structure contains: collections and exhibitions, visit planning and conditions, new acquisitions, projects and activities, museum organizational schemes, and

educational programs. Several museums on the Web follow this approach. Among them it may be worth a visit to the Museo Arqueológico Nacional of Madrid (http://man.mcu.es/), online Picasso Project (http://csdll.cs.tamu.edu:8080/picasso/), the Asian Art Museum of San Francisco (www.asianart.org), the Museum of Modern Art (www.moma.org), and the Library of Congress Vatican Exhibit (www.ibiblio.org/expo/vatican.exhibit/exhibit/Main_Hall.html); this site has a good image quality, but with a traditional structure to present the exhibition themes.

Some museums demonstrate greater innovation in their Web presences; they have temporary exhibitions online, promote virtual visits and access to their databases, present technical information for museums professionals and researchers, keep available information about previous activities and exhibitions, and organize links to related sites. For these museums, the Web is also an exhibition and a presentation medium that must be integrated in the communication policy of the museum. Among them, it may be worth a visit to the Musée des Beaux Arts de Montréal (www.mbam.qc.ca/en/index.html), the Museum of Anthropology at University of British Columbia (www.moa.ubc.ca/), and the Museo del Prado (http://museoprado.mcu.es/home.html).

Latest advances are becoming popular 3D (plus color) scanners, which allow the measurement of 3D artifacts such as art works (Gómez García-Bermejo, Díaz Pernas, & López Coronado, 1997; Rocchini, Cignoni, Montani, Pingi, & Scopigno, 2001). After measuring, a 3D plus color model from the real object can be obtained. 3D scanning technology has been adopted in a number of recent projects in the framework of cultural heritage. Just to give an example, we may cite the Digital Michelangelo Project of the Stanford University (Levoy et al., 2000) or the acquisition of a section of the Coliseum in Rome. Unfortunately, a detailed 3D (plus color) model of a free form object usually requires a great amount of data. This data can hardly pass through the Web, even when using compression. Therefore, additional reduction of transmission requirements is desirable.

A few years ago, some image-based modeling and rendering techniques were developed making it possible to simulate photo-realistic environments. One of the most popular image-based modeling and rendering techniques is the virtual reality modeling language/extensible 3D (*VRML/X3D*). *VRML/X3D* (Carey et al., 1997; Web3D Consortium, 2004) became an open standard for the delivery of 3D models over the Internet. It combines both geometry and runtime behavioral descriptions into a single file that has a number of different file formats available for it. Last specifications have incorporated latest advances in security (encryption) and speed (compression) based on years of feedback from the VRML97 development community (Li & Kuo, 1998; Matsuba & Roehl, 1999; Taubin, Horn, Lazarus, & Rossignac, 1998).

Using these techniques, some systems allow us to see art works in 3D (Cignoni, Montani, Rocchini, & Scopigno, 2001), while others allow a virtual walk through the rooms of some real buildings such as The Virtual Living Kinka Kuji Tempers (Refsland, Ojika, & Berry, 2000), some have reconstructed scenario such as the Historic Villages of Shirakawa-go (Hirayu, Ojika, & Kijima, 2000), or some imaginary buildings such as Virtual Museum of Helsinki (www.virtualhelsinki.net/museum).

The main feature of our system is that users may walk through a three-dimensional (3D) representation of the whole Fabio Neri's Palace, the building where the Museum of Valladolid is located, viewing its collections, and seeing pictures in 2D and archaeological objects in 3D, together with information about them. To allow all this, an architecture of interactive dynamic Web pages has been designed (Díez-Higuera & Díaz-Pernas, 2002). In order to capture 3D information, we have used the laser acquisition system developed by the Industrial Telematic Group of Telecommunications Engineering School of Valladolid (Gómez et al., 1997). These data, together with 2D images and information files, are compressed and stored in a remote server, and can be retrieved over the Internet. Rather than transmitting a high-resolution object, our system at the client end allows users to selectively retrieve images at specific resolutions. This selective retrieval is achieved by implementing a client-server communication protocol. Information is accessed through intuitive exploration of the site and therefore each session varies depending on both the participant and the path chosen. In this manner, the visitor becomes familiar with the virtual museum in much the same way as they would become familiar with the physical museum. Users may identify particular areas of interest, which may be revisited using familiar routes or accessed via browsing.

Within this framework, a distributed telecommunications system for the remote accessing of multiple virtual environments is implemented. This system is divided into the virtual worlds' systematization and the information's distribution. The objective of the virtual worlds' systematization is not only reducing the development time of new museums but extending the systems' useful life by easing the edition of those virtual worlds already deployed. The distribution of heterogeneous information among different servers gives the users the possibility of visiting multiple online museums within a same virtual reality environment (homogeneous looks) and getting in touch among them in order to contribute with their active participation in the creation of information sharing communities. The server will know at all times the location of the user inside the system to facilitate the communication between different end users. This is possible by an easy-to-use IRC software (Mutton, 2004; Oikarinen & Reed, 1993).

DESCRIPTION OF THE SYSTEM

Figure 1 shows the general architecture of the system. It has two main parts: the dynamic Web pages system based on the *Microsoft Internet Information Server*, which embraces the virtual visit to the 3D museum and the access to data and its 3D visualization; and the platform of telematic services, which implements the server-client architecture, allowing the transmission of three-dimensional and colorimetric data of the objects in several resolutions.

Figure 2 shows the basic communication structures between clients and servers. Server to server communication is done using RMI (*remote method invocation*) while the information exchange between client (applet) and server goes through sockets. This makes necessary the elaboration of an application protocol, as it is shown in Figure 3. The protocol will start working once the browser has loaded the Web page and the corresponding applet. The server application communicating with the applet will be in charge of collecting all clients' requests and sending them, through RMI, to the request serving application, either locally or remotely.

Client-Server Architecture

Servers are used to store the huge amount of scene data that is being requested by the user, while the client is designed to interact with the user and retrieve the necessary scene data from the server. Java programming language has been chosen for the implementation of the server-client architecture. The reason is that Java allows the introduction of executable codes in Web pages, and, therefore, giving the desired portability, security and interactivity to the system.

Figure 1. Global architecture of the proposed system

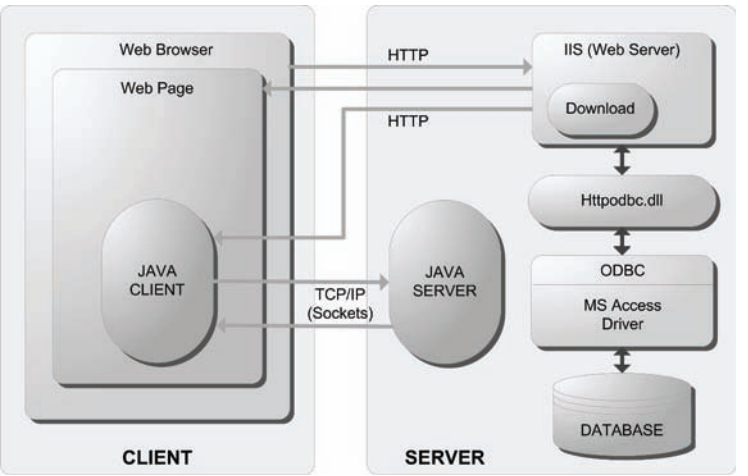

Figure 2. Basic communication structures between clients and server

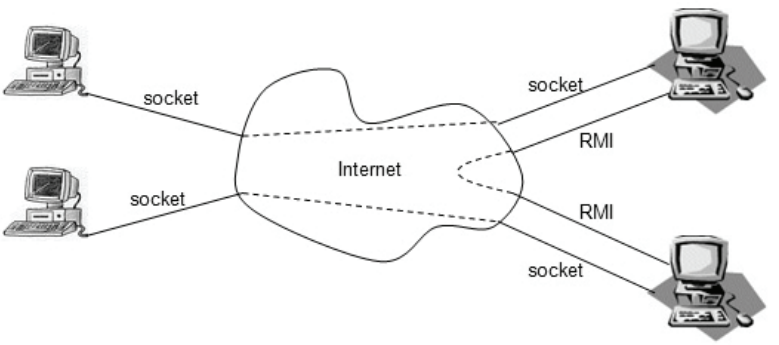

Figure 3. Client-server and server-server communication protocol

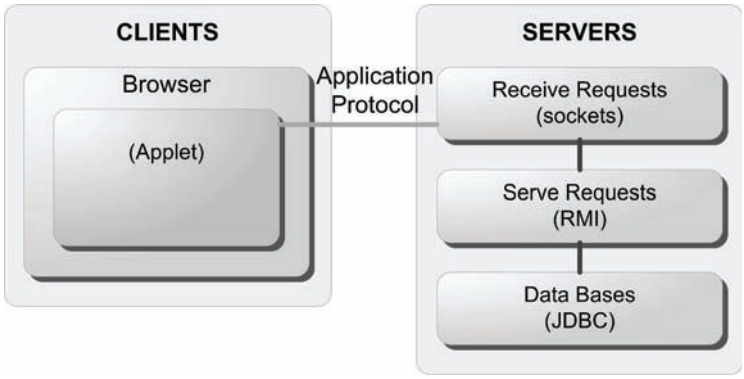

Dynamic Web Pages System

A dynamic Web pages system has been implemented to give access to the database so the information required by the user about any object can be shown. This system has also been used for a 3D virtual walk through the museum.

Each section, or room, implemented in the museum becomes a specific *VRML/X3D* file (sometimes, even a single room is divided in several *VRML/X3D* files). Using smart nodes from *VRML/X3D* language, which activate any element in a 3D universe when the user clicks on it, the file stored in the URL of the *VRML/X3D* file code shall be loaded, interconnect these files. Once the user is in a *VRML/X3D* file (containing any of the rooms where both 2D objects--pictures--and 3D ones are displayed) he or she can walk around the room at will: approach any object to have a first impression and, if wanted, click on it to acquire information about it (author, period, technique, etc.), as well as to visualize it in 3D (or with a higher resolution still image if the object is a picture). When the user clicks on any object, the dynamic Web pages system starts to work, giving access to the database and bringing the required information.

Format of the Data Used by the System

VRML/X3D is the working format for the 3D display of the objects, as it is standard and commonly used in the Web (Walsh & Bourges-Sevenier, 2000). First of all, 3D plus color data must be acquired from art works. The corresponding object model, obtained from the acquired data, could then be directly expressed in *VRML/X3D* format. However, the raw format of the data in our database is not *VRML/X3D*. Instead, it is the specific one given by the laser acquisition system (Gómez et al., 1997). This system, starting from a real object, gives a *.pie* file with the three-dimensional data, plus another three files (*.r, .g, and .b*) with its colorimetric information. Those files are converted into ASCII files using software developed by the industrial telematic group; these new files are *.pts*, with the Cartesian coordinates of all the points as read from the object, plus its colors, and *.tri*, with the triangular distribution of points for a certain resolution (which allows the construction of faces for the display of the object).

The servers store the last couple of files: one *.pts* file for each object, and several *.tri* (one for each different resolution). From them, and given a certain resolution, the server obtains the files needed by the client to reconstruct the *VRML/X3D* file. It is important to notice that there is no duplication of information in the server, as points and colors appear only once in the *.pts* file and the set required by the client at each moment is obtained from it. There are only several files of triangles, as the distribution of points on the faces is different for each resolution. Moreover, three-dimensional and colorimetric information is sent only once to the client. The result is that this design, as a whole, improves the efficiency of the system.

Also, we have developed an alternate solution, which allows lower transmission requirements. In short, we allow art works to be requested in different levels of detail (LOD). User begins with the lowest LOD model, and requests a set of progressively increasing LOD models as his interest on the object increases. We benefit from this by building the different LOD models in particular way: each LOD model is obtained from the immediately higher LOD model, by just picking some of its points. In this way, when the users ask for a higher LOD model, the whole model transmission is no more required. Instead, the new model can be reconstructed by adequately merging new points into the previously existing model. Unfortunately, this strategy is not implemented in actual *VRML/X3D*; so we have implemented it by using a dedicated Java client. Basically, when the user asks for a superior LOD model, only additional 3D points, and a new faces description, are sent. This faces description must then be translated by the client. This is done by means of a LUT

(*Look-Up Table*), which indicates actual position of the new points in a local *VRML/X3D* file.

User Interface

The user interface module is based on a Web page template in which the virtual world is represented on a part of the screen, while on the rest the name of the content plus the options that the user can select are left. In the main part of the page, visiting users can get to move all through the building, its rooms and exhibits, and once inside them, the user can select a picture or a 3D artifact in order to get information about it (Figures 4, 5, 6, and 7). Furthermore, users will be able to access all the available options using the applet on the left, features like accessing different museums, logging as a registered user which will allow the system to know information and the location of all users connected to it, thus facilitating the communication among them, for example using an IRC software (Figures 8, 9), conducting distributed information searches, and more. People in charge of the management will be able to include links to new museums as well as modifying existing ones (including new pieces or roving exhibits) as shown in Figure 10.

FUTURE TRENDS

Our system marks the advent of a new and interactive form of documenting, referencing, and archiving heritage structures. Future work involves advanced development of this system as follows:

- Include dynamic elements like 3D surround sound, voice-overs for history, culture, and other information along with traditional audio pieces to make a complete user-friendly interactive interface.
- Increase the number of works of art and information in texts in order to give a more detailed presentation of Archaeology in Spain.
- Incorporate accurate details by using the latest photogrammetric techniques.
- Depict "as was," "as is," and "as it could be" transitions for studies specific to architecture, conservation, games for children and light simulations.

CONCLUSION

Our project resulted in the following observations:

- We achieved a fairly accurate 3D model of a complex heritage structure using archaeological orthographic projections as reference material.

- Construction of a virtual museum is possible, allowing users to examine, conduct research, or navigate any part of the building at their own convenience where they not only can see photos, and 3D objects, and even have the opportunity to play with them.
- Homogeneous access to a set of museums, either self-managed or managed by a third entity, is offered by this application, allowing for a greater content diversity.
- Fast and easy access to the information kept in different virtual museums, even if those museums are deployed in distinct servers, and so, allowing access to distributed information.
- User can navigate through the virtual environment of a museum and, in any moment, can request information from other museums according to a search term.
- An appropriate management of users' information allows the system to know the number of visitors inside the museum at any moment, allowing users to be in contact which each other—using a custom IRC software—and this way the museum not only becomes a space for collecting and showing valuable pieces but also a catalyst to create information sharing communities.
- The developed system is easily updatable and scalable. Any room's content can be modified and even new rooms can be added or removed to any museum.
- The viability of the system has been demonstrated, as well as its correct operation in the net in the particular case of the Museum of Valladolid.

KEY TERMS

Dynamic HTML: A collective term for a combination of new HTML tags and options, style sheets and programming, which enable you to create Web pages that are more interactive and faster to download.

Internet Relay Chat (IRC): A form of instant communication over the Internet. It is mainly designed for group (Many-to-many) communication in discussion forums called channels, but also allows one-to-one communication.

Java: A platform-independent programming language, produced by Sun Microsystems. Java is built as a method to provide services over the WWW. With Java, a Web site provides a Java application (called an applet) which is downloaded by the client and executed on the client machine. Java is specifically built so that an application can be run on any kind of system.

Virtual Museum: A collection of digitally recorded images, sound files, text documents, and other data of historical, scientific, or cultural interest that are accessed through electronic media. A virtual museum does not house actual objects and therefore lacks the permanence and unique qualities of a museum in the institutional definition of the term.

Virtual Reality (VR): The use of computer modeling and simulation to enable a person to interact with an artificial three-dimensional visual or other sensory environment. VR applications immerse the user in a computer-generated environment that simulates reality through the use of interactive devices, which send and receive information and are worn as goggles, headsets, gloves, etc.

VRML (Virtual reality modeling language): A programming language for the creation of virtual worlds. Using a VRML viewer, you can take a virtual tour of a 3D model building, or manipulate animations of 3D objects. Hyperlinks to other sites and files can be embedded in the world you visit.

X3D: Extensible 3D (X3D) is a software standard for defining interactive Web- and broadcast-based 3D content integrated with multimedia. X3D is the successor to the Virtual Reality Modeling Language (VRML), the original ISO standard for Web-based 3D graphics (ISO/IEC 14772). It improves upon VRML with new features and a componentized architecture that allows for a modular approach to supporting the standard.

A Duplicate Chinese Document Image Retrieval System

INTRODUCTION

An optical character recognition (OCR) system enables a user to feed an article directly into an electronic computer file and translate the optically scanned bitmaps of text characters into machine-readable codes; that is, ASCII, Chinese GB, as well as Big5 codes, and then edits it by using a word processor. OCR is hence being employed by libraries to digitize and preserve their holdings. Billions of letters are sorted every day by OCR machines, which can considerably speed up mail delivery.

The techniques of OCR can be divided into two approaches: template matching and structure analysis (Mori, Suen & Yamamoto, 1992). The template matching approach is to reduce the complexity of matching by projecting from two-dimensional information onto one; the structure analysis approach is to analyze the variation of shapes of characters. The template matching approach is only suitable for recognizing printed characters; however, the structure analysis approach can be applied to recognize handwritten characters.

Several OCR techniques have been proposed, based on statistical, matching, transform and shape features (Abdelazim & Hashish, 1989; Papamarkos, Spilioties & Zoumadakis, 1994). Recently, integrated OCR systems have been proposed, and they take advantage of specific character-driven hardware implementations (Pereira & Bourbakis, 1995). OCR generally involves four discrete processes (Khoubyari & Hull, 1996; Liu, Tang & Suen, 1997; Wang, Fan & Wu, 1997):

1. separate the text and the image blocks; then finds columns, paragraphs, text lines, words, and characters;
2. extract the features of characters, and compare their features with a set of rules that can distinguish each character/font from others;
3. correct the incorrect words by using spell checking tools; and
4. translate each symbol into a machine-readable code.

The duplicate document image retrieval (DDIR) system transforms document formatted data into document images, then stores these images and their corresponding features in a database for the purpose of data backup. The document images are called duplicate document images. When retrieving a duplicate document image from the database, users input the first several text lines of the original document into the system to create a query document image. Then the system figures out the features of the image, and transmits to the users the duplicate document image whose image features are similar to those of the query document image (Nagy & Xu, 1997).

Some approaches have been proposed for the DDIR system. Doermann, Li, and Kia (1997) classified and encoded character types according to the condition that four base lines cross each text line, and uses the codes as the feature of the document image. Caprari (2000) extracted a small region from one document, assigned this region to the template (signature generation), and then scanned this template over a search area in another document. If the template also appears in the second document (signature matching), the two documents are classified as duplicates. Angelina, Yasser, and Essam (2000) transformed a scanned form into a frameset composed of a number of cells. The maximal grid encompassing all of the horizontal and vertical lines in the form is generated; meanwhile, the number of cells in the frameset, where each cell was created by the maximal grid, was cal-

culated. Additionally, an algorithm for similarity matching of document framesets based on their grid representations is proposed too. Peng, Long, Chi, and Siu (2001) used the size of each component block containing a paragraph text image in a duplicate document image and its relative location as the features of the duplicate document image.

The approaches mentioned previously are only suitable for stating the characteristics of an English document image. The characteristics of Chinese characters are quite different from those of English ones, and the strokes and shapes of Chinese characters are much more complicated than those of English characters. Chan, Chen, and Ho (2003) provided a line segment feature to represent a character image block and presented a duplicate Chinese document image retrieval (DCDIR) system based on this feature. The purpose of this short article is to give a brief overview of the duplicate Chinese DDIR systems.

BACKGROUND

Traditional information retrieval methods use keywords for textual databases. However, it is difficult to describe an image using exact information, and defining manually keywords is tedious or even impossible for a large image database. Moreover, some non-text components cannot be represented in a converted form without sufficient accuracy. One solution is to convert a document into digital images; meanwhile, some methods are applied to extract the features of the images. Based on the feature, some document images with database satisfying query requirements are returned.

A duplicate document image retrieval (DDIR) system has to own the following properties (Doermann, Li, & Kia, 1997):

- **Robust:** The features should be reliably extracted even when the document becomes degraded.
- **Unique:** The extracted features can distinguish each document image from others.
- **Compact:** The storage capacity required to hold the features should be as small as possible.
- **Fast:** The system needs a quick response with an answer to the query.
- **Scalable:** As more documents are processed, the size of the database could grow to tens of millions.
- **Accurate:** The system should accurately response with an answer, which satisfies the query requirement.

Unfortunately, many DDIR systems are vulnerable to poor qualities of document images, such as the scale, translation, rotation, and noise variants. Because of different resolution setup of a scanner, the same image may be scanned to become two images with different sizes. We call this phenomenon the scale variant. When an image is added with a great amount of noises, it may be regarded as a different image from the original one. It is named a noise variant image of the original one. In a particular document, images with rotation and translation variants may be generated owing to placing the document on different orientation angles or on different positions on a scanner. The variants mentioned previously will cause many troubles in feature extracting and image matching stages. They should be removed in advance.

A CHINESE DDIR SYSTEM

Many techniques about the DDIR system have been proposed (Caprari, 2000; Doermann, Li, & Kia, 1997; Peng, Chi, Siu, & Long, 2000; Peng, Long, Chi, & Siu, 2001). Since an English document mostly consists of approximately **70** commonly-used characters which contain **52** uppercase as well as lowercase English letters and punctuation marks, the classification and encoding procedure based on the feature of these characters' font types are possible. However, these techniques are only suitable for duplicate English document images, but not for duplicate Chinese document image retrieval (DCDIR) because the number of different Chinese characters is about **45,000**. What is more, the shapes of Chinese characters are complex, and many different characters have similar shapes to each other. Hence, there are several major problems with Chinese character recognition, that is, Chinese characters are distinct and ideographic, the size of a character is large, and there exist many structurally similar characters (Amin & Singh, 1996; Chan, Chen, & Ho, 2003).

It is necessary to develop a feature offering an excellent identification capability to classify Chinese characters by only using a little extra memory space. To reduce the extra memory space, it is feasible to segment a duplicate document image into blocks, each of which contains a set of adjacent characters, and then to extract the features from the blocks. Since the number of the blocks in a duplicate document image is much smaller than that of the characters in an identical duplicate document image, the feature dimensions are reduced greatly; however, its identification capability is lessened.

I. DCDIR System

The proposed duplicate document image retrieval system approximately includes three parts — image preprocessing, database creation, and document retrieval. This section will introduce these three parts in details.

A. Image Preprocessing

When scanning a document to generate a duplicate document binary image, the position of the document on the

scanner may be misplaced so that the duplicate document image may become inclined. Figure 1(a) shows an original image and Figure 1(b) is its duplicate document image that appears inclined. The inclined condition of a document image may lead to inconvenience to users and cause the errors in extracting its image features. Peng et al. (2000) used a correlation-based method to detect the inclination of an image, and then applied an interpolation technique to turn the image back according to the detected inclination. The DCDIR system will use this technique to turn the inclined document image back. Figure 1(c) is the duplicate document image after adjusting the inclination.

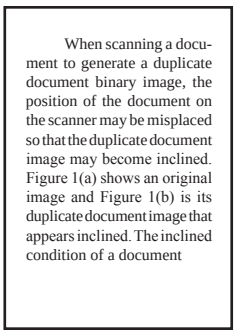
As in Figure 1(c), after turning back the duplicate document image, the frame of the duplicate document image will become inclined. It is necessary to cut off the border blank of the document image. While removing the border blank, the system starts scanning the duplicate document image from the left-top pixel. Then, in the order from left to right and top to bottom, each pixel is scanned until one certain black pixel ***P*** is found. Finally, all pixels locating on the lines, which are prior to the line containing ***P*** are removed to cut off the top border blank of the document image. By using the same method, the bottom, left, and right border blanks of the document image are removed as well. Figure 1(d) demonstrates the final duplicate document image after cutting off the border blanks of the document image as illustrated in Figure 1(c).

B. Database Creation

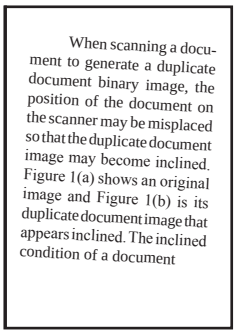
After that, the DCDIR system extracts the character image features from the duplicate document image ***I*** in which its border blanks have been cut off and the system stores the features in the database. Before extracting the character image features of ***I***, the system first performs the text line segmentation on ***I*** to make every line image block contain only the complete image of one certain line text in the original document. Then, the system segments out all character image blocks from each previously segmented line image block so that every character image block contains only one Chinese character. Finally, the feature of each character image block is then extracted.

Figure 1. Normalization of an inclined document image

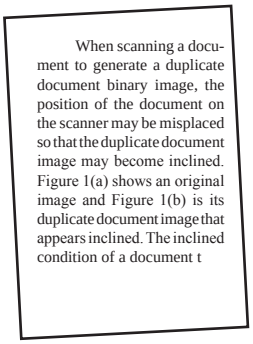
(a) Original document



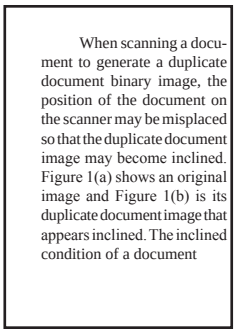
(b) Duplicate document image after scanning



(c) Duplicate document image after inclination adjusting



(d) Duplicate document image after cutting off the border blanks



Concerning the steps of segmenting line image blocks from a duplicate document image, first, all of the black pixels in the duplicate document image are projected in horizontal direction onto a projection vertical axis. The length of a black section on the projection vertical axis is just the height of the corresponding text line containing those character images whose black pixels are projected onto the black section.

Next, all of the black pixels in every line image block is projected in vertical direction onto a certain projection horizontal axis. In this case, the distribution borders of the black pixels and the white pixels on the projection horizontal axis are the locations of the left and the right boundaries of the character image blocks. On the projection horizontal axis, the length of a black section is just the width of the corresponding character image block whose black pixels are projected onto the black section.

The sizes of most Chinese characters are close. When the height of a certain character image block ***CB*** is smaller than three-fourths of the average height of all character image blocks in the document image, and the width of ***CB*** is also smaller than three-fourths of the average width of all character image blocks, the system will then regard the character in ***CB*** as a noise, and then remove it.

After that, three horizontal scanning lines are drawn on each character image block. These three horizontal scanning lines are respectively located at ***1/4×H***, ***2/4×H*** and ***3/4×H*** character heights in the block. Here ***H*** represents the height of the character image block. According to the ratio of the total number of the black pixels to that of the white pixels, which the scanning line goes through, an encoding process is executed to reduce the memory space required to store the feature of the character image block. The way of encoding is shown as follows

$$X_i = \begin{cases} 0, \text{ if } D_{i,b} \times m > D_{i,w} \\ 1, \text{ if } D_{i,b} \times m \le D_{i,w} \end{cases} \text{, for } i = 0, 1, \text{ and } 2.$$

In this equation, $D_{i,w}$ and $D_{i,b}$ are respectively the total numbers of the white pixels and the black pixels that the ***i***-th scanning line passes through, and ***m*** is the weight (a given constant value) for the ratio from the total numbers of the black pixels and the white pixels on the scanning line. Thus, each character image block can be represented by a three-bit ($X_0X_1X_2$) code; we name the code the feature code of the character image block. There are ***8*** different binary codes ***000***, ***001***, ***010***, ***011***, ***100***, ***101***, ***110***, and ***111*** corresponding to decimal feature codes ***0, 1, …,*** and ***7*** respectively.

Because the resolution setup of a scanner may be different, the same original document may be scanned to become duplicate document images of different sizes. This proposed feature adopts the ratio from the number of black pixels and white pixels, so the feature encoding will not be affected due to the scale variant of images. Moreover, the desired duplicate document image and the query document image are both from the same original document. Therefore, the problem that the font type and style of the characters in the query document are different from those in the desired duplicate document image will not occur in this system.

C. Document Retrieval

Let $\boldsymbol{Q} = q_1q_2\ldots q_l$ be the feature code of query document image $\boldsymbol{I}_q$, and the length of the feature code be ***l***. Next, the system extracts the first feature codes with the length ***l*** from every duplicate document image $\boldsymbol{I}_d$ in the database. Let the extracted feature codes be $\boldsymbol{D} = d_1d_2\ldots d_l$. Then, the system compares the corresponding bit pair q_i and d_i between ***Q*** and ***D*** from left to right, respectively. When $q_i = d_i$, the system adds ***1*** to the value of ***S***. The final value of ***S*** is the similarity between $\boldsymbol{I}_q$ and $\boldsymbol{I}_d$. Finally, the duplicate document image with the largest similarity value is found out.

II. Experiments

Experiment 1 is to explore the constant weight ***m***. As for different values of ***m***, the character image blocks of ***5401*** in commonly used Chinese characters among Big5 codes, are categorized into eight groups each of which corresponds to one feature code. Table 1 shows the number of members in each group for ***m = 2***, ***3***, and ***4***, where σ_c^2 is the variance of the number of members of the eight groups. The experimental results shows that when ***m = 3***, σ_c^2 is minimal. This means, when ***m = 3***, all Chinese character image blocks are most uniformly mapped to various kinds of feature codes. The next experiment will set ***m = 3***.

Experiment 2 is to investigate the performance of the DCDIR system. This experiment scans each page of the book "朝花夕拾、呐喊" with ***336*** sheets to become images by a scanner. This experiment rescans ***101*** sheets of the book to generate the query document images. Here, the first ***L*** text lines of the ***101*** document sheets are respectively used as the contents of the query document images. Table 2 shows the experimental results. The average searching time is approximately ***8*** seconds for each query.

FUTURE TRENDS

After a paper document is used over a long period, the document may be stained or worn out, so that its contents may be indistinct. How to develop an effective image feature insensitive to the rotation, scale, translation, and noise variations is an important task in the future. Many documents are printed or handwritten texts, are multilingual, or are composed of basic composition style and font for text. A future document image indexing method should own the robustness of the above variants.

Table 1. Results of the first experiment

Feature code \ m	2	3	4
000	372	1253	2266
001	596	773	763
010	262	387	402
011	813	525	312
100	337	564	628
101	817	591	324
110	390	374	262
111	1798	918	428
S_c^2	220549	74523	387785

Moreover, the following topics have been explored, and will continue to be researched. The first is to find or to match the instances of a document image with known content in a database. The techniques can be applied to maintaining database integrity by eliminating duplicates and retrieval itself. The second is to index image captions and to establish a relationship between the content and the images they describe. Then the caption can be a valuable tool of their duplicate document images. Ideally, a duplicate detection algorithm can find both exact duplicates which have just the same content, and partial duplicates, which have a large percentage of their text in common. Locating exact duplicates could reduce the storage required for a large database. Finding partial duplicates will allow users to easily find other versions of a given document.

KEY TERMS

Character Segmentation: The technique that partitions images of lines or words into individual characters.

Content-Based Image Retrieval (CBIR): The technique of image retrieval based on the features automatically extracted from the images themselves.

Duplicate Document Detection: The technique to find the exact duplicates, which have exactly the same content, or partial duplicates which have a large percentage of their text in common.

Duplicate Document Image Retrieval (DDIR): A system for finding the image-formatted duplicate of documents from a database.

MFU: Most frequently used characters in a character set with enormous members.

Optical Character Recognition (OCR): The technique of automatically translating the content of an image formatted document into text-formatted materials.

Skew Correction: The technology detects and compensates for the inclination angle of a document image.

Template Matching: The approach involves designing template masks, which are capable of detecting incidences of the relevant feature at different orientations.

Dynamic Taxonomies for Intelligent Information Access

Giovanni M. Sacco
Università di Torino, Italy

INTRODUCTION

End-user interactive access to complex information is a key requirement in most applications, from knowledge management, to e-commerce, to portals. Traditionally, only access paradigms based on the retrieval of data on the basis of precise specifications have been supported. Examples include queries on structured databases and information retrieval. There is now a growing perception that this type of paradigm does not model a large number of search tasks, such as product selection in e-commerce sites among many others, that are imprecise and require exploration, weighting of alternatives and information thinning. The recent debate on findability (Morville, 2002) and the widespread feeling that "search does not work" and "information is too hard to find" shows evidence of the crisis of traditional access paradigms.

New access paradigms supporting exploration are needed. Because the goal is end-user interactive access, a holistic approach in which modeling, interface and interaction issues are considered together, must be used and will be discussed in the following.

BACKGROUND

Four retrieval techniques are commonly used: (a) information retrieval (IR) systems (van Rijsbergen, 1979), also search engines; (b) queries on structured databases; (c) hypertext/hypermedia links and d) static taxonomies, such as Yahoo!.

IR systems exhibit an extremely wide semantic gap between the user model (concepts) and the model used by commercial retrieval systems (words). This leads to a significant loss of relevant information (Blair & Maron, 1985), and to poor user interaction because query formulation is difficult and no or very little assistance is given. In addition, because results are presented as a flat list with no systematic organization, no exploration is possible. Database queries require structured data and are not applicable to situations in which information are textual and not structured or loosely structured. Exploration is usually limited to sorting flat result lists according to different ordering criteria.

Hypermedia techniques (Groenbaek & Trigg, 1994) have become pervasive and support exploration. However, they do not support abstraction so that exploration is performed one-document-at-a-time, which is quite time consuming. Building and maintaining nontrivial hypermedia networks is very expensive.

Traditional taxonomies are based on a hierarchy of concepts that can be used to select areas of interest and restrict the portion of the infobase to be retrieved. They are easily understood by end-users, but they are not scalable for large information bases (Sacco, 2006b), so that the average number of documents retrieved becomes rapidly too large for manual inspection.

A more recent approach is the Semantic Web (Berners-Lee, Hendler, & Lassila, 2001). Although one of the driving forces behind it is retrieval, the general semantic schemata proposed are intended for programmatic access and are known to be difficult to understand and manipulate by the casual user. User interaction must be mediated by specialized agents, which increases costs, time to market and decreases the transparence and flexibility of user access.

DYNAMIC TAXONOMIES

Dynamic taxonomies (Sacco, 1987, 2000), also called *faceted search systems*, are a general knowledge management model based on a multidimensional classification of heterogeneous data items and are used to explore/browse complex information bases in a guided yet unconstrained way through a visual interface.

The intension of a dynamic taxonomy is a taxonomy designed by an expert. This taxonomy is a concept hierarchy going from the most general to the most specific concepts. A dynamic taxonomy does not require any other relationships in addition to *subsumptions* (e.g., IS-A and PART-OF relationships). Directed acyclic graph taxonomies modeling multiple inheritance are supported but rarely required.

In the extension, items can be freely classified under n (n>1) concepts at any level of abstraction (i.e., at any level in the conceptual tree). The multidimensional classification required by dynamic taxonomies is a generalization of the monodimensional classification scheme used in conventional taxonomies and models common real-life situations. First, items are very often about different concepts: for example, a news item on September 11th, 2001 can be classified under "terrorism," "airlines," "USA," and so forth. Second, items to be classified usually have different features, "perspectives"

or facets (e.g., Time, Location, etc.), each of which can be described by an independent taxonomy.

In dynamic taxonomies, a concept C is just a label that identifies all the items classified under C. Because of the subsumption relationship between a concept and its descendants, the items classified under C (items(C)) are all those items in the *deep extension* of C, that is, the set of items identified by C includes the *shallow extension* of C (i.e., all the items directly classified under C) union the deep extension of C's sons. By construction, the shallow and the deep extension for a terminal concept are the same. This set-oriented approach implies that logical operations on concepts can be performed by the corresponding set operations on their extension, and therefore the user is able to restrict the information base (and to create derived concepts) by combining concepts through all the standard logical operations (and, or, not).

A fundamental feature of this model is that dynamic taxonomies can find all the concepts related to a given concept C: these concepts represent the conceptual summary of C. Concept relationships other than subsumptions are inferred on the basis of empirical evidence through the extension only, according to the following *extensional inference rule*: two concepts A and B are related if there is at least one item *d* in the knowledge base which is classified at the same time under A or under one of A's descendants and under B or under one of B's descendants. For example, we can infer an unnamed relationship between *terrorism* and *New York*, if an item classified under *terrorism* and *New York* exists. At the same time, because *New York* is a descendant of *USA*, also a relationship between *terrorism* and *USA* can be inferred.

The extensional inference rule can be easily extended to cover the relationship between a given concept C and a concept expressed by an arbitrary subset S of the universe: C is related to S if there is at least one item d in S which is also in items(C). Hence, the extensional inference rule can produce conceptual summaries not only for base concepts, but also for any logical combination of concepts. In addition, because it is immaterial how S is produced, dynamic taxonomies can produce summaries for sets of items produced by other retrieval methods such as database queries, shape retrieval, and so forth, and therefore access through dynamic taxonomies can be easily combined with any other retrieval method.

Dynamic taxonomies are defined in terms of conceptual descriptions of items, so that heterogeneous items of any type and format can be managed in a single, coherent framework. Finally, because concept C is just a label that identifies the set of the items classified under C, concepts are language-invariant, and multilingual access can be easily supported by maintaining different language directories, holding language-specific labels for each concept in the taxonomy.

Exploration

The user is initially presented with a tree representation of the initial taxonomy for the entire knowledge base. The initial user focus F is the universe, that is, all the items in the information base. In the simplest case, the user selects a concept C in the taxonomy and zooms over it. The *zoom* operation changes the current state in the following way:

1. Concept C is used to refine the current *user focus* F, which becomes F∩items(C). Items not in the focus are discarded.
2. The tree representation of the taxonomy is modified in order to summarize the new focus. All and only the concepts related to F are retained and the count for each retained concept C' is updated to reflect the number of items in the focus F that are classified under C'. The *reduced taxonomy* is derived from the initial taxonomy by pruning all the concepts not related to F, and it is a conceptual summary of the set of documents identified by F, exactly in the same way as the original taxonomy was a conceptual summary of the universe. In fact, the term *dynamic taxonomy* indicates that the taxonomy can dynamically adapt to the subset of the universe on which the user is focusing, whereas traditional, static taxonomies can only describe the entire universe.

The retrieval process can be seen as an iterative thinning of the information base: the user selects a focus, which restricts the information base by discarding all the items not in the current focus. Only the concepts used to classify the items in the focus and their ancestors are retained. These concepts, which summarize the current focus, are those and only those concepts that can be used for further refinements. From the human computer interaction point of view, the user is effectively guided to reach his goal by a clear and consistent listing of all possible alternatives, and, in fact, this type of interaction is often called *guided thinning* or *guided navigation.* Such an iterative refinement terminates when the number of items in the focus is sufficiently small for manual inspection. In order to assist the user in deciding whether a simple concept expansion or a zoom operation is required, each concept label usually shows a count of all the items classified under it, that is, the cardinality of items(C) for all C's.

Dynamic taxonomies can be integrated with other retrieval methods in two basic ways. First, focus restrictions on the dynamic taxonomy can provide a context on which other retrieval methods can be applied, thereby increasing the precision of subsequent searches. Second, the user can start from an external retrieval method, and see a conceptual summary of the concepts that describe the result. Concepts in this summary can be used to set additional foci. These

two approaches can be intermixed in different iteration steps during a single exploration.

Figures 1 to 5 show how the zoom operation works. Figure 1 shows a dynamic taxonomy: the upper half represents the intension with circles representing concepts; the lower half is the extension, and documents are represented by rectangles. Arcs going down represent subsumptions; arcs going up represent classifications. In order to compute all the concepts related to C, we first compute, in Figure 2, all the documents classified under C (that is, the deep extension of C, items(C)) by following all the arcs incident to C and its descendants, H and I, from the extension: items(C)={ c, d }. All the items not in the deep extension of C (Figure 3) are removed from the extension. In Figure 4, the set of all the concepts under which the documents in items(C) are classified, B(C), is found by following all the arcs leaving each element in the set: B(C)={ F, G, H, I }. Because of the inclusion constraint implied by subsumption, if items(C) denotes the set of documents classified under C and C' is a descendant of C in the taxonomy, then items(C')⊆items(C) (Sacco, 2000), or, equivalently, a document classified under C' is also classified under C. Hence, the set of concepts related to C is given by B(C) union all the ancestors of all the concepts in B(C), that is, the set of all concepts related to C is {F, G, H, I, B, C, A}. Finally, in Figure 5, all the concepts not related to C are discarded, thus producing a reduced taxonomy that fully describes all and only the items in the current focus.

Figure 1. A dynamic taxonomy: The intension is above, the extension below. Arrows going down denote subsumptions, going up classification.

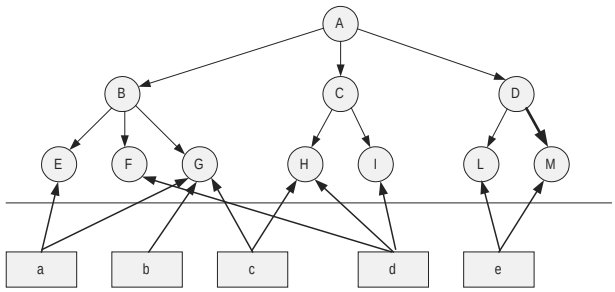

Figure 2. Focusing on concept C: Fnding all the items classified under C, that is, the deep extension of C

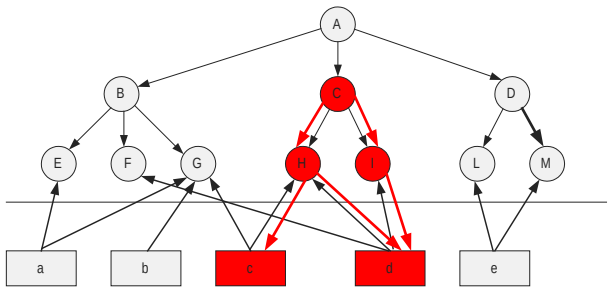

Figure 3. All the items not classified under C are removed

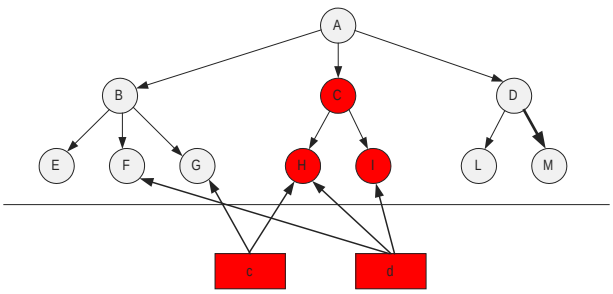

Figure 4. All the concepts under which the items in the focus are classified and (because of subsumptions) their ancestors are related to C

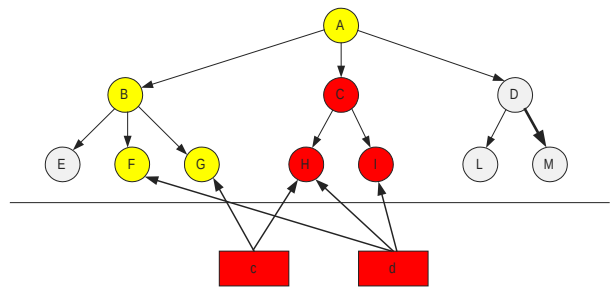
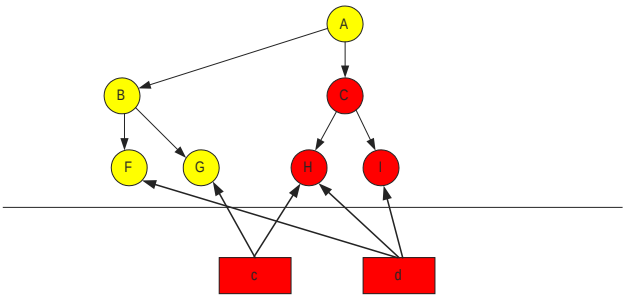


Advantages

The advantages of dynamic taxonomies over traditional methods are dramatic in terms of convergence of exploratory patterns and in terms of human factors. The analysis by Sacco (Sacco, 2006a) shows that 3 zoom operations on terminal concepts are sufficient to reduce a 10 million item infobase, described by a compact taxonomy with 1,000 terminal concepts organized according to 10 independent facets, to an average 10 items. Experimental data on a real newspaper corpus of over 110,000 articles, classified through a taxonomy of 1,100 concepts, reports an average 1,246 documents to be inspected by the user of a static taxonomy vs. an average 27 documents after a single zoom on a dynamic taxonomy.

Dynamic taxonomies only require the concept of a taxonomic organization and the zoom operation, which seems to be very quickly understood by end-users. Usability tests on a corpus of art images were conducted by Yee, Swearingen, Li, and Hearst (2003). Despite slow response times, access through a dynamic taxonomy was shown to produce a faster overall interaction and a significantly better recall than access through text retrieval. Perhaps more important are the intangibles: the feeling that one has actually considered all

Figure 5. The reduced taxonomy: All concepts not related to the current focus are pruned



the alternatives in reaching a result. Although few usability studies exist, the recent, widespread adoption by e-commerce portals, such as Yahoo!, Lycos, Bizrate, and so forth, strongly supports this initial evidence.

The extensional inference rule as a device to derive concept relationships has important implications on conceptual modeling. First, it simplifies taxonomy creation and maintenance. In dynamic taxonomies, no relationships in addition to subsumptions are required, because concepts relationships are automatically derived from the actual classification. For this reason, dynamic taxonomies easily adapt to new relationships and are able to discover new, unexpected ones. By converse, in traditional approaches, only the relationships among concepts explicitly described in the conceptual schema are available to the user for browsing and retrieval, so that all possible relationships must be anticipated and described: a very difficult if not helpless task.

Second, because dynamic taxonomies synthesize compound concepts, they need usually not be represented explicitly, so that the main cause of the combinatorial growth of traditional taxonomies is removed. Sacco (2000) developed guidelines that produce taxonomies that are compact and easily understood by users. Some are similar to basic faceted classification (Ranganathan, 1965; Hearst, 2002), at least in its basic form: the taxonomy is organized as a set of independent, "orthogonal" subtaxonomies (facets or perspectives) to be used to describe data. As an example of faceted design guidelines, consider a compound concept such as "19th century French paintings." It can be split into its **facets**: a Location taxonomy (of which France is a descendant), a Time taxonomy (of which the nineteenth century is a descendant) and finally an Art taxonomy (of which painting is a descendant). The items to be classified under the compound concept will be classified under Location>France, Time>19th century and Art>Painting instead. The extensional inference rule establishes a relationship among these concepts and the compound concept can be recovered by zooming on any permutation of them.

In a conventional classification scheme, such as Dewey indexing (Dewey, Mitchell, Beall, & Matthews, 1997), in which every item is classified under a single concept, a number of different concepts equal to the cartesian product of the terminals in the three taxonomies has to be defined. Such a combinatorial growth either results in extremely large conceptual taxonomies or in a gross conceptual granularity (Sacco, 2000). In addition, faceted design coupled with dynamic taxonomies makes it simple to focus on a concept, for example, 19th century, and immediately see all related concepts such as literature, painting, politics, and so forth, which are recovered through the extensional inference rule. In the compound concept approach, these correlations are unavailable because they are hidden inside the concept label.

Additional advantages include the uniform management of heterogeneous items of any type and format, easy multilingual access and easy integration with other retrieval methods. Dynamic taxonomies do not support reasoning beyond the extensional inference rule, and are therefore less powerful than general ontologies. However, they can be directly manipulated by users without the mediation of specialized agents and represent a quicker, less costly and more transparent alternative.

APPLICATIONS

The main industrial application is currently e-commerce. Assisted product selection is a critical step in most large-scale e-commerce systems (Sacco, 2003) and the advantages of dynamic taxonomies in user interaction are so significant as to justify the restructuring of well-established e-commerce portals: current examples include Yahoo, Lycos, Bizrate, and so forth.

However, dynamic taxonomies have an extremely wide application range and a growing body of literature indicates that their adoption benefits most search tasks. In addition to e-commerce, e-auctions and e-catalogs, key areas include e-government (Sacco, 2005a, 2005c), human resources and job placement portals (Berio, Harzallah, & Sacco, 2007), news portals, art and museum portals (Yee et al., 2003; Hyvönen, Saarela, & Viljanen, 2004), medical guidelines (Wollersheim & Rahayu, 2002) and diagnostic systems (Sacco, 2005b), among others. An additional area is multimedia databases, where dynamic taxonomies can be used to integrate access by conceptual metadata and access by primitive multimedia features (color, texture, etc.) into a single, coherent framework (Sacco, 2004).

A growing number of Web-based commercial systems based on dynamic taxonomies exist. Among these, Knowledge Processors, Endeca, i411 and Siderean Software.

FUTURE TRENDS

Current applications of dynamic taxonomies are relatively simple and use shallow taxonomies to access small to medium databases. However, the widespread adoption by e-commerce portals will make the model familiar to a large number of users and will make them aware of its significant benefits. For this reason, we expect widespread adoption and applications to evolve according to four coordinates:

1. New and emerging application areas, such as the ones reviewed above;
2. Larger information bases. Although the advantages of dynamic taxonomies over traditional search technologies are evident even with tens of documents, the superior convergence of this method makes it almost a forced choice for large multimillion item databases, which we expect will become the dominant application area in the near future;
3. Richer semantics. Current e-commerce applications have a relatively poor semantic content and require very simple taxonomies, but potential application areas can be much more complex and demanding in the design of multilevel taxonomies with thousands of concepts; and
4. Different architectures. Dynamic taxonomies are currently deployed in traditional Web sites with pull technology. Currently, push implementations are being experimented (Sacco, 2005e) and we expect early adoption in P2P networks, where access is currently based on a primitive form of text retrieval and no exploration capabilities are present. A significant use of dynamic taxonomies in mobile equipments is also expected, because the access model, coupled with a careful design of the taxonomy, is especially suited to low-resolution devices.

In order to achieve these results, continuing research is required. A review of research issues can be found in Sacco (2006b). They can be grouped into three main areas:

1. **Automatic classification and data modeling:** Dynamic taxonomies define how an existing classified corpus can be accessed and explored, but how documents are actually classified is left undefined. This is by design, because different types of data items (text, audio, video, etc.) need different classification strategies. Current research includes automatic text classification (Dakka, Ipeirtis, & Wood, 2005) and automatic classification from structured data (Sacco, 1998). Other research addresses the problem of specifying valid term composition rules in faceted taxonomies for textual information (Tzitzikas, Analyti, & Spyratos, 2005).

   As regards data modeling, recent investigations (Sacco, 2005d) suggest that dynamic taxonomies can be automatically derived from semantically rich conceptual schemata and used as a user-centered front-end to complex information. Extensions to the current model, in order to account for a fuzzy (Zadeh, 1965) classification, in which a document can be classified under several concepts with different probabilities, are also being investigated (Sacco, 2004).
2. **Human factors:** Because of its user-centered approach, human factors play a central role in the model, and especially in critical issues such as the presentation and manipulation of the taxonomy, where several alternatives exist (see Yee et al., 2003 vs. Sacco, 2000, 2004).
3. **Implementation:** The zoom operation and the subsequent reduction of the corpus taxonomy must be performed in real time because a slower execution would severely impair the sense of free exploration that the user of dynamic taxonomy systems experiences. Special data structures and evaluation strategies must be used (Sacco, 1998). In addition, distributed and federated architectures need to be investigated because centralized architectures are not always appropriate, because of organization needs and of performance and reliability bottlenecks.

CONCLUSION

Exploratory browsing applies to most search tasks: an extremely wide application range going from multilingual portals, to e-commerce, e-auctions, e-government, human resources management, CRM, and so forth. In this context, dynamic taxonomies represent a dramatic improvement over other search and browsing methods, both in terms of convergence and in terms of full feedback on alternatives and complete guidance to reach the user goal. For these reasons, we expect dynamic taxonomies to become pervasive in the short period, and to replace or integrate traditional techniques in a growing number of applications.

KEY TERMS

Extension, Deep: Of a concept C, denotes the shallow extension of C union the deep extension of C's sons.

Extension, Shallow: Of a concept C, denotes the set of documents classified directly under C.

Extensional Inference Rule: Two concepts A and B are related if there is at least one item *d* in the knowledge base which is classified at the same time under A (or under one of A's descendants) and under B (or under one of B's descendants).

Facet: One of several top level (most general) concepts in a multidimensional taxonomy. In general, facets are independent and define a set of "orthogonal" conceptual coordinates.

Subsumption: A subsumes B if the set denoted by B is a subset of the set denoted by A ($B \subseteq A$)

Taxonomy: A hierarchical organization of concepts going from the most general (topmost) to the most specific concepts. A taxonomy supports abstraction and models subsumption (IS-A and/or PART-OF) relations between a concept and its father. Tree taxonomies can be extended to support multiple inheritance (i.e., a concept having several fathers).

Taxonomy, Monodimensional: Taxonomy where an item can be classified under a single concept only

Taxonomy, Multidimensional: Taxonomy where an item can be classified under several concepts

Taxonomy, Reduced: In a dynamic taxonomy, a taxonomy, describing the current user focus set F, which is derived from the original taxonomy by pruning from it all the concepts not related to F.

User Focus: The set of documents corresponding to a user-defined composition of concepts; initially, the entire knowledge base.

Zoom: A user interface operation, that defines a new user focus by OR'ing user-selected concepts and AND'ing them with the previous focus; a reduced taxonomy is then computed and shown to the user.

E-Book Technology in Libraries

Linda C. Wilkins

Elsie S. K. Chan
Australian Catholic University, Australia

INTRODUCTION

The shift towards electronically mediated texts entails major structural issues for libraries and the publishers and aggregators who supply them. Stakeholders within the digital supply chain are struggling to reconceptualize the book as an artefact (Esposito, 2003). Academic and scholarly libraries are at the forefront of these changes. In this article we review some recent developments in the technology underpinning e-books, introduce some of the key players, and review influences affecting uptake.

BACKGROUND

Libraries have traditionally played a key role in providing access to and disseminating information across a community. That role has now extended to facilitating access to innovative technologies. Technological improvements such as Amazon's Look inside the Book technology and Google Print offering pages of a book on the Web drive accelerate demand for access ("The Economist," 2005). Such developments have generated pressures on libraries to make research output more widely available through search engines and open access mechanisms which in turn result in rising accessibility of research material via downloads and citations (Rosenzweig, 2005). Electronic access in the form of electronic journal subscriptions, e-books, and databases has resulted in the rapid and continuing evolution of library facilities. Many public libraries have experimented with a variety of e-book devices while academic libraries have overseen a dramatic shift in the percentage of their budget allocation dedicated to the provision of digital resources.[1] Hence, a review of the current provisions of electronic resources in libraries appears to be timely.

ENGAGING WITH E-BOOK TECHNOLOGY

The term *e-book* is unsatisfactory in many respects. In the case of traditional print books, users can immediately understand and identify elements belonging to book technology. By contrast, the term e-book does not explain either the form or its operations (for further information see Lynch, 2001, p. 125). As a generalised term it was initially applied to three types of appliances: e-book, e-tablet, and Personal Digital Assistant (PDA). Only their design, purpose, and size distinguished them from software book readers. Table 1 lists devices available in 2005.

Reader software can be categorised by e-book formats. Abobe, HTML, and Microsoft readers are some examples of e-book formats. Table 2 lists different formats of e-book software.

E-Books in Public Libraries

The period between 1999 and 2001 saw a surge in e-book reader trials in libraries in the United States, Canada, Denmark, Norway, and Australia.[2] Trials of e-book reader hardware in Australia, Canada, and the U.S. recorded overwhelmingly positive responses from pilot group users and librarians alike (Wilkins, Coburn, Burrows, & Loi, 2001). In Australia, user participants in the Brisbane Public Library e-book reader pilot study loved the compact, portable nature, adjustable font size, dictionary, and search and bookmark functions of dedicated e-book readers while librarians were keen to showcase the new technology. Many saw the readers as an opportunity to expose their community to technology as it "came down the pipeline" (Glencoe Public Library Illinois, USA, as cited in, Wilkins et al., 2001, pp. 252-253).

A generic feature of rapid technological change is the proliferation of designs, many of which will inevitably fail over time (Bijker, 1995). At a time when proprietary platforms dominated the marketplace, librarians found it difficult to make decisions about which device to go with, which text format to choose, and what copyright arrangements to take up. Eventually those librarians who had pioneered e-book reader technology trials in multi-year pilot projects found themselves tied to restrictive access models with exclusive proprietary book file format.[3] Unique formats that can become obsolete at any moment slow uptake and support for e-book reader hardware. The limited range of titles available on the available hardware also meant their appeal to borrowers faded over time (Lynch, 2001). By 2005 these early adopters found that "dedicated readers with pre-loaded content were

Table 1. e-book reader device (adapted from eBookMall (2005a)

Device	Example Image	eBook Format	Weight in oz.	Size	Screen Description
Gemstar eBook		Gemstar eBook	17	largish	4.75" x 3" Monochrome Back lit Touch screen
Handspring Visor		Palm Reader Mobipocket	5.4-6.9	smallish	about 3" x 4", some color, some not
hiebook		hiebook	8.8	115.4 x 146 x 17 mm	Back lit 480 X 320 px touch screen LCD display
Palm		Palm Reader Mobipocket	4-6	4.82" x 3.1" x .87"	Advanced LCD with backlight
Pocket PC		Microsoft Reader Mobipocket	6-16	Depends on device	Reflective or Transflective LCD, 16+ colors

not what patrons most wanted in an eBook" (M. Williams, personal communication, November 30, 2005).

The introduction of software book readers that run on general purpose computers and require no additional financial outlay for a separate hardware device or book reading appliance has effectively turned the desktop or laptop into book reading appliances. Many of those users accessing texts electronically on general purpose computers appear to be doing so in academic and research library settings.

E-books in Academic and Research Libraries

Our customers expect electronic content. (Woodward, 2005, p. 3)

Academic libraries are particularly well suited to the e-market with their large, expensive, and rapidly dated reference books that are costly to weed out (Michael, 2005). While all librarians have a professional commitment to efficient document delivery and place priority on offering content that their users require, librarians in research settings experience significant additional pressures to seek optimal methods for providing access, disseminating, receiving, and reporting publications. All students have now come to expect free Internet access; on-campus and part-time students require remote and 24/7 access via private ISPs. Researchers place priority on speed, timing, and knowing the latest in cutting-edge technology.[4] Institutional requirements for the library to provide information in a cost-effective way add to these pressures from competing constituencies.

Electronic delivery systems appear to offer solutions to many of these needs and requirements. Online search functions, easier navigation, the ability to cut and paste, well-organised and up-to-date materials, convenience (no carrying of books), paper saving, and lower levels of physical maintenance are all attractive features of e-book provision. Academics also appreciate that requirements for accessing e-books encourage students to copy with appropriate acknowledgement.

These features of the research constituency favour electronic delivery and hence offer a partial explanation for the dramatic growth in e-resources as a proportion of academic library budgets. Underpinning the drive for uptake is the fact that electronic publishing has transformed the book into a

Table 2. e-book formats (adapted from eBookMall, 2005b)

Format	Advantages	Reader Software	Navigation	Platforms
Adobe Reader	Cross-platform compatibility, printable, single or double page view	Get Adobe Reader	Library, Table of contents, Chapter links, bookmarkable	Windows PC, Macintosh, Palm
eBookMall	Dedicated reader for eBooks, carry titles with you		Library, Table of contents, bookmarks	Gemstar & Rocket eBook devices
hiebook	Dedicated reader for eBooks, includes lots of other programs	hiebook	Library, Table of contents, bookmarks	Hiebook devices
HTML	Easy to use, customizable, can be read on anything with a browser	Get Microsoft Internet Explorer Netscape Now! MOBIPOCKET Reader	Hypertext links	Windows PC, Macintosh, Linux, Unix, Palm, Pocket PC, eBookMan
Instant eBook	No special reader software required (only Internet Explorer), easy to use	Get Microsoft Internet Explorer	Hypertext links	Windows PC
Microsoft Reader	ClearType Display Technology, book-like reading environment, bookmarks and annotations	eBooks are Here!	Library, Table of contents, Chapter links, bookmarkable	Windows PC, Pocket PC
MOBIPOCKET	Can be used on any PDA	MOBIPOCKET Reader	Library, Table of contents, Chapter links, bookmarkable	Palm, Pocket PC, eBookMan, Windows PC
palm	Great eBooks for your PDA	palmreader MOBIPOCKET Reader	Library, Table of contents, Chapter links, bookmarkable	Palm OS, Pocket PC, Handheld PC, Windows CE, Windows PC

digital product and hence into a market offering. The potential for growing this market underpins the considerable economic interest in e-books among publishers and aggregators.

Key Players

The following list introduces some of the e-book suppliers to libraries currently active in this market.

- **EBL (www.eblib.com):** EBL offers around 18,000 titles from around 90 publishers. EBL was launched in 2004 by Ebooks Corporation (ebooks.com) and developed in collaboration with academic publishers and libraries in Australia, the U.S., the UK, and Europe. EBL's distinctive access requirements were designed primarily for academic and research libraries. Lending models include options for multiple concurrent use, unlimited access, and short-term circulation. As well as, individual e-book chapters can be set aside for reserve lending or be included within course packs. Academic publishers associated with EBL are Taylor and Francis, Oxford University Press, Cambridge University Press, Kluwer, and World Scientific Press. Distributors Blackwell's Book Services and Dawson Books have signed partnership agreements regarding content for North America, the UK, and Australia. EBL e-books are to be integrated into Collection Manager, Blackwell's Web-based collection development and acquisition system. Librarians' workflow requirements are catered for by EBL's publisher interface (Pi), which offers an Extensible Markup Language (XML) service to expedite entry of new electronic titles and requires only an ISBN entry.

- **Proquest Safari Computer eBooks (www.proquest.com):** Connection to the Proquest Safari Computer eBooks Web site is through a personal computer with registration via Library card. Books can be checked out and read online using the Web browser. Titles can be changed monthly with accurate usage data allowing removal of unused titles. Individual chapters can be downloaded to the user's personal computer (PC). Prices are weighted based on book demand. Safari publishes mainly information technology (IT) books—a category frequently selected by librarians undertaking e-book trials who perceive this audience as more accepting of their delivery mechanisms (Michael, 2005). Safari offers outright purchase rather than subscription as well as the option of a small starter package. Safari's purchase model has become popular with a number of librarians in research-based settings (Cox, 2004). As a low risk option it has proven particularly attractive to librarians seeking to trial e-books within budget constraints (H. Pearsall, personal communication, November 17, 2005).
- **NetLibrary (http://www.netlibrary.com):** A pioneer in the delivery of e-books to universities — is a subsidiary of the huge OCLC library cooperative, the world's largest bibliographic database built and maintained collectively by librarians http://www.oclc.org/worldcat/about/default.htm (retrieved 30th June 2006). Netlibrary offers a collection of some 90,000 e-book titles, from more than 300 publishers via a purchase-based model. Customers accessing NetLibrary e-books include 5,500 libraries and organizations.
- **ebrary (http://www.ebrary.com):** ebrary's subscription model offers more than 60,000 e-book titles from more than 200 publishers, accessed by some 500 libraries in 60 countries.
- **Questia (http://www.questia.com):** Questia offers 50,000 e-book titles, more than 119,000 journal articles, and over 159,000 newspaper articles and claims to be the world's largest online library of books and journal articles.

FUTURE TRENDS

International multi-year pilot studies, focus groups, and case studies conducted with publishers, librarians, and library users between 2001 and 2005 revealed a number of concerns that continue to have an impact on e-book uptake in libraries.

- **Competing Constituencies:** Instead of joining forces in the digital era, libraries and publishers have been fighting a battle sometimes described by librarians as the fight between good and evil (Vigen & Paulson, 2003). Frequently at issue is the fact that libraries aim to address community needs on the basis of sharing, borrowing, and recycling—facilities traditionally offered to patrons on a nonpaying basis. Publishers' transaction models for e-books accommodate the concept of controlled sharing only with considerable difficulty (Hoorebeck, 2003).
- Within the research community itself, libraries must also cater to diverse stakeholders. Students welcome the additional features e-texts offer. They want and expect uninhibited access to information in multiple formats where and when they require it. Academics and researchers, by contrast, place far greater priority on the *quality* of content (Michael, 2005).
- Within the library community, archivists represent another constituency concerned that the move to e-resources leaves unanswered questions about preservation issues and continuity of access over time.
- **A Plethora of Standards and Devices:** Despite attempts by the Open E-book Forum (now The International Digital Publishing Forum[5]) a variety of proprietary standards still exist rendering most e-books compatible only with certain devices. The lack of an agreed standard implies that an agreeable machine to deliver books to a mass audience has not yet arrived on the scene (Turney, 2005).
- **Content:** Low levels of currency and relevance to reader requirements and the time lag between printed and electronic versions of texts have presented serious drawbacks to the spread of e-books, particularly in research collections.
- **Authentication:** Products developed by providers and distributors are often not geared to procedures that libraries use for controlling access to e-resources. Agents offering competitive "deals," cast librarians in the unfamiliar and time-consuming role of negotiating terms, generating increased work loads for librarians.
- **Work Flows:** Collection managers find that making new monthly selections can generate considerable additional work for some of the library staff (Abbott & Kelly, 2004). Payment methods can also be comparatively cumbersome and a disincentive for uptake. Clearly for e-books to succeed, selecting and purchasing them needs to be as easy as ordering and buying from the campus bookstore (Abbott & Kelly, 2004).
- **Budgetary Pressures:** Research resources are provided or supported by major national institutions and organisations, and by many local bodies including universities, libraries, and archive offices. These bodies are all experiencing funding pressures and challenges in balancing electronic and nonelectronic resource provision (British Academy Report, 2005).

CONCLUSION

The e-book delivery supply chain as it currently exists has been described as "ad hoc and fragmented, lacking in leadership and coordinated strategy" (British Academy Report, 2005). Despite these problems, some signs of progress do exist. Major publishers have now come to the realisation that they cannot afford to not have a fully developed e-books strategy (Turney, 2005). Google's commitment to an e-book scanning project in partnership with leading universities in the U.S. and the UK represents a major push to address the dearth of quality material on the Web. These developments have accelerated adaptations in publishers' business models and supply chains to facilitate e-book uptake (Rosenblatt, 2004).

Other drivers are also emerging. We have already discussed market forces favouring digital delivery of information to libraries. Governments are now also under increasing fiscal pressure to maximise return on public investment. Hence, barriers to the free flow of information and the costs these barriers represent to publicly funded research are beginning to draw attention at the national level (for UK see Harnad, 2003; for Australia see Department of Education, Science and Training [DEST], 2004). Policy and/or legislative moves to lift these barriers may well stimulate further progress in diffusion of e-book technology.

ACKNOWLEDGMENTS

Special thanks to Mike Williams, Indianapolis-Marion County Public Library USA for information about e-book reader pilot studies; and to Heather Pearsall, Library Manager (Electronic Services), Australian Catholic University (ACU) for the information on e-book uptake at the ACU.

KEY TERMS

Amazon.com: Amazon's "Search Inside the Book" feature introduced in 2003 and now available as a feature for half of all books sold, allows people to use keywords to search text inside books. The firm has plans to introduce the "Amazon Pages" program in 2006, enabling the purchase of online access to text—up to and including an entire work, and "Amazon Upgrade" a program to access books electronically that have been shipped in printed form.

E-Book Supply Chain: A sequence of activities and organisations involved in producing and delivering a good or service. An IT supply chain—as required for e-books—is the flow of resources into and out of the firm's IT operations.

Electronic Book (e-Book): An e-book is an electronic (or digital) version of a book that can be downloaded to computers or handheld devices.

Electronically Mediated Text E-Book Reader or Device: An e-book reader can be a software application for use on a computer, such as Microsoft's free Reader application, or a book-sized computer that is used solely as a reading device, such as Nuvomedia's Rocket e-book. Users can purchase an e-book on diskette or CD, but the most popular method of getting an e-book is to purchase a downloadable file of the e-book (or other reading material) from a Web site (such as Barnes and Noble) to be read from the user's computer or reading device. Generally, an e-book can be downloaded in 5 minutes or less.

Google Book Search: Launched in 2004, the Google Print Library Project digitises and makes online texts searchable from the university library collections at Harvard, Stanford, Michigan, Oxford, and the New York Public Library giving locations for purchase or borrowing. Copyright issues are yet to be resolved. Database access will only be via Google's search engine.

Open E-Book Forum: The International Digital Publishing Forum (IDPF), formerly the Open eBook Forum is the trade and standards association for the digital publishing industry (http://www.idpf.org/).

ENDNOTES

1 U.S. figures show a 227% increase in serial expenditure since 1986 or by an average of 7.7% per annum (ARL Statistics, 2001-2002). In Australia, academic libraries such as those of the Australian Catholic University and the University of Western Australia have overseen similar marked growth in their expenditure on e-book subscriptions (H. Pearsall, personal communication, November 17, 2005; Kennewell, 2005).

2 For example, Maricopa County Public Library in Phoenix, Arizona had 100 Rocket e-Book Pro readers available for loan in 2001 (Wilkins et al., 2001).

3 In Table 2 we show that the majority of e-book reader formats currently available are no longer restricted to proprietary platforms.

4 For example, on an individual basis, members of medical faculties typically rate as the highest users of electronic resources (Kennewell, 2005).

5 The URL of the International Digital Publishing Forum is www.idpf.org

E-Business Systems Security in Intelligent Organizations

Denis Trček
Jožef Stefan Institute, Slovenia

INTRODUCTION

Security as we perceive it today became a topic of research with the introduction of *networked information systems*, or networked ISs, in the early 1980s. In the mid-1990s the proliferation of the Internet in the business area exposed security as one of the key factors for successful online business, and the majority of efforts to provide it were focused on technology. However, due to lessons learned during this period, the paradigms have since changed, with increasing emphasis on human factors. It is a fact that security of networked ISs is becoming part of the core processes in all e-business environments. While data is clearly one of the key assets and has to be protected accordingly, ISs have to be highly integrated and open. Appropriate treatment of these contradictory issues is not a trivial task for managers of contemporary intelligent organizations. It requires new approaches, especially in light of new technologies.

BACKGROUND

Proper management of security in *e-business systems* requires a holistic methodology that can be viewed on three planes: technology, organization, and legislation (Trček, 2006). ISs security management starts with the identification of threats and threats analysis. A typical approach is based on risk probability and derived damage estimates (Raepple, 2001). Following this, the approach differs according to the plane:

- The technological plane takes into account machine-related interactions. This plane is about deployment of appropriate *security services* that are based on *security mechanisms*. To become operational, key management issues (i.e., handling of cryptographic algorithms' keys) have to be resolved. Finally, human-to-machine interactions have to be addressed carefully.
- The organizational plane takes human resources management into account. It emphasizes the organizational issues and socio-technical nature of contemporary IS, where various modern methodologies play a central role.
- In parallel, it is necessary to address legal issues. Not only national, but also international legislation in this area is becoming increasingly broad and complex. Each and every security policy has to take this into account, especially cryptography regulations, digital signature issues, privacy issues, and intellectual property rights.

METHODOLOGICAL APPROACHES TO E-BUSINESS SYSTEMS

From the technological point of view, the prevention of threats is achieved by use of security mechanisms and security services (ISO, 1995). Mechanisms include symmetric and asymmetric cryptographic algorithms, for example, AES (Foti, 2001) and RSA (RSA Labs, 2002); one-way hash functions such as SHA-1 (Eastlake & Jones, 2001); and physical mechanisms. For devices with weak processing capabilities like smart-cards, elliptic curve-based systems such as ECDSA (ANSI, 1998) can be used. Regarding physical security, using cryptographic algorithms one can only reduce the amount of data that have to be physically protected, but physical protection cannot be eliminated.

To ensure that a particular public key indeed belongs to the claimed person, a trusted third party called *certification authority*, or CA, has to be introduced. The CA issues *public key certificates* that are digitally signed electronic documents, which bind entities to the corresponding public keys (certificates can be verified by CA's public key). CA also maintains certificate revocation lists, or CRLs. These should be checked every time a certificate is processed in order to ensure that a private/public key is still valid. The de iure and de facto standard for certificate format is X.509 standard (ITU-T, 2000).

By use of security mechanisms, the following security services are implemented:

- **Authentication:** Ensures that the peer communicating entity is the one claimed.
- **Confidentiality:** Prevents unauthorized disclosure of data.
- **Integrity:** Ensures that any modification, insertion, or deletion of data is detected.

Table 1. Summary of basic security related elements—technological plane

• **Security Mechanisms:** Symmetric and asymmetric algorithms, one-way hash functions, physical mechanisms • **Security Services:** Authentication, confidentiality, integrity, non-repudiation, access control, auditing • **Security Infrastructure:** Public key infrastructure, commercial off-the-shelf solutions (firewalls, intrusion detection systems), technologies IPSec, SSL, S/MIME, EAP, RADIUS, and WPA

- **Access Control:** Enables authorized use of resources.
- **Non-Repudiation:** Provides proof of origin and proof of delivery, where false denying of the message content is prevented.
- **Auditing:** Enables detection of suspicious activities and analysis of successful breaches, and serves as evidence when resolving legal disputes.

To enable these services, a certain infrastructure has to be set up. It includes a registration authority (RA) that serves as an interface between a user and CA, identifies users, and submits certificate requests to CA. In addition, a synchronized time base system is needed for proper operation, along with a global directory for distribution of certificates and CRLs. All these elements, together with necessary procedures, form a so-called *public key infrastructure* or PKI (Arsenault & Turner, 2002).

To provide security, mostly commercial off-the-shelf solutions are used. Such solutions typically include firewalls, which are specialized computer systems that operate on the border between the corporate network and the Internet, where all traffic must pass through these systems (Cheswick & Bellovin, 1994). Further, real-time intrusion detection systems (Kemmerer & Vigna, 2002) are deployed for detecting acts that differ from normal, known patterns of operation, or for detecting wrong behavior. Further, IPSec (Thayer, Doraswamy, Glenn, 1998), which is a security enhancement for IP protocol, is becoming a norm to prevent masquerade, monitoring of a communication, modification of data, and session overtaking. IPSec is suitable for virtual private networks, or VPNs, where one can establish secure private networks using public networks such as the Internet. Further, secure sockets layer protocol, or SSL (Freier, Karlton, & Kocher, 1996), provides a common security layer for Web and other applications and is available by default in Web browsers. It provides authentication, confidentiality, and integrity with the possibility of negotiating crypto primitives and encryption keys. Last but not least, secure/multipurpose Internet mail extensions standard, or S/MIME (Ramsdell, 1999), is often deployed as security enhancement for ordinary e-mail. It provides authentication, confidentiality, integrity, and non-repudiation.

Increased penetration of wireless communications into business environments brings new topics on the agenda that are specific to *wireless security* (Miller, 2001). In this area it is nowadays common to deploy physical/link level security by using IEEE 802.1X standard (IEEE, 2004). 802.1X is a framework for authentication, access control, and key-exchange. Its authentication deploys Extensible Authentication Protocol, or EAP (Aboba, Blunk, Vollbrecht, Carlson, & Levkowitz, 2004), which is usually used together with RADIUS server (Rigney, Willens, Rubens, & Simpson, 2000) for remote authentication and accounting. In addition, a derivative of 802.1X, called WiFi Protected Access, or WPA, is very common. Despite these technologies, wireless networks are inherently more vulnerable than wired networks, thus wireless access points are often put outside corporate firewalls.

However, even superior technological solutions will be in vain, if the complementary organizational and legal issues are not treated properly. Therefore, the second plane that is concentrated on organizational issues through human resources management has to be properly covered by *security policy*. In addition, the third plane has to be taken into account to assure that all efforts are aligned with existing legislation.

The first standard in the area of security policies was BS 7799 (BSI, 1995), with its most current international successor being ISO (2005). This standard plays a central role as far as security policy management is concerned. However, to implement successfully security policy, it is essential to support managers of contemporary intelligent organizations with appropriate techniques. The organizational plane is characterized by a complex interplay between human factor and technology. The two constituent parts are coupled in many ways, such as by interactions. A large number of these interactions form various feedback loops. There are also soft factors that have to be taken into account, for example, human perception of various phenomena like trust. Therefore, to support decision making properly with regard to security, one has to deal with physical and information flows. Additionally, decisions are often to be made in circumstances where there is not enough time or resources to test decisions in a real environment; often such checks are not possible at all. Therefore, support from computer simulations is highly desirable.

The methodology that can be used to support the resolution of the previously mentioned problems is *business dynam-*

Table 2. A summary of advanced security related elements—organizational and legal planes

• **Security Policy:** An organization's document covering its networked information systems security from technological, organizational, and legal plane • **Business (or System) Dynamics:** A modeling methodology for socio-technical systems • **Business Intelligence:** Enabling integral capturing of data with knowledge extraction to support decision making

ics (Sterman, 2000). It enables qualitative and quantitative modeling of contemporary IS. Using this methodology, one starts with the identification of variables that are relevant to system behavior and defines the boundary distinguishing between endogenous and exogenous variables. Variables are connected by causal links, which have positive polarity if increase/decrease of input variable results in increase/decrease of output variable. In a case when increase/decrease of input variable results in decrease/increase of output variable, the polarity is negative. Some variables are of a stock nature (also called levels), and these introduce persistency (inertia) into the system. They decouple inflows and outflows, and thus present a kind of buffer or absorber. When building a model of a system by this approach, so-called causal loop diagrams are obtained, which provide a very useful means for management of e-business systems security. Finally, causal loop diagrams are upgraded with appropriate equations and tuned using real data to enable quantitative analysis, that is, computer simulation.

Summing up, security policy is the main document about risk management in every organization, and its introduction and maintenance has to be adequately supported by use of modern business intelligence techniques. Using causal loop diagramming, decision makers can get a holistic perspective on their systems, but to verify and properly adjust these models, they have to link them to appropriate sources to obtain real-time data for simulations. The resulting architecture provides an important tool for information security management of intelligent organizations with emphasis on human factors that are critical in the context of security policy. However, due to increasingly expanding and complex legal issues in the area of e-business systems security, no security policy shall be treated solely as a techno-organizational issue. In fact, security policy is becoming primarily a legal document and should be treated as such. A lawyer or a legal expert should be involved in its derivation and maintenance process.

FUTURE TRENDS

Emerging new paradigms will be covered in this section. From the technology plane perspective these paradigms include objects, components, mobile code (computing), and intelligent agents. Every code (and object) can be treated as an electronic document. The creator defines its initial data and behavior (methods) and, optionally, signs it. The signature on the code gives a user the possibility to be assured of proper functioning of this object, where the problem is analogous to that of ensuring authentication and integrity for ordinary electronic documents. When considering intelligent mobile agents that are objects that satisfy certain conditions (Griss, 2001), the security paradigm is reversed. Agents operate in unpredictable environments and have to be protected from malicious hosts. These important issues have yet to be resolved.

With regard to organization plane, business dynamics can be further enhanced by linking it to *business intelligence* (Ortiz, 2002) in order to achieve an appropriate architecture for qualitative and quantitative management of security in intelligent organizations. The basis is operational security-related data that come from various sources: general host logs, router logs, application logs, phone and fax logs, physical security system logs, and so forth. These operational, legacy data have to be transformed in the next step, which means preparation of data for a security data warehouse. The exact data that have to be captured in a security warehouse are defined in line with the causal loop diagram model of an organization. This also implies that such a solution will have to be tailored to the needs of each particular organization.

Finally, an interesting trend is emerging where business dynamics is complemented by intelligent agents-based simulations (Trček, 2006). Business dynamics operates at the aggregates level and is top-down oriented, while agents-based simulations operate at the level of individuals and are bottom-up by nature. Thus using both methodologies as an input to business intelligence enables further improvement of security policy related decision making.

CONCLUSIONS

Even in the era of intelligent organizations, security management cannot avoid technical foundations. It is a fact that classical, cryptography-based approaches form the core of all security management so that each IS security has to start with addressing these issues. However, this basis serves as a starting point for further development of methodolo-

gies for risk management that are concentrated on human resources. Experience shows that human factors play an increasingly important role. Taking this into account and due to the emergence of business intelligence, it is possible to further support the management of IS security. Using business dynamics, intelligent agents, and business intelligence techniques, decision-makers can obtain data in real time and simulate the effects of their decisions in advance. This way they are armed with additional tools for successful protection of their ISs through appropriate security policies. And finally, increasingly expanding and complex legislation is becoming a fact in the area of e-business systems security, and thus requires proper attention.

KEY TERMS

Business Intelligence: Deployment of (usually artificial intelligence-based) techniques such as online analytical processing (OLAP) and data mining to analyze information in the operational data sources.

Certification Authority (CA): An authority trusted by one or more users to create and assign public key certificates.

E-Business System: An organized, structured whole that implements business activities, which are based on electronic technologies, methodologies, and processes.

Networked Information Systems: An IS that is strongly integrated in a global network. From the technological point of view, the difference between the IS and the global network is blurred; however, it exists from the administrative point of view.

Public Key Certificate: The public key of a user, together with some other information, rendered unforgeable by encryption with the private key of the CA that issued it.

Public Key Infrastructure: The infrastructure capable of supporting the management of public keys able to enable authentication, encryption, integrity, or non-repudiation services.

Security Mechanism: A basis for a security service—using particular security mechanism (e.g., cryptographic algorithm), the security service is implemented.

Security Policy: Documented procedures that focus on the organization's management of security; it is about information confidentiality, integrity, and availability of resources.

Security Service: A service provided by an entity to ensure adequate security of data or systems.

Wireless Security: Security assurance for communicating information in electro-magnetic media over a distance through a free-space environment.

E-Collaboration in Organizations

Deborah S. Carstens
Florida Institute of Technology, USA

Stephanie M. Rockfield
Florida Institute of Technology, USA

INTRODUCTION

Organizations are shedding conventional work team structures in favor of virtual team structures that are increasing in popularity (Lee-Kelley, Crossman, & Cannings, 2004). E-collaboration enables collaboration between individuals not constrained by geographical distance or time. The emergence of the virtual team concept provides organizations with an alternate approach to managing work and individuals that are geographically separated (Gatlin-Watts, Carson, Horton, Maxwell, & Marltby, 2007). An advantage of virtual teams is that organizations can tap into resources rapidly to create a specialized work team that acts like a team, works like a team but doesn't look like a typical team because team members may not be co-located (Stough, Eom, & Buckenmyer, 2000). E-collaborative technologies such as computer-based conferencing systems are of critical importance to the success of a virtual team (Arnison & Miller, 2002). In the absence of water-cooler philosophizing, virtual teams rely on technology to build trust between team members, resulting in greater synergy and ultimately team success in carrying out work tasks (Arnison & Miller, 2002; Stough et al., 2000). The article focus is on technological and organizational aspects of e-collaboration occurring today and forecasted for tomorrow. The specific topics addressed are e-collaboration in organizations, e-collaboration in organizations of today, specific e-collaboration success factors and future trends of e-collaboration in organizations of tomorrow.

BACKGROUND

Collaboration is simply described as individuals working together while sharing information (Yen, Wen, Lin, & Chou, 1999). E-collaboration is merely taking collaboration to an electronic level. The expansion of the Internet has created opportunities to increase business collaboration, resulting in enhanced information sharing while reducing the amount of uncertainty in decision-making resulting in better profits (Rudberg, Klingenberg, & Kronhamn, 2002). E-business consists of more than buying and selling of goods and services on the Internet, as it also entails the servicing of customers and collaborating with business partners. Information management both internally and externally is an increasing concern for organizations as paper-based systems can be very slow, prone to error and difficult to update. With a growing interest in e-business solutions that facilitate information sharing between organizations, organizations within a supply chain are looking to achieve greater synergies with e-businesses and specifically participation in e-collaboration. By integrating e-collaboration in supply chain services through an electronic marketplace, companies are able to work together more efficiently through sharing vital information to assist in supply chain activities without the implementation of expensive EDI networks. With the globalization in business, e-collaboration has become almost a requirement for an organization to successfully compete in the marketplace in terms of optimizing productivity, quality and ultimately profits (Yen et al., 1999).

E-COLLABORATION IN ORGANIZATIONS OF TODAY

Contemporary workplaces are allowing employees to work from home and other off-site locations which are changing the view of traditional organizational work teams (Rudberg et al., 2002). Over the last decade, organizations are becoming flatter resulting in the need to increase the number of virtual teams that bring internal and external people with diverse disciplines together (Dustdar, 2005). These virtual teams survive based on a combination of mobile and fixed people, devices and applications. E-collaboration technologies influence how people process, manage and manipulate information, which is useful for both co-located and virtual work teams (Rudberg et al., 2002). E-collaboration provides a mechanism for virtual teams to accomplish work tasks while providing the foundation for productive team work accomplished through nontraditional means. Team-based structures in workplaces are common and in great demand because work teams are often comprised of individuals with different backgrounds due to the nature of work being multidisciplinary as well as global. In working on joint projects between businesses, there can be a reduction in the risks, making innovation less costly for any one business with regard to new ventures.

There are several e-collaborative technologies available today that allow organizations to have instant communication within a business, between businesses or between businesses and consumers (Rudberg et al., 2002). The range of activities that e-collaborative technologies support is e-mail to videoconferencing to file sharing, regardless of geographical time and distance. Groupware commonly consists of e-mail, computer-based conferencing systems, collaborative writing, programming and drawing systems (Stough et al., 2000; Yen et al., 1999). Groupware enables virtual teams to experience more traditional group life because team members can interact with each other by actually seeing each other and jointly manipulating information real-time. Groupware can also be called Teamware, as the focus of both is in assisting groups or teams in successfully performing work, whether helping a face-to-face team with brainstorming anonymously or helping distributed teams see each other through videoconferencing (Yen et al., 1999). Technology is useful for the exchange and sharing of information (Yen et al., 1999). There are many different products available which integrate several features such as e-mail, calendaring, instant messaging, multiperson chats or discussions, mobile, wireless, social software, team collaboration, e-forms, enterprise-wide discussion forums, team spaces, Web-conferencing, instant remote access control, instant desktop sharing, two-way file sharing, online meetings and Web-content management (Bal & Teo, 2001).

However, technology alone will not constitute virtual team success. Teams that switch from a collaboration to an e-collaboration environment will likely experience a transformation process that involves complex team dynamics and work processes that at first may create new challenges. For example, virtual teams may need to find alternative ways to form trust between team members, as water cooler philosophizing as a way for team members to form bonds don't exist as easily in virtual teams (Arnison & Miller, 2002; Stough et al., 2000). Early literature of the 1930s and 1940s approached conflict as dysfunctional for group dynamics, resulting in researchers studying causes and prevention of conflict (Passos & Caetano, 2005). Later literature discussed other views such as the human relations' approach, where conflict was viewed as natural or even positive for teams to experience, resulting in studies to identify situations where conflict was either good or bad for team dynamics. Conflict is another aspect of teams where virtual teams have an added challenge when resolving. Molleman (2005) suggests those individual team members' attributes such as age, skills or personality traits can be noticeable, which can lead to subgroups and possibly result in conflict among the subgroups. Group cohesion, mutual trust and team efficacy can be shared team characteristics, provided e-collaborative technologies aid in relationship building for teams (Bal & Teo, 2001; Molleman, 2005).

ACHIEVING SUCCESS TODAY AND TOMORROW WITH E-COLLABORATION

E-collaboration technologies enable virtual teams or even face-to-face teams to be more productive and therefore successful. When considering a virtual team, it is important to also consider all of those factors which contribute to the team's success. With most virtual teams being separated by geographical time and distance, it is not surprising that a team's success can be greatly influenced by the availability and capability of technology (Stough et al., 2000). Aside from specifically e-collaboration technologies, team members that have access to different knowledge databases also have greater opportunities to have successful collaborative efforts in developing new ideas, products, markets, strategies, organizational designs and visions (Shani, Sena, & Stebbins, 2000). Technology assists in all collaborations, making it easier for individuals with different backgrounds to come together and virtually resulting in higher creativity and innovation. Technologies such as the Internet, e-mail, groupware, video-conferencing, cellular phones and intranets will continue to aid in information sharing and communication between team members (Arnison & Miller, 2002).

There are several identified sources that lead to creative performance as being resource availability, leadership, group size, group cohesiveness, communication patterns and group diversity (Molleman, 2005; Shani et al., 2000). Furthermore, the structure of group interaction within teams significantly impacts team members' creativity. The work on a team can be delegated best when team members are aware of each other's skill set even when tasks are unclear (Cruz, Perez, & Ramos, 2007). Technology has been a contributor leading to improvements in communication for virtual team members through enabling more closely knit work teams (Arnison & Miller, 2002). Of equal importance, the virtual team must be able to keep up with any new technologies utilized to aid team performance. Training in e-collaborative technologies may be a necessity for the vitality of virtual teams. Technologies have drastically improved, yet the mobility of technology is still in need of being improved, as employees need to have the ability to work anytime anywhere in order for an organization to compete globally in the marketplace.

Virtual teams must have a purpose and vision to ensure that every team member is focused and understands the goals of the team. If a virtual team lacks productive interactions, the effectiveness of the team could be compromised (Arnison & Miller, 2002). Because virtual teams may not have a chance to check-in with their team members as often as face-to-face teams, team members must be provided with clear goals to help the team in achieving a cohesive contribution (Arnison & Miller, 2002; Bal & Teo, 2001; Molleman, 2005). Team members in a virtual team as well as a face-to-face team must have an identity within their team through having

an understanding of exactly how they fit within their team structure (Arnison & Miller, 2002). Also, teams must have an understanding of the role played by every member to assist teams toward achieving their goals. Without clarity in the role played by an individual on a virtual team as well as the roles played by others on the team, poor interaction among members could occur because of a lack of understanding of how each team member's performance impacts the other members and ultimately the virtual team's goals.

Poor interaction can also lead to the lack of trust among team members, resulting in reduced opportunities for cohesiveness. Duarte and Snyder (1999) identified three factors that assist virtual teams in building trust among team members. The three factors are performance and competence, integrity and concern for the well-being of others. If team members view each other as high performers and as competent, trust can be built. Integrity can be preserved due to various collaboration technologies that have anonymity features of team member's input. Bal and Teo (2001) identify that trust can be built through ensuring that all team members have understanding of the team's purpose and process for continuous improvements. Virtual teams that are self-managed teams are unlike traditional work groups in that the leaders can be more informal leaders and the leadership role may even be divided among many of the team members (Yukl, 2002). Virtual teams can be easily compared to self-managed teams due to the definite and distinctive independence that exists in virtual teams caused from the distance between team members (Arnison & Miller, 2002). Strong leadership is not only essential but also the key for the successful operations of a purely virtual team. Leadership is of even further importance when the skills and knowledge within the team are highly diverse. Individuals need to stay motivated in performing work and this may even be more crucial for virtual teams (Stough et al., 2000). Therefore, even small wins should not go unnoticed by the leadership of the virtual teams. Virtual teaming effectiveness measures should be identified and utilized as an aid not only to virtual team leaders but team members as well to contribute toward keeping the team focused and on task. Furthermore, there should be shared rewards among team members for milestones being accomplished.

FUTURE TRENDS

Rudall and Mann (2007) discuss how computing is shifting to be more cognizant of the importance of a relationship between computing and our environments, taking into consideration both social and technological aspects. Duarte and Snyder (1999) identified how different modes of communication such as audio, video or data assist with different types of tasks. For instance, technical or interpersonal conflicts are not easily resolved through e-mail. Therefore, e-collaborative technologies of the future should build on past research to ensure that new features optimize team interactions to enhance productivity and quality of the team output.

The 2010 Internet access network is anticipated to have an improved capacity from the currently available spectrum, as it will begin to move away from a cellular-only system to one that integrates broadcast, cellular, cordless, wireless LAN, point-to-multipoint and fixed access technologies (Reynolds, 2003). With the expansion of smart systems, e-collaborative technologies will benefit through virtual team members being empowered through digital environments that have intelligence built-in to the design (Rudall & Mann, 2007). For instance, digital environments are being predicted to have the ability to be aware of people's presence and context. Furthermore, the new digital environments would have capabilities such as being sensitive, adaptive and responsive to individuals' needs, habits, gestures and emotions of those individuals' part of the environment. These smart systems will eventually achieve a level of maturity resulting in computers communicating back and forth with each other, taking into account the needs of surrounding individuals as well as the environment while being completely hidden within environments.

The potential for enhanced smart systems with embedded intelligence has resulted in new and emerging fields such as the combining of pervasive computing, cognitive intelligence and expansion of software-intensive systems (Rudall & Mann, 2007). Pervasive computing can be described as computing that is embedded into professional or personal environments providing seamless computing anytime and anywhere. Whereas, cognitive intelligence refers to computing that is able to act as intelligent agents that not only understand individuals' mental states but also have the capability to socialize with individuals, much like individuals interact with each other. There are a variety of technologies being researched such as pervasive computing, energy autonomy and networking. The Coopers project focuses on integrated traffic management with a vision that vehicles connect through continuous wireless communications with road infrastructures in order to exchange data and information that would be relevant for specific road segments. This information would increase overall road safety through enhancing traffic management. Ultimately, future e-collaboration technologies must assist the growing number of virtual teams by not merely making mobility of content but also making mobility of context (Dustdar, 2005). Content is described as any information (work procedures, work documents, etc.) that teams need to have access to, whereas context refers to the ability to trace and support dynamic relationships between people, information and team processes.

CONCLUSION

Successful virtual teams must rely on several factors such as e-collaboration technologies, highly skilled team members and strong leadership (Stough et al., 2000). Virtual teams should have access to technologies that go beyond groupware products that focus on mobility of content but also technologies that assist with mobility of context that integrates managing work, people and their processes (Dustdar, 2005). These factors provide the setting and appropriate groundwork for success (Stough et al., 2000). Collectively, these factors support activities such as setting clear goals, coordinating and negotiating with others, building trust among team members, planning and managing work processes, enhancing decision-making skills, contributing to relationship building and performing management functions to include budgeting and scheduling (Bal & Teo, 2001; Molleman, 2005; Stough et al., 2000). Virtual teams as well as face-to-face teams must be recognized and rewarded by their organization for their successes (Stough et al., 2000). E-collaborative technologies of today appear on first glance as groundbreaking, but the e-collaborative technologies of the future haven't even begun to break ground.

KEY TERMS

Cognitive Intelligence: Cognitive intelligence refers to computing that is able to act as intelligent agents that not only understand individuals' mental states but also have the capability to socialize with individuals much like individuals interact with each other.

Collaboration: Collaboration occurs when two or more individuals work together to accomplish a work goal.

E-Collaboration: E-collaboration occurs when two or more individuals work together with the use of technology to assist in accomplishing a work goal.

E-Collaborative Technologies: E-collaborative technologies consist of any form of computing that is used to assist a virtual team in accomplishing a work goal.

Virtual Teams: Virtual teams are work teams where a minimum of one team member is separated from other team members due to geographical time and distance.

Groupware: Groupware is a type of e-collaborative technology developed solely for the purpose of supporting virtual teams in communicating and information sharing to accomplish their work goals.

Pervasive Computing: Pervasive computing can be described as computing that is embedded into professional or personal environments to provide seamless computing anytime and anywhere.

E–Commerce Taxation Issues

Mahesh S. Raisinghani
TWU School of Management, USA

Dan S. Petty
North Texas Commission, USA

INTRODUCTION

This article is designed to give the reader a balanced perspective on some of the issues surrounding the current discussions related to state and local taxation of Internet access fees and sales transactions. It attempts to express the issues being discussed and presents several viewpoints. The proponents of Internet taxation are searching for technological and administrative system to meet their goal. After much deliberation, the Advisory Commission on Electronic Commerce released its final recommendations to Congress in April 2000. Major emphasis is being placed on simplification, neutrality, avoiding double taxation and accepting the existing tax rules with no new taxes.

The United States economy has benefited tremendously by e-commerce. This escalation has created numerous highly skilled jobs, providing the consumer with goods and services at competitive prices. The Internet Tax Fairness Coalition and many other groups feel that implementing taxes on the Internet transaction can have an adverse affect on the businesses. According to the Supreme Court of United States, a vendor has a sales tax obligation only when the buyer and seller are in the same state or has a physical presence (nexus) in the buyer's state. These coalitions feel that entry barriers for new and old companies, who have yet to exploit the e-commerce, will slow the growth in this sector. With over 30,000 taxing jurisdictions, tax collection and payment can be a complex process. Many street retailers collect at a single rate, and prepare and file a single tax return at one place. Taxation of online transactions would require the vendor to identify and send forms to all taxing jurisdictions. Under the present circumstances, the ever-changing maze of state and local tax policies makes application of a single Internet transaction tax policy virtually impossible.

The complicated, complex and ever changing maze of state and local tax policies and laws make application of a sensible, fair and easily understood Internet transaction tax policy virtually impossible under the present circumstances. James Plummer, a policy analyst at Consumer Alert wrote, "Nefarious new taxes and regulations will kill many new start-up e-businesses before they even start up; denying consumers their chance to find the specialized products and services for their needs" (Plummer, 2000).

The anti-tax community and coalitions have a strong adversary in the National Governor's Association. The State is worried that the brick and mortar stores are jeopardized by the popularization of Internet commerce, which is tax-free. The Governors suggest that government tax policy offers a competitive advantage to Internet stores. Major brick and mortar retailers such as Sears and Wal-Mart are concerned that if unresolved, this issue may gain much public resistance, thus making the taxing of e-commerce politically impossible.

BACKGROUND

The United States Congress enacted The Internet Tax Freedom Act in 1998, imposing a three-year moratorium on new Internet taxation. It also established the Advisory Commission on Electronic Commerce to address the issues related to Internet taxation (Advisory Commission on Electronic Commerce, 2000).

The Advisory Commission has representatives from state and local governments and e-commerce industry. It is to conduct a study of federal, state, local and international taxation and tariff treatment of transactions using the Internet and Internet access, and other comparable sales activities. The Commission's recommendations are to be submitted to Congress no later than April of 2000. Based on testimonies, the Commission is reviewing barriers imposed in foreign markets on U.S. property, goods or services engaged in Internet and its impact on U.S. consumers, and ways to simplify federal, state and local taxes imposed on telecommunications services.

The National Governor's Association's Perspective

Today, 46 states have a sales tax of some sort. All of the 46 states that have a sales tax also have what is called a complementary use tax. Consumers pay the sales tax when they buy goods and services in their own state and use tax when they buy from other states. This strategy avoids double taxation. When the consumer buys from an out of state merchant, such as mail order or the Internet, tax is collected and sent to the consumer's state only if the merchant has a nexus in the consumer's state. According to U.S. Supreme Court 1967, National Bellas Hess and 1992

Quill decisions, the merchant is not required to collect the use tax and remit it to the state of residence of the consumer. Consumers then are responsible for paying taxes on goods they purchase through mail-order catalogues and over the Internet. This subsidizes one category of businesses at the expense of their competitors.

The Governors have suggested a streamlined sales tax system for the 21st century. Some of the features of the governor's proposed streamlined system include:

- Maintain the current definitions of nexus and eliminate collection of state and government taxes
- Simplify the current system and without any federal government intervention
- Eliminate the cost of compliance, tax returns and payments and tax audits
- Eliminate tax-rate monitoring and implementation.
- Eliminate risks for sellers exercising reasonable care

The states would implement uniform laws, practices, technology applications, and collections systems to achieve the goals and results. These goals, when implemented, would achieve the first step of the streamlined system. The second step would be for all state and local governments to adopt the same classification systems, definitions and audits

The overall concept of the streamlined system is to reduce the costs and burden of sales tax compliance by shifting sales tax administration to a technology oriented business model operated by trusted third parties (TTPs).

THE E-COMMERCE COALITION PERSPECTIVE

The e-Commerce Coalition is a broadly based national coalition dedicated to providing sound policy information on electronic commerce taxation, and includes AOL, Bank One, Cisco Systems, and the like. Can e-commerce step up the process of making each state responsible for administration of its own tax system and simplification? Time is of the essence because of the speed at which this industry is growing and changing.

GOVERNOR JAMES GILMORE'S PERSPECTIVE

Governor James Gilmore of Virginia is Chairman of the Advisory Commission on Electronic Commerce. Governor Gilmore submitted a proposal to the Commission on November 8, 1999 entitled "No Internet Tax" (Gilmore, 1999).

The Governor believes that American public policy should embrace the Internet and the borderless economy it creates.

- Prohibit all sales and use taxes on business-to-consumer interactions and protect companies from unfair taxes imposed due to their virtual presence
- Amend the Tax Freedom Act to prohibit all taxes on Internet access
- Abolish the federal 3% excise tax on telephone service
- No international tariffs or taxes on e-commerce

E-COMMERCE TAXATION FROM AN INTERNATIONAL PERSPECTIVE

The problem with international taxation is essentially that it is likely not possible to govern well when there is no international government to create an appropriate incentive structure to induce and compel good behavior (Bird, 2003). Molina and Michilli (2003) discuss how e-commerce is emerging in European regions. For instance, the region of Veneto has implemented "Bollo Auto" — the payment of car taxes through a digital network making use of lottery terminals located in the popular tobacco shops (*tabacchinos*). Since July 1, under the aegis of "leveling the playing field," the European Union (EU) has been imposing a value-added tax (VAT) on digital goods — namely games, music, and software — downloaded from non-EU companies via the Internet by EU citizens (Pappas, 2003). McLure (2003) concludes that any failure to apply value-added tax (VAT) to electronic commerce crossing borders between EU member states and other countries should not affect the value added-tax liability of registered traders, even if the reverse charge rule (taxation in the hands of recipients) is not applied. The study notes that the sales of digital content to consumers and unregistered traders that constitutes a minuscule fraction of purchases by households and unregistered traders (given the extremely low level of small-business exemptions) is problematic.

Li (2003) provides a technical and policy analysis of the Canadian Goods and Services Tax (GST) in the context of e-commerce and suggests some options for reform. Even though the GST has had a bad reputation in Canada and its integrity is now threatened by growing online cross-border shopping, based on the revenue potential of the GST, a replacement is highly unlikely, and a cleaned-up or reformed GST is more practical. Thus the government should take advantage of the opportunity presented by e-commerce to reform the GST.

In an application of the substance over form doctrine to the international e-commerce taxation issue, Ngoy (2003) proposes an approach consisting of applying what is called

here the permanent establishment (PE) function test to e-commerce infrastructures in order to see whether they qualify for being fiscally treated as PE, if they pass the concerned test. The study concludes that some of them substantially have the same function as the category of office PE, and they should be fiscally treated as this category of PE no matter the form they have.

SUMMARY OF OPTIONS FOR RESOLUTION OF INTERNET TAXATION ISSUES

The European Union has worked out a system where all 15 members impose hefty value-added taxes and all retailers must collect the tax for all sales within the union. United States negotiators are working with groups internationally to come to some understanding regarding these complex issues (Landers, 2000). Senator Ron Wyden and Representative Christopher Cox state that they would work to extend the e-tax moratorium for 5 more years and permanently bar all access taxes (Business Week, 2001).

On the other hand, the taxing entities feel that the online retailers should have to collect the same taxes as brick and mortar businesses. They have signed on to the Streamlined Sales Tax Project, whereby they have agreed to pattern their tax system from a model code (The Wall Street Journal, 2001). Four states, California, Massachusetts, Virginia and Colorado, who are leading technology states, put forth the argument that taxing Internet access and commerce would harm the growth sector of their economies.

Congress has taken the first steps to make sure states cannot impose sales taxes on Internet access, use or content and cannot impose multiple or discriminatory new taxes. Congress has also encouraged and supported the work of the Streamlined Sales Tax Project so states can continue to receive sales tax revenues from Internet transactions, just as they would if the transactions took place in a brick and mortar location. Retail businesses that enter into Internet commerce will be required to collect sales taxes on Internet sales in accordance with the rules that state develops. Sales taxes will remain solely under the jurisdiction of state and local governments for the foreseeable future (Goold, 2003).

The Streamlined Sales Tax Agreement (SSTA) sets uniform definitions and other standards that will make it easier for retailers to collect tax from out-of-state purchasers. The SSTA would make it easier for states to collect taxes on Internet purchases — an extra-territorial money grab strikingly similar to the EU's plan. Although 31 states have already approved the new SSTA, the agreement is voluntary since remote Internet and mail-order sellers are still not legally obligated to collect any tax from out-of-state consumers. However the new Simplified Sales and Use Tax Act of 2003 introduced in Congress by Representative Ernest Istook (R-OK) and a companion bill sponsored by Senator Mike Enzi (R-WY) would effectively make the SSTA mandatory (Pappas, 2003; Rankin, 2003).

Most of the 45 states in the United States that impose sales and use taxes consider the advent and expansion of e-commerce the greatest threat to their financial stability since catalog merchandising. The Constitution's Commerce Clause grants Congress the power to regulate commerce among the several States. In Quill Corp. v. North Dakota, the Supreme Court revisited its long-standing rule that a state could not establish nexus with a remote seller unless the remote seller was physically present in the state. The U.S. Supreme Court reaffirmed that nexus cannot be established in the absence of a remote seller's physical presence in a state (Trealease & Storum, 2003).

FUTURE TRENDS

After reviewing some of the information available, it appears that an interim solution might evolve from the final report and recommendations of the Advisory Commission on Electronic Commerce, including an extension of the moratorium on taxes on Internet access. The infant industry argument is that a tax hurts an emerging industry that still needs a small boost to continue expanding and developing new products and new technology. Critics of Internet taxation charge that it is also unconstitutional and unfair. However, "unfair" is also what land-based retailers might cry, as they claim that Internet retailers have an undue advantage. For both catalog and Internet sales, states want to be able to tax those purchasers who live in their state (Jossi, 2003). Although there are serious and complex issues, it appears that a resolution can be constructed that will be favorable to consumers and businesses alike, including technology being applied to the collection process, standardization of tax systems, and state and local governments being responsible to pay the costs of newly developed and technologically sophisticated collection systems. In February 2003, high-profile retailers such as –INCLUDEPICTURE "http://proquest.umi.com/images/common/circlei3.gif" * MERGEFORMATINET —Wal-Mart, –INCLUDEPICTURE "http://proquest.umi.com/images/common/circlei3.gif" * MERGEFORMATINET —Target, Toys R Us, Marshall Field's, and –INCLUDEPICTURE "http://proquest.umi.com/images/common/circlei3.gif" * MERGEFORMATINET —Mervyn's began voluntarily collecting sales taxes from their online customers. However, substantial nexus is the keystone of a state's taxing jurisdiction over remote sellers. If substantial nexus does not exist between the state and a remote seller (whether an Internet seller or not), the state may not validly impose tax liability on the remote seller or require it to collect and remit such tax. Perhaps, just as the Internet added new confusion to the

area of sales and use taxation, emerging technology-based alternatives may eventually help Internet sellers efficiently carry some of the burdens of multistate tax compliance (Trealease & Storum, 2003). A system currently being used in Europe contains most of the features that states would find necessary for the proper and efficient collection of their taxes. The European Union has worked out a system where all 15 members impose hefty value-added taxes and all retailers must collect the tax for all sales within the union. That is, an Internet purchase made in Germany by a customer in Portugal gets taxed at the VAT rate for Portugal; the German seller collects it. United States negotiators are working with groups internationally to come to some understanding regarding these complex issues (Landers, 2000). State and local governments have acknowledged that their system of sales and use taxes must change in a substantial manner if they are to remain viable in the 21st century.

CONCLUSION

Seven criteria have been laid out for use in designing an acceptable cyber tax system. The system should be equitable and simple, ensure user confidence, prevent tax evasion and economic distortion, maintain a fair balance among countries, and not introduce a new form of taxation (Lee & Hwangbo, 2000). Without the assurance of a uniform nationwide approach, even the most sophisticated technological solution will collapse. It is critical to resolve the e-commerce taxation issue by finding a feasible way to implement a multi-state system for collecting taxes from literally hundreds of tax jurisdictions across the country. The Streamlined Sales Tax Project has been launched by some 30 state governments "to develop a radically simplified sales and use tax system that eases the burden of state use and tax compliance for all types of retailers, particularly those operating on a multi-state basis" (Rankin, 2000). The outcome will have long-term consequences for U.S. retailing, and, according to some, for the American system of government itself.

KEY TERMS

Double Taxation: When the same taxable item is taxed more than once by either the same or by different government agencies, there is said to be double taxation. The juridical type of double taxation happens when comparable taxes are imposed by two or more taxing jurisdictions on the same taxpayer in respect of the same taxable income or capital.

E-Commerce: Conducting commercial transactions on the Internet, where goods, information or services are bought and then paid for.

Moratorium: Temporary suspension of payments due under a financial or tax agreement. For example, a governmental body may offer a tax moratorium as an incentive to entice a business to locate and/or start up operations in its jurisdiction.

Nexus: The general concept of some connection or link to the taxing jurisdiction. In the U.S., jurisdiction for levying taxes has a Constitutional basis.

Sales Tax: An excise tax imposed on the transfer of goods, typically at retail. States vary as to whether the tax is imposed on the seller of goods or on the buyer; however, sales taxes are almost universally collected from the purchaser at the time of sale.

Use Tax: A complementary or compensating tax imposed by all states that impose a sales tax. Use taxes are typically charged on the "storage, use, or consumption" of goods in the taxing state. Liability to remit use taxes usually falls on the buyer of taxable property or services. Since it is administratively difficult to compel individual self-assessment of use taxes, most of those taxes will go uncollected unless the states can compel sellers to collect them. Significantly, a state may impose use tax collection responsibilities on Internet sellers if they have nexus with the state. The use tax is intended to stem the erosion of the sales tax base when a state's residents purchase taxable goods or services from sellers located outside of the state.

E-Contracting Challenges

Lai Xu

Paul de Vrieze
CSIRO ICT Centre, Australia

INTRODUCTION

A decade ago, IT — through its innovations in business process reengineering — led the way in breaking down the inefficiencies within companies. Firms in the new millennium now face relentless pressure to perform better, faster, cheaper, while maintaining a high level of guaranteed results. Firms must thus focus on their core competencies and outsource all other activities. Working with a partner, however, requires breaking down the inefficiencies between organizations and coping with frequent change across the entire end-to-end value chain. In this new world of collaborative commerce and collaborative souring, a standard business process is simply inadequate. Using e-contracts to build new business relationships and to fulfill e-contracts through the Internet are important trends. E-contracting is however not a new concept. The history of e-contracting can be reviewed from legal and technology aspects.

Over the last 20 years or so, a growing body of research in artificial intelligence has focused on the representation of legislation and regulations (Sergor, 1991). As specific regulations, contracts are used to regulate the actions of two- or multi-party interactions. Gardner (1987) has developed contract formation rules. Her work concerns legislation about the nature of exchanges that lead to contractual relations. The ALDUS project and Legal Expert project investigated drafting the Sale Goods contract (ALDUS, 1992) and the United Nations Convention on contracts for the international sale of goods (Yoshino 1997, 1998), respectively. Detailed information on developing logic-based tools for the analysis and representation of legal contracts can be found in Daskalopulu (1997, 1999).

The law regards contracts as collections of obligations; research in this area includes automated inference methods, which are intended to facilitate application of the theory to the analysis of practical problems. The purpose of a legal e-contracting system is to clarify and expand an incomplete and imprecise statement of requirements into a precise formal specification.

In the early 1990s, the development of EDI (electronic data interchange) was a significant movement for electronic commerce. EDI was considered a term that refers solely to electronic transactions and contracts (Justice Canada, 1995). EDI requires an agreement between trading partners that not only dictates a standard data format for their computer-to-computer communications, but also governs all related legal issues of EDI usage. In 1987, the first set of EDI rules was named the Uniform Rules of Conduct for Interchange of Trade Data by Teletransmission (UNCID, 1987). In 1990, the American Bar Association (ABA) published a Model Trading Partner Agreement and Commentary, together with an explanatory report (Winn & Wright, 2001). In 2000 IBM submitted to OASIS (for standardization) the first example of an XML-based EDI TPA language, called Trading Partner Agreement Markup Language (tpaML).

While the EDI standard introduced efficient communication channels between companies, its implementation was not widely accepted due to its high installation costs, lack of flexibility, and technological limitations (Raman, 1996). With the development of the Internet, electronic contracting began to be interpreted in broader terms. In this new view, an e-contract is not only used as a legally binding agreement between a buyer and seller, but it can also used across different workflow systems to cross different organizational business processes (Koetsier, Grefen, & Vonk, 1999; Kafeza, Chiu, & Kafeza, 2001; Cheung, Chiu & Till, 2002) to integrate different Web services (Cheung et al., 2002, 2003). E-contracting has become synonymous with business integration over electronic networks.

BACKGROUND

New technologies, the Internet, and other networks have changed business environments and provided the trading processes in e-business more efficiency. Legal regulations, such as the European directive for electronic signatures (EU Directive, 2000) and national e-commerce regulations, have set up a framework for using electronic contracts in business. Concepts of e-contracts under the network environment definitely have different characteristics than the concepts for traditional paper contracts. Whereas a paper-based contract document is a static view on the obligations, an e-contracting system could monitor the responsibilities of each contractual party and the performance of the obligations.

In a networked environment, the definition of the concept of e-contracts can be emphasized as "a contract is a guarantee" or "contracts build new business collaborations between contractual partners" (Xu, 2004a). First, the contract provides a guarantee to all contractual partners according

to the clauses of the signed contract and relevant laws. An agreement between consumers and retailers in B2C commerce is a typical example of "a contract is a guarantee." The agreement provides protection to both consumers and retailers. Second, contractual partners build a business relationship using a contract such as an "arm's length transaction." Two (or multi) parties who used different workflows can cooperate using e-contracts to support business automation (Koetsier et al., 1999; Kafeza et al., 2001). Web service composition can also be implemented using e-contracts. There also exist some e-contract applications that actually cover both sides' concepts. For instance, Trading Partner Agreement (TPA) in ebXML provides a guaranteed business exchange with a certain quality. It also specifies a long-term business relationship/collaboration between partners to conduct the business. It is important to realize though that the concept of e-contract has only a partial overlap with the concept of a paper contract. Both have features that do not have their representation in the other one.

Under electronic communications, e-contracting processes have their unique characteristics. The result of e-contracting, the contract, is a semi-structured document, which stored in any format (e.g., MS Word, PDF, or XML, etc.). Most e-contracts contain semi-structured information, such as XML-based words, sentences, clauses, or meta-information. Furthermore, some e-contracts have the legal status of digital documents. Depending on whether networks are used during the e-contract establishment stage, e-contracts can be created online (i.e., through networks) or electronically without networks. The collaboration in the contract formation phase can be asynchronous (e.g., by e-mail) or synchronous (e.g., through online collaboration). Moreover, the e-contracting process can be finished on a shared platform (e.g., e-marketplace) or be interconnected between contractual partners. The ownership of the contracting platform can thus be with a third party (ASP) or with the contractual partners. The e-contract can be fulfilled online (e.g., digital goods, services) or off-line (e.g., physical goods). As e-contracts serve different purposes, different opportunities will bring extra values during the e-contracting stages. For example, in the contract execution/performance stage, extra monitoring information can be provided by different messages over networks. This is a significant difference with traditional contracting.

In short, e-contracting can protect contractual partners in electronic environments, reduce time-to-contract, and reduce process costs. It can also provide new opportunities on contract management, contract content re-use, and contract monitoring. Benefits of e-contracting are:

- Avoiding errors,
- re-using content after closing,
- reducing time-to-contract,
- providing machine-processable document,
- minimizing risks in a contractual agreement for ad-hoc business relationships over public networks (such as the Internet), and
- reducing contract management costs.

E-CONTRACTING

Although there exist different descriptions for the e-contracting process (Milosevic & Bond, 1995; Goodchild, Herring, & Milosevic, 2000), the general e-contracting process includes two stages: contract establishment (contract formation) and contract enactment (contract performance or contract fulfillment) (Xu, 2004a; Angelov, 2005). E-contracting activities such as identifying, checking, and validating of contractual parties, negotiation, and validation contract are included in the stage of contract establishment. The contract enactment is further separated into two phases: performance and post-contractual activities. Monitoring of contract performance and compensation activities belongs to the contract performance phase, while contract enforcement may be involved in both the contract performance and post-contractual activities.

The research area of electronic contracting focuses on negotiation of the terms and conditions of the contract and the monitoring of contract performance (Lee, 1998). Contract negotiation is described as the process in which contracting parties come to a mutual agreement on the contract content. Contract negotiation can be performed with or without the help of a third party. There are three critical aspects for the negotiation of a contract (Burgwinkel, 2002a). First, the subject of the contract needs to be defined exactly. Second, the legal validity is formulated. Third, the price and conditions of each clause need to be negotiated in relation to the quality of deliverables and the quality of services, and in relation to the legal terms.

Contract monitoring is the process of observing the activities performed by the parties for the purpose of proactive imminent contract violations or detecting contract violations. To prevent undue costs, it is important for the contractual parties to monitor the performance of the other collaborating parties, especially if the transactions are business critical. The monitoring of contract performance can be split into two parts divided by the occurrence of an anomalous action (Xu & Jeusfeld, 2003; Xu, 2004a). The part preceding the occurrence of anomalous actions is called the proactive monitoring of contract performance. The part following it is called the reactive monitoring of contract performance. In the proactive monitoring stage, anomalous actions can be avoided and anticipated before contract violation occurrence — for example, by warning about impending deadline violations. In the reactive monitoring stage, anomalous actions can be detected, the partners who are responsible for the violations need to be identified, the relevant partner needs

to be compensated, and unsolvable disputes can be stored for future, human-involved resolution.

Contract enforcement is the process of persuading the noncompliant party to perform corrective actions. Contract enforcement can be performed in three ways: proactively (through constraints provided in the contract), reactively (via auxiliary corrective measures aiming at minimizing the deviations from the contract), and post-contractually (by constraining future activities of that company in this domain) (Angelov, 2005).

In order to format and fulfill a contract electronically, e-contracts must be managed. There are different views to look at contract management. From a contract platform view, contract management includes:

- A single repository for all contracts, related documents, and information to users;
- searching, reporting, and reusing capabilities to access all information in contracts and attachments;
- capabilities partners to track and monitor key performance indicators (KPIs) and performance over the contract execution, and use this information to target improvement actions and to determine preferred status, rankings, and so forth;
- maintenance of different versions of contracts, automatically reconcile changes to terms and clause language, and compare different versions;
- clause and template library to capture standard and alternate clauses along with guidelines; and
- alerts and reminders to inform contract partners of any upcoming dates, events, and milestones.

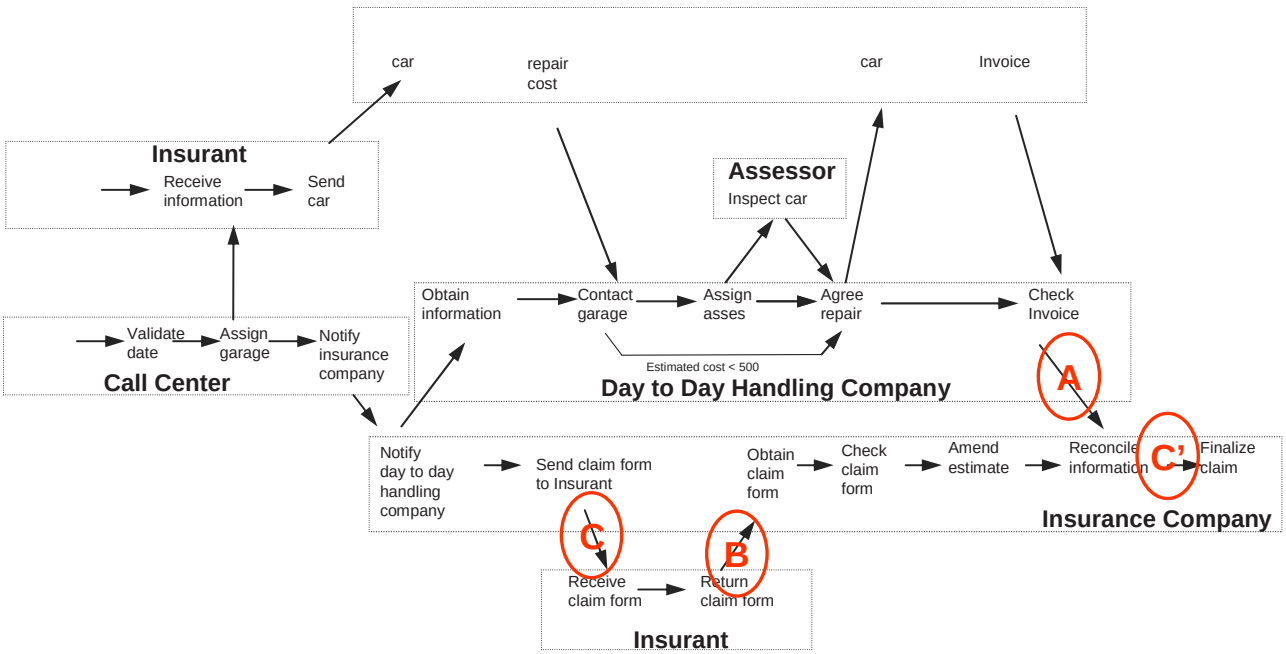
From one contractual party point of view, both its supplier and customer contracts need be managed. Moreover, the interrelation between these internal and external obligations, rights, and penalties must be synchronized.

MULTI-PARTY CONTRACT CASE AND ISSUES

We provide a multi-party contract case to explain the existing issues in multi-party contract execution. The case outlines the manner in which a car damage claim is handled by a car insurance company. The contract parties work together to provide a service level that facilitates efficient claim settlement. The parties involved are a call center, a day-to-day handling company, a group of garages, and an association of assessors. The call center is responsible for registering the insurant information, suggesting an appropriate garage (most times a close-by garage is assigned), and notifying the insurance company about the insurant's claim. The day-to-day handling company coordinates and manages the operation on a day-to-day level on behalf of the insurance company. A group of garages is assigned to assess car damages and to repair damaged cars for an insurant, who has bought car insurance from the car insurance company. The assessors conduct the physical inspections of damaged vehicles and agree upon repair figures with the garages.

The general processing of a claim in the car insurance case is as follows (see Figure 1): The insurant phones the call center using a toll-free phone number to give notification of

Figure 1. Process of car insurance case



a new claim. The call centre will register the information, suggest an appropriate garage, and notify the car insurance company, which will check whether the policy is valid and covers this claim. After the car insurance company receives this claim, the car insurance company sends the claim details to the day-to-day handling company. The car insurance company will send a letter to the insurant to ask for a completed claim form. The day-to-day handling company will agree upon repair costs if an assessor is not required for small damages; otherwise, an assessor will be assigned. The assessor will check the damaged vehicle and agree upon repair costs with the garage. After receiving an agreement for repairing the car from the day-to-day handling company, the garage will then commence repairs. After finishing repairs, the garage will issue an invoice to the day-to-day handling company, which will check the invoice against the original estimate. The day-to-day handling company returns all invoices to the car insurance company. After the car insurance company also receives the completed claim form from the insurant, the payment is processed. In the whole process, if the claim is found invalid, all contractual parties will be contacted and the process will be stopped.

There are many potential contract violations in this case; for example, after sending invoices to the day-to-day handling company, the garage does not get money back from the car insurance company. It could be caused, for example, by:

- The day-to-day handling company, because it does not forward the invoices to the car insurance company (Figure 1, with mark A);
- the insurant, because the insurant did not return the completed claim form to the car insurance company (Figure 1, with mark B);
- the car insurance company, because the car insurance company forgot to send the claim form to the insurant or simply because it did not pay the garage in time (Figure 1, with mark C and C'); or
- any combination from above.

Contract Specification

A multi-party contract is specified as a set of actions, a set of commitments, and a commitment graph of a contract. An action is specified as *action = (name, sender, receiver, deadline)*. For example, Action (A_agreeRepairCar,L,G",3) describes agreement of the day-to-day handling company for the garage to repair the car and that the day-to-day handling company has three days to respond.

A commitment is specified as *commitment = (name, sender, receiver, n, {(a_1, u_1), (a_2, u_2), . . . , (a_n, u_n) : ai — A, ui — U})*. An example of a commitment, *C_repairService* is specified as *(C_repairService,G, P,{(A_sendCar, tr), (A_estimateRepairCost, fi), (A_agreeRepairCar, tr), (A_repairCar, fi)})*. The garage will offer the repair service to the insurant. After the insurant sends his or her car to the garage (action *A_sendCar* has a trigger attribute), the garage estimates the repair costs (action *A_estimateRepairCost* has a finish attribute). After the garage receives an agreement from the day-to-day handling company about the repair costs (action *A_agreeRepairCar* has a trigger attribute), the garage repairs the car (action *A_repairCar* has a finish attribute).

Due to space limitation, readers are referred to Xu (2004a) and Xu, Jeusfeld, and Grefen (2005) for more details on multi-party contract specification and formal reasoning.

FUTURE TRENDS

Several technological, business, and legal hurdles must be overcome to establish e-contracting as a collaboration technology.

Multi-Party E-Contract vs. Multiple Bilateral E-Contracts

Little research has been done on multi-party contracts. Almost all research on multi-party contracts tries to break down a multi-party contract into a number of bilateral contracts (Xu et al., 2005). The semantics of a multi-party relationship are not always the same as multiple binary relationships. Only in some cases is it possible to see multi-party contracts as multiple binary contracts without losing valuable information. However, as more multi-party relations develop between companies, more contracts will be in force that would result in loss of information and increased complexity if relationships got hidden. The issues of how to represent or model multi-party e-contracts, how to identify the responsible partner(s) for a contract violation, and how to provide extra services for multi-party contracting (e.g., proactive monitoring functions) are critical in the area of e-contracting.

E-Contracting Challenges on Modeling and Representing Contractual Relationships

Existing contract models, such as the e-contracting logic model (Lee, 1998), aim to improve both expressiveness and inferential capabilities of the contracts. The model proposed in Weigand and Xu (2001) focuses on task allocations and process coordination. The proactive monitoring contract model (Xu, 2003, 2004a) and multi-party contract model (Xu, 2004b) provide contract models for different objects. These models represent trading contracts.

A model for e-contracts needs to present an integrated view on both the regular contracts and the technical agreement to be able for e-contracts to be fulfilled over networks. XML-based e-contracts have been investigated by several

research projects: SeCo (Greunz, Schopp, & Stanoevska-Slabeva, 2002), COSMOS (Merz, Griffel, Boger, Weinreich, & Lamersdorf, 1999), OCTANE (Kühne, Jungemann-Dorner, & Lam, 2001), and eLEGAL (Carter, White, Hassan, Shelbourn, & Baldwin, 2002). An XML-based electronic contracting editor is currently developed and can be deployed in different contract domains (Burgwinkel, 2002b). It enables all collaborating parties to create contracts from existing templates, to exchange and negotiate them, and finally to sign them over the Internet. The contract is a domain-specific XML document. The semantics of legal clauses can be expressed using clause types and structuring rules for legal documents. The e-contracts can be signed electronically using XML signatures. Ponton X/E, a visual XML editor, was developed by the German Ponton consulting company. The possibilities and limitations of XML-based e-contracting are discussed in Burgwinkel (2002b). Applying Semantic Web technology and business rules for e-contracting is studied in Grosof (2001).

There are some specific communities that publish standards and rules for the formation of contracts, such as the International Chamber of Commerce's model international sale contract (*www.modelcontracts.com*) and the Swiss IT association.

E-Contracting Challenges on Negotiation

Electronic environments have a great impact on contract negotiation. The benefits of e-negotiation could reduce the need for face-to-face meetings and traveling, improve the quality of agreements and mutual satisfaction, and reduce the damage caused by lasting and unresolved disputes. Contracts can be negotiated by exchange of messages over networks or using a negotiation platform. Studies on e-mail negotiation have shown that trading partners behave differently in electronic negotiation than they would in a face-to-face meeting (Shell, 2001). E-negotiation is a challenging task from the legal as well as from the business point of view. New laws and new legal frameworks for e-contracting such as building e-notaries are needed. User acceptance, security, and confidentiality are also important challenges of e-negotiation.

E-Contracting Challenges on Monitoring

A considerable amount of recent research and industrial application effort has concentrated on the provision of standards for automated establishment and subsequent implementation of electronic contracts. In general terms, an e-contract between multiple business partners contains some statements about their business relationship — in particular, on their physical and informational interactions over networks. One purpose of such an e-contract is to distinguish expected and acceptable behavior from behavior violating some clause in the multi-party contract. During the contract fulfillment, all necessary messages will be exchanged over networks. Those messages, events, or actions of contractual partners can be used to provide extra information for (proactive) monitoring services. Most of the current work focuses on the automation of contracting processes, rather than the development of services for contract fulfillment support, such as monitoring. Value-adding services — such as proactive monitoring and detecting the party (or parties) responsible for a contract violation in multi-party contract performance — are the new opportunities as well as the key issues for realizing a trustworthy e-commerce environment.

E-Contracting Challenges on Contract Management

When a company is engaged in many contractual business relationships, all using different e-commerce standards, management of the relations between the contractual parties and their e-commerce service providers becomes especially interesting. For each contractual party, it is important to monitor the performance of their providers, especially if the transaction is business critical, such as a payment service with a guaranteed payment.

Besides, from one contractual party's perspective, challenges for contract management are being able to achieve the maximum benefit of a contractual party, pre-calculating the cost of the contract violation, and trying to reduce the potential costs.

Currently, some contract management applications are offered by Dicarta and Oracle.

CONCLUSION

Electronic contracting affects the traditional roles and attitudes of sales and purchasing departments as well as lawyers. Growing IT support for contract management will provide assistance in handling the growing complexity of contractual relationships.

As an important component for trusted e-business in a global environment, e-contracting will help to reduce time to contract, improve the collaboration between the trading partners, and reduce minimize financial and legal risk. However, deployment of e-contracting has great challenges from the technical, business, and legal view. To handle the complexity of the setup and operation of contractual relations based on e-contracts, further research is needed.

KEY TERMS

Business Collaboration: A set of activities or processes that lead to the accomplishment of an explicitly shared business goal by coordinated business parties; involves at least two autonomous business parties.

Contract: A legally binding exchange of promises or agreement between parties that the law will enforce.

Contract Enforcement: The process of persuading the noncompliant party to perform corrective actions.

Contract Monitoring: The process of observing the activities performed by the parties, knowing the state of contract execution and detecting contract violations.

Contract Violation: Refers to breaking or failing to comply with a term of the contract by a party.

E-Contract: A contractual agreement, represented as digital information and signed with digital signatures of the parties.

E-Contracting: The processes of formatting and negotiating of contracts electronically, and also monitoring the contract performance over networks.

E-Negotiation: Negotiation over networks where interested parties resolve disputes, agree upon courses of action, bargain for individual or collective advantages, and/or attempt to craft outcomes that serve their mutual interests.

eCRM Marketing Intelligence in a Manufacturing Environment

INTRODUCTION

This article examines the issue of electronic customer relationship management (eCRM) in a manufacturing context. ECRM has been described as the fusion of a process, a strategy, and technology to blend sales, marketing, and service information to identify, attract, and build partnerships with customers (Bettis-Outland & Johnston, 2003; Jaworski & Jocz, 2002). Although some customers still pay a premium for face-to-face or voice-to-voice interaction in today's high-tech world, through external (e.g., advertising) and internal (e.g., word-of-mouth) influence, the diffusion of the use of eCRM to build and sustain customer loyalty as a firm's strategy is on the rise. Manufacturers use the knowledge of their customers' needs and preferences to manage profitable customer interactions. This increased use of eCRM as a new manifestation (technological consolidation) of firmly established customer relationship management techniques has been shown to improve customer relationships and enhance customization (Kennedy, 2006).

BACKGROUND

Before the 1930s, the production era in which firms pushed to be the "provider" of products, whether customers needed, wanted, or could afford them was prevalent. From the 1930s to the 1960s, the selling era dictated the commerce arena in which salespersons were encouraged to make sells, regardless of costs. The onset of the 1960s to the 1990s portrayed the infancy of the marketing era in which the marketing concept (or satisfaction of the customer) laid the historical foundation of eCRM. From the 1990s, the partnering era has predominated and some functions previously performed by marketing have become absorbed into other functional areas such as manufacturing. Today, value lies within customer relationships that are satisfying to both the customer and the company. Applying principles to marketing that are enabled by technology with huge reservoirs of data, empowered by insight, and informed by history can provide the ROI that firms expect. Customer satisfaction is, in many cases, considered on par with revenue and profits as the performance metric by which companies are measured (Wu & Wu, 2005).

VALUE OF ONLINE SPACE

In reaching the maximization of value, businesses must define value, deliver it, and communicate it to customers. Value to the customer is his or her perception of the use of a product or service in relation to expectations. Managing the flow and not just the manufacturing process itself allows manufacturers to reduce non-value adding activities. Having the tools and enablers in place to integrate and automate processes allows all organizations to have marketing performance data (Freeland, 2003). Drivers of value differ in physical (off-line) and online places. Krishnamurthy (2003) viewed online operations as either profit centers (sources of income) or loss centers (offered as service to consumers). The 4 Ps (product, price, place, and promotion) primarily drive physical places. Online, the 6 Cs are the drivers—commerce, content, communication, connectivity, community, and computing (Krishnamurthy, 2003). *Commerce* describes the selling of products from the manufacturing, distribution, and retail firms to customers. Included in this category are the large businesses buying from other businesses in electronic marketplaces. *Content* is applicable to the news publishers (e.g., CNN, *New York Times, etc.)*, e-books, or companies using the Internet to educate their customers (e.g., Procter and Gamble at Crest.com). *Communication* involves Web-based seminars, Internet company meetings, and e-mail-based customer service. *Connectivity* refers to

the interconnections that employees and users have through the use of the Internet or other knowledge management tools. *Community* is portrayed through special user groups. *Computing* is manifested through tools such as mapping software, tracking software, and other portfolio management tools that empower customers. Manufacturers build online trust and commitment and potentially increase their value to customers by designing interactive Web sites (Merrilees, 2002). As businesses expand internationally, *culture* needs consideration as a seventh "C" as companies develop online experiences for their customers (Sigala, 2006). An organization's attitude is now its lifeblood. Integrating online operations with physical operations and leveraging company assets provides synergy between physical and online stores—a key to effective eCRM.

DIGITALITY

Digitality refers to the proportion of a company's business that is online (Krishnamurthy, 2003). The digitality of a business lies between zero and one. A business that is completely online with no physical components has a digitality of one. An example is one in which all employees telecommute, digital products such as software are sold, and customers communicate directly with the company's Web site. Alternatively, businesses with no representation in the online space have a digitality of zero. Most manufacturing firms would have digitality close to zero, except those that have incorporated online activities like Dell or Boeing.

MANUFACTURING PROCESSES

Manufacturing processes are the most likely places for sources of innovation and are probably 10 years ahead of service or customer-facing processes (Dixon & Duffy, 1990). Although speed of production still reigns in importance in manufacturing processes, the quality of the manufactured product, the flexibility to manufacture different types of products, reliable, predictable adherence to manufacturing timetables, and lowering of the cost and price of products must be matched against the marketing, engineering, and manufacturing capabilities for firms to become world-class competitors in the eCRM world (National Center for Manufacturing Services, 1990).

Typically, sales, manufacturing, and logistics are tightly woven. In coordinating manufacturing with sales, companies attempt to manufacture products and quantities to customer specifications and to minimize delays in delivery. This process has been described as the "lean production system" in automobile manufacturing (c.f. Davenport, 1993). In consumer foods processing, sales and manufacturing are driven to retail, wholesale, and distribution outlets by consumer demand. A common eCRM tool used is the salesperson's handheld computer that assists with the aggregation of store-level data, enabling linkages to materials and inventory systems, logistics, and sales departments.

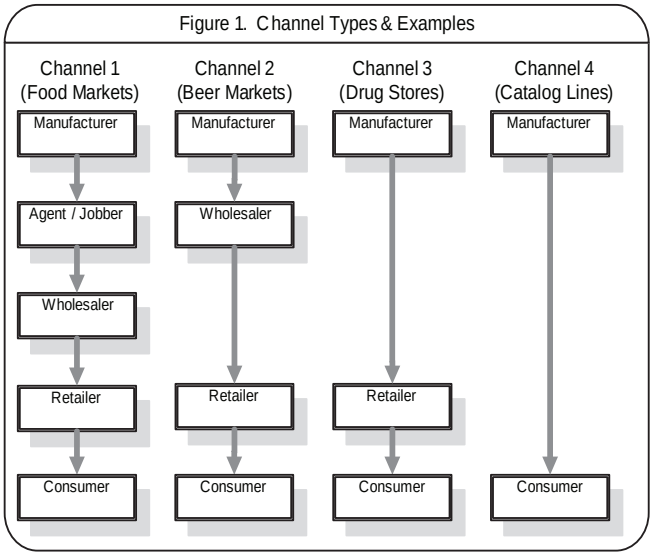
Equipment maintenance is another key area in which knowledge and information must be shared in a manufacturing environment to avoid downtime or scheduling and resource requirements conflicts. Radical changes, even lofty customer-initiated improvements, have to be phased in incrementally due to interfaces with legacy systems and logistical concerns in manufacturing arenas, regardless of the company's eagerness to be customer responsive. Many companies innovating with eCRM to coordinate the procurement and delivery of goods, on the outbound logistics side, find it advantageous to use just-in-time delivery or electronic data interchange to shorten the order-to-delivery cycle (Borders, Johnston, & Rigdon, 2001). Intense global competition and less loyal but more sophisticated customers are demanding a growing corporate emphasis on just-in-time marketing to make it faster, cheaper, and better to get products into the marketplace (Freeland, 2003). Manufacturers had to change from merely managing the direct labor content and variances in component costs to optimizing throughput and quality. ECRM data, along with the appropriate integrated technology speeds execution and improves information delivery to the point of need. From this workbench, the different stakeholders have information tailored to meet their needs. Finished goods customization, in some instances, is created only to fill customer orders and to ship goods to the customer, eliminating the need for warehousing. Customers with great bargaining power relative to their suppliers often initiate influence tactics that force suppliers to deliver on rapid, short terms (Borders, 2006).

DISINTERMEDIATION

In many cases, the Internet has become another sales channel with complementary features for bricks-and-mortar stores. The role of intermediaries is to facilitate buyer-seller transactions. Understanding disintermediation (the process of eliminating intermediates) requires familiarity with traditional business-to-business channels. Figure 1 illustrates business-to-business channels 1, 2, and 3.

In Figure 1, channel 1 is common in food markets, channel 2 in beer markets, and channel 3 in drugstore lines. Channel 4 is pervasive in the catalog line. Because the Internet makes it easy and relatively inexpensive to interact with customers directly, disintermediaries must prove their value. Channel 4 represents a business-to-consumer (B2C) disintermediated channel in which brokers or infomediaries prevail, as follows:

Figure 1. Channel types and examples



B2C intermediaries:

- Brokers (facilitate transactions, charge a fee on transactions)
- Infomediaries (serve fulfillment roles, act as filters between companies and consumers, sell market research reports, and help advertisers target their ads (e.g., ETrade), virtual malls that help consumers buy from a variety of stores, etc.)

Other disintermediated channels are consumed by metamediary figures to encourage procurement activity. These channel members offer consumers access to a variety of stores or provide transaction services and include search agents (e.g., My Simon, that helps consumers compare different stores); bounty brokers that charge a fee to locate a person, place, or idea, (e.g., Bounty Quest); or advertisement-based businesses (pop-ups, banners, other Internet linkages). In disintermediated channels, the major challenges that manufacturing firms face include building online traffic and sustaining customer loyalty and derived demand.

DERIVED DEMAND

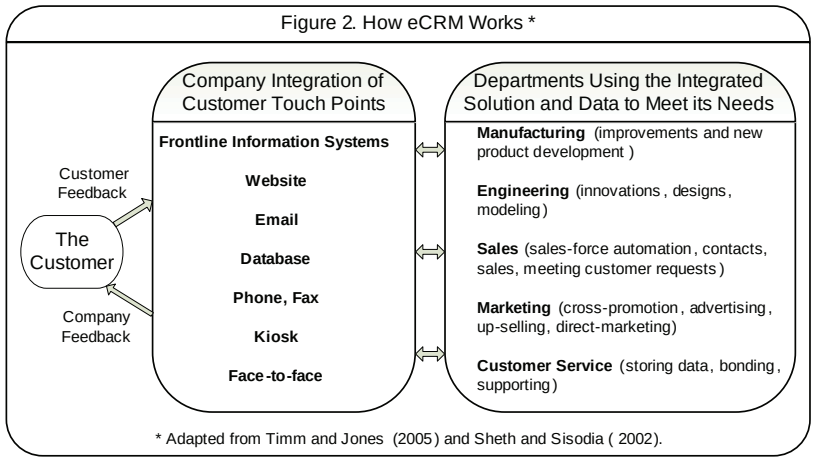
Once a manufacturer builds customer traffic, switching costs for the customer increase. The provision of detailed personal and payment information, and "mental transaction costs" relating to trust and privacy by using too many vendors, can be costs that customers will choose to avoid. In employing eCRM, firms should use the appropriate mix of low-tech, middle tech and high tech tools to acquire customers and satisfy them, and the appropriate metrics should be in place for low-profit or high-profit customers.

Krishnamurthy (2003) recommended that firms steer clear of too much eCRM customization and characterized online customers as simplifiers, surfers, bargainers, connectors, routiners, and sportsters. *Simplifiers* respond positively to easier and faster on- than off-line experiences. *Surfers* like to spend a lot of time online, thus companies must have a huge variety of products and constant updates. *Bargainers* are looking for the best price. *Connectors* like to relate to others. *Routiners* want content. *Sportsters* like sports and entertainment sites. Manufacturers target and build positive brand associations through opinion leaders that identify and attract customers most economically (Krishnamurthy, 2003). This subset of market segmentation, also described as "customer profiling," is conducted through data mining or optimization searches from consumer data as well as internal information systems (Padmanabhan & Tuzhilin, 2003). Once these customers begin using the products, they serve as role models and influencers of others in their communities and subcultures in the persuasion of purchasing products.

HOW ECRM WORKS

Successful e-commerce operations involve three elements (Figure 2)—Internet technology, a business model, and marketing (Krishnamurthy, 2003). ECRM describes an Internet-enabled system that leverages the power of the Web to deliver the best possible customer experience. The cost per customer runs from a low of $5 for individual customers to a high of $6,244 for business customers (Chatham,

Figure 2. How eCRM works



2001). Figure 2 shows how eCRM works by connecting the customer to different departments that need and make use of an integrated data solution.

Effective eCRM solutions create synergy among sales, marketing, and customer service activities. With multiple customer contact points, time frames, and systems, customer conversations can be disruptive and content lost, if they are not managed properly. eCRM consolidates customer information, such as personal data, preferences, inquiries, and order information and eliminates customers being given the run-around from department to department. eCRM is a supportive technology, whereby timely, targeted, personalized information and solutions are possible for customers.

ONLINE KNOWLEDGE

The quality of the online customer relationship is influenced by the *interactivity* between the customer and the firm, as mediated by the computer (Merrilees, 2002). Interactivity is described in terms of communication as follows:

1. The ability to address someone
2. The ability to gather information and responses from someone
3. The ability to re-address the individual with a unique response (Deighton, 1996)

Internationally, as well as in the United States, utilization of online knowledge (and often proactive database research) on the part of manufacturers has increased customer satisfaction and demand, as well as produced changes in organizational structures of firms (Stefanou, Saramaniotis, & Stafyla, 2003). It is prudent to use a database to target different consumers for different direct mail campaigns. However, junk mail (online or off-line) should not be directed at customers merely because the firm has customer contact information. On the other hand, some customers such as "surfers" welcome any contact with the firm. What might be right for a financial institution may be entirely wrong for a small appliances manufacturer. eCRM allows for the creation of the type of relationship that best suits and satisfies the customer's needs. When the information is "siloed" or stored in different places and is not easily accessible or compatible, there is a call for eCRM.

eCRM is embraced through automated quote generations where customers can provide specifications for products (e.g., computers, sales referral tracking, travel expense reporting, account management, and sales activity). By studying Web site traffic, companies are in better shape for advertisement placement, budget preparation, and demographic campaign management.

ECRM AS A SOLUTION

"The true business of every company is to make and keep customers" (Drucker, 1954). The Web has become an outstanding channel for delivery of customer assistance and effective customer support activities. In an eCRM environment, the Web allows customers to troubleshoot their own problems with a computerized assistant guide. In a manufacturing environment, when moving customer support to the Web, a firm might start with a static Web page, similar to an electronic version of a marketing brochure, or an information base of common questions and answers. From the company's perspective, these "low-assistance delayed communication" forms are the least expensive to implement. Self-serve personalized answers such as tracking status, personalized pages, and real-time data are also eCRM

features tailored to meet customers' needs. Self-service can be provided through quick, simple, and accurate global 24/7 representations. Moving past the self-serve common-answer category is a self-learning knowledge base. Manufacturers that encourage customers to use online knowledge to answer their own questions share in the wealth of information gained from service resolution, abandonment rates, average site connect time, and they are able to better serve their customers by improving content site and contact information (Timm & Jones, 2005).

When customers cannot find the answers they need from self-serve sites, they can then turn to e-mail in which customer service representatives respond. In comparing transaction costs per channel, Timm et al. (2005) contended that firms have come to realize that the average transaction cost for Web self-service and interactive voice response (IVR) self-service, ($0.24 and $0.45, respectively) compares more favorably than e-mail and phone customer care ($5.00 and $5.50, respectively).

THE BRICKS-AND-CLICKS BUSINESS MODEL IN THE ECRM MANUFACTURING ENVIRONMENT

In several manufacturing areas, it makes sense to combine online capabilities (clicks) with the advantages of traditional stores (bricks). The Internet allows an additional channel for customers to reach businesses and, in turn, through which businesses can reach their customers. For several product categories, such as furniture and apparel, individuals like to touch, feel, order, or try on the product before buying. Manufacturers set up "virtual dressing rooms" that provide customers the opportunity to try on a dress or shirt or other product before ordering it. Therefore, the bricks-and-clicks models can assimilate the experience of the product. The Internet could be used to locate the store or the variety of merchandise and to keep track of the status of the order.

Partnerships with brick-and-mortar stores can help alleviate delivery problems by providing another outlet for a customer to pick up a delivery that may have been placed online. Likewise, brick-and-mortar outlets that assort several items for shipping, and reduce the cost of shipment per item can aid in returning items to manufacturers. Functionality that makes it convenient for the customer is the motivation behind several eCRM efforts. Deshpandé and Farley (2002) agreed that the appropriate level of customer attention [market orientation] should be what the *customer* thinks it should be.

WHEN A MANUFACTURER MUST CHOOSE

When manufacturers diversify to create new revenue streams (by creating online tangential sales), they expose themselves to new levels of competition and vulnerability. Firms enhance the shopping experience by remembering relevant information about customers that can establish switching costs. They then use the positive brand-associated name to introduce other products through e-mail alerts, and they provide recommendations.

When implementing eCRM, economies of scale can be garnered when spreading costs across greater categories and leveraging the same brand name and customer base. In the electronics business, manufacturers have stringent requirements for retailers on how they will display and sell their products. Thus, after becoming an authorized dealer, one can get lower prices, money for cooperative advertising, and the right to sell warranties. Improved cross marketing, copromotion programs, and customer acquisition are provided when manufacturers such as metal companies, thermoplastics companies, and automobile and airplane manufacturers participate in *buy-centric markets,* whereby large, influential buyers find a place where small and fragmented sellers can sell their goods.

EFFECTIVENESS OF ECRM

The hallmark of eCRM is perceived personalization. It promotes cross selling of additional products, and up selling of more profitable products. Determining the needs and wants of customers and satisfying these needs better than the competition while keeping and strengthening the customer relationship bond is the business of eCRM (Kalwani & Narayandas, 1995). ECRM allows firms to solve the problem (competence), apologize for inconvenience (care), and offer a peace token such as waiving fees (comfort).

FUTURE TRENDS

An interesting aspect of some manufacturers' eCRM strategy is to implement programs similar to Amazon's associates or affiliates program. The thrust behind these programs is to have small sites generate traffic by having content with a link to Amazon or other manufacturers. The originating site receives a commission for referred purchases and a smaller commission for other purchases made by the customer. Amazon's brand enhances the smaller site's presence. Partnering with other businesses that sell products the manufacturer does not is a profitable revenue stream (Timm et al., 2005).

Manufacturing operations and other backroom processes are now absorbing previous frontline customer-facing functions. Large numbers of food products previously sold in bulk to retailers are now being shipped and sold by manufacturers in smaller packages or multiple size packages, as customers demand (Sheth & Sisodia, 2002). Although many agree that eCRM is a business strategy to select and manage the most valuable customer relationships, business processes are aligning with customer strategies to build customer loyalty and increase profits over time (Rigby, Reichheld, & Schefter, 2002). Quantitative approaches to eCRM market targeting and optimization are advancing rapidly. As new methods in this area are indexed, more powerful customer data systems are emerging (Padmanabhan et al., 2003).

Increasingly enabled by new technologies and applications, eCRM is the current generation of marketing intelligence tools for understanding how interactions and relationships with customers influence consumer behavior. While the hallmark of eCRM is perceived personalization, the next wave of marketing intelligence moves from customer "relationship" management to customer "experience" management (CEM). Negroponte (1995) predicted the onset of this capability when he asserted that everything is made to order, and information is extremely personalized. He purported that individualization is the extrapolation of narrowcasting—you go from a large to a small to a smaller group, ultimately to the individual. CEM is focused on defining and understanding the individual characteristics of a customer and having the ability to manufacture and sell that individual extraordinarily customized goods and services. By using real-time customer tracking enabled through the use of radio frequency devices (RFID), global positioning systems (GPS), video, portable shopping devices (PSDs), and analysis of clickstream data, CEM has become a reality (Burke, 2005).

CONCLUSION

Three areas of importance that cannot be neglected in eCRM manufacturing processes are the leveraging of database technology, the value of frontline information systems, and the importance of having the right employees (Sheth et al., 2002). Leveraging database technology leads to better targeting of and maintenance of customers. The frontline information systems (FISs) approach allows customers and frontline employees to be at the cutting edge of information technology that supports relationships and directly impacts customer satisfaction. Having employees that are responsive, courteous, professional, and competent improves a firm's productivity, profitability, and employee and customer satisfaction. Considering the operating costs of serving customers over time and the costs of customer turnover, manufacturers may find the value from customer loyalty, behavior, and satisfaction far exceeds the costs of implementing and maintaining appropriate eCRM systems (Jones & Sasser, 1995; Kundisch, Wolfersberger & Kloepfer, 2001).

KEY TERMS

Commerce: The selling of products from the manufacturing, distribution, and retail firms to customers.

Connectivity: The interconnections that employees and users have through the use of the Internet or other knowledge management tools.

Customer Profiling: Selecting customers you want to find, going after them, and keeping them.

Digitality: The proportion of a company's business that is online.

Disintermediation: The process of eliminating intermediaries in the channels of distribution.

eCRM: The fusion of a process, a strategy, and technology to blend sales, marketing, and service information to identify, attract, and build partnerships with customers.

Interaction Management: An entire system that monitors customer communications at every possible contact point, regardless of source (i.e., Web, telephone, fax, e-mail, kiosks, or in person).

Knowledge Base: An online repository of information that represents the collective wisdom regarding a product or service.

Education for Library and Information Science Professionals

Vicki L. Gregory
University of South Florida, USA

INTRODUCTION

Libraries and information centers today are very different places from those that existed at the beginning of the 20th century, and very different as well from the libraries of only 25 years ago. Education for library and information science has striven to keep pace with all the myriads of changes. Within the last 100 years, fortunately and necessarily in order to retain its relevance, professional library education and practice has evolved from the centrality of teaching and writing the "library hand" to providing modern curricula such as services for distance learners and Web-based instruction using course management systems such as Blackboard, WebCT, and so forth. Along the way, the library profession has often been first not only to accept but also to adopt and apply the technological innovations now common to modern civilization. One of the newest trends involves the "I-Schools" where information is taught as the overarching discipline with librarianship just one of the programs in a larger college offering programs in informatics, information science, information architecture, knowledge management, and so forth. Throughout, library and information science educators have paved the way to the acceptance of innovation in libraries and information centers by instructing students to use and apply new technologies.

BACKGROUND

The revolutionary changes over the past 25 years in the educational curriculum for schools of library and information science, which are necessitated by the exponential expansion of computer-based technologies, require an almost constant and continuous reexamination of the skills and expertise needed to be acquired by the next generation of librarians. Although much has changed in libraries, the core of who we are and what we are truly remains the same. Librarianship is and will continue to be a profession devoted to bringing users and information together, as effectively and efficiently as possible. To meet that ideal, librarians have used technology to enhance and create services. In addition, it is important to meet emerging educational needs of our increasingly multicultural and diverse society. Librarians have recognized that changing expectations and lean budgets require organizations to call upon the talents of everyone (Butcher, 1999). And, librarians have become more engaged in teaching and research in order to serve the needs of users better (Bahr & Zemon, 2000).

THE I-SCHOOLS

The I-Schools are a group that has been coming together over the last few years of schools/colleges that are taking a broad approach to the study of information. The deans and faculty of those schools held their first conference in September of 2005 to explore the similarities and differences among the schools present and basis upon which to build a foundation for a new type of College. The I-Schools include a number of schools with traditional LIS programs such as Syracuse, Pittsburgh, Rutgers, and others, plus a number of other programs such as the College of Information Sciences and Technology at Pennsylvania State University. John King describes the I-Schools thusly:

The I-School movement is made up of novel academic programs that embrace new intellectual and professional challenges in a world awash in information. I-Schools move beyond traditional programs, while building on the intellectual and institutional legacies of those programs. I-Schools straddle the academy's ancient engagement with information and the contemporary challenges of ubiquitous information affecting all aspects of society. (King, 2006)

The I-Schools bring together a variety of disciplines that are scattered among different colleges and departments into one college of information. Some areas of what is traditionally in computer science departments are also a part of this movement (Carroll et al., 2006). The proximity and interaction among these programs by being brought together in a new college should lead to an enriched research and teaching environment.

IMPORTANCE OF PEOPLE AND PEOPLE SKILLS

Computer technologies and communication systems have had an undeniable impact on society as a whole and our

profession, but it is also critical to remember the importance of the individual and of the need for interpersonal skills in our profession, which at its heart remains basically a "people profession." We harness technology for a reason—to promote learning and the dissemination of information—and we do not simply revere technology for its own sake. With the aid of computer specialists, we could design the best information system imaginable, but unless it operates in a manner that is accessible to people, nobody will use it. The ability of librarians (whether through collecting, organizing, or retrieving information) to act as intermediaries between users and the world's information resources will, in my opinion, never become outdated (Gilbert, 1998). In sum, the rapid changes in all types of libraries and the burgeoning of new technologies for librarians to learn, while increasing the amount of information that students need to have under their "academic belts" if they are to enter successfully into a library career, nevertheless remain rooted in the need to carry out the traditional librarian roles—though hopefully faster, cheaper, smarter, and more effectively.

PREPARING STUDENTS IN TRADITIONAL AREAS OF LIBRARY RESPONSIBILITIES

The traditional heart and sole of a library is and remains, of course, its collections—from the time of the great Alexandrine library of the Classical era, libraries have been, in essence, civilization's repositories of learning, and hence the materials through which learning is transmitted down the generations. Current students preparing for the future (and indeed the present) electronic library cannot be permitted to overlook the continued, lasting importance of print publications in the library's carrying out of its role, but they by necessity must be equipped to deal with the rapidly expanding world of digital materials. Thus, collection development courses must reflect an appropriately balanced approach, emphasizing the latest technology not as an end in itself, but rather as simply another tool to use in addressing the problems arising in acquiring adequate resources for a library collection in whatever format is most appropriate for the particular library and the "task at hand" (Thornton, 2000).

As librarians and information professionals go about the process of acquiring electronic information resources in carrying out their collection development role, they must also continue to recognize and care about the important questions that have always concerned libraries respecting questions of future accessibility and preservation of library resources. Electronic materials with their typical provision to libraries only through a licensing regime rather than through outright purchase present altogether different problems for the library than do print materials. Collection development and preservation must remain an important part of the library school curriculum no matter how dominated the library may become with electronic materials (Kenney et al., 2002).

In most conceptions of the libraries of the future, reference librarians may expect to continue to play many of the same reference roles that they have traditionally performed in interacting with their library's users. Reference librarians will continue to serve in an intermediary role to assist users in finding needed information and providing important "value-added" services through the production of instructional materials and guides to information resources. However, many of these functions, out of necessity, will be performed in media other than those that have been traditionally utilized. Collaboration and instruction may be expected to take place in a Web-based "chat" environment or by e-mail rather than through a face-to-face meeting over the reference desk (Abels, 1996; Domas White, 2001).

Reference librarians of the future must therefore acquire teaching skills as well as informational skills. They will need to be able to teach information literacy skills as students discover that just finding some online information on a topic and pushing the "print" or "download" button is not enough. In the electronic information world, librarians must be prepared to evaluate resources in a somewhat more in-depth way than was necessary when they could often depend upon refereed print journals for the majority of their information (Grassian & Kaplowitz, 2001).

In addition to all the vagaries involved with the classification and cataloging of traditional print materials, today technical services librarians will have to be prepared to cope with all the exponential varieties and forms that electronic resources may take. Technical services professionals are increasingly dealing with so many different formats and kinds of materials that may defy classification and are often not traditionally cataloged; other approaches, such as indexing and abstracting techniques and the development of in-house library-constructed databases, as well as Webliographies, may be undertaken as methods of organizing the access and retrieval process.

Future graduates planning a career in the technical services areas should place a much greater focus than is presently typically allowed for in most library school curriculums on the technological aspects of information provision. Concurrently, library and information science schools need to take steps to provide for the programs and/or the courses that will include building student skills in document creation for the digital library environment. Unfortunately, all this cannot be allowed to serve as a replacement for the traditional knowledge and skills involved in cataloging and classification. As a minimum, students will need to gain a hands-on knowledge of the architecture of the infrastructure and databases behind a digital library. This means that LIS schools must develop additional specific courses, rather than trying to make room in the already overstuffed basic

"organization of knowledge" classes that most schools currently offer (Vellucci, 1997).

DISTANCE EDUCATION

In the foreseeable future, it is probable that more and more instruction will be provided in a distance mode utilizing Web delivery, videoconferencing, and other technological means of providing instruction. A burden on many LIS faculty members at present is how to adapt a course, originally designed for a face-to-face classroom encounter, to a Web-based encounter. Although the goals, objectives, and major assignments for a class might remain the same, the overall means of delivery puts more pressure on faculty members to devise new ways of delivering material (Gregory, 2003). Both virtual and print reserve materials may become problematic as distance from the home site increases, although the increasing amounts of electronic materials held by academic libraries have been making access to library materials easier for students at a distance.

Faculty members have become increasingly innovative in finding ways to bring some feeling of community to students involved in distance education. Examples include PowerPoint slides with a voice-over by the instructor, text and voice chat over the Web, and the construction of virtual community sites, often in the same software environment as the classes (Gregory, 2006; Nicholson, 2005).

Compounding the traditional instructional component, there is the additional element of computer support on a 24 hour, seven days a week basis (Young, 2002). Increasingly, when something goes wrong with the computer on a student's end, the faculty member is expected to be able to do computer troubleshooting over the telephone or by e-mail. It is common for programs and universities to provide technical support, but even so the faculty member usually gets caught up in the technical support problems, obviously much more so than when the class is taught in the traditional manner (Carey & Gregory, 2002; Newton, 2003). Of course, when the academic computing staff person or the faculty member is unavailable, the next major organization on the campus that fields these questions is most likely the library. Librarians must be able to deal with technical, computing, or network issues and attempt to aid the beleaguered student (or faculty member). So although these issues primarily affect the teaching of library and information studies classes, they also have a major impact on the services demanded of the library (Barron, 2003).

FUTURE TRENDS

For the past 10 years or so, a rift has occurred between the information science and librarianship sides of the field. The I-School movement is one manifestation of that divide, but the concern of library practitioners is the other (Stofle & Leeder, 2005). Michael Gorman, president of the American Library Association for 2005-2006, took on the side of the practitioners in a series of meetings and presentations. His major points were that LIS education had become too concentrated on information and technology and not enough attention was being spent on the traditional core of librarianship (Gorman, 2005). While others have disputed Gorman's position (Dillon and Norris 2005), this debate seems to be a point of contention that will continue for some time.

Is "information" itself a discipline/field of study, or is it just a part of librarianship and other traditional academic disciplines? Does any one field of study own "information?" Only time will tell the outcome.

CONCLUSION

The rapidly changing requirements in the educational curriculum of schools of library and information science resulting from the exponential expansion of computer-based technologies naturally result in a re-examination of the knowledge and skills that need to be acquired by the next wave of library and information professionals. Skills in the use of new technologies are not only important in professional work, but also in the education process itself, as more and more LIS courses are being offered via the Web with faculty and students utilizing course management software.

KEY TERMS

Collection Development: The portion of collection management activities that has primarily to do with selection decisions.

Collection Management: All the activities involved in information gathering, communication, coordination, policy formulation, evaluation, and planning that result in decisions about the acquisition, retention, and provision of access to information sources in support of the needs of a specific library community.

Course Management Systems (CMS): Computer software system that provides a course shell with a number of integrated tools that may include chat software, threaded discussion board, online grade books, online testing, and other classroom functions.

Digital Libraries: Organized collections of digital information.

Distance Education: A planned teaching and learning experience that may use a wide spectrum of technologies to reach learners at a site other than that of the campus or institution delivering the course.

Information Literacy: An integrated set of skills and the knowledge of information tools and resources that allow a person to recognize an information need and locate, evaluate, and use information effectively.

I-Schools: A group of schools/colleges that focus on the discipline of information with programs in information architecture, information technology, information science, knowledge management, librarianship, and other disciplines associated with the production, organization, and use of information.

Videoconferencing: Conducting a conference between two or more participants at different geographical sites by using computer networks to transmit audio and video data.

The Effect of Sound Relationships on SLA's

AC Leonard
University of Pretoria, South Africa

INTRODUCTION

End users have expectations regarding services and *support,* and the quality thereof, provided by the supplier. They compare their expectations to the received service to assess the service quality (Coye, 2004).

In order to ensure that the service supplied by the service provider meets the expectations of end users, a successful *service level agreement (SLA)* is required. Quality *SLA's* clearly define, amongst many other elements, the commitments and responsibilities of the IT service provider and end users within the *service delivery* processes (Larson, 1998). One method of measuring the success of SLA's is by using service metrics with regard to the availability, reliability, serviceability, response, and user satisfaction of the SLA (Larson, 1998). Therefore, the success of the SLA depends on a clear, common understanding of the services and service quality between the service provider and end users. Furthermore *commitment*, trust, and cooperation between all parties is necessary to achieve success with SLA's (Hiles, 1994). However, in this paper it is argued that all these soft issues can only form a basis when sound relationships are established and maintained between the IT service provider and end users (Leonard, 2002).

This paper aims to determine how the establishment of a sound IT-*end user* relationship can add value to the SLA for both the IT service provider and the end users, and increase the success of SLA's.

PROBLEM BACKGROUND AND RESEARCH APPROACH

According to Parish (1997), the benefit of an SLA is that the identification of accountability in the service delivery process can be determined more easily, even when more than one service provider is involved in the process. Therefore, *commitment* from service providers and end users in the service delivery process can be determined. Secondly, the SLA will promote a focus on the quality of service required by *end users* to support their business needs. Thirdly, it will enable the service provider to clearly identify the key service needs of the end user organization to ensure that the business operations of the end user organization are operating at optimal level. Finally, a successful SLA will enable the service provider and the end users to implement correct service metrics to monitor the quality of service, which will enable them to perceive any service problems in advance and implement contingent plans. According to Lehr and McKnight (2002) the service metrics can be described as the commitments from the IT service provider to guarantee the quality of service delivered to end users at the agreed service level stated in the SLA.

According to Hiles (1994), the reasons for unsuccessful SLA's are insufficient service definition, poor measurement of service quality, inconveniently large documentation of SLAs, a lack of mutual understanding and, most commonly, a lack of commitment from the *end users*.

According to Leonard (2002), *commitment* and mutual understanding form, amongst other *soft issues*, the basis of any sound relationship between end users and IT professionals. Leonard (2002) states that an *IT-end user relationship* consists of physical and abstract elements which impact on the soundness of the IT-end user relationship. It is, therefore, argued that the elements of the abstract dimension of a sound IT-end user relationship contribute to the successfulness of the SLA. The most important elements that play a role in this regard, are a supportive culture, commitment, and cooperation (Leonard 2002). On the contrary, it is argued that a lack of commitment from *end users* and IT service providers will result in a poorly drafted SLA due to an unclear service definition and a lack of proper service quality metrics. Pratt (2003) has indicated that poorly drafted service elements in the SLA will create a poor picture of the services provided by the service provider from the point of view of the end users, resulting in an unsuccessful SLA.

An interpretive research approach was followed, taking into consideration the important principles for interpretive research as stated by Klein & Myers (1995) and Sahay et al. (1994). Apart from doing a theoretical study of the field, employees of about 15 different companies were approached to respond to a number of questions. The feedback on these questions, and the theory of IT-end user relationships and SLA's serve as basis for the arguments followed in this paper.

The next section starts with a discussion on service level agreements, followed by a brief discussion of the theory of IT-end user relationships. The paper concludes with a proposed conceptual framework showing how sound relationships enhance the worthiness of SLA's.

THE ESTABLISHMENT OF SLA'S

According to Larson (1998), a *service level agreement (SLA)* is a formal contract between the IT service provider and the business unit within an organization. The SLA provides a common understanding of the quality of service that the IT service provider will provide. It also helps create reasonable expectations amongst end users at a specific business unit. Apart from defining the standard of service quality and setting customer expectations, the SLA outlines the role of the *end users* and the role of the service provider. Therefore, an SLA will enable the end users to be fully aware of the *service delivery* capabilities and limitations of the service provider, while the service provider will understand the expectation and IT service needs of the end users. This common understanding about the service delivery between the IT service provider and end users is an important component for establishing a successful IT service provider-end user relationship as indicated by Smith (1996).

Once there are common interests and mutual understandings between the end users and IT service provider, it will enable the IT service provider to include the services and quality of service needed by end users in the draft SLA. According to Pratt (2003), the SLA will only be of value if the IT service provider has a clear understanding of the end user organization's core business operations and business needs.

Tonks and Flanagan (1994) state that the *SLA* should focus on adding value to the *service delivery* process for the service provider and the end users. Therefore, it should not be regarded as a contract to penalize the service provider should he/she fail to deliver the service. Instead, it should be used as a condition to set the desired service required from the service provider and how the quality of service will be measured and reported to the end users.

DEFINING AN IT-END USER RELATIONSHIP

According to Leonard (2002) an *IT-end user relationship* consists of two dimensions, namely, a *physical dimension* and an *abstract dimension*. The physical dimension describes those elements required to enable contact between IT and its end users, whereas the abstract dimension describes the *soft issues* (such as trust, commitment) of a relationship. These two dimensions enable one to fully describe the holistic nature of such a relationship and encapsulate the important elements of a *support*-oriented organization, namely mutuality, belonging, and connection, as mentioned by Pheysey (1993) in her book *Organizational Cultures*.

HOW THE ELEMENTS OF THE PHYSICAL AND ABSTRACT ELEMENTS IMPACT ON THE PROCESSES OF SLA CONSTRUCTION AND USE

In this section a brief description is given of the elements of both the *physical* and *abstract* dimensions which have the most significant impact on the worthiness of SLA's. In this regard, research has indicated that *people*, *technology*, and *procedures* are the most important elements from the physical dimension, whilst *knowledge base*, *supportive culture*, *commitment*, *cooperation*, and *holistic nature* are the most important elements from the abstract dimension.

Elements of the Physical Dimension

According to Leonard (2002) a sound *IT-end user relationship* consists of all the responsible people involved at a given time. "Responsibilities are negotiated and shared …" (Referring to the work of Dahlbom and Mathiassen (1993)). In terms of the *people* element, it follows that sound relationships will have a positive impact on the development of an *SLA*. Furthermore, the parties involved communicate through communication technology (e.g., video conferencing technology, helpdesk) as indicated by Leonard (2002). This communication technology also enables the IT service provider and end users to communicate with each other during the development and implementation of the *SLA*, which should have a positive impact on the development process of an SLA. Finally, communication technology will improve the response performance of the SLA as the IT service provider can attend to requests from end users and reply back to them with lesser turn-around time (Larson 1998).

The development of an *SLA* will be affected by existing policies and procedures. On the other hand, a new SLA can also introduce new policies and standards into the end user company. Therefore, any procedures (which form part of the physical dimension of an IT-end user relationship) will ensure that the implementation of the SLA does not compromise the business operations of the end user organization.

Elements of the Abstract Dimension

The impact of a sound *IT-end user relationship* will enable end users to have a highly affective *commitment* with the service provider. End users who have such commitment are less likely to switch to a new service provider (Mattila, 2004). Therefore, there is a large possibility that the end users will continue using the service of the current service provider or develop new SLA's with them instead of searching for a new provider in case of poor services or support.

According to Leonard (2002) a sound *IT end-user relationship* has a knowledge base. This enables end users to understand the limitations/trade-offs of their desired service in terms of availability, reliability, pricing, and serviceability. Furthermore, it enables end users to participate more effectively during the SLA development process.

A supportive culture exists during sound *IT-end user relationships* (Leonard, 2002), which establishes a mutual understanding and support between the IT service provider and end users. This supportive culture allows the IT service provider and *end users* to work together as a team striving to gain mutual benefits. According to Smith (1996), the success of managing services is that the end user must have a clear understanding of the IT *service* provider's capabilities. The IT service provider must also understand the expectations of end users, and both parties should appreciate the limitation of their partner organization. Therefore, the supportive culture will enable the IT service provider to clearly understand the expectations and needs of end users. On the other hand, end users will understand the capabilities of the IT service provider and services offered by them. This will result in a well-defined *service* definition between the end users and the IT service provider.

According to Leonard (2002), a sound relationship also implies that cooperative behavior exists between all role players. This means that an IT *service* provider and its end users will work together towards gaining positive future results. The *service* defined in an SLA is affected by the changes in service needs of the end user organization. *Service* needs of the *end user* organization are affected by the changes in the markets. A successful SLA should therefore be modifiable, to accommodate the service needs of end users (Larson, 1998). Therefore, if the IT service provider and the end users have a sound IT-end user relationship, they can cooperate to modify the SLA and re-define the service deliverables and service definitions in the SLA to accommodate the changes in service needs of the end users.

An IT-end user relationship has an holistic nature as indicated by Leonard (2002). The holistic nature emphasizes the cooperative behavior and support culture in the IT-end user relationship, which also enhances the successfulness of the SLA.

A sound IT-end user relationship has *commitment* from both the end users and IT service provider (Leonard, 2002), which enables both parties to work towards the same goal to gain mutual benefit and appreciation of each other's capabilities and limitations. According to Hiles (1994), a lack of commitment is one of the primary reasons for the failure of SLA's. Therefore, commitment from both the end user and IT service provider has a positive impact on the success of SLA development.

ANALYSIS OF FEEDBACK RECEIVED FROM PRACTITIONERS

The purpose of this part is to interpret/analyze some of the feedback received from different role players (IT professionals and end users) in the private sector using SLA's. The responses given by the participants are given literally. In other words, no changes have been made to the grammar of the feedback. Only spelling mistakes were corrected. Furthermore, only those parts of responses that could be regarded as of interest to the phenomenon under investigation, are cited. The responses are also not given in a specific order:

- Sound relationships between the two groups bring understanding of the problems, challenges and needs of both sides. It therefore encourages the service providers to give their best and the users to gauge their expectations, thus reducing on conflict and misunderstanding.
- I believe sound relationships with the users will result in the IT department knowing the user's needs better, which will help in developing SLA's with the user's needs at the center of their development.
- If there is not a sound relationship, the two/more parties involved tend to do just enough. I speak from personal experience that the relationship influences the effectiveness of SLA's in business. If the parties involved do not have a sound relationship, even well developed SLAs are not as effective as they should be.
- Sound relations ensure that SLA communicate effectively to both IT and end user departments. This also ensures that both parties expectations are aligned.
- Unlike traditional purchasing contracts, SLAs require all parties to have a higher understanding of the customer's business requirements. This understanding can only be obtained through a sound relationship. In addition, an SLA is actually a contractual embodiment of desired or existing business relationships. The purpose of an SLA is to ensure business continuity, necessitating a deep understanding of the existing business processes. An SLA is an organic document in that it changes with changing business requirements.
- Sound relationships and SLA are closely related in a sense that without sound relationships between IT department and business units, then it will be difficult to have well defined SLAs and without SLA, then the relationship might get sour due to different expectations of the outcome of services that are provided by IT departments for other business units and the users of the service will not have sufficient information necessary to understand and use the services. This

might also lead to poor relationships between different departments.

- I do believe that a link exists between a sound relationship and an SLA. The reason for this is that in order to know the what, where, and when of a *service,* a sound relationship should be built between a service buyer and a service provider. Getting all partners involved through sound relationships of trust, commitment, and the like, will improve the quality of the service level agreement and ensure that all its interdependencies are not left out.

INTERPRETATION/ANALYSIS OF THE ABOVEMENTIONED CITATIONS

The abovementioned citations not only indicate the importance of sound "working relationships" between IT professionals and *end users*, but also regard it as an indispensable piece of "equipment" or "tool" which is necessary to *support* all participants in addressing the needs of end users or business units. The citations also refer to important aspects regarding the establishment and maintenance of sound relationships. First of all, the culture gap is addressed, and, as such, the importance of a common knowledge base, which will surely help all participants of a given IT-end user relationship to "realize" what is expected of them. In terms of how sound relationships would impact on the construction and operations of an SLA, everyone refers to the fact that if sound relationships do not exist or are not maintained, trust between all role players would be in jeopardy. In such a case SLA's would not be honored.

From the above analysis, it is clear that the elements of the physical and abstract dimensions have a direct impact on the quality and operational success of SLA's. This impact is illustrated in the following conceptual framework.

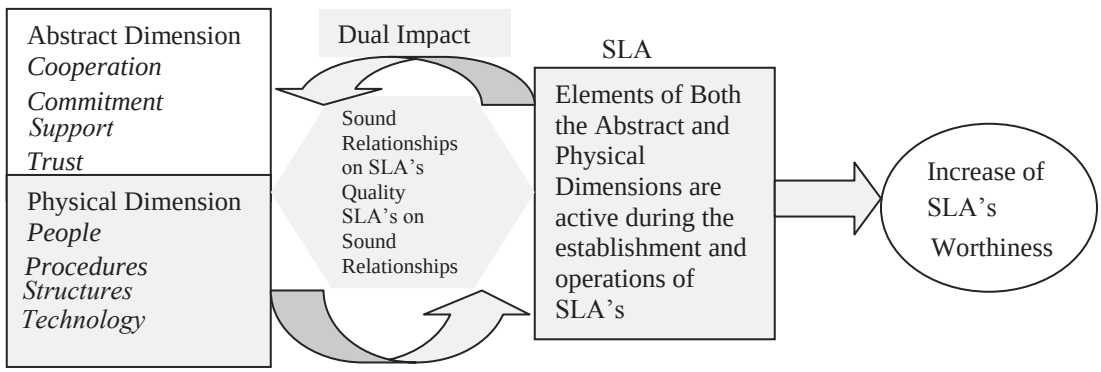
FUTURE TRENDS

It is clear that in the future much more research needs to go into the management of relationships and service level agreements to get a better understanding of the nature of the impact relationships have, not only on the operational value of SLA's but also on the behavior of people. In this regard the role and impact of organizational culture cannot be ignored. Leonard (2002) lists several examples of cultural differences between end users and IT professionals that lead to poor relationships which, on their part, impact negatively on the construction and operation of service level agreements. Therefore, in terms of the future of IT service management it is clear that cultural differences should also become part of the picture.

CONCLUDING SUMMARY

In this paper the impact of sound *IT-end user relationships* on the construction and operations of *SLA*'s is discussed. To illustrate this, the most important elements of the *physical* and *abstract* dimensions that play an important role in this regard are discussed. It was argued that each of these elements exist during the processes necessary to negotiate and construct SLA's of a high quality.

Figure 1. The dual impact of sound IT-end user relationships on SLA operations



Based on the definition and theory of sound *IT-end user relationships,* one can argue that the elements of the physical and abstract dimensions enhance the communication, effective commitment, and trust between the IT service provider and end users. On the other hand, this ensures that all role players strive to gain mutual benefit for all parties involved.

A conceptual framework is also proposed illustrating how sound *IT-end user relationships* enhance the worthiness of *SLA's*. This enhancement takes place in terms of the SLA development process as well as all operations concerning the SLA. Furthermore, this enhancement should have a dual effect in the sense that it not only supports the SLA design and operations process, but all the elements of the physical and abstract dimensions should, in turn, be enhanced.

KEY TERMS

Abstract Dimension: The abstract dimension describes the soft issues of such a relationship.

IT/End-User Relationship: A relationship between IT and the end user consists of two dimensions, namely, a physical dimension and an abstract dimension. The physical dimension describes those elements that are necessary in order to enable contact between IT and its end users; whereas, the abstract dimension describes the soft issues of a relationship.

Physical Dimension: The physical dimension describes those elements that are necessary in order to enable contact between an IT professional and its end users.

SLA: Service level agreement.

Soft Issues*:* Those elements that describes how a person behaves under specific circumstances. Examples of such soft issues are trust, commitment, support, cooperation, and so forth.

Effective Leadership of Virtual Teams

David Tuffley
Griffith University, Australia

INTRODUCTION

Geographically dispersed project teams collaborating in virtual environments face a range of challenges in the successful completion of IT development projects. This is particularly the case when the project teams are nonhomogenous, comprising multidisciplinary members with a range of skills, professional orientations and cultural backgrounds. Of interest to the global enterprise are those leadership mechanisms and attributes that may serve to optimize team functioning.

With an increasing portion of the estimated US$600,000,000,000 (Cusamano, 2004) global software industry being performed by virtual teams, and with the mechanics and dynamics of virtual team operations being a relatively new area of study, the significance of the problem can be firmly established.

Virtual teams, and the leadership thereof, is therefore a significant aspect of the global software development industry. Yet as Cusamano (2004) asserts, it is the *business* itself (and the processes therein), not the technology that determines the success or failure of the organizations that produce the software.

BACKGROUND

The past 50 years have seen a remarkable proliferation of what might be termed the *global enterprise*, organizations that transcend national borders and extend across the globe. Commercial organizations in industrialised economies have increasingly established international networks of subsidiaries and affiliates with which to pursue a global agenda, taking advantage of economies of scale and effort. This trend inevitably leads to the advent of distributed work environments and the consequent formation of multidisciplinary virtual teams (teams that operate across different time and physical space).

Collaborative technologies (messaging and discussion forums, audio and video conferencing, as well as knowledge portals, business directories, Web cams) are assumed to facilitate team functioning in virtual environments, yet it is nonetheless important that we examine the broad issue of team work processes and optimising. The building of functional social networks in virtual environments can be a difficult task, particularly on an international scale. The respective cultures of the team members are a significant factor. Other factors include physical environments, information technology support, communication policies and procedures, as well as leadership.

VIRTUAL TEAMS

Distinguishing Virtual Teams From Conventional Teams

Bell and Kozlowski (2002), quoting a widely cited earlier study by Townsend, DeMarie, and Hendrickson (1998) define virtual teams as:

Groups of geographically and/or organizationally dispersed co-workers that are assembled using a combination of telecommunications and information technologies to accomplish and organizational task.

Virtual teams can therefore be distinguished from conventional teams in two fundamental ways; their *spatial proximity* and the *communications technologies* employed.

When contrasting Townsend et al.'s (1998) definition of virtual teams with that of conventional teams (Humphrey, 2000), we see that the Humphrey definition offers a good general purpose view of what a team is:

A team consists of:

1. *At least two people, who*
2. *Are working toward a common goal/objective/mission, where*
3. *Each person has been assigned specific roles or functions to perform, and where*
4. *Completion of the mission requires some form of dependency among group members.*

Operational Definition of Virtual Team

It might be reasonable, therefore, to combine these definitions:

A virtual team consists of:

1. At least two mutually interdependent people, who
2. Are geographically dispersed, and who

3. Are working toward a common goal/objective/mission, where
4. Each person is assigned specific roles or functions to perform, and where
5. Communication is facilitated by a combination of telecommunications and information technologies to work toward the completion of the project/mission.

Leadership

Until "kings were philosophers or philosophers were kings" there will be injustice in the world. (Plato)

The classical period of ancient Greece produced concepts and modalities that have become the foundation of western civilization. In relation to leadership studies the philosopher Plato (427-347 BC) in his renowned dialogue *The Republic* outlined certain enduring leadership principles that Western administrative thinking has based itself upon (Takala, 1998). Plato developed systematic administrative thinking for the efficient running of the city-sate (polis) which over time allowed the evolution of democracy. Plato described in detail the appropriate relationship between the state and individual citizens. This relationship was so close that it was not possible to think of a citizen living outside of his state (Takala, 1998). The purpose of this state is to educate people to become "good." The state is like the human body in which parts complement each other and act harmoniously. In terms of organizational theory, Plato would be regarded as a premodern functionalist.

Distinguishing Leaders and Managers

The terms leader and manager are sometimes used interchangeably, adding to the ambiguity surrounding the study of leadership. Yet studies of administrative science usually find the terms differentiated. How is this done?

According to Takala (1998) what they have in common is the ability to get things done. We then distinguish them by managers being a kind of instructor who puts pieces together and manages the "things." A manager is primarily concerned with making an organization function by evolving routines that serve the ongoing and sometimes changing purposes of the organization.

Leadership Qualities of Great Groups

Bennis and Beiderman (1997) discuss at length the leadership qualities required in Great Groups. They observe that group leaders can vary widely. There can be facilitators, doers, contrarians. Leaders are catalytic completers; taking on roles that nobody else plays and that are needed for the group to achieve its goal. They have an intuitive understanding of the "chemistry" of the group and the dynamics of the work process. Furthermore, they encourage dissent in the establishment and maintenance of a shared vision. They can distinguish between healthy, creative dissent and self-serving obstructionism.

Bennis and Beiderman (1997) identify four behavioral traits of effective group leaders:

1. **Provide direction and meaning:** Group members are kept up-to-date on what is important and why their work makes a difference.
2. **Generate and sustain trust:** The group has trust in itself and its leadership. This allows members to accept dissent and tolerate the turbulence of the group process.
3. **Display a bias toward action, risk taking, and curiosity:** A sense of urgency and willingness to risk failure to achieve results.
4. **Are purveyors of hope:**. Find tangible and symbolic ways to demonstrate that the group can overcome difficulties.

Personality Traits and Competencies of Effective Leaders

Bennis (1994) in a wide-ranging study determined that effective leaders display four distinct personality traits, and five specific competencies, the sum of which tends to manifest in strong and effective leadership. Personality traits include guiding vision, passion, integrity, and daring (Bennis, 1994). The competencies are technical competence, interpersonal skills, conceptual skills, judgment, and character (Bennis, 1999a). No pairing order is implied by this table, as it is a listing only.

Bennis (1999a) asserts that it is character that is the essential element determining a leader's effectiveness, saying "leaders rarely fail because of technical incompetence" but more so for lack of character. (Bennis, 1999b)

Table 1. Personality traits and competencies of effective leader (Bennis, 1994, 1999a)

Personality Traits	Competencies
Guiding vision	Technical competence
Passion	Interpersonal skills
Integrity	Conceptual skills
Daring	Judgment
	Character

Strong character can manifest in positive and negative ways, as the lessons of history inform us. Strong character makes for a strong leader, but character can be strong and negative/destructive. Offerman, Hanges, and Day (2001) relates that a person's character will be determined by the sum total of his or her values. Offerman et al. (2001) identified the source of an employee's dissatisfaction and disillusionment as the particular values held by leaders and the actions that these values motivate.

Underlying Qualities of Effective Leaders

The qualities that inspire people to persevere in the face of great difficulty, and that engender trust and a sense of worth among team members are not always readily identifiable. They are qualities that are not easily detected, but that are found in the best of leaders.

Champy (2003) identifies these underlying qualities as:

- **Empathy:** Macaluso (2003) suggests that empathy is the secret weapon of corporate success, an indispensable quality for any successful leader. Empathy is described as the ability to see the world through another's eyes, to experience it as they would, or "To walk a mile in another's shoes."
- **Personal responsibility:** Effective leaders accept that the circumstances in which they find themselves are largely the result of their own previous actions. They do not blame others (Macaluso, 2003).
- **Openness to discovering truth:** Effective leaders fearlessly search for truth, knowing that sometimes the truth will not be pleasant to face (Macaluso, 2003).

Transformational vs. Transactional

Zhang, Fjermestad and Tremaine (2005) identify two parallel dimensions of leadership: *transformational vs. transactional,* and *participative vs. directive*. These have been derived from a body of foundational work in the area of leadership styles in a virtual team context.

On the Transformational/Transactional dimension we see the *Transformational* element as comprising four behavioural components (Bass, 1985; Bass, Avolio, & Goodheim, 1987; Lowe, Kroeck, & Sivasubramaniam, 1996):

- **Charisma or idealized influence:** The leader engenders in the members a sense of pride, respect, faith and respect, together with a sense of purpose/mission.
- **Individualized consideration:** The leader manifests a deep concern for the well-being of the members, and provides mentoring.
- **Intellectual stimulation:** The leader stimulates members to think in original ways, emphasising the triumph of reason over irrationality, and challenging established ways of thinking.
- **Inspirational motivation:** The leader creates high standards, communicating high expectations.

Continuing with the Transformational/Transactional dimension we see the *Transactional* element as comprising three behavioural elements (Bass, 1985; Bass et al., 1987; Lowe et al., 1996):

- **Contingent reward:** The leader rewards performance on the basis of it having fulfilled prescribed obligations.
- **Management-by exception:** The leader ensures the standards are met.
- **Management-by-exception (passive):** The leader adopts a laissez-faire attitude until noncompliance of standards has occurred.

Leadership of Virtual Teams

The concept and practice of distributed work is not new, and in fact enjoys a long and colourful history, as discussed by O'Leary, Orlikowski and Yates (2002) in their extended case study of the Hudson Bay Company from 1670 to 1826. Yet it has been the advent and subsequent advances in communications technology that has been a critical enabler of the development of this organisational form and practice (Ahuja, Carley, & Galletta, 1997).

It has been observed (Cascio & Shurygailo, 2003) that distributed teams (or virtual teams as they might be called) face particular problems in relation to leadership. Organizational and management research has focused intensively on the issue of leadership, as seen in a previous section, yet there is relatively little research done thus far on the emerging challenge of leadership in virtual teams (Cascio & Shurygailo, 2003).

Leadership Challenges for Virtual Teams

An in-depth study into the typology of virtual teams, and the implications therein for effective leadership, is found in Bell and Kozlowski's (2002) work. This work proposes 11 distinct challenges for the leadership of virtual teams.

Bell and Kozlowski (2002) identify four broad categories of leadership challenge in virtual teams; (a) temporal distribution, (b) boundary spanning, (c) life cycle and (d) member roles. The categories are described by Bell and Kozlowski (2002) as shown in Table 2. Table 3 elaborates the 11 propositions relating to leadership challenges in vir-

Table 2. Bell and Kozlowski's (2002) four categories of leadership challenge in virtual teams

Category	Description
Temporal Distribution	Virtual teams operating in real-time use rich, synchronous communication media and temporal entrainment to effect performance management.
Boundary spanning	Individualized consideration for and performance management of team members who span different functional areas, organizations or cultures.
Member Roles	Members holding multiple roles within and across virtual teams.
Lifecycle	Performance management effectiveness is improved when team membership is stable and ongoing, allowing time for relationships to be established and developed.

Table 3. Bell and Kozlowski's (2002) 11 propositions of leadership challenge in virtual teams

Category	Leadership challenge
Temporal Distribution	Distributed virtual teams are more likely to use synchronous, richly textured communications media.
Temporal Distribution	Effective virtual team leaders are more likely to develop substitutes for face-to-face contact.
Temporal Distribution	The more complex the virtual project, the more likely it will be performed in real time, not distributed time.
Boundary spanning	The more complex the task, the more likely the team will be distributed.
Boundary spanning	Virtual team boundaries will be less permeable in complex projects where established operating procedures and stable relationships are needed.
Boundary spanning	Effective team leaders are likely to create proactive performance management functions, AND be good at using technology to provide members with team development experiences.
Boundary spanning	Effective leaders are good at evaluating the effectiveness of self regulation mechanisms, AND that these developmental functions will be more difficult to implement across multiple boundaries.
Boundary spanning	More complex projects are likely to require stable team membership.
Member Roles	More complex projects are likely to require clearly defined singular roles for members.
Member Roles	Multiple roles and boundaries are likely to make performance management more difficult, AND effective leaders are more likely to clearly specify roles and role interrelationships, particularly in more complex projects.
Lifecycle	Discrete life cycle of virtual projects will be experienced integrated difficulty with establishing performance regulating functions, AND leaders will therefore focus on the most critical issue of establishing effective working relationships with members.

Table 4. Characteristics of empirical studies of leadership in virtual teams (Adapted from Misiolek (2006) and Dube & Pare (2004)

Authors	Main research method	Theoretical perspective
Balthazard et al. (2004)	Lab experiment	Shared leadership; leadership style; transformational and transactional leadership
Cogburn et al. (2002)	Quasi-experimental field study	Behavioural; two-factor theory
Connaughton & Daly (2004)	Interviews	Implicitly behavioural
Hoyt & Blascovich (2003)	Lab experiment	Transformational and transactional leadership
Authors	**Main research method**	**Theoretical perspective**
Kayworth & Leidner (2002)	Field experiment	Behavioural; behavioural complexity theory; trust
Pauleen (2003)	Case study	General theoretical discussion
Pauleen (2004)	Interviews & two 10-week action learning sessions + grounded theory analysis	General theoretical discussion with focus on relationship-building and trust
Piccoli & Ives (2000); Piccoli et al. (2004)	Field experiment	Team control structure; self-managing teams
Sarker et al. (2002); Nicholson et al. (2002)	Field experiment	Emergent leadership; propose new theoretical model incorporating culture, communication, technical ability, trust, gender, performance, and client location
Sudweeks & Simoff (2005)	2 case studies	Behavioural; implied two-factor theory; emergent leadership
Tyran et al. (2003)	Field experiment	Behavioural; two-factor theory; emergent leadership
Weisband (2002)	Field experiment	Behavioural; two-factor theory; group awareness
Yoo & Alavi (2004)	Field experiment + grounded theory analysis of transcripts of team interactions	Behavioural; two-factor theory; emergent leadership

tual teams outlined by Bell and Kozlowski (2002). They are grouped into the four categories discussed above.

Summary of Empirical Studies of Leadership in Virtual Teams

Dube and Pare (2004) surveyed virtual team characteristics published in empirical studies. Misiolek (2006) used this as a basis for further investigation into leadership aspects of virtual teams. The combination of these two sources, plus additional investigation, results in the table below. It summarizes the broad sweep of theoretical perspectives developed in these empirical studies.

FUTURE TRENDS AND CONCLUSION

Effective leadership of virtual teams in the world of tomorrow will be facilitated by increasingly rich communications media that allows collaboration between individuals as if they were in the same physical location. Broadband communications technologies such as fiber optics promises to deliver

the capability to create virtual environments rich enough with subtle detail to make this possible. The commercial potential for organizations to develop such technologies is high, ensuring a vibrant and competitive market for such products. This is potentially a major benefit.

The qualities of a good leader remain constant, whether they operate in the same space or in virtual space. The challenge for the leaders of tomorrow will be to negotiate successfully with the emerging collaborative technology to make the best use of it.

Such qualities have been displayed by notable leaders throughout history, are being displayed by effective leaders today, and can reasonably be expected to be displayed by the leaders of tomorrow, extending into the far distant future. These qualities are functions of human nature that have co-evolved during millions of years of human evolution. Indeed, the human capacity to collaborate to solve problems is a defining aspect of the human species, and is responsible in large part for our phenomenal success as a species. Implicit to this ability to collaborate is the need for someone to facilitate that collaboration (a leader).

Human kind stands today on the threshold of a major step in an evolutionary history stretching back 5 million years. We are making the transition from operating in a physical environment only, to operating in a hybrid physical-virtual environment, with the trend toward increasingly virtual environments. Humans evolved the ability to adapt themselves to a wide range of physical environments, practically the whole world from the Equator to the Poles, and beyond into space. This distinguishes humans from all other species. Having exhausted the physical environment in this unceasing expansion, human kind is now developing the technology to create virtual worlds in which to live and work. Leaders in these virtual worlds will be those that combine traditional leadership qualities with the ability to make these virtual worlds seem real.

KEY TERMS

Charisma: The ability to develop or inspire in others an ideological commitment to a particular point of view.

Collaborative Technologies: Technology that allows people to interact effectively in virtual environments. Includes messaging and discussion forums, audio and video conferencing, knowledge portals, business directories, and Web cams.

Directive Leadership: Providing and seeking compliance with directions for accomplishing a problem solving task.

Empathy: The ability to see the world through another's eyes, to experience it as they would. An essential leadership quality.

Global Enterprise: An emerging phenomena facilitated by communications technology in which multinational organizations extend their operations globally, effectively removing themselves from the control of any one jurisdiction.

IPPD: Integrated Product and Process Development (a body of knowledge).

Integrated Team: A group of people with complementary skills who collaborate to deliver specified work products. An integrated team may be either colocated or distributed. Contrast with Virtual Team (below).

Laissez-Faire: From the French "allowed to be." Refers in this context to the management style where employees function best when left alone.

Participative Leadership: The equalization of power and sharing of problem solving with followers by consulting them before making a decision.

Transformation Leadership: Combining four dimensions; charisma, individualized consideration, intellectual stimulation, and inspirational motivation.

Transactional Leadership: Combining three dimensions; contingent reward, management-by exception, management-by-exception (passive).

Virtual Team: Group of geographically or organizationally dispersed coworkers that are assembled using a combination of telecommunications and information technologies to accomplish an organizational task.

Effective Learning Through Optimum Distance Among Team Members

Bishwajit Choudhary
Information Resources Management Association, USA

INTRODUCTION

For several years, researchers have argued that too much closeness or distance among the team members inhibits intellectual debate and lowers the quality of decision-making. In fact it is often said that if two people always agree, then one is useless and if they always disagree, then both are useless. While too much "closeness" leads to copycat attitude, too much "distance" among the team members results in incompatibility. Creating teams in which the members experience "optimum distance" is not easy.

In this backdrop, we have identified certain gaps in the contemporary organizational learning theories and developed conceptual constructs and conditions that are likely to cause optimum distance in teams.

BACKGROUND

Organizational learning (OL) gained currency when interpreting market information ahead of competitors was seen as a source of competitive advantage (DeGeus, 1988). Organizations increasingly realize the need to maintain a right degree of balance between exploiting the existing and exploring new knowledge base (Cox, 1993; Jackson et al., 1995). Concepts such as double loop learning (Argyris, 1977) and generative learning (Senge, 1990) have underlined the need for innovation and creativity in learning processes.

Research in organizational networks has primarily focused on knowledge creation at organizational levels (Nonaka et al., 1994). Almost all the analyses of networks have focused on inter-organizational groupings (Van De Ven & Walker, 1984). Andersen et al. (1994) define a business network as a set of two or more inter-connected business relationships and claim that the parties in networks have traditionally been shown to come from the same industry.

MAIN THRUST OF THE ARTICLE

In spite of pioneering attempts to conceptualize OL, lately, the researchers have expressed concerns. Ritcher (1998) remarks that the current literature does not adequately explore the dynamics of learning process. Nonaka et al. (1995) claim that "There is very little research on how knowledge is actually created *and hence there is a need to understand the dynamics of knowledge creation*" (italics added).

Alter and Hage (1993) have argued that new theories should be developed to encompass knowledge creation as a result of inter-firm collaboration. Macdonald (1995) claims that the current theories have neglected external-to-firm factors. The aim of OL should be to enhance innovation and not learning merely for the sake of it (Nonaka et al., 1994). D'Aveni (1995) argues that businesses need breakthrough innovations through industry-oriented learning processes and adequately respond to the dynamic external environment.

We now summarize the critical overview of the OL literature presented previously:

- Absence of external-to-firm factors in OL processes.
- Unclear conceptualization of optimum distance in teams.

WHAT IS OPTIMUM DISTANCE?

We delve deeper into OL processes by understanding the factors that constitute perceived distance among the team members by defining the relevant concepts.

Member Distance (MD)

Inkpen (1988) argues that in inter-organizational teams, distrust among members from the participating firms (who perceive each other as competitors) inhibits learning. We believe that this distrust among the team members is the result of the so-called "member distance". Member distance (or MD) reflects overall differences among the members due to objective factors (e.g., members' experience and education) and subjective factors (e.g., members' behavior, values and personality).

Extending Inkpen's (1988) classification of inter-organizational teams, we propose three team compositions comprising managers from:

- Different departments within the same firm (cross-functional teams).

- Same industry-sector but different firms (forums comprising partners).
- Different industries, but similar department (e.g., co-ordination forums for inter-sector policies or standards body, etc.).

Knowledge Distance (KD)

Managers in different industries need to know some basic industry-specific issues. For example, in the banking sector, managers need the knowledge of payment systems, customer support, and so forth, while in the telecommunication sector, managers need the knowledge of communication networks, mobile devices and so on. Knowledge distance (KD) conceptualizes industry-specific knowledge differences among managers from different sectors.

Professional Distance (PD)

Prolonged working and dedicated experiences within a specific department can influence managers' behavior at the workplace. Zuboff (1988) cites several examples (showing the impact of automation on employees' behavior). We refer to job-specific behavioral differences among managers as professional distance. Stated formally, professional distance (PD) comprises intuitive and often subjective personality differences among managers from different departments.

We now summarize some important observations on KD and PD:

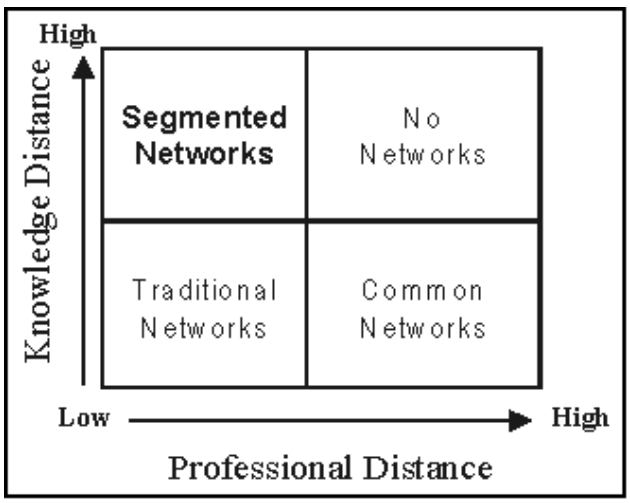
- KD captures dissimilarities among managers due to external-to-firm and knowledge specific factors. PD conceptualizes department-specific, behavioral differences among managers.
- KD represents the member-distance at a macro (inter-sector or firm) level. PD represents subjective and more complex personality-based differences at a micro (or department) level.
- Since PD depends on the department dynamics (which impact managers' behavior at the workplace), PD will be low between managers of similar departments even if they come from different industries. KD in a team will be low only when the managers come from firms within the same industry.
- The unit of analyses of learning processes in an individual (manager).

Since the large firms usually have a number of specialized departments, we may conceptualize such departments as micro-level "professional personality domains" and firms as "macro-level knowledge domains". KD and PD can then be used to conceptualize different team compositions as shown in Figure 1.

It is evident that the traditional networks occur when both KD and PD are low. These are the internal-department teams and found in all organizations. We refer to them as the "traditional networks".

When integrating knowledge from different departments is needed (in projects, for example), cross-functional teams are often created. In such teams, members have different behavioral approaches to problem solving (hence, high PD). However, their behavioral approaches are often complementary as well given their respective dedicated experience in different functional areas (as technology, business, finance and so on). However, as the managers in cross-functional teams come from the same firm, they share similar broad-based knowledge on industry-level issues (hence, low KD). In addition to low KD, the managers also

Figure 1. Balancing member distance for effective learning in various teams



share common objectives as they work for the same firm. Since such teams are very common, we refer to them as the "common networks".

When KD and PD are both high, no teams can (and should) be formed. Such teams would be difficult to manage and lack common interest areas. We do not discuss this scenario further.

SEGMENTED NETWORK

Varying knowledge-based competencies and similar professional personalities mark the conditions in this team. The presence of high KD creates knowledge-based differences, while low PD implies that members essentially share similar behavior at workplace. This so-called optimum balance between members' distance and closeness is achieved through knowledge-based differences but behavior-based similarities. High KD (through task-oriented conflicts) will lead to higher quality decisions as well (Schweiger et al., 1986) as well.

Segmented network (SN) is hence a team with conditions for optimum distance. It can typically be a forum to create best practices and inter-sector policies (e.g., standards, benchmarks, quality requirements). Use of macro (firm and industry) level and micro (department and individual) level factors facilitate our conceptual understanding of the relation between manageability of knowledge flow and team compositions. Such cross-sector forums are emerging fast (e.g., standards bodies, benchmarking forums, professional services (as consulting, law) firms). Although the participants in SNs come from different sectors, they usually serve the same (or same type of) user base, putting customers at the center-stage.

FUTURE RESEARCH

We now summarize the limitations of this work and identify areas of future research.

Measuring KD and (especially) PD may not be easy, but must be done one way or another. Conceptualizing learning processes with the assumptions of discrete activity is not realistic in a network sector where the value-creating activities are highly information-intensive and overlapping. We also ignored the impact of hierarchy and power on team dynamics for the sake of simplicity. Finally, the challenge in managing segmented networks would be high-level political issues and in turn, that would test the leadership skills of the team's coordinator.

CONCLUSION

By using the conceptual constructs as KD and PD we tried to plug the gaps in the contemporary organizational learning research. As the impact of external forces on firms' performance becomes increasingly pronounced, organizations will need learning processes that are inter-sector and not merely internal to the firm. Segmented networks fulfill this very important premise. Past research also supports our view that high degree of task-oriented conflicts (or high KD, as is the case in segmented networks) increases the quality of decision (Schweiger et al., 1986, 1989). Teams with a high degree of task-oriented conflicts are easier to manage than and may indeed be preferred to teams with a high degree of personality-oriented conflicts. Manageability of teams is a key issue.

Note that the common networks (or the cross-functional teams) also carry the important element of balance within them and their usefulness is well known. SNs offer a similar possibility at an inter-sector level, thereby complementing the internal-to-firm focus of the common networks. SNs are novel and manageable. Inter-sectors forums are growing especially fast in the network industries and so is the need for OL theories to conceptualize and understand SNs. In the network industries (such as banking, telecom sectors), interoperability of systems and procedures is a key success factor.

KEY TERMS

Knowledge Distance (KD): Conceptualizes industry-specific knowledge differences among managers from different sectors.

Member Distance (MD): Reflects overall differences in approach among the members due to objective factors (e.g., members' experience etc.) and subjective factors (e.g., members' values etc.).

Optimum Distance (OD): Appropriate degree of closeness (or distance) among the team members achieved through the combination of KD and PD, leading to the so-called creative tension.

Professional Distance (PD): Comprises behavioral differences among managers from different departments.

Segmented Network (SN): Inter-sector teams with high KD and low PD, leading to conditions for the so-called optimum distance.

Effective Virtual Teams

INTRODUCTION

Virtual teams are now being used by many organizations to enhance the productivity of their employees and to bring together a diversity of skills and resources (Gignac, 2005; Majchrzak, Malhotra, Stamps, & Lipnack, 2004), and it has been suggested that this will become the normal way of working in teams in the near future (Jones, Oyund, & Pace, 2005). Virtual teams are groups of individuals who work together from different locations (i.e., are geographically dispersed), work at interdependent tasks, share responsibilities for outcomes, and rely on technology for much of their communication (Cohen & Gibson, 2003). While the use of virtual teams is more common in today's organization, working in these teams is more complex and challenging than working in traditional, collocated teams (Dewar, 2006), and success rates in virtual teams are low (Goodbody, 2005). This article suggests best practices that organizations and virtual team members can follow to help their virtual teams reach their full potential.

In this article, virtual team best practices are identified from three perspectives: organizational best practices, team leadership best practices, and team member best practices. Ideas for best practices were identified from three sources: six case studies of actual virtual teams (Staples, Wong, & Cameron, 2004); the existing literature on virtual teams; and the existing literature on traditional (i.e., collocated) teams and telecommuting (i.e., research on virtual work at the individual level).

Table 1. Organizational best practices for effective virtual teams

• Carefully select team members for diversity
• Supply the team with sufficient resources, support, and information technology tools
• Develop human resource policies that reward team efforts and stimulate virtual team performance
• Provide the team with an appropriate level of autonomy
• Use standard processes and procedures
• Develop an organizational culture that stimulates the sharing of information

ORGANIZATIONAL BEST PRACTICES

There are six best practices that organizations that employ virtual teams should follow. Table 1 contains a list of these practices, each of which is explained next.

Carefully Select Team Members for Diversity

The distributed nature of virtual teams allows a diversity of backgrounds, experiences, ideas, thoughts, abilities, and perspectives to be assembled within a single team. Organizations forming virtual teams should take advantage of this, selecting team members with diverse backgrounds and skills. The importance of team diversity was identified in both the case studies and the traditional team literature (e.g., Bettenhausen, 1991; Cohen, 1994). In particular, research has shown that diversity provides information-processing benefits to teams such that they are more effective at their tasks (Dahlin, Weingart, & Hinds, 2004). Working on a diverse team can also be more rewarding, interesting, and fun as team members get the opportunity to learn about new cultures and interact with people beyond their own work location.

Supply Sufficient Resources, Support, and Information Technology (IT) Tools

Organizations have to supply virtual teams with sufficient resources including financial resources, time, facilities, hardware, software, information technology (IT) support, communication channels, technical equipment, and proper training (Jones et al., 2005). The traditional team literature suggests that team building activities and training members

how to work in teams are important because they ensure that employees develop the knowledge required to contribute to organizational performance (Cohen, 1994). In virtual teams it is especially difficult for team members to get to know one another. Thus, organizations may need to provide extra resources for extensive team building exercises.

Since virtual teams often need to communicate electronically, appropriate IT tools, training on how to use available IT and communication systems, and readily-available technical support are also important to virtual teams (Duarte & Snyder, 2001; Fisher & Fisher, 2001; O'Hara-Devereaux & Johansen, 1994; Pinsonneault & Boisvert, 2001; Staples et al., 2004). High quality systems for audioconferencing are essential, as are e-mail systems and systems for storing, accessing, and sharing electronic files. Collaborative whiteboard tools are very useful, as they support the interactive sharing of information during electronic meetings. Electronic voting and brainstorming tools can also be useful, depending upon the nature of the team's task. Instant messaging is a powerful tool that enhances the presence and connectedness of remote parties, and its informal nature enhances social interaction. Blogging tools give people the ability to share their views (Jones et al., 2005), possibly helping others understand their situation and perspective.

Develop Human Resource Policies that Stimulate High Virtual Team Performance

Policies must be designed in such a way that virtual team members are recognized, supported, and rewarded for their work (Duarte & Snyder, 2001; Jones et al., 2005). Providing team-based (rather than individual performance-based) rewards to team members can increase team cohesiveness, motivation, and effectiveness (e.g., Cohen, Ledford, & Spreitzer, 1996; Hertel, Konradt, & Orlikowski, 2004; Lawler, 1986, 1992). Since virtual team members are not seen every day in a central office, it is also possible that they may be overlooked for promotional opportunities (Duarte & Snyder, 2001). Therefore, special career development opportunities, such as job rotations and opportunities to present to team sponsors/executive groups, should be created for virtual team members so that this "out of sight, out of mind" phenomenon does not occur (Jones et al., 2005; Pinsonneault & Boisvert, 2001).

Provide the Team with Appropriate Autonomy

Consistent with traditional team research (Cohen & Bailey, 1997), virtual team members interviewed in the case studies reported that little involvement from senior management was usually preferred over hands-on management, as long as the organization still provides the necessary funds and resources. Worker autonomy is shown to have clear benefits such as enhanced worker attitudes and performance (Stewart, 2006). Organizations should give team members the power to take action and make decisions while still providing the team with the information it needs to make sound business decisions (Cohen, 1994). Organizations should provide information on processes, quality, customer feedback, business results, competitor performance, and organizational changes.

Use Standard Processes and Procedures

The use of standard processes and procedures, such as having a project charter, can reduce the time needed for team start-up and may eliminate the need for unnecessary reinvention of operating practices every time a new team is created (Duarte & Snyder, 2001; Gignac, 2005). For virtual teams that rarely meet face-to-face, standard communication procedures and policies are extremely important so that norms and expectations are clear (Duarte & Snyder, 2001; Fisher & Fisher, 2001; Grenier & Metes, 1995). An initial face-to-face team meeting can allow team members to develop communication norms and agreements on how they are going to work together. An experienced virtual team facilitator for the start-up phase can be valuable to ensure a team starts with a strong foundation (Gignac, 2005).

Develop an Organizational Culture that Stimulates the Sharing of Information

Sharing information effectively is critical to virtual team success (Gignac, 2005; Jones et al., 2005). Organizational culture influences how individuals in an organization behave and, thus, plays a large role in determining how well a virtual team functions. Therefore, organizations should work to build norms and values that promote communication and the sharing of information (Goodbody, 2005). The traditional team research also identified the importance of having a supportive culture. Organizations should create a cooperative work environment where norms are established that reinforce and support team behaviors such as sharing information, responding appropriately to team members, and cooperating (Bettenhausen, 1991), as such an environment is critical for effective team performance (Tjosvold, 1988).

TEAM LEADERSHIP BEST PRACTICES

There are seven best practices relating to the leadership and management of the virtual team. Table 2 contains a list of all seven team leadership practices, each of which is explained next.

Table 2. Management and team leader best practices for effective virtual teams

• Set goals and establish direction
• Recognize and manage the diversity within the team
• Provide feedback via coaching and modelling
• Build trust through open communication, honest behavior, and delivering on commitments
• Empower the team
• Motivate the team
• Use appropriate leadership styles at appropriate times

Set Goals and Establish Direction

The virtual team literature strongly suggests that effective leaders understand the importance of defining a vision for the virtual team (Fisher & Fisher, 2001; Grenier & Metes, 1995; Lipnack & Stamps, 1997; O'Hara-Devereaux & Johansen, 1994). According to Lipnack and Stamps (1997), a predictor of virtual team success is the clarity of its purpose and vision. To succeed, teams must turn their purpose and vision into action by assigning roles and responsibilities (Fisher & Fisher, 2001; Grenier & Metes, 1995; O'Hara-Devereaux & Johansen, 1994; Pinsonneault & Boisvert, 2001) and setting clear objectives goals (Jones et al., 2005; Lipnack & Stamps, 1997).

In the virtual team case studies, 64% of team members recognized this need to carefully set clear goals and realistic timelines. To accomplish this, management and team leaders can first develop a "roadmap" with realistic timelines that are compatible with the expectations of senior management. Next, the critical path through the project should be identified. Based on this path, major milestones should be set. Whether or not it affects them directly, all team members should be frequently reminded of the next milestone so that the team is aware of their interdependencies and how their work affects others. Focusing on milestones and deliverable dates will help members keep the "big picture" in mind when working on their individual tasks. Successful virtual teams are those that, with the help of a focused manager, are consistently able to meet milestones within the allotted time.

Recognize and Manage the Diversity within the Team

Virtual teams are typically more diverse than traditional teams since team members are drawn from multiple locations (Gibson & Cohen, 2003). Information diversity is a benefit for a team since it brings wider knowledge and expertise to bear on the team's task. However, some types of diversity can potentially impede teamwork and communication. People from different countries and cultures may have different values, expectations, language skills, communication norms, and appearances (Goodbody, 2005; Jones et al., 2005). If not managed well, these differences can easily lead to misunderstandings and the formation of team sub-groups, which fracture the team and impede sharing and performance. Managers must help the team recognize the diversity within the team, and openly discuss individual differences and expectations such that new team-level expectations are established (Gibson & Cohen, 2003). Also, diversity of location often means working across multiple time zones, which creates scheduling challenges. Managers should ensure that time differences are visible, respected, and that one group is not favored at the expense of the rest of the team.

Provide Feedback via Effective Coaching and Modeling

Team leaders need to provide members with timely feedback about their performance so team members know what they can do to continuously improve their performance (Duarte & Snyder, 2001). A manager's ability to provide remote employees with advice and help can increase the effectiveness of the remote employees (Staples, 2001). In virtual teams, this may require getting informal input from various people who interact with team members both within and outside of the organization. Virtual leaders also need to model appropriate virtual work habits (Jones et al., 2005; Staples, Hulland, & Higgins, 1999). To accomplish this, the telecommuting literature suggests managers should keep remote employees well-informed of organizational activities, provide regular feedback on performance and progress, establish well-structured and constant communications, and be available at hours that fit with work routines of remote employees (Pinsonneault & Boisvert, 2001).

Build Trust through Open Communication, Honest Behavior, and Delivering on Commitments

Establishing trust within a virtual team is critical (Gignac, 2005: Jones et al., 2005). Without trust, productivity suffers as team members spend time playing politics instead of working on real business issues (Fisher & Fisher, 2001). To build trust, it is important for team leaders to communicate openly and frequently with team members. The use of instant messaging (IM) can help do this (Jones et al., 2005). Perhaps the single most important variable that affects trust is honesty. Leaders who demonstrate openness about their actions will find that members respond with sincerity. How a leader listens and

communicates with his or her team members is very much related to team effectiveness and trust (Cohen & Bailey, 1997). Listening to team members and visibly keeping commitments increases trust, whereas broken promises diminish it (Fisher & Fisher, 2001). Effective leader communication is especially important to the performance of teams that are geographically dispersed (Cummings, 2006).

Empower the Team

This best practice is related to the organizational practice of more generally providing autonomy to teams. Team leaders also have to provide the appropriate level of autonomy, setting overall team goals and establishing direction while allowing individual team members to decide how they carry out their own specific tasks (Cohen & Bailey, 1997; Fisher & Fisher, 2001). Leaders who trust team decisions can give the members a sense of ownership. This approach is particularly important in a virtual team environment where geographic separation makes micromanagement and direct observation impractical.

Motivate the Team

In a virtual team environment where tasks may appear unconnected, the "big picture" is not always easy to visualize, making it difficult for employees to remain committed to the project. Thus, team leaders can play a key role in keeping virtual team members motivated. Motivation can be stimulated by making the importance of the team's task clear (such that passion for the team's cause is created) and by demonstrating how the project will result in significant outcomes for the individual team members (Fisher & Fisher, 2001; Staples et al., 2004). By linking team success to individual success and opportunities, team members will be highly motivated to succeed on the project. Visibly celebrating achievements can also build motivation and enthusiasm (Goodbody, 2005).

Use Appropriate Leadership Style

Over a quarter of case study team members (Staples et al., 2004) reported that appropriate leadership at the *appropriate time* was one of the key elements of a successful virtual team. Case study participants suggested that during the initial phases of the project, the appropriate leader is one who can "whip up enthusiasm" to motivate the team and create a sense of team spirit. During the later stages, the effective leader is someone who is "getting the right people together and keeping everybody on task and keeping everything going." Therefore, the style and activities of team leaders have to be appropriate for the team's development stage and needs at that particular time.

Table 3. Team member best practices for effective virtual teams

• Communicate effectively
• Have the necessary skill sets
• Be highly motivated
• Be supportive of other team members
• Be action-oriented

TEAM MEMBER BEST PRACTICES

Suggestions for what makes individual members of virtual teams effective include specific behaviors, as well as attitudes and beliefs. The five general characteristics of effective virtual team members are listed in Table 3 and described next.

Communicate Effectively

Research in traditional teams, virtual teams, and telecommuting recognizes that the ability to communicate effectively is a critical skill (Cohen, 1994; Goodbody, 2005; Jones et al., 2005; Pinsonneault & Boisvert, 2001; Staples, 2001). Eighty-four percent of team members interviewed in the case studies also recognized the importance of effective communication in building a successful team. Communication involves transferring ideas, sharing information, listening and internalizing the ideas of others, and notifying team members of any problems or issues. This can be challenging in a virtual team where face-to-face communication and impromptu meetings are infrequent, if not impossible. To solve this problem, virtual team members suggest working hard to keep lines of communication open, and developing or finding the right communications tools that make up for the loss of face-to-face time and provide for informal interactions. For example, team members can use e-mail or IM as a "virtual coffee pot or water cooler" around which personal conversations can occur or as an alternative medium to reach other team members (Cameron & Webster, 2004; O'Hara-Devereaux & Johansen, 1994). These informal interactions can also help to create team spirit.

In addition, team members themselves have to be responsive, quickly returning telephone calls and responding to e-mails, even if it is just to say, "I don't have time right now but I'll get back to you in two days with the answer." Recipients can also confirm that the message was received and ensure that the major points in the message were understood. Setting communication norms such as these helps to avoid misunderstanding that can occur when communicating electronically. IM tools also have the ability to indicate availability (i.e., online, temporarily away, off-line, etc.), potentially enhancing the presence a virtual team member projects to others and his/her awareness of the other team members' availability (Jones et al., 2005).

Have the Necessary Skill Sets

The effectiveness of a team depends on the collective knowledge and skills of its members. In order to make good decisions, team members need the appropriate knowledge and skills (Cohen, 1994; Jones et al., 2005). Specific skills mentioned by the virtual team members in the case studies included the ability to organize effectively, a strong competency in an individual's functional area of responsibility, adequate technical skills to use the information and technology tools available, and good time management skills. Specific social skills mentioned in the virtual team literature include learning how to negotiate creatively, mediating online disputes, and making new members of the team feel included (Grenier & Metes, 1995).

Be Highly Motivated

In some cases, a particular practice may exist at both the management and individual level. As described previously, motivating is an activity that must be performed by team leaders. The self-managing nature of many virtual teams means that *self*-motivation and *self*-discipline are also essential. Virtual team members must be able to work independently and be motivated to make appropriate decisions. This is made possible by having clear goals and responsibilities, and having high personal commitment and motivation to the team, along with having the resources and information needed to do the job (Lipnack & Stamps, 1997). The ability to self-motivate is important since virtual team members are often working far apart from their other team members. Virtual workers should also have a low preference or need for social interaction or have the ability to fulfill this need outside of the work team (Pinsonneault & Boisvert, 2001).

Be Supportive of Other Team Members

The way in which team members interact with each other influences team effectiveness (Cohen, 1994; Jones et al., 2005). Supporting team members involves working together with a sense of energy and team spirit and sharing ideas and expertise to help others (Cohen, 1994). Several dimensions of a supportive team emerged during the case study interviews. First, team members felt that it was important to recognize when someone else did a good job, and to congratulate or thank them accordingly. Second, interviewees sought a respectful team environment where members were not afraid to openly discuss ideas. Third, interviewees reported that the ability to get along with other team members was an essential quality of an effective virtual team member.

Be Action-Oriented

Interviewees felt that individuals should have an action-oriented approach when participating in a virtual team. Case study members of one team described a top performing virtual team member as someone who is a "doer," is "proactive," "uses an entrepreneurial approach," and "looks for solutions." One virtual team member stated that successful virtual team members are those who "organize their thoughts into actions or proposals that get a good buy" or influence the rest of the group.

FUTURE TRENDS AND OPPORTUNITIES

As global competition increases and trading barriers decline, the creation of teams comprised of members from many different locations is expected to become the norm. With this virtual team growth, knowing the best practices for team members, leaders, and organizations with virtual teams becomes very important. While some useful best practices are explained previously, some questions are left unanswered. These questions create many opportunities for future research such as:

- Which of the best practices are most critical for team effectiveness?
- Does the impact of certain practices on effectiveness vary depending on the task, organizational context, and/or the national and cultural background of the team members? How?
- Does one set of practices (i.e., individual, managerial, or organizational) take precedence such that those practices have to be in place before the other practices have a positive effect?
- How does an organization ensure that best practices are followed?
- Can training programs be developed for managers and leaders, and for members of virtual teams? What should be in these training programs, and how should they be delivered?
- Can policies be developed and norms established in organizations such that supportive practices, which research suggests lead to effective virtual work, are followed? How can this be done most effectively?
- Do the best practices vary for hybrid teams, in which some members are co-located and others are working remotely?

CONCLUSION

The ideas presented in this article should help organizations create and maintain more effective virtual teams. Individual virtual team members, virtual team leaders, and organizations can all follow best practices that contribute to virtual team effectiveness. Given the growing use of virtual teams in organizations today, there is a need to more deeply understand what makes a virtual team effective. We hope we have made a contribution in that direction, and we look forward to other researchers and practitioners answering some of the additional questions posed.

KEY TERMS

Blog: A blog (short for Weblog) is a personal online journal, containing the author's views and reflections on some topic about which he/she chooses to write.

Communication Norms: In the context of virtual teams, communication norms are typical routines and expectations for communicating within a virtual team using the communication media that the team has available to it (e.g., electronic communication such as e-mail or instant messaging, telephone, etc.). Responding within a day to all e-mails, even if just to say, "I'm busy but will get to this tomorrow," is an example of a virtual team communication norm.

Hybrid Team: A team (i.e., a group of individuals who work on interdependent tasks and who share responsibility for outcomes) in which some team members work in the same location and other members work remotely.

Instant Messaging (IM): Information systems that enable team members to exchange real time electronic messages and presence information (e.g., I'm off-line, online, busy, away, on the phone, etc.). Logs of the interaction can be captured, and some systems allow files to be exchanged.

Organizational Culture: The collective programming of the mind that distinguishes the members of one organization (or part of an organization) from another (Hofstede, 1997)

Remote Worker: An individual who works at a different location than his/her co-worker and/or manager. That person is remote, in terms of physical presence from his/her colleagues.

Team Diversity: The combined variety of skills, backgrounds, experiences, ideas, thoughts, abilities, and perspectives that individuals bring to their team.

Team Effectiveness: The ability of a team to perform its tasks on time, on budget, and with acceptable quality, as well as the satisfaction, motivation, and commitment of the team members.

Telecommuting: The practice of working from the employee's home instead of physically commuting to a company office location. The connection to the office is done via telecommunications, rather than physically commuting (i.e., travelling) to the office.

Traditional Team/Collocated Team: A traditional team is a group of individuals who work on interdependent tasks, who share responsibility for outcomes, and who work together at the same location (i.e., their office/work area is in the same general location).

Virtual Coffee Pot/Virtual Water Cooler: Using electronic communication (such as e-mail or instant messaging) to conduct informal interactions (personal or non-work conversations) that would normally be discussed around the office water cooler or coffee areas in a face-to-face work environment.

Virtual Team: A group of individuals who work together from different locations (i.e., are geographically dispersed), work at interdependent tasks, share responsibilities for outcomes, and rely on technology for much of their communication.

Effectiveness of Web Services: Mobile Agents Approach in E-Commerce System

Kamel Karoui
University of Manouba, Tunisia

Fakher Ben Ftima
University of Manouba, Tunisia

INTRODUCTION

With the development of the Internet, the number of people buying, selling, and performing transactions is expected to increase at a phenomenal rate. The emergence of e-commerce applications has resulted in new net-centric business models. This has created a need for new ways of structuring applications to provide cost-effective and scalable models.

Mobile Agents (MA) systems are seen as a promising paradigm for the design and implementation of distributed applications, including e-commerce. MA are also useful in applications requiring distributed information retrieval because they move the location of execution closer to the data to be processed. While MA have generated considerable excitement among the research community, they have not been applied into a significant number of real applications.

Web services (WS) are emerging as a dominant paradigm for constructing distributed business applications and enabling enterprise-wide interoperability. A critical factor to the overall utility of WS is a scalable, flexible and robust discovery mechanism; an application can be built by integrating multiple services together to make a more efficient service. WS represent a major development in the e-commerce sector. They enable companies to capitalize on their existing architecture by making their application services accessible via the Internet.

The application of MA and WS technologies to e-commerce will provide a new way to conduct business-to-business (B2B), business-to-consumer (B2C), and consumer-to-consumer transactions (C2C) and facilitate the communication between heterogeneous environments.

In this article, we first focus on these two technologies of actuality and show their integration in an e-commerce system. Second, we present different kinds of interaction between MA and WS and study their effect on application performance. We also study an example that illustrates an e-commerce system including three categories of transactions:

-Shopping transactions: a customer delegates one MA for research and purchase of articles online. The MA will interact with available WS to find the article and its best price.

-Salesman transactions: to valorize their products, WS will invoke MA to make publicity for the customers.

-Auction transactions: for this type of transaction, a MA (respectively a WS) can sell and buy a product from/to others MA (WS) by auction.

Finally, we conclude with a discussion on our inferences and their implications.

This work is structured as follows:

Section "background" reviews the notions of e-commerce system, WS and MA paradigms. Section "Web services and mobile agents' technologies on e-commerce system" presents the integration of these two paradigms on the e-commerce system. In section "performance evaluation," we evaluate the performances of our approach and we study an illustrated example in the section "a case study." The section "future trends" presents our future perspectives and we end this work with the "conclusion" in the last section.

BACKGROUND

E-Commerce

E-commerce can be viewed as a set of processes that support commercial activities within an information network (Chaves, Martins, Monteiro, & Boavida, 2002). These activities produce information about products, events, services, suppliers, consumers, publicists, transactions, advanced search algorithms, transactional security, authentication, and so forth. In brief, e-commerce entails the development of a business vision, supported by information technology with the goal of enhancing efficiency within the process of trade (Adam, Dogramaci, Gangopadhyay, & Yesha, 1999). The fact that this technology is so fast, transactions require less human interaction and a greater reliance on autonomous software agents (Chaves, Simões, & Monteiro, 2003).

Web Services

WS are a new kind of Web application. They are self-contained, self-describing and modular applications that can be published, located, and invoked across the Web. WS perform functions, which can be anything from simple requests to complicated business processes. Once a WS is

deployed, other applications (and other WS) can discover and invoke the deployed service (Lemahieu, 2001). WS can significantly increase the Web architecture's potential, by providing a way of automated program communication, discovery of services, and so forth. Therefore, they are the focus of much interest from various software development companies (WSAP, 2000).

Mobiles Agents

MA are software programs that can travel autonomously from host to host to perform one or more tasks on behalf of a user. They can communicate (and even negotiate) with other agents and hosts. The MA paradigm proposes a new approach for designing applications in open and heterogeneous distributed environments (Nwana, Rosenschein, Sandholm, Sierra, Maes, & Guttman, 1998). Several application areas can benefit from the adoption of the MA technology: It can support electronic commerce transactions and help in information gathering, filtering, and negotiation. MA solutions provide mobility, autonomy and easy personalisation (Guttman, Moukas, & Maes, 1998).

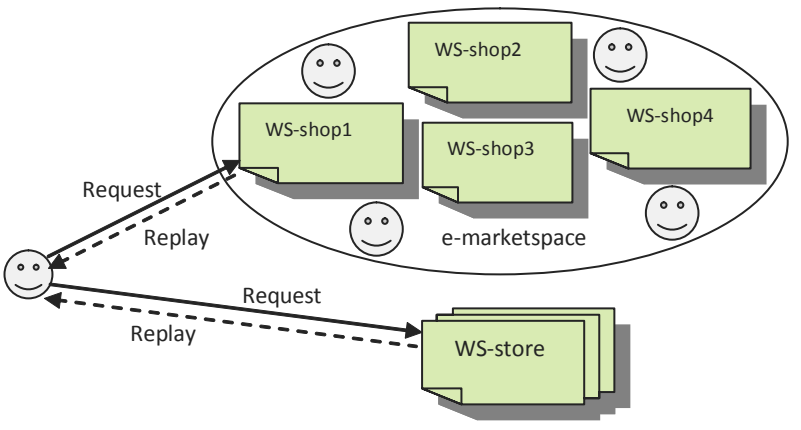
WEB SERVICES AND MOBILE AGENTS TECHNOLOGIES ON E-COMMERCE SYSTEM

E-commerce covers any form of business or administrative transaction or information exchange that is executed using any information and communication technology. It refers especially to the commercial activities conducted on the Internet. E-commerce systems not only provide commercial information, such as product price and features, but also facilitate various commercial actions, such as buying, selling, and negotiation. The popularity of software agents, in the execution of tasks related to information filtering, mapping of people with similar interests and automation of repetitive behaviours is well known (Maes, Guttman, & Moukas, 1999). It is thus without surprise that agent-based technology is seen as the one that will revolutionize e-commerce in the way it is seen today, promising a new and innovative approach in the way transactions are processed, whether they are business-to-business, business-to-consumer or even consumer-to-consumer. Using MA represents an important leap in the development of first generation (static) agent systems (El Falou & Bourdon, 2004). The possibility of working off-line, thus saving network resources, is one of the main advantages. There is no need to keep a connection active while a transaction is processed.

To achieve a result, a program tasked (e.g., a MA) can use Web services as support for its computation or processing. The program can discover Web services and invoke them fully automated. Hence, it becomes a service requester. If the Web services have a cost attached, the program knows when to search for a cheaper service and knows all the possible payment methods. Furthermore, the program might be able to mediate any differences between its specific needs and a Web service that almost fits (Bernard, 2000).

In e-commerce, this translates into automatic cooperation between enterprises (Shaw, 2000). Any enterprise requiring a business interaction with another enterprise can automatically discover and select the appropriate optimal Web services relying on selection policies. They can be invoked automatically and payment processes can be initiated. Any necessary mediation applied is based on data and process ontologies and the automatic translation of their concepts into each other (Papaioannou & Edwards, 1998; Sandholm, 1999).

Figure 1. Shopping transaction



The idea of this work is to construct a simple and efficient e-commerce system that helps customers find the best possible offer for their needs. MA plays an important role in this process, as they represent the users in their interaction with the ever-growing marketplace represented by WS. We classify interactions between MA and WS (Karoui & Ftima, 2008), in the e-commerce system into three categories: shopping transactions, salesman transactions and auction transactions.

Shopping Transactions

For this type of transaction, MA purchases in e-marketplaces (a collection of e-shops represented by WS) on behalf of their owner according to user-defined specifications. This model of e-commerce uses a customer-driven marketplace. A typical shopping agent may compare features of different products by visiting several online stores and report the best choice to its owner. The MA carries the set of features to be considered and their ideal values as specified by its owner. The MA is given one or more WS to visit and may dynamically visit other WS based on subsequent information. One example of a system that implements shopping agents is illustrated in Figure 1, where agents deal with many WS to find a product.

Salesman Transactions

For this type of transaction, MA behave like a travelling salesman who visits customers to sell his wares. This model of e-commerce uses a supplier driven marketplace and is particularly attractive for products with a short shelf-life. A supplier (WS) creates and dispatches a MA to potential buyers by giving it a list of stores (WS-s) or e-marketplaces (WS-m) to visit. The MA carries with it information about available stock and the product price. A schema implementing a salesman agent is illustrated in Figure 2.

Auction Transactions

In this type of transaction, MA can bid for and sell items in an online auction on behalf of their owners (a user or a WS). In the presence of multiple auction hosts (e-marketplace, e-store…), MA can be used for collecting information across them. An agent can make a decision to migrate to one of them dynamically, depending on the amount of information transmitted, latency, and so forth. Some advantages of using MA include allowing disconnected operation of auction agents, reducing network traffic, and facilitating quicker response during auction. One example of a system that implements mobile auction agents is illustrated in Figure 3.

PERFORMANCE EVALUATION

The quantity of information exchanged between the different WS, the type of application as well as the characteristics of the network are decisive parameters for the choice of the technology to be implemented. In this section, we will show the advantages of our system compared to the client/server model.

Figure 2. Salesman transaction

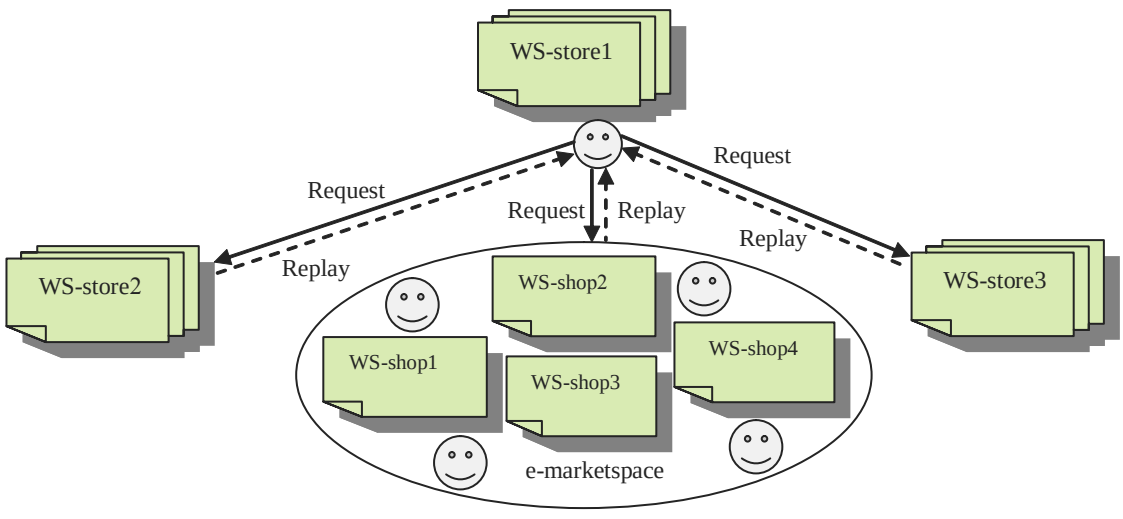


Figure 3. Auction transaction

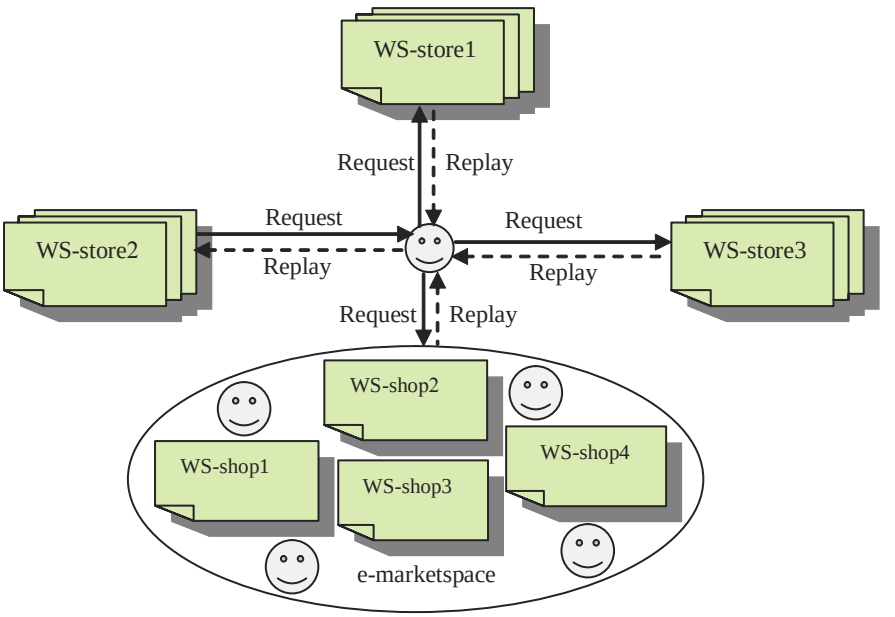


By using the client/server technology, the different components of an e-commerce system communicate with a permanent link for requests and answers. Exchanges proceed mostly by a manager machine that redirects requests toward the concerned components.

The use of the MA-WS technology will allow:

- To make the circulation of information between the various components of the e-commerce system easier: MA move from a WS (host) to another without a well-defined route.
- To accomplish the request tasks asynchronously contrary to the client/server technology that requires a permanent link for the execution of their tasks.
- To lighten the bandwidth use: The client/server technology consumes a big part of the bandwidth due to the big volume of requests exchanged. MA encapsulate the request and migrate from a WS (host) to another when necessary.
- To reduce the number of the exchanged requests as the MA moves from host to host without every time returning the results to the original host.
- To reduce the requests execution time: by studying the communication's parameters between hosts, requests will be executed faster with the MA-WS (see details on the next paragraph).

Requests Execution Time Reduction

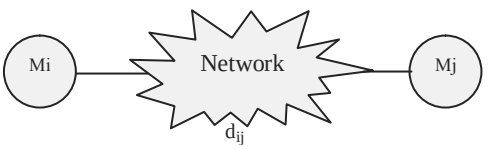
We will compare the two approaches in the case of an exchange between two hosts M_i and M_j joined by a network with a bit rate d_{ij} (bits/s). In order to compute the transmission time (Halsall, 2002), we need to divide the size of the request (bits) by d_{ij} (Figure 4).

Client/server approach:

The client sends requests to the server across the link d_{ij}. Q_{ijk} is the size of the client's request "k," A_{ijk} the size of the server's answer "k" and N is the number of exchanged requests between M_i and M_j. The transmission time is (El Falou & Bourdon, 2006):

$$T_{CS} = \sum_{k=1}^{N} \frac{A_{ijk}}{d_{ij}} + \sum_{k=1}^{N} \frac{Q_{ijk}}{d_{ij}} = \sum_{k=1}^{N} \frac{(A_{ijk} + Q_{ijk})}{d_{ij}} \quad (1)$$

Figure 4. Communication between two hosts



If we suppose that (A_{ij1}= A_{ij2}=… $A_{ijk)}$ and (Q_{ij1}= Q_{ij2}=… Q_{ijk}). The expression (1) becomes:

$$T_{CS} = \frac{N \times (A_{ij} + Q_{ij})}{d_{ij}} \quad (2)$$

MA Approach

The client creates a MA on M_i and sends it toward M_j. At the end of the interaction, the MA turns back to the client on Mi with the result. The transmission time corresponds to the elapsed time between the dispatching of the MA by the client and the reception of the result by the MA, knowing that an agent on a server M_i is composed of two elements: processing part (S) and data part (D_i). The global size of the agent on M_i is S+ D_i (respectively S+ D_j on server M_j). The transmission time is:

$$T_{MA} = \frac{S + D_i}{d_{ij}} + \frac{S + D_j}{d_{ij}} = \frac{2 \times S + D_i + D_j}{d_{ij}} \quad (3)$$

A comparison between the expressions (2) and (3) allows us to say that the more the value of N increases, the more the MA-WS approach is beneficial.

$$\frac{T_{MA}}{T_{CS}} < 1 \Rightarrow \frac{2 \times S + D_i + D_j}{A_{ij} + Q_{ij}} < N \quad (4)$$

A CASE STUDY

We have chosen a typical e-commerce application (Sohn & Yoo, 1998), that of a user organizing a complete holiday trip. We have produced a prototype using the three strategies mentioned. We didn't take into account the security parameters (for buying and selling owners) during the elaboration of our prototype. We have used the Aglets platform for MA implementations (Lang & Oschima, 1998). It is implemented in Java and provides support for mobiles objects and autonomous MA. We have also implemented this application with the Client/server model to evaluate our prototype. The reservation steps are the following (Figure 5):

Step 1: The user sends a MA.

The user wants to organize a complete holiday trip, including flight reservation, hotel booking, car rental, day trip arrangements, and so forth. For these different parts of his holiday, he sends a customized MA to the network that will find the best bargains. Obviously, the MA will have to exchange information to be able to jointly organize the holiday according to the overall requirements of the user (Figure 5-Link 1). After the MA is sent to the network, the user can disconnect from the network.

Step 2: The MA travels and collects data.

The MA travels from host (WS) to host; only the agent parameters and collected data are transferred between the agent platforms (they constitute the personalization and customization of the code). The MA will collect offers from different WS and other information at each platform (Figure 5-Link 2); this kind of interaction illustrates the interaction MA-WS outlined previously.

Step 3: The MA conducts a payment transaction.

The MA will decide or need to conduct a payment transaction nearby a bank. This latter (the bank represented by a WS-b) will then ask the cooperation of other agents in order to verify the client's identity (e.g., his digital signature). After checking on this information, the bank validates the operation and the MA finishes its transaction (Figure 5-Link 3); this kind of interaction illustrates the interaction WS-MA outlined previously.

Step 4: The MA conducts its proper transactions.

At the end of its research, the MA will return to its platform. The data possibly includes transactions conducted by this MA; to guarantee the best offer for the customer, a MA can carry out its own transactions (Figure 5-Link 4 & 5); these transactions are hybrid type interactions. This kind of interaction illustrates the interaction WS- MA and MA-S outlined previously.

Step 5: The user consults the result.

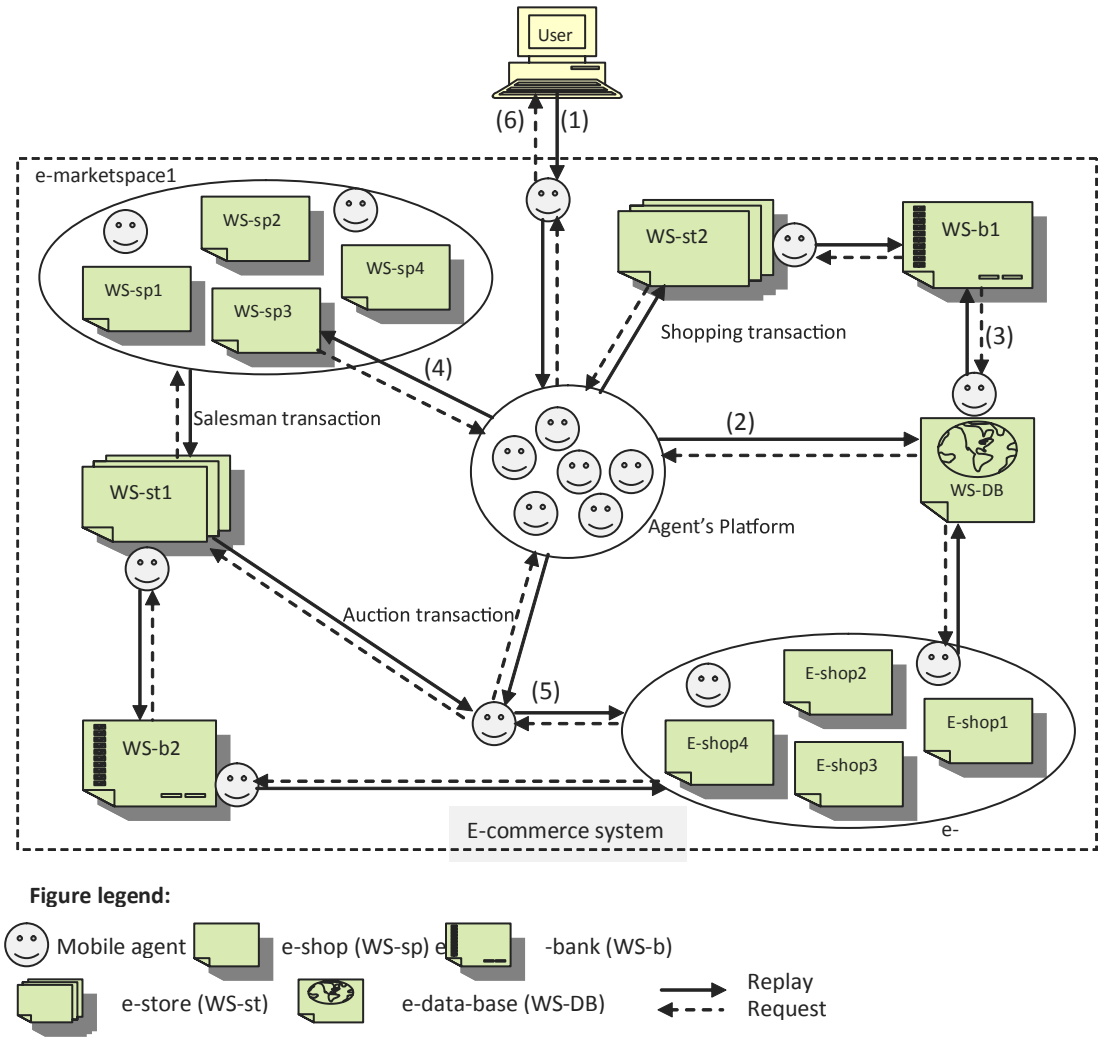
When the users reconnect to the network, they can request the status of their MA and retract the returned agents from the network (Figure 5-Link 6). They can then disconnect again and interpret the collected data of the agents.

Measures and Interpretations

To evaluate this application, we have implemented it with both approaches: MA-WS and Client/server. For our example, we restrict to following steps of the holiday trip:

Holiday trip = flight reservation + hotel booking + car rental.We suppose that the links joining the three hosts have the same bit rate (56 kbits/s) and the global size of the MA is 20 kbits.

Figure 5. E-commerce system



Client/Server Approach

$$\text{Flight reservation} = \frac{A_{ij} + Q_{ij}}{d_{ij}} = \frac{64{,}36 + 52{,}12}{56} = 2{,}08\text{s}$$

$$\text{Hotel booking} = \frac{A_{ik} + Q_{ik}}{d_{ik}} = \frac{117{,}52 + 113{,}20}{56} = 4{,}12\text{s}$$

$$\text{Car rental} = \frac{A_{in} + Q_{in}}{d_{in}} = \frac{36{,}52 + 32{,}36}{56} = 1{,}23\text{s}$$

According to (1), the three steps are fulfilled in 7,43s.

MA Approach

$$\text{Flight reservation} = \frac{S + D_i}{d_{ij}} = \frac{20 + 52{,}24}{56} = 1{,}29\text{s}$$

$$\text{Hotel booking} = \frac{S + D_k}{d_{jk}} = \frac{20 + 117{,}2}{56} = 2{,}45\text{s}$$

$$\text{Car rental} = \frac{S + D_n}{d_{kn}} = \frac{20 + 37{,}68}{56} = 1{,}03\text{s}$$

According to (3), these even steps are fulfilled in 4,77s.

It is clear that our approach is more interesting in comparison with that of the Client/server on the theoretical and experimental plans.

FUTURE TRENDS

In this work, we have compared the two approaches according to the transmission time. In future work, we will study the effectiveness of our approach using other criterias as, for example, propagation time, bandwidth, and so forth. This work is under realization on theoretical as well as experimental plans.

CONCLUSION

In this article, we have proposed the integration of MA-WS in an e-commerce system. In effect, usually e-commerce systems are based on client/server model. Then, we have listed the advantages of this approach in comparison with the client/server model. Also, we have compared both approaches according to the transmission time and we have implemented an application based on both approaches, from which we have calculated the transmission time of each of them. Acquired results confirm theoretical study that we accomplished.

KEY TERMS

Aglets: It is a java-based mobile agent platform and library for building mobile agents-based applications.

Client/Server: It is a distributed computing model in which client applications request services from server. Clients and servers typically run on different computers interconnected by a computer network.

Distributed Application: It is an application composed of distinct components running in separate runtime environments, usually on different platforms connected via a network.

E-Commerce: It is the buying and selling of goods and services on the Internet, especially the World Wide Web.

Hybrid Interaction: It is a mixture of MA-WS interactions and WS-MA interactions.

MA-WS Interaction: It is an interaction in which a mobile agent invokes a Web service for a request execution

Mobile Agent: It is a mobile software entity that can migrate from one host to another in order to satisfy client requests.

Web Service: It is a paradigm that allows interaction between distant applications via Internet independently of their platforms and languages.

WS-MA Interaction: It is an interaction in which a Web service invokes a mobile agent for a request execution.

Effects of Extrinsic Rewards on Knowledge Sharing Initiatives

Gee Woo Bock
Sungkyunkwan University, Korea

Chen Way Siew
IBM Consulting Services, Singapore

Youn Jung Kang
Sungkyunkwan University, Korea

INTRODUCTION

In the field of motivation, incentives are seen as a means of motivating people. Incentives are usually applied in the form of a scheme, such as piece-rate and fixed-rate monetary rewards. Since the field of knowledge management involves a certain measure of motivation, a number of organizations have used incentives to encourage their employees to share knowledge. Research to date concerning the role of incentives in knowledge sharing seems to contradict one another. Furthermore, when an incentive is sufficiently large, some individuals are inspired to increase their performance to reflect the incentive received (London & Oldham, 1976).

Along with this negative disposition, intrinsically motivated individuals would experience a deterioration of such motivation due to the introduction of incentives, thus jeopardizing the whole knowledge sharing initiative (Deci, Koestner, & Ryan, 1999; Jordan, 1986).

Some research (Bock & Kim, 2002; O'Dell & Grayson, 1998) has suggested a trigger effect that comes from implementing incentives. Empirical evidence concerning the long-term effects of incentives in the field of knowledge sharing is also lacking (Fossum, 1979; O'Dell & Grayson). This research seeks to consolidate the many different views of past research, investigating areas that are lacking. Is it possible to consolidate the different views of incentives in knowledge sharing? Are there differences between having fixed-rate, piece-rate, or no incentive schemes in knowledge sharing initiatives? Do incentives exhibit a triggering effect in motivating individuals to share their knowledge? Would the removal of incentives after the trigger period affect a knowledge sharing initiative? Will the continual increase of incentives remain effective in the long term for knowledge sharing initiatives? These research questions will be answered as the article progresses.

BACKGROUND

This research into the effects of extrinsic rewards on knowledge sharing initiatives encompasses a number of constructs. These constructs were grouped into three sections—knowledge sharing, the introduction of incentives in knowledge sharing, and overcoming past research limitations—and are as described below.

Knowledge Sharing

Knowledge is defined to be a justified belief that enables effective action through the increase of an entity's capacity (Nonaka, 1994). It is considered to be a vital part of an organization's resources. In the resource-based view (Barney, 1991), resources that are valuable, are rare, lack substitutes, and are imperfectly imitable, such as knowledge, offer a source of sustained competitive advantage. In order for an organization to exploit its knowledge, there is a need for the management of knowledge. According to von Krogh (1998), knowledge management is the process of identifying and leveraging the knowledge within an organization so as to help maintain its competitiveness.

Organizations are able to manage knowledge through the use of specialized information systems: knowledge management systems. Knowledge management systems are also referred to as knowledge repositories, shared knowledge bases, or knowledge-based systems, and can include bulletin-board systems (BBS) as well as online forums that archive users' posts.

In the field of knowledge management, the process of transferring knowledge (i.e., knowledge sharing) is considered to be of utmost important. Knowledge sharing is defined as the voluntary process of transferring or disseminating knowledge from one person to another person

or group in an organization (Nelson & Cooprider, 1996). If there were no knowledge transfer activities, the field of knowledge management would not exist. For the purpose of this research, the process of knowledge sharing is taken from the viewpoint where it is empowered by technology through the use of knowledge management systems.

Incentives in Knowledge Sharing

In the knowledge sharing field, incentives are used as a means to an end, easing individuals into parting with their knowledge (Ba, Stallaert, & Whinston, 2001; von Krogh, 1998). There exist costs in the preparation of knowledge for sharing purposes and individuals may not share unless they are duly compensated. Should the benefit exceed the cost, individuals will share knowledge (Constant, Keisler, & Sproull, 1994). These costs arise from lost work time, reduced power and influence, as well as the extra effort needed to articulate knowledge into a comprehendible form. Incentive schemes are the means implemented in organizations to compensate for these costs.

Incentives are usually administered in the form of a structured scheme commonly known as an incentive scheme. Schemes are structured according to the needs of the organization, guided by the purpose for which it would be used and the personnel it is directed at (Jennergren, 1980). The functions of incentives, in addition to inciting action, include affecting the individual's goals and intentions, suggesting to varying degrees goals or intentions, and aiding in the ensuring of an individual's commitment to various goals (Dobmeyer, 1972).

For the purpose of this research, extrinsic rewards would follow the definition provided by Deci et al. (1999) and would specifically imply monetary rewards. Monetary rewards are able to trigger action because "it can provide outcomes that satisfy physiological and psychological needs" (Stajkovic & Luthans, 2001, p. 581). When it comes to extrinsic rewards, a number of researchers have either found a negligible or negative relation between incentives and knowledge sharing. Although individuals interviewed by Bock and Kim (2002) prior to conducting a survey seem to place an emphasis on extrinsic rewards, the result of the study found a negligible relation between rewards and knowledge sharing activities. They justified this result based on motivation literature such as that of Herzberg (1968). Extrinsic rewards do not motivate, but move. Individuals move to avoid the punitive effects from both extrinsic rewards and punishment of the carrot-and-stick philosophy. Once the work environment changes and the carrots are no longer desirable, extrinsic rewards would lose its effectiveness (Levinson, 1973).

In fact, most experienced employees regard knowledge sharing as part of their work responsibilities, and thus hold a negative perception toward the introduction of extrinsic rewards (Constant et al., 1994). The presence of extrinsic rewards can attract nonintrinsically motivated individuals to participate in knowledge sharing (Davenport, Prusak, & Wilson, 2003). The presence of such individuals could prove disruptive to the knowledge sharing initiative as they would share knowledge of low or no quality for the sole purpose of attaining the reward. Alongside this, extrinsic rewards would simultaneously decrease the motivation of individuals who are intrinsically motivated (Deci et al., 1999; Jordan, 1986). The presence of extrinsic rewards would change their focus to that of the reward (Kerr, 1999). They would dispense all of their efforts in pursuit of the rewards, thus affecting their perception of the task at hand (Kreps, 1997; Meyer, 1975; Pfeffer, 1998). A negative perception of the task arises because if they have to be bribed to perform it, the task must be something that they would not otherwise perform (Kohn, 1993).

Overcoming Past Research Limitations

Past research with regard to extrinsic rewards and knowledge sharing were limited in a number of ways. Bock and Kim (2002) and O'Dell and Grayson (1998) also made mention of the possibility of extrinsic rewards having a triggering effect on knowledge sharing initiatives. Empirical evidence is also lacking when it comes to the long-term usage of incentive schemes. O'Dell and Grayson mention that "explicit rewards and incentives go only so far" (p. 168) while Fossum (1979) mentions "reward receipt did not lead to higher performance in subsequent periods, whether appropriately or inappropriately administered" (p. 586). The types of incentive schemes used are frequently generalized, failing to differentiate between the types of schemes: piece-rate, fixed-rate, as well as the absence of an incentive scheme. Piece-rate monetary incentive is defined as paying individuals for each unit produced predetermined amounts of money (Stajkovic & Luthans, 2001), while fixed-rate incentive is the fixed payment of a predetermined sum to individuals for their participation in a task (London & Oldham, 1976).

In order to address these limitations—view disparity, trigger effect, long-term effects, and incentive-schemes differentiation—four research questions were synthesized to guide this research.

- Is it possible to consolidate the different views of incentives in knowledge sharing? This question seeks to address the disparity in views.
- Are there differences between having fixed-rate, piece-rate, or no incentive schemes in knowledge sharing initiatives? Here we address the lack of comparison in this area.
- Do incentives exhibit a triggering effect in motivating individuals to share their knowledge? We want to

validate this trigger nature of incentives with empirical evidence.

- Will the continual increase of incentives remain effective in the long term for knowledge sharing initiatives? This question is asked to investigate the effectiveness of long-term incentive schemes.

METHODOLOGY

In order to investigate the above research questions, six groups of participants are classified. This can be simplified into a 2x3 matrix research design, as shown in Table 1. As its name implies, fixed-rate rewards do not have increasing or decreasing amounts throughout the experiment.

Research Hypotheses

London and Oldham (1976) found that a group provided with fixed-rate extrinsic rewards actually performed worse than that of a group without rewards. A group that does not receive any extrinsic rewards would be intrinsically motivated. With regard to this experiment, the participants from Experimental Group A were informed about their fixed-rate rewards and were expected to perform better than the control group throughout the experiment.

On the other hand, a piece-rate incentive scheme would provide individuals with a goal to work toward. The amount of rewards that an individual receives corresponds to the amount of knowledge shared. Fossum (1979) supported this view when he found that there was no performance difference between a group with piece-rate and a group without extrinsic rewards in the long term. With regard to this experiment, the participants from Experimental Group B were informed about their piece-rate rewards and their performance increase was expected to trickle off toward the experiment's end.

Kohn (1993) as well as Wasko and Faraj (2000) found that extrinsic rewards do not secure anything but temporary compliance from individuals. When individuals comply in the short run, it was able to help trigger knowledge sharing activities. This trigger effect has been suggested in the work of Bock and Kim (2002) as well as O'Dell and Grayson (1998). With regard to this experiment, the participants from Experimental Group B, C, and E are expected to show a performance increase over the control group in the initial stages of the experiment due to the triggering effect of extrinsic rewards.

Herzberg (1968) mentions that it is a myth to think that increasing rewards would offset the long-term negative effects. Coupled with the trigger effects mentioned earlier, even the continuous increase of rewards would only kick-start the initiative. Continuously increasing rewards would not only falter just as with any other long-term incentive schemes, but is also not cost effective. With regard to this experiment, the participants from Experimental Group E would initially perform better than the control group, but increasing rewards do not help in the long term.

The hypotheses for this study are as a shown in Table 2.

Experiment

In order to empirically test the above-mentioned hypotheses, an experiment was conducted. Experimental research was chosen because the research questions sought to observe the changes in knowledge sharing behavior through the manipulation of extrinsic rewards.

The IVLE (Integrated Virtual Learning Environment) online forum, the medium that facilitates students' knowledge sharing activities in the School of Computing (SoC) of the National University of Singapore (NUS), allowed students to share their knowledge with ease, and all knowledge shared would be archived for the whole semester. A module in programming was chosen as the platform to conduct the experiment because the likelihood of students sharing their knowledge on the IVLE online forum is high. Participants were randomly assigned to one of five different groups that

Table 1. Experiment's groups and 2 x 3 matrix research design

Trends / Scheme	**Constant**	**Increasing**	**Decreasing**
Fixed-Rate	Experimental group A. Fixed-rate rewards	Not Applicable	
Piece-Rate	Experimental group B. Piece-rate rewards	Experimental group D. Increasing piece-rate rewards	Experimental group C. A period of piece-rate rewards followed by a period of no rewards

Table 2. Hypotheses

Hypotheses
H1: Fixed-rate extrinsic rewards do not significantly affect knowledge sharing activities.
H2: Piece-rate extrinsic rewards do not significantly affect knowledge sharing activities in the long term.
H3: Extrinsic rewards exhibit a triggering effect towards knowledge sharing activities.
H4: Increasing extrinsic rewards above a certain threshold would no longer be effective in influencing knowledge sharing activities

consisted of one control group and four experimental groups. Depending on the group that they were in, participants were given varying amounts of extrinsic rewards, and the amount of knowledge sharing that occurred was monitored. Senior students who have previously taken this module were asked about their opinions regarding the amount of rewards that would spur them on to share knowledge. For fixed-rate rewards, the amount of $5.00 was estimated to be half the average amount that students receiving piece-rate rewards will achieve. As for the group with increasing rewards, the piece-rate reward of $1.00 was recorded for a period longer than 2 weeks to place emphasis on the middle amount paid to the students.

Data Collection

Depending on which group students were in, they were individually informed by e-mail at the appropriate time that they would be rewarded for shared knowledge. The knowledge shared by students is classified into six categories, of which only two would be rewarded. First and foremost, knowledge is classified into explicit, implicit, or a combination of both as listed in Table 4. Second, knowledge is categorized as relevant or irrelevant. The two categories of knowledge that will be rewarded are the relevant implicit knowledge and the combination of explicit and implicit knowledge that is relevant, as shown in Table 3. Sample knowledge from all the relevant categories and a single irrelevant piece of knowledge are listed in Table 4.

Data Analysis and Result

As can be seen from Figure 1, the graph pattern of the control group seemed to mainly hover below 5. It starts off slow and experiences multiple peaks and dips as it moves along, reaching its highest point at the sixth week.

Experimental Group A (fixed-rate-rewards group) seemed to initially follow closely the pattern of the control group, albeit at a higher level. Experimental Group B (piece-rate-rewards group) hovered close to the level of the control group but followed a different pattern. Experimental Group D (increasing-piece-rate-rewards group) seemed to oppose the pattern of the control group for the first four weeks.

The control group started their knowledge sharing activities later than the other groups. Experimental Group A (fixed-rate-rewards group) actually started well, surpassing the levels of the control group as well as the piece-rate-rewards group. Experimental Group B (piece-rate-rewards group) started higher than both the control group as well as the deferred-piece-rate-rewards group, but was comparatively much lower than that of other groups. Experimental Group C (initial-piece-rate-rewards group) had continuously increasing amounts of shared knowledge up until the third week. Finally, although Experimental Group E (increasing-piece-rate rewards group) started off with the lowest amount of piece-rate rewards, it is the group with the highest starting point.

From the data analyzed, it was found that all hypotheses were supported. Although Figure 1 showed that the fixed-rate group shared much knowledge initially before tapering off, statistical results showed otherwise. Fixed-rate rewards

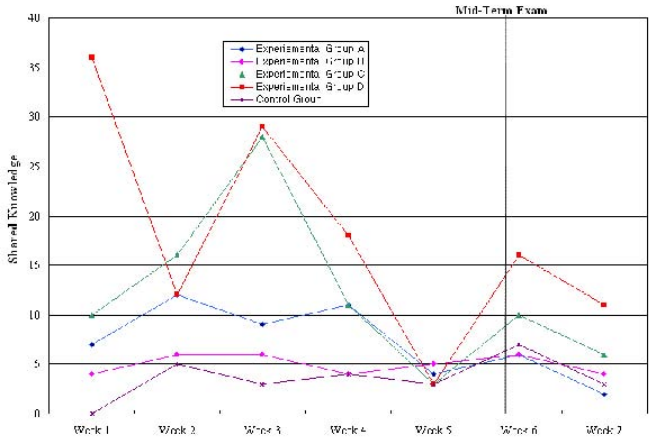
Figure 1.



did not significantly influence knowledge sharing activities throughout the 7 weeks of observation. Trigger effects seemed to be exhibited by the piece-rate, initial-piece-rate, and increasing-piece-rate groups. Following the trigger period, the initial-piece-rate group dropped in the amount of knowledge shared. A number of those within this group that shared much knowledge said that they were initially spurred on by the extrinsic reward. Since shared knowledge becomes a public good, most people would choose to consume rather than contribute to the shared knowledge base.

From the results of this study, it might seem that extrinsic rewards do not help at all with a knowledge sharing initiative. The future of extrinsic rewards in knowledge sharing may not be as bleak as it seems. Rewards are only able to explain 9% of variances in knowledge sharing activities. Rewarding knowledge sharing activities when the organizational culture does not support it would bring about cynicism among employees.

FUTURE TRENDS

This research has shown that it is possible to reconcile the disparity in past research, having shown that incentives do exhibit both facilitating and inhibiting views: It all depends on how a scheme is implemented. Continued research along these lines would bring about meaningful results that could easily be ported for practitioners' usage. This study has shown that extrinsic rewards do exhibit a triggering effect, and this can be exploited to aid in successful knowledge sharing initiatives.

When implementing an incentive scheme, organizations should be aware of the type of schemes used. One should utilize a piece-rate scheme, coupling it with proper organizational norms to aid in achieving a successful knowledge sharing initiative. Recognize that the continual increase of extrinsic rewards does not work if the scheme is used by itself. In addition to not being cost effective, it could fairly well jeopardize the whole initiative.

CONCLUSION

This study set out to build on the foundations of past research, fusing together the differing views of past literature. Based on the results shown, it is believed that this study has achieved this goal. Incentives exhibit both facilitating and inhibiting nature. What is needed is for organizations to utilize them so as to maximize the facilitating and minimize the inhibiting factors. It is important for organizations to properly design a performance-dependent incentive scheme that appropriately rewards employees. This scheme has to be coupled with an organizational culture that emphasizes the collective wellness of the organization. Do not allow an incentive scheme to proceed, especially for the long term if a knowledge sharing culture is not initially embedded in the organization. This would only result in detrimental effects.

KEY TERMS

Explicit Knowledge: It is knowledge that has been captured and codified into manuals, procedures, and rules, and is easy to disseminate.

Fixed-Rate Incentive: It is a scheme that pays individuals predetermined amounts of money for each unit produced.

Implicit Knowledge: It is knowledge that can be expressed in verbal, symbolic, or written form but has yet to be expressed.

Incentive or Rewards: They are events or objects external to the individual that can incite action.

Irrelevant Knowledge: Knowledge that is erroneous and incomplete, unrelated to the course work, does not answer the question of the knowledge seeker, and was previously shared by another student.

Knowledge Management Systems: These are a class of information systems developed to support and enhance the organizational processes of knowledge creation, storage and retrieval, transfer, and application.

Knowledge Sharing: It is the voluntary process of transferring or disseminating knowledge from one person to another person or group in an organization.

Piece-Rate Incentive: It is a scheme that pays a predetermined sum to individuals for their participation in a task.

Relevant Knowledge: It is knowledge that is correct and complete, related to the course work of students, answers the question posed by another student, and was not previously shared before by another student.

Efficient Multirate Filtering

Ljiljana D. Milić
University of Belgrade, Serbia

INTRODUCTION

A *multirate filter* can be defined as a digital filter in which the input data rate is changed in one or more intermediate points. With the efficient multirate approach, computations are evaluated at the lowest possible sampling rate, thus improving the computational efficiency, increasing the computation speed, and lowering the power consumption. Multirate filters are of essential importance for communications, image processing, digital audio, and multimedia. The role of multirate filtering in modern signal processing systems is threefold: Firstly, they are used whenever there is a need to preserve the signal properties when connecting two systems operating at different sampling rates. Secondly, multirate techniques are used for constructing filters with stringent spectral constraints that are very difficult, even impossible, to be solved otherwise. Thirdly, multirate filters are used in constructing multirate filter banks.

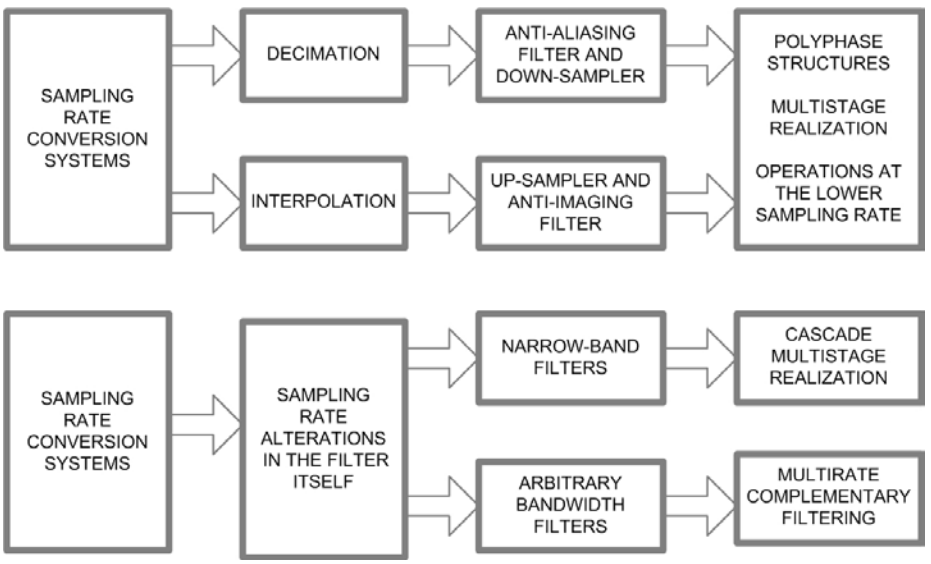
BACKGROUND

Efficient multirate filtering techniques have been developed during the past three decades for implementation of digital filters with stringent spectral constraints (Ansari & Liu, 1993; Bellanger, 1984, 1989; Crochiere & Rabiner, 1981, 1983; DeFata, Lucas & Hodgkiss, 1998; Fliege, 1994; Harris, 2004; Hentchel, 2002; Milić & Lutovac, 2002; Milić, Saramäki & Bregović, 2006; Mitra, 2006; Proakis & Manolakis, 1996; Vaidyanathan, 1990, 1993; Zelniker & Taylor, 1994).

MULTIRATE FILTERING TECHNIQUES

Multirate filtering is one of the best approaches for solving complex filtering problems when a single filter operating at a fixed sampling rate is of a very high order. With a multirate filter, the number of arithmetic operations per second

Figure 1. An overview of multirate filtering techniques



is considerably reduced. The multirate technique is used in filters for sampling rate conversion where the input and output rates are different, and also in constructing filters with equal input and output rates. For multirate filters, FIR (finite impulse response) or IIR (infinite impulse response) transfer functions can be used. An FIR filter easily achieves a strictly linear phase response, but requires a larger number of operations per output sample when compared with an equal magnitude response IIR filter. Multirate techniques significantly improve the efficiency of FIR filters that makes them very desirable in practice.

Figure 1 depicts an overview of different multirate filtering techniques.

Polyphase Realization

Polyphase realization is used to provide an efficient implementation of multirate filters. A *polyphase structure* is obtained when an Nth order filter transfer function is decomposed into M polyphase components, M<N. For FIR filters, polyphase decomposition is obtained simply by inspection of the transfer function (Crochiere, & Rabiner, 1983; Fliege, 1994; Harris, 2004; Mitra, 2006; Proakis & Manolakis 1996; Vaidyanathan, 1993). For multirate IIR filters, several approaches to polyphase decomposition have been developed (Bellanger, Bonnerot & Coudreuse, 1976; Crochiere, & Rabiner 1983; Drews & Gaszi, 1986; Krukowski & Kale, 2003; Renfors & Saramäki, 1987; Russel, 2000).

Multirate Filters for Sampling Rate Conversion

Filters are used in decimation to suppress aliasing, and in interpolation to remove imaging. The performance of the system for sampling rate conversion is mainly determined by filter characteristics. Since an ideal frequency response cannot be achieved, the choice of an appropriate specification is the first step in filter design.

Reducing the sampling rate by a factor of M is achieved by omitting every M-1 sample, or equivalently keeping every Mth sample. This operation is called down–sampling. In order to avoid aliasing, a low-pass *anti-aliasing filter* before down-sampling is needed. Therefore, a *decimator* is a cascade of an anti-aliasing filter and a down-sampler. To increase the sampling rate (interpolation by factor L), L-1 zeros are inserted between every two samples (up-sampling). An interpolation filter has to be used to prevent imaging in the frequency band above the low-pass cutoff frequency. An *interpolator* is a cascade of an up-sampler and an *anti-imaging* filter.

The efficiency of FIR filters for sampling rate conversion is significantly improved using the *polyphase realization*. Filtering is embedded in the decimation/interpolation process and a *polyphase structure* is used to simultaneously achieve the interpolation/decimation by a given factor but running at a low data rate.

Due to the *polyphase multirate implementation*, the number of arithmetic operations in linear-phase FIR filters is decreased by a factor M (or L). An effective method, which leads to high efficiency for a high-order FIR filter is proposed in Muramatsu & Kiya (1997). Efficient decimation and interpolation for the factor M=2 (L=2) is achieved with FIR half-band filters since the number of constants is a half of the filter length.

Very sharp filters with reduced computational efficiency can be achieved by combining the multirate approach and frequency response masking techniques (Lim & Yang, 2005).

Polyphase IIR filters require lower computation rates among the known decimators and interpolators (Renfors & Saramäki, 1987). If a strictly linear phase characteristic is not requested, an IIR filter is an adequate choice. Moreover, an IIR transfer function can be designed to approximate a linear phase in the pass-band (Jaworski & Saramäki, 1994; Lawson, 1994; Surmo-Aho & Saramäki, 1999). An IIR decimator or interpolator is particularly useful in applications that cannot tolerate a considerably large delay of an adequate FIR decimator or interpolator. For a restricted class of filter specifications, an attractive solution based on all-pass subfilters can be used leading to very efficient implementation (Krukowski & Kale, 2003; Renfors & Saramäki, 1987). The most attractive solution is an IIR half-band filter implemented with two all-pass subfilters (Johansson & Wanhammar, 1999; Krukowski & Kale, 2003; Milić & Lutovac, 2002; Renfors & Saramäki, 1987). For a rational conversion factor L/M a very efficient decomposition of IIR filter is proposed in Russel (2000).

There are many applications requiring the sampling rate conversion between arbitrary sampling rates. The sampling rate alteration by an arbitrary factor can be viewed as the computation of the new sample values at arbitrary time instants between the existing samples. There are many valuable contributions in the literature, which concentrate on the various solutions of this important problem (Harris, 2004; Mitra, 2006; Vesma & Saramäki, 2007).

Multirate Filters with Equal Input and Output Rates

Digital filters with sharp transition bands are difficult, sometimes impossible, to be implemented using conventional structures. A serious problem with a sharp FIR filter is its complexity. The FIR filter length is inversely proportional to transition–width and complexity becomes prohibitively high for sharp filters (Crochiere & Rabiner, 1983; Fliege, 1994; Mitra, 2006; Proakis & Manolakis, 1996; Saramäki, 1993; Vaidyanathan, 1993). In a very long FIR filter, the

finite word-length effects produce a significant derogation of the filtering characteristics in fixed-point implementation (Mitra, 2006). IIR filters with sharp transition bands suffer from extremely high sensitivities of transfer function poles that make them inconvenient for fixed-point implementation (Lutovac, Tošić & Evans, 2000). In many practical cases, the multirate approach is the only solution that could be applied for the implementation of a sharp FIR or IIR filter. Thus, to design a multirate narrowband low-pass FIR or IIR filter, a classical time-invariant filter is replaced with three stages consisting of: (1) a low-pass anti-aliasing filter and down-sampler, (2) a low-pass kernel filter, and (3) an up-sampler and low-pass anti-imaging filter (Crochiere & Rabiner, 1983; Fliege, 1994; Milić & Lutovac, 2002; Mitra, 2006). The total number of coefficients in a multirate solution is considerably lower than the number of coefficients of a single rate time invariant filter.

Multistage Filtering

For decimators and interpolators, and for multirate narrowband filters, additional efficiency may be achieved by cascading several stages, each of them consisting of an anti-aliasing filter and down-sampler for decimation and an up-sampler and an anti-imaging filter for interpolation (Fliege, 1994; Milić & Lutovac 2002; Mitra, 2006). Design constraints for subfilters are relaxed if compared to an overall filter. Hence, by using the multistage approach, the total number of coefficients is significantly reduced when compared with the single stage-design. The effects of finite word-length in subfilters are low in comparison with the single-stage overall filter. When a decimation/interpolation factor is expressible as a power-of-two, the application of half-band filters improves the efficiency of the system.

Multirate Complementary Filters

This method can be used in designing filters with any pass-band bandwidth. The multirate techniques are included to reduce the computational complexity. Using the complementary property, the multirate, narrow pass-band filter designs can be used to develop high-pass and low-pass filters with wide pass-bands (Fliege, 1994; Mitra, 2006; Ramstad & Saramäki, 1990). When the output of a low-pass multirate filter is subtracted from the delayed replica of the input signal, the result is a wideband high-pass filter. The delay has to be selected to exactly equal the group delay of the multirate filter. For a low-pass wideband filter the multirate narrowband high-pass filter has to be used.

Efficient FIR filters with an arbitrary bandwidth can be designed using multirate and complementary filtering (Fliege, 1994; Johansson & Wanhammar, 2002; Ramstad & Saramäki, 1990). The overall design is evaluated by cascading complementary multirate filtering two-ports composed of two series branches and one parallel branch. The cascade is terminated with a simple kernel filter. One series branch of the cascade is a *decimator* (filter and down-sampler), while the other is an *interpolator* (up-sampler and filter). The parallel branch is a delay. The most efficient solution is obtained when *half-band filters* are used in the cascade.

Recently, the complementary filtering approach is extended to IIR filters (Johansson, 2003). The overall filter makes use of an IIR filter as a kernel filter, the periodic all-pass filters for constructing complementary pair, and linear phase FIR filters for the sampling rate alterations.

Half-Band Filters

Half-band filters are basic building blocks in multirate systems. A *half–band filter* divides the basis band of a discrete-time system in two equal bands with symmetry properties. The FIR filters are most often used as half-band filters. For a linear-phase FIR half-band filter, half of the constants are zero valued when the filter order is an even number (Mitra, 2006; Saramäki, 1993). A half-band IIR filter can have fewer multipliers than the FIR filter for the same sharp cutoff specification. An IIR elliptic half-band filter when implemented as a parallel connection of two all-pass branches is an efficient solution (Milić & Lutovac, 2002, 2003). The main disadvantage of elliptic IIR filters is their very nonlinear phase response. To overcome the phase distortion one can use optimization to design an IIR filter with an approximate linear phase response (Surma-Aho & Saramäki, 1999), or one can apply the double filtering with the block processing technique for real-time processing (Lutovac & Milić, 2000; Powel & Chau, 1991).

For the appropriate usage of digital filter design software in half-band filter design, it is necessary to calculate the exact relations between the filter design parameters in advance (Milić & Lutovac, 2002, 2003). The accurate FIR half-band filter design methods can be found in Saramäki (1993), Vaidyanathan & Nguen (1987), and Wilsson & Orchard (1999). For the IIR half-band filter design see Milić & Lutovac (2002, 2003), Mitra, (2006), and Schüssler & Stefen (1998).

Complementary Filter Pairs

Complementary filter pairs are used to split the input signal in two adjacent bands, and also are of importance for constructing complex multirate systems and filter banks. A low-pass/high-pass filter pair can be designed to exhibit strictly complementary, all-pass complementary, power complementary, or magnitude complementary properties (Mitra, 2006; Vaidyanathan, 1993). This solution benefits the possibility of implementing the complementary filter pair at the cost of a single FIR (IIR) filter (Fliege, 1994;

Mitra, 2006; Vaidyanathan, 1993). In the most applications, half-band filter pairs with the crossover frequency located in the middle of the base band are used to divide the frequency band in two equal sub-bands. It was shown recently that a *complementary IIR filter pair* with the arbitrary crossover frequency can be easily obtained by simple transformation of the start-up half-band prototype filter pair (Damjanović, Milić, & Saramäki, 2005, Milić & Saramäki, 2003; Milić, Damjanović & Nikolić, 2006). This new filter pair retains the complementary properties of the start-up half-band filter pair.

Multiplierless Solutions

The efficiency of *multirate filters* is significantly improved by simplifying arithmetic operations. This is achieved by replacing a multiplier with a small number of shifters-and-adders. Generally, implementing multiplierless design techniques in subfilters, at the cost of a slight derogation of filtering performances, increases the efficiency of the overall multirate filter.

For instance, one can use the optimization technique (Yli-Kaakinen & Saramäki, 1999 and 2007), multiple constant multiplication (MCM) technique (Dempster & Macleod, 1999), or design based on EMQF (Elliptic Minimal Q-Factors) transfer functions (Milić & Lutovac, 1999, 2003; Lutovac & Milić 2000). It was shown recently (Gustafsson & Dempster, 2004; Gustafsson, Johansson, Johansson & Wanhammer, 2006; Eghbali, Gustafsson, Johansson & Löwenberg, 2007) that multiple constant multiplication (MCM) technique is an efficient way to reduce the computational workload in the polyphase decimators and interpolators. An effective method for designing the multiplierless highly-selective FIR half-band decimators and interpolators was proposed by Saramäki and Yli-Kaakinen (2006). A well-known solution for large conversion factors in decimation is a cascaded integrated comb (CIC) filter, which performs multiplierless filtering (Harris, 2004; Hentchel, 2002; Hogenauer, 1981; Jovanović-Doleček & Mitra, 2005; Mitra, 2006).

Future Trends

The rapid development of new algorithms and new design methods in the area of multirate filtering has been influenced by the advances in computer technology and software development. Although the existing literature on the subject is very large, the multirate filtering is an open area of research. The future trends coincide with the general demand for decreasing the computational complexity, increasing the computational speed, and lowering the power consumption. In the case of multirate filters, those goals can be achieved by following several directions: developing new optimization methods for constructing high-performance multirate filters; integrating the multirate filtering and the frequency-response masking techniques; and developing new methods for simplifying implementation structures of subfilters and of overall multirate systems.

CONCLUSION

The multirate filtering techniques are widely used in sampling rate conversion systems, and for constructing filters with equal input and output sampling rates. Various multirate design techniques provide that the overall filtering characteristic is shared between several simplified subfilters that operate at the lowest possible sampling rates. Design constraints for subfilters are relaxed if compared to a single rate overall filter. Hence, by using the multistage approach, the total number of coefficients is significantly reduced. As a consequence of the reduced design constraints, the effects of quantization (finite word-length effects) in subfilters are decreased. Multirate filters provide a practical solution for digital filters with narrow spectral constraints that are very difficult to solve otherwise.

KEY TERMS

Decimation: Decreasing the sampling rate. Decimation process consists of filtering and down-sampling.

Down-Sampling: Discarding every M-1 samples (retaining every Mth sample).

FIR Filter: A finite impulse response digital filter.

Half-Band Filters: A low-pass or high-pass filter that divides the basis band in two equal bands, and satisfies prescribed symmetry conditions.

IIR Filter: An infinite impulse response digital filter.

Interpolation: Increasing the sampling rate. Interpolation consists of up-sampling and filtering.

Multirate Filter: A digital filter, which changes the input data rate in one or more intermediate points in the filter itself.

Multistage Filtering: Cascade of filters and decimators (interpolators and filters).

Polyphase Decomposition: Decomposition of a transfer function in M (L) polyphase components that provide sequential processing of the input signal at the lower sampling rate.

Up-Sampling: Inserting L-1 zeros between every two samples.

From E-Governance Towards E-Societal Management

Nicolae Costake
Certified Management Consultant, Romania

INTRODUCTION

The purpose of this article is to contribute to the definition of the still emerging strategic concept of e-societal management (e-SM) as a key component of the information society (IS). It is a continuation of articles published in the *Encyclopedia of Digital Government* (Antiroikko, 2006; see also, Costake, 2008a, 2008b) which describe the concepts of:

(1) e-government (e-Gvt) as a set of e-services provided by the public administration (i.e., executive authority) to citizens and organizations, and
(2) e-governance (e-G) as including also the set of e-services provided by the judicial and legislative authorities of the state.

The two quoted chapters contain the historical perspectives mainly between the mid-1990s (e.g., G7 Conference on Information Society, 1995) and the mid 2000s (e.g., the EU's i2010 Program, 2006). The above definition of e-G may be interpreted also as equivalent to the e-SM at the country level and below, provided that the actions of the three authorities converge to assure continuous and sustainable socio-economic development. On the other hand, the new century started with increased global threats and also opportunities (e.g., the development of the IS). Both suggest the importance of the societal management, as well as the difference between *enterprise management,* which aims to achieve performance within a given national and international societal environment, and *societal management,* which aims to assure the societal environment best supporting developments of the economy and civilization.

It follows that the historical development of e-SM is connected to the rather slow evolution of SM and the rapidly developing IS, including e-Gvt and e-G. Its start can be considered the UN General Assembly's Declaration on Computer and Development (UN, 1968), followed by the UN's World Summit for the IS (e.g., WSIS, 2005), which adopted requirements for national and international e-SM (implicitly addressed). E-procurement for public acquisitions, the "Trans-European Administration Network" recommended for the EU by Bangemann et al. (1994), and the start of the Single Euro Payment Area project in 2002 (see SEPA, 2007, which contains complete chronology and content) are examples of other relevant milestones. E-SM is a concept built on those of socio-economic system (SES) and societal management. Many opinions were expressed.

This article begins by sketching a model of the socio-economic system as a foundation; selects, with the risk of being subjective, a number of relevant positions taken by individual institutional and authors; describes e-SM and its associated issues and trends; and proposes conclusions.

BACKGROUND

The general model of the global SES, suggested in Figure 1, includes natural resources (a component of the natural system) and the human activities system (HAS), layered above the natural system. In the absence of the HAS, the natural system was stationary, its biologic components being in a dynamic equilibrium (their growth and levels limited by the available resources). The HAS also transforms data into information, and information into knowledge, thus accumulating experience. It also enforces the concept of ownership, developing the economic activity. Some frequently mentioned risks and issues for the global SES are mentioned in Table 1.

Table 1 suggests that societal management cannot be restricted to the national domain, mankind is faced with possible irreversible dangerous processes, and the permitted duration for decision and action is shortening. The obvious conclusion is the need for e-SM.

The model of a generic SES is presented in Figure 2 as having two subsystems: (1) a societal operational subsystem (SOS) in which social, energy, material, financial, and informational processes based on natural resources and artifacts take place in communities, enterprises (non-financial and financial), markets, NGOs, and other organizations; and (2) a societal management subsystem (SMS), the institutions of which generate regulations and actions necessary for the proper organization, functioning, and development of the SES, including defense of the system's domain, protection of public order and of property, mandatory education, social security, solving conflicts and breaches of regulations (assures the necessary homeostasis), assuring relationships with the external environment, and so forth. The two subsystems are interconnected and connected with the external environment by flows of energy/matter/products/services, financial means, information, and personnel. SES may be basic (such as household), organization, territorial community

Table 1. Frequently mentioned global risks and issues

Risk and/or Issue	Comments and/or Mitigation
Global warming (Gore, 2006; Kyoto 2007)	Measures agreed at the Kyoto conference, but still not implemented by the highly polluting countries
Deterioration of the environment (Gore, 2006)	De-forestation, pollution of water, destruction of the ozone layer, destruction of species
Exhaustion of natural hydrocarbon energy reserves due to the increase of their consumption (Laherrère, 1998)	Implies changing the energy orientation of many present technologies, for example: use of renewable energies, green and zero-waste technologies (Greyson, 2007), increase of the efficiency of energy generators and consumers, and also possibly controlled thermonuclear power generation
Overpopulation: total human population may exceed the capacity to be supported by the natural resources (e.g., P&P, 2007)	Mitigation implies, for example: (a) genetic engineering of biological natural resources (b) industrialized food (c) conversion of sea water into drinking water
Endemic local wars, other armed conflicts (some with religious character), and terrorism	A large amount of resources is spent in weaponry and wars and/or other use of armed forces, the global arsenal being sufficient to destroy life on the planet
Global societal division, by large gaps*: (i) between rich and poor countries; (ii) between rich and poor people; (iii) digital divide (BECTA, 2001)	See also the world model with three economies: natural, developing, and advanced (e.g., Hart, 1997) and applicable theories, for example of the Open Society (e.g., Soros, 1998; Dror, 2002)
Deterioration of human behavior (e.g., Huxley, 1958; Lorenz, 1973)	Naisbit (1984) and Toffler (1970) underlined changes and the need for adaptation to change

** This issue can be also considered as a gap between long-term and general interests against short-term interests oriented on gaining as much as possible, as quickly as possible.*

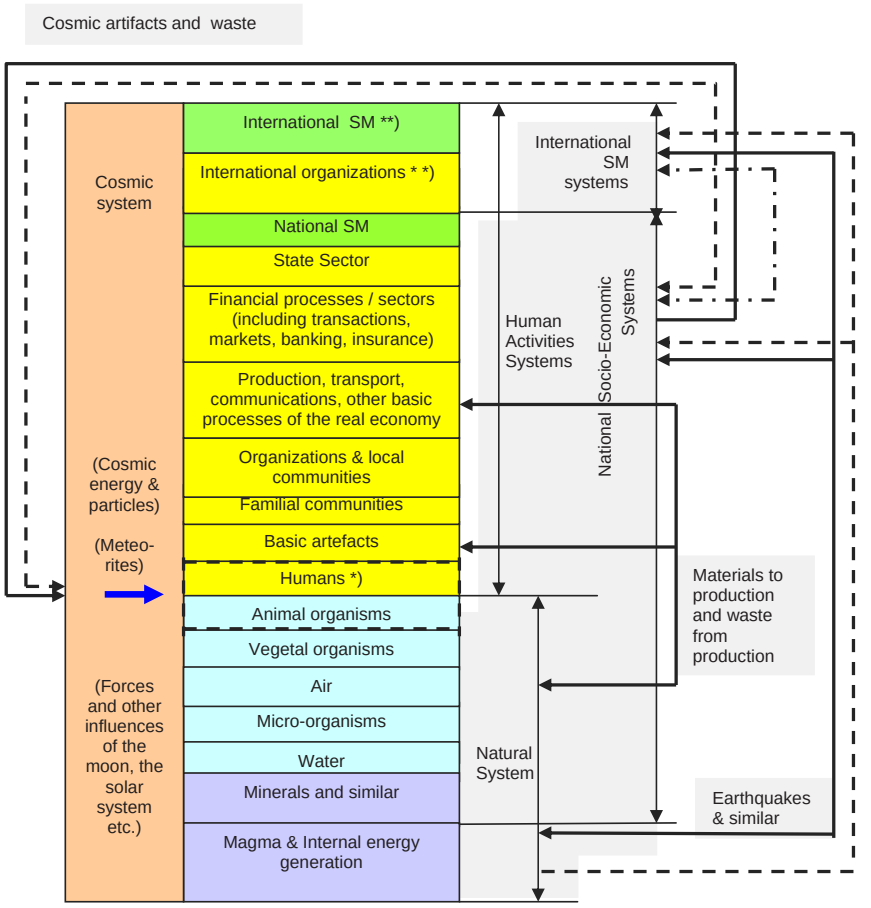
(such as municipality), a group of organizations, national, supranational, international, or global. As the national and supranational SESs raise most SM issues, they are first for discussion in this article.

There is a very large bibliography on SM and e-SM. As a comprehensive referencing is impossible, just a few examples are quoted. They are classified in streams and sub-streams:

Theoretical (some references are already included in Tables 1 and 2)

- *Global Governance:* Biermann (2006) proposes principles, research, and challenges such as "adaptive state." Heylinghen (2007) foresees the future "networked society."
- *SM Theory and Models:* Dror (2002) proposes capacity to govern in condition of global transformations, concluding also of the need for an independent societal feedback. Greer (2005) proposes an explanation why civilizations grow and then collapse due to unsustainable use of resources. Situngkir (2003) proposes an automatic control system analogy with Montesquieu's model of the powers in the state.
- *E-G Research:* E-Gvt (e.g., Lenk & Traunmuller, 2000; Scholl, 2003) => e-G (e.g., Lenk, 2003; Traunmuller & Wimmer, 2004) => Innovative e-G (e.g., Bicking & Wimmer, 2006). This sub-stream also proposes

Figure 1. Layered model of the global SES (Legend: flows of ⟶ matter/energy/products/services, - - → information, -·-·→ financial means)



** Above the level of other animal organisms*
*** Including supranational*

technical targets for 2020 and so on. See also Gupta, Kumar, and Bhattacharya (2005) and Klischewski and Scholl (2006).

Political Studies and Recommendations

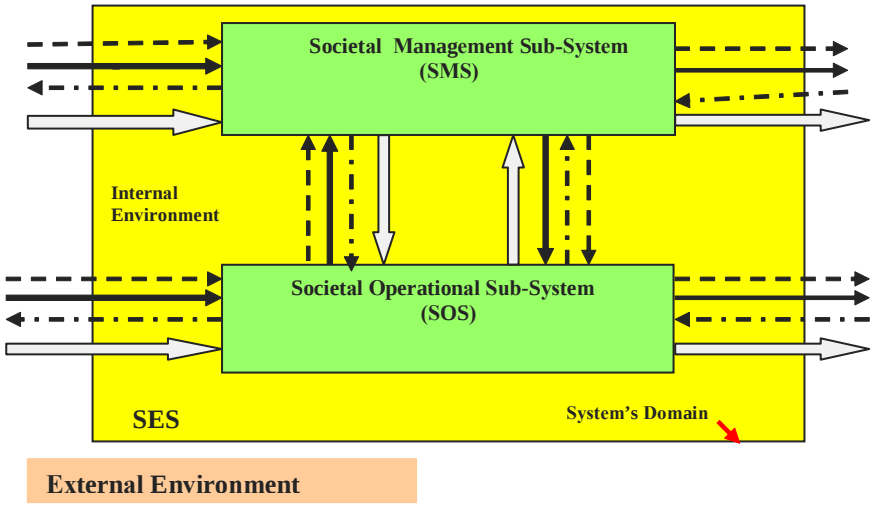
- *Specific Studies by International Organizations:* The OECD (2001) considers that as traditional governance becomes ineffective, the new governance will make changes in allocating and structuring power. EICTA (2004) formulates recommendations to the European Commission regarding the development of the European ICT industry.
- *Internationally Adopted Action Plans:* WSIS and i2010 Action Plans.

Practical, Generating Institutional Changes and/or Newly Implemented Solutions and/or Information Systems

There is vast literature at local and national/federal levels, a very small sample being about Canada and the United States (e-Govt, 2005), China (Lovelock & Urel, 2002), Malaysia (Tahir, 2005), and Singapore (Lee Boon Yang, 2007). The EU has a supra-national SES with all the components of an SMS:

- *A Legislative Authority* produces normative acts, to be mandatorily implemented by the member countries. One example is the draft directive of the infrastructure for spatial information (INSPIRE, 2004).

Figure 2. Generic model of a SES (⟹ flow of personnel; the significances of the other arrows is the same as in Figure 1)



- *The Legislative and the Judicial Authorities* (see Justice, 2007) are supported by the legislative information system and database (EUR-Lex, 2007).
- *An Executive Authority* offers many examples: drafting of European Programs, action plans, workshops, projects, studies, and reports for Development of the Information Society (e.g., IDABC, 2007, 2008). They succeeded to produce EU information systems such as the Schengen border control (e.g., Migrationsverket, 2001), the Single Euro Payment Area (SEPA, 2007), the EU network for implementing European policies (e.g., TESTA, 2005), and the European Interoperability Framework (Gartner, 2007). One recent example is reported by Undheim (2008), and general economic studies were also launched (e.g., MODINIS, 2006). In recent years, assessments of potential benefits from e-SM appeared, for example, approximately 1% GDP from e-procurement for public acquisitions (Timmers, 2005) and approximately 5% GDP from reducing the administrative burden of businesses (Reading, 2007). The French e-administration (ADELE, 2004) is an example of a high-return-on-investments national program. The EU's Executive Authority is supported also by Eurostat, and the Observatories for IT (EITO, 2007) and for e-government (now accessible via IDABC > eGovernment practice).

There are many points of view. Except e-G research, the theoretical works and political studies are mainly sociologically, economically, and politically oriented. Only a few mention the possible contribution of cybernetics (e.g., automatic or artificial closed loops) or the necessary informatic support; they do not consider the importance of the IS for SM. The practical approaches bring tangible results but do not include vision based on a comprehensive socio-economic model. Most do not discuss key performance indicators (KPIs) and do not foresee actions against two sources of losses, particularly in developing and transitional countries: underground economy and corruption.

THE EMERGING E-SOCIETAL MANAGEMENT

e-SM can be defined as ICT-enabled SM, assuring the integration and interoperability of the public information systems for:

- friendly online serving citizens and organizations;
- increasing the performance of the enterprises by supporting e-business and minimizing the administrative burdens;
- maximizing the performance of the socio-economic development of the SES; and
- complying to a set of constraints, such as laws, including free-market competition, democracy, and human rights.

The main dangers are:

- the accumulation of personal power (hence needing

autonomous feedback);

- the bureaucratization (hence needing the reduction of administrative burden including the single entry of an information element into the general public information system);
- the underground economy (hence needing a public finance management-integrated information system);
- corruption (needing, e.g., e-procurement for public acquisitions, specific legislation, plus an information system); and
- poor quality of strategic decisions (hence needing use of ICT including decision support tools and public societal feedback).

There are two direct consequences: a structure of the societal management subsystem and a specific architecture of the e-SM information system. They can be complemented by criteria for e-SM. The resulting necessary structure of the societal management sub-system is represented in Figure 3 as performing four functions (executive authority, judicial authority, legislative authority, and public societal feedback authority). The symbolic person (e.g., president or monarch), the ombudsman (if applicable), the spiritual authority (acting on the population), flows of personnel, and flows exchanged with the international environment were omitted, and other main flows only were drawn, not to complicate excessively the diagram. The legislative authority assures the regulations at the national and local levels. The judicial authority assures the homeostasy of the SES. The executive authority assures the current management (including drafting laws and international accords, implementation/enforcement of law and judicial decisions, provision of services to population and organizations, redistribution of revenues collected or generated by owned resources, etc.). The proposed public societal feedback authority (PSFA) refers to a group of activities usually considered components of the executive authority: e-voting (component of e-democracy), official statistics (generating information formatted as statistical tables and knowledge, i.e., statistical mathematical models and *caeteris paribus* mathematical models), and court of accounts. The PSFA closes the loop for permanent improvement. The resulting necessary high-level architecture of the e-SM information system is described in Figure 4. It is in line with the European best practice in the field (e.g., Vanvelthoven., 2005; IDABC, 2007, 2008). A sample of possible criteria for e-SM is suggested in Table 2, which also summarizes proposals formulated in previous papers (e.g., Costake 2006a).

FUTURE TRENDS AND FURTHER RESEARCH OPPORTUNITIES

The increasing planetary problems can be a key factor for the promotion of e-SM. A number of further research opportunities can be suggested, such as:

Figure 3. Necessary structure of the societal management subsystem (1, 2, 3, 4 are connectors, to avoid the drawing of many lines. The meaning of the arrows is the same as in Figures 1 and 2)

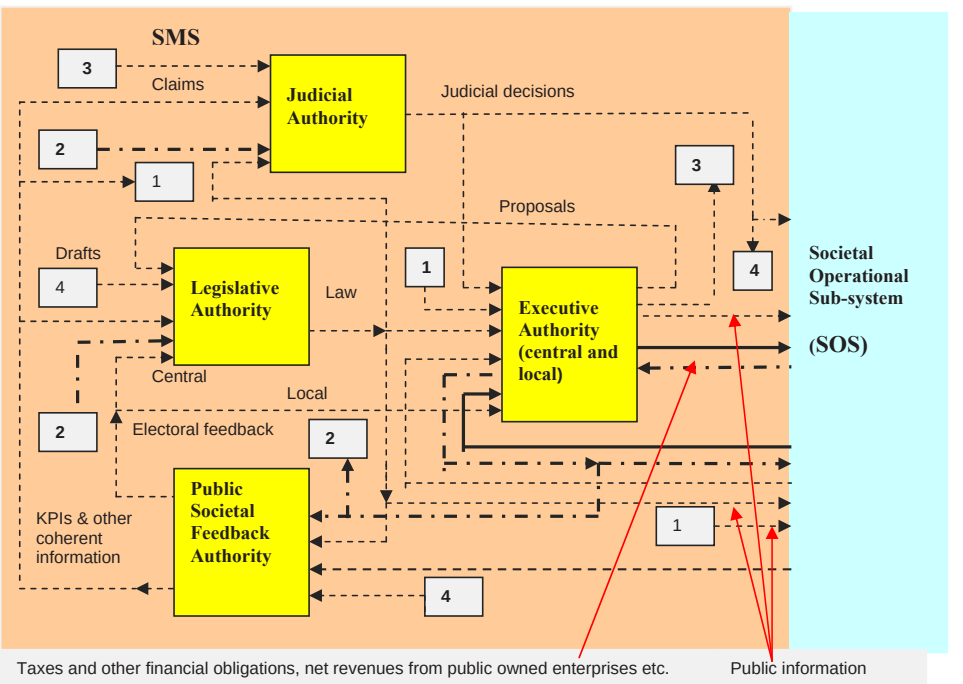


Figure 4. High-level architecture of the e-SM information system with five levels

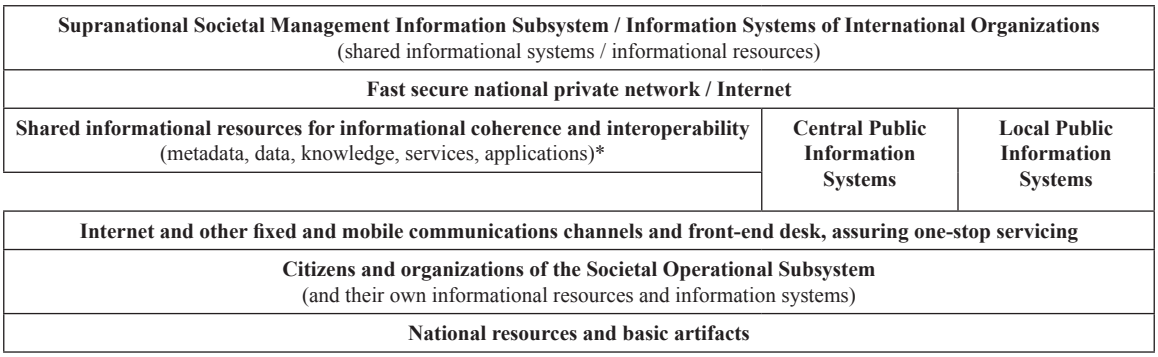

** Can be hosted by public data centers*

(1) formulating societal management as a scientific discipline complementing the classical enterprise management science;
(2) exhaustively identifying potential sources of costs, benefits, and losses in the SM and e-SM, and solutions for achieving performance in sustainable growth;
(3) selecting the minimal number of KPIs capable to describe the performance of e-SM;
(4) creating blueprints for e-SM information systems at the national/federal and super-national/international levels;
(5) clustering countries and corresponding recommended specific actions at the national, international, and supranational levels;
(6) developing e-SM strategies at the national and supranational levels; and
(7) formulating a system engineering theory of e-SM, including a comprehensive model of the SES at various levels, identifying automatic closed loops and their effects, as well as possible informational artificial (new) virtuous circuits.

CONCLUSION

The following two conclusions are proposed:

(1) E-SM implies:
  (a) technical re-engineering of the activities of the public institutions (see Table 2);
  (b) specific functional structure (see Figure 3) and architecture of the supporting information system (see Figure 4); and
  (c) a new culture of the public sector in which every organizational entity is a component of a subsystem which supports and encourages:
    - development of very friendly e-services to citizens and organizations;
    - the development of the SES to the best medium and long-term interests of its stakeholders; and
    - a set of values, of a set of objectives and constraints, in a responsible and accountable manner, characterized and followed by KPIs.

(2) The economic benefits of e-SM have three sources:
  (a) better SM through better decisions;
  (b) savings (e.g., elimination of redundant collection of data and data processing/storage, economies of scale, replacement of obsolete legacy ICT, etc.); and
  (c) minimization of losses (including underground economy and corruption, in the countries where applicable).

Table 2. Criteria for e-SM

Criterion	Examples of Requirements
General	
Conception of the target e-SM	Vision, general objectives, strategic planning, standards, KPIs, cost-benefit analysis, etc. (see note below)
Specific e-SM infrastructure	As shown in Figure 4
Performance of the governance	Minimization of commands, in favor of creating new feedback informational circuits and/or tuning existing automatic closed loops
Legislative Authority	
Methodology	Use of electronic documents and archives, shared legislative database, computerized standard workflow(s) and validation of drafts, shared knowledge base defining the general concepts and basic procedures and standards
KPIs	For example, annual total number of valid normative documents, mean time between amendments, compliance to the agreed international and supranational legislation
Judicial Authority	
Integrated judicial information system	Central database and data warehouse for uniquely identified cases, used by courts, prosecutor offices, other investigating organizations, and penitentiaries; interfaces to the other public information systems; standard workflow using e-documents and e-archives; computer-aided support for detecting incompatibilities and conflicts of interest
KPIs	For example, duration of cases (from start of investigation until final solution) per components and categories of cases, number of rotations of dossiers, degree uniformity of solutions per similar cases and circumstances (cluster analysis)
Executive Authority	
Integrated interoperable information systems (central, sectoral, and territorial components)	Information systems assuring e-services to people and organizations, protection of human rights, administration of public properties, optimization of taxation and similar obligations, specialized e-services and information systems supporting e-business, minimization of administrative burdens for citizens and organizations, coherent decentralization of decisions, anti-underground economy and corruption information system(s)
Current management of the SES	Compliant to the requirements of the target e-SM: assuring the necessary continuity and, at the same time, integrating change and technical and technological progress, protecting against concentration of power in the political and economic sense, protecting against consequences of possible disasters
KPIs	For example, GDP/capita, distribution of incomes (e.g., Gini coefficient), life expectancy at birth, use of ICT, population with higher use of ICT (%), proportion of population per economic sectors, economic growth correlated with (un)employment and foreign debt, territorial distribution of values added per capita per economic sector, total state budget/GDP, degree of e-inclusion
Public Societal Feedback Authority	
Functioning of the official statistics	Collection of relevant data only if not possible to obtain by interfacing to public information systems, determination of KPIs and comparisons to planned values, generation of coherent tabular, graphic and cartographic statistical information and mathematical models (statistical knowledge) + *caeteris paribus* extrapolations
Functioning of the electoral information system	Online general and local e-voting free from electoral fraud, participative democracy information system
Functioning of auditing information systems	Audit of public finance and specialized auditing information systems (e.g., anti-trust, protection of consumers, etc.)
KPIs	Accuracy, timeliness, integrity

Note: Moon, Welch, and Wong (2005) analyzed pushing and pulling factors on e-government performance and various KPIs. The World Bank uses E6 governance indicators, based on data and surveys (World Bank, 2007b): voice and accountability; political stability and absence of violence; government effectiveness; regulations quality; rule of law, control of corruption. An example of a synthetic indicator is a proposed societal management index (Costake, 2007): SMI = ((GDP/capita [k EUR])/ (Rate of unemployment [%])) (corruption perception index)*

KEY TERMS

E-Administration: Synonym to local e-SM (e-SM of communities). Its use is not recommended, because it may suggest a domain of the executive authority only, unless the meaning in the national language is more general.

E-Governance: ICT-enabled management of an SES whose domain is limited to a national/federal one, including e-government as one component, and not necessarily including the executive (strategic) management.

E-Government: ICT-enabled management of the executive authority of a local or national SES. Its main content is made up of the e-services provided to people and organizations (obviously has the highest political content for a government which may be changed every four or five years).

E-Societal Management: ICT-enabled management of the SES whose domain may include an international component and covers the entire management content, including strategic management.

Human Rights: Rights defined in the UN Declaration of 1948, updated by similar international documents.

Public Institution: Organization whose mission is to serve the SES and is financed at least in large part by public money.

Public Sector: System of public institutions, and enterprises owned or managed by public institutions. This system may have many levels: international, regional, national (central, sectoral, or territorial), usually hierarchically organized. It covers executive (e.g., central and local governments, public finance, etc.), legislative (e.g., Parliament, etc.), homeostatic (e.g., Judiciary, etc.), and societal feedback (e.g., electoral, statistic, auditing, etc.) oriented institutions.

E-Government and Digital Divide in Developing Countries

Udo Richard Averweg
eThekwini Municipality and University of KwaZulu-Natal, South Africa

INTRODUCTION

The transition of the global economy from an industrial focus to one based on knowledge and information presents numerous opportunities and challenges to countries, especially those in the developing world (Cape IT Initiative, 2003). The government sector (and especially the local government sector) needs to embrace information and communication technologies (ICTs) that enable it to operate more efficiently and communicate better with its citizens.

ICTs encompass all technologies that facilitate the processing and transfer of information and communication services (United Nations, 2002). Many factors affect how local governments (i.e., municipalities) in developing countries access ICTs. In order to bridge the digital divide—which separates the technology 'haves' from the technology 'have nots'—it is necessary to gauge where citizens are in terms of ICT adoption, that is, their e-readiness. E-readiness can be defined in terms of availability of ICT infrastructure, the accessibility of ICT to the general citizen population, and the effect of the legal and regulatory framework on ICT use in, for example, an e-government strategy.

eThekwini Municipality (2003), in the city of Durban in the developing country of South Africa, sees the e-government strategy and its Web site at *http://www.durban.gov.za* as important management tools for improved citizen service delivery and communication. The objective of this article is to report, as an example, on the survey of ICT and information needs of a selected metropolitan municipal area (eThekwini Municipality in South Africa). Such a report maybe useful to other municipalities in developing countries for their e-government strategies.

This article is organized as follows. The background to e-government and the digital divide are discussed. eThekwini Municipality in South Africa is then described. The research goals are outlined, the research method and data gathering are discussed, the survey results and discussion are given, and future trends for implementing an e-government strategy in municipalities in developing countries are suggested. Finally, a conclusion is given.

BACKGROUND TO E-GOVERNMENT AND THE DIGITAL DIVIDE

Nowadays governments around the world are embracing electronic government. In a broad sense, e-government can be defined as the process by which government communication and administration processes are made available using ICTs. All such technologies can improve service and output in the same way that they have revolutionized work and leisure of lives—the main difference being that e-government programs recognize that not all citizens have equal access to technology and need to be implemented accordingly. In the literature it is also recognized that e-government in the developing world must accommodate certain unique conditions, needs, and obstacles. E-government gives citizens access to relevant information and makes government more accountable to its citizens. Ultimately, e-government aims to enhance access to and delivery of government services to benefit citizens (Pascual, 2003).

In the same way that there are social and economic divides between poor and rich countries, in the field of ICTs there are also divides between those who can access and use ICT to gain the associated benefits and those who do not have access to the technology or cannot use it for one reason or another (Bridges.org, 2002). These digital divides exist between countries ('international divide') and between groups within countries ('domestic divide'). In looking at the difference in access between developed and developing countries, Gumucio-Dagron (2003) notes that the "divide has never been only a 'digital' or technological divide. It is a social, economic and political fracture." The divide between technology 'haves' and technology 'have nots' is significantly wide.

eTheKwini MUNICIPALITY IN SOUTH AFRICA

eThekwini Municipality's population is 3.09 million citizens (Statistics South Africa, 2001) within the eThekwini Municipal Area (EMA). The population is an amalgamation of racial and cultural diversity. The Black African community comprises 68.3%, Coloured citizens 2.8%, Asian citizens

19.9%, and White citizens 9.0% (Statistics South Africa, 2001). In the EMA 51.9% of the population are female and 48.1% are male.

eThekwini Municipality's Long Term Development Framework (LTDF) maps out the strategic vision for eThekwini Municipality during the next 20 years. The essence of the LTDF "is to achieve a balance between meeting basic needs, strengthening the economy and developing people skills and a technology base for the future" (eThekwini Municipality, 2007b). eThekwini Municipality has a capital budget of ZAR4.2 billion (approximately €0.42 billion) and an operating budget of ZAR12.90 billion (approximately €1.29 billion) for the 2007/2008 financial year (see *www.durban.gov.za*).

Durban is currently rationalizing its wide area network (WAN) infrastructure to streamline and enhance service delivery. Broadband access delivered via fiber optic, wireless, and power lines are leveraged by information and collaboration portals as well as offering EMA citizens services via fixed and mobile devices. The WAN's wireless component is being extended to offer access to municipal libraries, clinics, and other eThekwini Municipality facilities. ICT and Web sites can be seen as effective mechanisms to access municipal information and developmental information in general. South African Web sites which seek a local and global reach must cater for the digital divide that exists between the technological 'haves' and 'have nots' (Averweg, Barraclough, & Spencer, 2003). Bridging the digital divide in the EMA is not the end but the beginning to bring positive changes in the development of a municipal information society (MIS). An MIS is the innovative use of ICT to improve the internal operation of a municipality, as well as its communication and collaboration with citizens, the private sector, and civil society in a municipal area.

RESEARCH GOALS

eThekwini Municipality embarked on an initiative to understand the needs of its users and non-users in utilizing ICT as a tool to improve service delivery and establishing effective media communication between itself and its constituencies. This article reports on these initiatives and findings from two surveys conducted in the EMA.

Research Method and Data Gathering

Two survey instruments (hereinafter referred to as 'ICT Status Survey' and 'Library Survey') were developed to gauge EMA citizens' ICT and information needs. The first survey tool (ICT Status Survey) represents an attempt to obtain a snapshot of the ICT status of EMA citizens; the second tool (Library Survey) focused on citizens' ICT and information needs over a broad spectrum.

The ICT Status Survey and Library Survey instruments and their associated survey methods are now described.

ICT Status Survey Instrument and Survey Method

This survey instrument comprised two sections: (1) general information and (2) citizen's information needs. During May 2003, the survey instrument was administered face-to-face to 465 EMA citizens by seven temporary staff members under the auspices of an eThekwini Municipal official. The duration of each interview was approximately 10 minutes. The selected sample was on a random basis to gather quantitative data to develop qualitative information. Interviews were conducted at EMA customer service offices and municipal libraries. The requirement for effective e-government requires a good understanding of the cultural or social background of its end users (citizens in its communities). The citizen survey thus focused on the e-readiness of EMA citizens to 'tap' into the new methods of communication for e-government.

Library Survey Instrument and Survey Method

The Library Survey focused on library usage, citizens' needs and expectations of library services and facilities, and/or reasons for non-usage. This survey was undertaken by the research organization, Urban-Econ, based in Durban, South Africa. For the purpose of this article, the results of the ICT-related requirements of citizens' needs from the Library Survey are considered complementary to the ICT Status Survey.

During June 2002 the survey instrument was administered face-to-face by librarians to 471 library users in different age categories. This was undertaken at selected municipal libraries in the EMA in accordance with the established sample profile for the various socio-economic groups. Two experienced fieldworkers conducted 144 interviews at pre-

Table 1. Race grouping and gender of respondents surveyed

Race Grouping	Percentage (%) of Male Respondents	Percentage (%) of Female Respondents
Black	49.0%	51.0%
Asian	52.9%	47.1%
Coloured	42.9%	57.1%
White	36.8%	63.2%
Average	**48.2%**	**51.8%**

Table 2. Computer experience by race grouping of respondents surveyed

Race Grouping	Percentage (%) of Respondents Who Have Some Computer Experience	Percentage (%) of Respondents Who Have NO Computer Experience
Black	46.8%	53.2%
Asian	77.5%	22.5%
Coloured	64.3%	35.7%
White	85.7%	14.3%
Average	**58.7%**	**41.3%**

Table 3. Occupation status by socio-economic group of respondents surveyed (adapted from eThekwini Municipal Libraries, 2002)

Occupation Status	Percentage (%) Distribution of Occupation Status by Socio-Economic Groups				
	Rural Low	Urban Low	Urban Middle	Urban Upper	Total
Studying/ scholar	58.6%	53.8%	29.8%	25.0%	43.6%
Employed	20.7%	17.9%	31.6%	25.0%	23.4%
Self-employed	10.3%	5.1%	3.5%	0.0%	4.8%
Not working	10.3%	20.5%	24.6%	11.7%	19.8%
Pensioner	0.0%	2.5%	10.5%	33.3%	8.5%
Total	**100.0%**	**100.0%**	**100.0%**	**100.0%**	**100.0%**

selected households, which ensured sample representivity of the surveyed areas. The results from this survey are contained in the "eThekwini Municipal Libraries: User and Non-User Survey" report, dated August 26, 2002, and used to inform the author's study.

SURVEY RESULTS AND DISCUSSION

From the ICT Status Survey, Table 1 reflects the race grouping and gender of respondents surveyed.

A comparable gender composition was reported in the Library Survey.

From the ICT Status Survey, Table 2 reflects the computer experience by race grouping of respondents surveyed.

From Table 2, an average of 58.7% of citizens reported that they have some computer experience. Computer experience by White citizens is relatively high (85.7%), followed by Asian citizens (77.5%). Black citizens reported the least computer experience (46.8%).

From the Library Survey, Table 3 reflects the occupation status by socio-economic group of respondents surveyed.

From Table 3, the need for information is greatest among students/scholars (43.6%), followed by employed citizens (23.4%). Unemployed (not working) citizens also indicated a significant need for information (19.8%).

From the ICT Status Survey, Table 4 reflects the computer literacy by socio-economic group of respondents surveyed.

From Table 4, 20.7% of citizens reported that they had no computer literacy, while 53.7% of citizens indicated

Table 4. Computer literacy by socio-economic group of respondents surveyed (adapted from eThekwini Municipal Libraries, 2002)

Computer Literacy	Percentage (%) Distribution of Computer Literacy by Socio-Economic Group				
	Rural Low	Urban Low	**Urban Middle**	**Urban Upper**	**Total**
Little bit	13.8%	34.6%	24.6%	12.5%	25.5%
No	31.0%	24.4%	3.3%	25.0%	20.7%
Yes	55.2%	41.0%	66.7%	62.5%	53.7%
Total	**100.0%**	**100.0%**	**100.0%**	**100.0%**	**100.0%**

Table 5. Respondents surveyed with Internet access who visited eThekwini Municipality's Web site

Percentage (%) of Respondents Who Have Visited eThekwini Municipality's Web Site	Percentage (%) of Respondents Who Have NOT Visited eThekwini Municipality's Web Site
16.7%	83.3%

Table 6. Internet usage patterns of respondents surveyed (adapted from eThekwini Municipal Libraries, 2002)

Reason for Internet Usage	Percentage (%) of Internet Usage by Library Users	Percentage (%) of Internet Usage by Library Non-Users
E-mail	42.2%	20.8%
Study assignments	43.6%	7.6%
School projects	35.1%	34.0%

General research	9.5%	18.8%
Other	1.6%	2.15%
Total	**100.0%**	**100.0%**

Table 7. Information needs by socio-economic group of respondents surveyed (adapted from eThekwini Municipal Libraries, 2002)

Information Required	Percentage (%) Distribution of Information Needs by Socio-Economic Group				
	Rural Low	Urban Low	Urban Middle	Urban Upper	Total
Business	13.8%	6.4%	1.5%	4.2%	8.0%
Community services	17.2%	16.7%	8.8%	20.8%	14.9%
eThekwini Municipality	0.0%	3.8%	3.5%	0.0%	2.7%
Health	20.7%	3.8%	5.3%	0.0%	6.4%
International	24.1%	17.9%	21.1%	8.3%	18.6%
Local government	3.4%	2.6%	3.5%	0.0%	2.7%
National government	3.4%	10.3%	14.0%	16.7%	11.2%
No response	0.0%	5.1%	10.5%	20.3%	8.0%
Study projects	17.2%	28.2%	21.1%	25.0%	23.9%
Other	0.0%	5.1%	1.8%	4.2%	3.2%
Total	**100.0%**	**100.0%**	**100.0%**	**100.0%**	**100.0%**

Table 8. Delivery mechanisms for receiving information about eThekwini Municipality

Delivery Mechanism	Percentage (%) of Respondents
Telephone	4.3%
Post Office	69.6%
Municipal customer service office	7.6%
Municipal publication	13.3%
Community meeting	4.4%
Internet	0.1%
School/tertiary	0.7%
Total	**100.0%**

that they are computer literate. Lesame (2005) reports that in South Africa, "[m]any schools make use of computers in the quest to create a computer literate society by teaching educators and learners computer skills required in the information society."

From the ICT Status Survey, Table 5 reflects the respondents surveyed with Internet access who visited eThekwini Municipality's Web site (*www.durban.gov.za*).

From Table 5, 16.7% of citizens reported that they had visited the Web site at *www.durban.gov.za*. The networking capability offered by the Internet and related technologies have the potential to transform structures and operations of government organizations. OleKambainei and Sintim-Misa (2003) argue:

"There is also a need to promote the use of ICT to provide better, cheaper and faster government services and information electronically, increase citizens' participation in decision-making and facilitate good governance (e-governance). To accomplish this, an effort should be made to develop comprehensive and active Web sites for governments."

From the Library Survey, Table 6 reflects the Internet usage patterns of respondents surveyed.

From Table 6, the Internet was used by library users mostly for study assignments (43.6%). This was closely followed by e-mail (42.2%) and school projects (35.1%). In the case of library non-users, the Internet was mostly used for school projects (34.0%).

From the Library Survey, Table 7 reflects the information needs by socio-economic group of respondents surveyed.

From Table 7, citizens' information needs focus on study projects (23.9%). This was followed by international infor-

mation (18.6%) and then community services information (14.9%). The need for business information (8.5%) and local government information (2.7%) rank relatively low.

From the ICT Status Survey, Table 8 reflects the delivery mechanisms for receiving information about eThekwini Municipality.

From Table 8, a significant number of citizens receive information about eThekwini Municipality via the *MetroBeat* publication (69.6%). The *MetroBeat* is delivered by the South African Post Office to citizens' post boxes.

The aim is not simply to deliver services electronically (e.g., Internet, short message service (SMS)) in the EMA, but to encourage its citizens to start learning about the Internet via its Web site and thereafter make use of the Internet for other services. The eThekwini Municipality Integrated Development Plan 2010 and Beyond report states that eThekwini Municipality's strategic commitment is to develop a smart city:

...to bridge the digital divide in eThekwini and to become a hub of information diffusion, as well as a centre for economic growth and integration. Bridging the digital divide will reduce the gap between those who have access to information and communication technology, and those who do not have access for socio-economic or infrastructure reasons. (eThekwini Municipality, 2007a)

It is argued that similar commitments to bridging the digital divide exist in other municipalities in developing countries.

The two surveys (ICT Status Survey and Library Survey) focused on establishing a better understanding of how ICT can contribute to eThekwini Municipality's citizen service delivery and development communication. From the eThekwini Municipality surveys, generic future trends are now presented which may be useful to other municipalities in developing countries for their e-government strategies.

FUTURE TRENDS

From this research, some future trends for implementing an e-government strategy in other municipalities in developing countries are suggested:

- Physical Access: All citizens should have equal access to the services to which they are entitled. Access to communications and the Internet are cornerstones of an MIS. Digital inclusion cannot be achieved without providing all citizens access with affordable ICT appliances to the information highway.
- Appropriate Technology: Network evolution has thus become an imperative for electronic service delivery (ESD). The challenge is to chart an appropriate course of network deployment which does not perpetuate Gumucio-Dagron's (2003) 'new apartheid' syndrome.
- Affordability: The communication mechanism should be affordable to citizens. Furthermore, public services should be provided economically and efficiently in order to give citizens the best possible value for their money.
- Human Capital: Training and re-skilling will be necessary. Since many citizens lack ICT skills and/or do not have access to desktop or laptop PCs, demonstrations on how to effectively utilize ICTs (e.g., e-mail/SMS) must be provided.
- Relevant Content: The content developed must be locally relevant to its constituency, especially in terms of language. Averweg et al. (2003) suggest that a Web site must facilitate access by end users not familiar with Internet norms and whose home language is not English. To bridge the digital divide through e-government, e-government must be relevant to citizens.
- Integration: ICT must not act as a further burden to citizens' lives. ICT should be integrated into priority sectors of the EMA economy and into citizens' daily lives. Okpaku (2003) suggests "ICTs have become so important to virtually all aspects of life…to systems of governance, that they have become fundamental to basic life."
- Socio-Economic Factors: A government has a responsibility for the well-being of its employees that cannot be ignored as new ICTs are introduced. The socio-economic status of citizens (end users) should be considered. By evaluating their e-readiness, this will determine the usability of e-government tools.
- Political Will: Government is a political organization in which elected officials are ultimately accountable to the voters (citizens), and this accountability should be acknowledged.
- Democratization of Society: Worldwide there has been an explosion in projects and initiatives—on a global, national, and (most often) local level—to exploit the potential of the Internet to draw citizens into civic participation and thereby enhance democratic participation (Tsagarousianou, 1998).
- Legal and Regulatory Framework: Government regulations affecting technology use and changes that need to be made to create an environment that fosters ICT usage must be considered. The effect of legal and regulatory frameworks on ICT use should be geared to facilitate the knowledge and information economy growth in the digital age in the developing world.

CONCLUSION

Given its location at the grassroots of any democratic society, a municipality faces the greatest challenge of all spheres of government when it comes to service delivery. While citizens interact with government at all levels, it is the services provided by local government with which citizens are most familiar and have the highest expectations. In response to the demands placed on municipalities in developing countries, e-government has a vital role to play in transforming the traditionally paper-based, paper-laden operations of municipalities' back offices and through streamlining the interaction between municipalities and their citizens. It is about how citizens change in relating to 'their' municipality and the degree to which e-government changes citizens relating to each other in an MIS.

To seek building an ICT capacity without a solid foundation of research and development is nothing but building a skyscraper in quicksand (Okpaku, 2003). Further research needs to be conducted by municipalities in developing countries regarding developmental issues that may impact their e-government development strategies. Should such research be undertaken, municipalities in developing countries will be able to ensure they adopt appropriate ICT infrastructures for their citizens, thereby improving ESD, operating more efficiently, communicating better with citizens, and narrowing the digital divide.

KEY TERMS

Digital Divide: A social, economic, and political fracture.

E-Governance: Refers to a government's inventiveness to electronically govern areas under its jurisdiction.

E-Government: The process by which government communication and administration processes are made available using information and communication technologies (ICTs).

E-Readiness: Defined in terms of availability of ICT infrastructure, the accessibility of ICT to the general citizen and business organization population, and the effect of the

legal and regulatory framework on ICT use in, for example, an e-government strategy.

Electronic Service Delivery (ESD): A method of delivering services and conducting business with customers, suppliers, and stakeholders to achieve local government developmental goals of improved customer service and business efficiency.

Information and Communication Technologies (ICTs): An umbrella term for a range of technological applications such as computer hardware and software, digital broadcast technologies, telecommunications technologies, and electronic information resources.

Municipal Information Society (MIS): A term used for the innovative use of ICT to improve the internal operation of a municipality, as well as its communication and collaboration with citizens, the private sector, and civil society in a municipal area.

E-Government and E-Democracy in the Making

Birgit Jaeger
Roskilde University, Denmark

INTRODUCTION

The development of electronic or digital government (e-government) has varied throughout the world. Although we give it the same name, we know from different studies that, for example, the concept of Information Society can be interpreted in different ways in different cultural settings (Jaeger, Slack, & Williams, 2000; Sancho, 2002). This article provides a general outline of the development of e-government in the West and is primarily based on European and Scandinavian experiences.

It is only possible to give an introduction to e-government if we can define what we are talking about. E-government is still a rather new concept, but most people agree that e-government includes the following features:

- E-government is based on information and communication technologies (ICTs).
- E-government is taking place in public administration.
- E-government concerns electronic ways to perform all kinds of internal administrative tasks.
- E-government also concerns the communication between the public administration and the citizens and other actors in the surrounding society (Jaeger, 2003: 50).

BACKGROUND

Based on the first part of this definition the history of e-government starts in the beginning of the 1960s when the magnetic tape replaced the punched card. During the 1960s and 1970s big central databases were built and were run on big mainframe computers. The databases mostly contained administrative data from fields where the law and regulations were clear and there was a large amount of data to process. In this period, large registers were formed, and software systems for the government of the economy including salaries, taxes and pensions were developed. These activities were often run centrally and the results were delivered to the relevant authority on paper.

When we turn to the second feature in the definition, we have to include the development of the public administration as well. During the 1980s and 1990s most Western countries had experienced a profound modernization of their public administration. At first, this modernisation was marked by reforms that have since been collectively labelled New Public Management. According to Rhodes (1997), New Public Management involves two different types of initiatives, the first of which relates to the management itself. These initiatives include a focus on management by objectives, clear standards, and evaluations of the quality of service, while at the same time granting greater attentiveness towards the users of the public service in question. The other type of initiative deals with the introduction of economic incentive structures. This involves the dissection of the public administration in demarcated services, contracting out some services, and other services are sought arranged in competitive-like situations by establishing quasi-markets in which the consumers of the services are provided with an opportunity to choose between different services.

These alterations have had a more or less unintended consequence—the emergence of new policy networks around the provision of public services (Heffen, Kickert & Thomassen, 2000; Rhodes, 1997; Stoker, 1998). These policy networks draw new agents into the management of the tasks in question, including agents from the business community as well as from civil society. Now we see private companies carrying out publicly-commissioned services. We also see civic groups in the local community; NGOs, sports clubs or interest organizations take over different tasks of more social and carrying kind, which were earlier defined as public. (Again we have to be aware of different traditions in different countries but especially in the Scandinavian countries; many of these tasks have been defined as public whereas in other Western countries the family and local community have played a much bigger part in taking care of these activities.) These agents are now engaged in relations with the public administration in collective, binding policy networks. This general development is often described in terms of the transformation of public sector regulation from government to governance.

These reforms differ from country to country (Rhodes, 1999), but the general picture is that these reforms have had great impacts on the way the public administrative tasks are preformed. Here the development of e-government plays a significant role. Many of these reforms would have been very difficult to realize without ICTs. An example of this is the decentralization of administrative tasks from town halls

to public institutions in Denmark. This reform was based on the use of PCs and the development of an internal electronic network between the town hall and all the public institutions. Today we describe it as the start of the development of the intranet in the authority in question (Jaeger, 2003).

This development has continued and today we have a wide range of different software systems for all kinds of administrative tasks. These include electronic archives, systems for handling electronic documents, systems for consideration of different cases and so forth. Garson (2000) provides an overview of this field as well as a review of the literature.

Rather early on, it became clear that the development of e-government was not just a question of the design of an information system and its implementation in an organization. Thus, over the years, a lot of effort has been put into developing methods for the process of design and implementation (Bødker, Kensing, & Simonsen, 2000). Based on analyses of different failures, it was acknowledged that it is very important to draw on the experience of the potential users in the design process. Otherwise, it is easy to produce systems that do not fit their needs. The experience also showed that the implementation of the system is very important if the organization is going to harvest the benefits of the system. A lot of parameters have to be taken into consideration in this process. The staff has to be informed and drawn into the process; it is likely that some training is needed; the way to organize the consideration of cases has to be carefully examined; and it is perhaps necessary to draw in other competences than those that already exist in the organization. The role of the users is not simply a question of starting to use the technology. Studies have shown that users have to domesticate a new technology before they are able to utilize it (Lie & Sørensen, 1996; Silverstone, Hirsch, & Morley, 1992). In this process they can also shape the technology and make it fit to the conditions under which it is utilized (Jaeger, 2005b; Oudshoorn & Pinch, 2003). The inclusion of all these factors is important if one wishes to ensure that the design and implementation of a new information system is to be a success for the public administration.

During the last couple of decades, public authorities on different levels have developed their own information systems for performing their tasks. This has lead to a situation where many public agencies are unable to communicate electronically because they use different technological protocols and standards. Thus there is a need today for developing common standards for electronic communication between public agencies at different levels. In recent years, this has become a barrier to the development of e-government and therefore a large amount of resources is now spent on solving this problem.

E-DEMOCRACY

Nevertheless, public authorities do not only communicate internally or with other public agencies, they also communicate with citizens, private companies and other users of public services. This is the last of the above listed features of e-government. With the introduction of the World Wide Web in the 1990s, the public authorities were given a tool for this external communication. During the late 1990s and since, most public agencies have developed their own Web site where they place a lot of information, and electronic forms citizens have to fill out to apply for a public service and so forth.

Also in this area of the e-government, we find different kinds of development. In a study of the development of digital cities in Europe (Bastelaer, Henin, & Lobet-Maris, 2000; Williams, Stewart, & Slack, 2005), it became clear that in some cities [e.g., Copenhagen (Jaeger, 2002)], the web site was developed as a part of the e-government and interpreted as a tool for communication between the public authorities and the citizens, while in other cities [e.g., Amsterdam, (Van Lieshout, 2001)], the web site was developed as a tool for communication between citizens and did not involve the public authorities very much.

In terms of definitions, this is the most debated aspect of e-government. Some people interpret a public web site only as being a tool for administrative tasks for use between the public agency and the citizens, while others see the web site as a place for debate and a tool for democracy as well. The first group defines the objectives of e-government as a way to rationalize public administration and increase its efficiency, thus democratic debate should, in their understanding, not be a part of a public authority's web site but should be developed as something else—as e-democracy. The last group defines the objectives of e-government as a tool for all the tasks a public authority has and, consequently, also a tool for the democratic process. In this understanding, the democratic use of ICTs should be developed side by side with the administrative use.

Whether e-democracy is developed as an integrated part of e-government or as a special service, it is the least developed use of ICTs. To further this development, it is necessary to define what kind of democracy the technology should support. Without going into a theoretical discussion of the concept of democracy, it is possible to state that we have at least two different kinds of democracy: representative democracy and participatory democracy. Representative democracy is what the Western world mostly defines as democracy, and functions through a parliament where all the citizens in a country have the possibility to elect some politicians to represent them. Participatory democracy is defined as the wide range of activities in which citizens participate in the political process. It

is important to remember that these two kinds of democracy are not mutually exclusive. In most Western countries, the two kinds of democracy exist side by side.

Technology will be developed differently in accordance with the type of democracy it should support (Hoff, Horrocks, & Tops, 2000). If e-democracy is going to be a tool for the representative democracy, it can be used for electronic voting or online referendums (Hauge & Loader, 1999). Or it can be used to support the political parties in their dialog with the voters (Löfgren, 2001). If e-democracy is going to be a tool for participatory democracy, it should be used to support political debate [e.g., in a local community or in other political processes, (Hoff & Storgaard, 2005)]. Then it is a question of making web sites containing information about the political process and chat rooms or newsgroups where people can discuss different political subjects and where politicians have an opportunity to argue for their opinions.

In recent years, there have been a row of small-scale experiments where ICTs have been tried out as a tool for e-democracy (Torpe, Nielsen, & Ulrich, 2005). Some of these have been promising, but many have more or less failed (especially the experiments with political debates on the Internet). Even if some of these experiments have been promising, we still lack a convincing example of large-scale use of ICTs in e-democracy.

THE POLITICIANS AND E-GOVERNMENT

The development of e-government has a great impact on the people who are affiliated to the public administration. During a Danish study of the role of politicians in the development of e-government (Jaeger, 2005a) it became clear that they play a very limited part in this development. It is mostly the civil servants who decide how to apply ICTs in e-government. Hesitancy among politicians towards becoming involved in the development of e-government and determining the means by which ICT is utilized in administration is largely due to their role conception, for example, whether or not they perceive involvement in such concrete, technical tasks, as being a part of their role.

The role of the politician builds on a sharp distinction between politics and administration. The politician is to represent the people and put forward grand political visions for societal development. Conversely, the administrator's role is to serve the politicians by carrying out their visions and generally administrating society on the basis of the politically defined framework. The means by which administrators implement and administer political decisions is regarded as a technical matter. The administrators can therefore choose the methods and instruments they consider to be most suitable and efficient in the given situation. According to this perception of the division of roles, it is clearly up to the administrators to determine how e-government should be shaped.

This distribution of roles between politicians and administrators has long historical roots and has been working well for generations. But due to the shift in the public administration from government to governance, the politicians have to change their role if they want to maintain their position as governors of the public sector. Sørensen (2002) describes the new requirements of politicians under governance regulation as different means of exercising meta-governance (Kooiman, 2000). The requirements of politicians exercising meta-governance concern the creation of frames to allow other actors to participate in the process. The role of the politicians as meta-governors is then to specify the competence that various actors have to perform, and to make decisions. In order to get this range of independent actors to work in the same direction, the politicians are also responsible for standing forth to offer political leadership capable of creating meaning via a common understanding of the general goals.

The development of e-government can serve as a possibility for the politicians to fulfill the requirements for exercising meta-governance. The manner in which public authorities are presently coordinating their utilization of ICTs will determine the electronic infrastructure these authorities must use internally and with external actors for many years to come. Accordingly, e-government can be configured in a way that supports the politicians as meta-governors. The use of ICTs can make it easier for the politicians to communicate with the external actors, and by doing so make the framework for cooperation visible just as they can use the technology for debates that are important in their efforts to create common understanding and meaning. But this development will not happen by itself. The politicians must perceive e-government as a dimension of the institutional framework for network regulation, just as they must conceive of technology as part of their work to create meaning and identity, as well as in their work with the construction and support of various policy networks. At the same time, the involvement of politicians in the e-government design process could probably lead to a further development of e-democracy where the democratic use of ICTs would receive greater emphasis.

FUTURE TRENDS

The potential of e-government is not yet fully discovered. In the coming years, we will see new ways of utilizing ICTs, which will enhance the performance of e-government. The field of communication between different public agencies especially can prove to increase the effectiveness of e-government if the developers succeed in agreeing to common standards for communication and the exchange of information. For the time being the buzzword for this development is: ICT architecture.

Furthermore, the field of a safe and accountable identification of the user has great potential for increased effectiveness.

With the successful development of one it will be possible to design a long row of forms, which require a safe identification of the user, and as a result shift a lot of work from the civil servants in the public administration to the individual user of public services. At the same time, an accountable identification of the user will make it possible for the public authority to give the citizens access to the information about them and to follow the consideration of their own cases. By doing this, it will be possible to have a much more open administration than the one we know today.

CONCLUSION

E-government is here to stay. Even though we still lack the results from a general study, which proves that e-government is a more efficient way to perform public administration and establishes how much money e-government has saved, some case studies have shown that a public administration using ICTs at least in these cases can perform more tasks, with the same amount of staff, serving a bigger population than the public administration without using ICTs (Jaeger, 2003, pp. 107-110).

The further success of the development of e-government is of course also dependent on the attitude of the citizens. If they do not have access to the technology, if they do not know how to utilize a computer, if they do not accept public services in an electronic way, or if they do not trust the electronic services but are afraid of misuse, then it will not be possible to realize the potentials in e-government. In this way, it becomes a task for the public authorities to prevent a digital divide among the citizens.

It is still rather unclear what will happen to the development of e-democracy. As it looks today, it is unlikely that e-democracy will be developed as an integrated part of e-government. On the other hand, the many small experiments with different forms for e-democracy point to an independent development where the democratic potentials of ICTs are tried out and new applications are developed. This situation is even more likely to take place if the politicians revise their role and start to interpret the development of e-government as a part of their role.

KEY TERMS

Accountable Identification: A way to identify a person in an electronic interaction and to give legal status to electronic documents. Different technologies have been tried out (e.g., chip cards and digital signatures).

Digital City: Usually a web site, which is centered on a city, where public authorities, business and citizens can communicate and exchange information.

E-Democracy: Depending on what type of democracy it should support, ICT can be used for electronic voting, online referendums, or to support the political parties in their dialog with the voters. It can also be used to support political debate in a local community or in other political processes.

E-Government: Is based on ICT, taking place in public administration, concerns electronic ways to perform administrative tasks, and the communication between the public administration and the citizens.

Meta-Governance: A way to govern independent policy networks. The politicians have to create the frames that make it possible for other actors to participate in the policy process. They have to specify the competence of the various actors and to create meaning via a common understanding of the goals for the performance of the network.

New Public Management: Includes initiatives which relate to management of the public administration (e.g., management by objectives, clear standards, and evaluation of the quality of service). It also includes initiatives that deal with the introduction of economic incentive structures (e.g., outsourcing of public tasks and establishing of quasi-markets for public services).

Policy Network: Are centered on the provision of public services and include, beside the public administration, agents from the business community as well as from civil society (e.g., NGOs, sports clubs or interest organizations). These agents are engaged in interdependent relations with the public administration.

E-Learning Adaptability and Social Responsibility

Karim A. Remtulla
University of Toronto, Canada

INTRODUCTION

The global, knowledge-based economy is causing rapid change when it comes to workforce composition and the nature and character of work itself. At the same time, 'e-learning' is increasingly positioned as the panacea for workplace learning needs for a transforming workplace and the global, knowledge-based economy (Industry Canada, 2005; Rohrbach, 2007). In this information age of intense political, social, technological, and environmental upheaval, do organizations bear any social responsibility towards their employees when mandating workplace learning from their employees through e-learning?

The International Organization for Standardization (ISO, 2007a) specifies four key areas that all organizations need to pay heed to for 'social responsibility' to be accomplished: "environment; human rights and labor practices; organizational governance and fair operating practices; and, consumer issues and community involvement/society development" (para. 6). Accordingly, given the criteria of "organizational governance and fair operating practices," this article argues for e-learning adaptability as a burgeoning social responsibility in the workplace, when thinking about workplace learning, by discussing: (a) the workforce diversity, and other workplace changes, that increasingly challenge the current approaches to e-learning at work; and then, (b) highlights the e-learning adaptability framework (Remtulla, 2007) as one methodology to assess and enable e-learning adaptability to meet this social responsibility for the benefit of a global workforce.

BACKGROUND

Diversity at Work

Skills shortages are becoming more severe in advanced economies (OECD, 2005; Rohrbach, 2007). This is primarily due to the fact that the European Union and North America are facing an aging workforce, a dwindling youth cohort, and declining birth rates, simultaneously, resulting in a smaller workforce in the future to fuel the needs of mega-corporations. This means that the workforce is not only becoming more demographically diverse, but also more multicultural, because immigration from developing countries will count for most of the labor force growth in advanced economies in the near future.

Workers are also becoming more multifaceted. To remain competitive, workers are assuming personal responsibility for their learning and upskilling. One outcome of this is mass underemployment as workers bring with them an increasing range of talents to each new job. Many workers' skills and knowledge already far exceed the career opportunities available to them and their employers' ability to use these skills despite demanding it of their workers to get work in the first place (Mirchandani, 2003).

Other Workplace Changes

Work is becoming more homogeneous when it comes to tasks and responsibilities. One widely accepted reason for this is the influence of international standards bodies that promulgate systems to harmonize various job tasks across various industries and regions. Well-known examples of this are the ISO, International Electrotechnical Commission (IEC), and International Telecommunication Union (ITU). In turn these standards become a form of accountability on the job, mandating everyone to act in accordance with these 'international' standards. These international standards bodies work together and construct uniformity as necessary and universally beneficial (ISO, 2006).

Jobs are also becoming more normalized around certain competencies and behaviors with respect to 'high skills'. This comes from a pervasive belief that high-skilled work and competencies, based on knowledge and continuous innovation, are universally tantamount to business continuity and profitability (Rohrbach, 2007).

Social Responsibility, Workplace Learning, and E-Learning

Given the knowledge-based economy and corresponding workplace changes, e-learning is being promoted as the 'grand solution' for workplace learning, ushering in an era of anytime education and anywhere access to knowledge (Gasco, Llopis, & Gonzalez, 2004; Pollitt, 2005). However, the expression 'e-learning' is at present associated with a number of definitions that take a highly limited view of this form of workplace learning, such as:

- "A wide set of applications and processes, such as Web-based learning, computer-based learning, virtual classrooms and digital collaboration. It includes the delivery of content via Internet, intranet/extranet (LAN/WAN), audio- and videotape, satellite broadcast, interactive TV and CD-ROM." (DeRouin, Fritzsche, & Salas, 2005, p. 920)
- "The use of Internet technologies in order to provide a wide range of solutions that might improve knowledge and performance." (Andrade et al., 2005, p. 658)

As exemplified by these definitions, the dominant focus on e-learning remains almost exclusively on the issues of instructional design, hardware, or software. They focus on the mechanics and not the people, nor learning. Similarly, workplace learning professionals respond by tailoring their programs and practices to support these same homogenizing, normalizing, and standardizing trends in jobs, skills, and competencies and to this fixation on the 'technology' (Gagnon & Doray, 2005; Remtulla, 2007). However, what of the changing workforce? The changing nature of the workforce necessitates some acknowledgment of the needs of the global workforce and their unique circumstances.

The relevance and urgency for such acknowledgment in the implementation of mass, workplace learning interventions like e-learning were identified as a social responsibility as far back as the late-1990s, when the global, knowledge-based economy began to unequivocally impact the daily lives of individuals at work (as described earlier). This is echoed, for example, in the following passage from "Adult Education: The Hamburg Declaration—The Agenda for the Future" (UNESCO-UIE, 1997):

The development of the new information and communication technologies brings with it new risks of social and occupational exclusion for groups of individuals and even businesses which are unable to adapt to this context. One of the roles of adult education in the future should therefore be to limit these risks of exclusion so that the information society does not lose sight of the human dimension. (p. 6)

Yet, as noticed from the above definitions of e-learning and approaches to workplace learning, the acknowledgment of the needs of the global workforce remains elusive. Recognizing the lack of the 'human dimension' in organizational standards, the ISO (2007b) is already working on the development of an international standard (ISO 26000) providing guidelines for social responsibility; it is scheduled for release by 2010. Ziva Patir, chair of the ISO Technical Management Board, sums up the inequities in the current situation this way:

Our traditional role was to promote the standardization of products, services, processes, materials and systems. Then we evolved by developing standardized tools for management practice and now we are evolving further to develop standards that address the human aspects.

Today, in the light of ISO strategic vision for 2005-2010, we understand that everything is interconnected and one can no longer differentiate between software and hardware, between product and service, between management tools and the values of the organization. ISO has developed a policy to ensure the global relevance of our work, and today there are few areas more relevant than social responsibility (SR). (p. 3)

The significance of e-learning, as an issue of social responsibility in acknowledging the workplace learning needs of the global workforce, will become paramount in the future, as already noted by the efforts of the ISO and its global partner organizations like the United Nations Educational, Scientific, and Cultural Organization (UNESCO).

THE E-LEARNING ADAPTABILITY FRAMEWORK

To assist organizations in meeting their social responsibility through organizational governance and fair organizational practices, a multiperspectival framework may be one approach for assessing e-learning adaptability that brings together the elements of the knowledge-based economy, workplace changes, hardware, software, instructional design, skills, competencies, workplace learning, and the global workforce into a socially responsible and cohesive methodology. Such a framework represents a more 'socially responsible' alternative to current hardware, software, and instructional design-only based approaches to e-learning because this framework looks not just at how e-learning influences the global workforce, but also how the cultural and the social variability of the global workforce influence e-learning and workplace learning through their needs, motivations, and attitudes.

The e-learning adaptability framework (Remtulla, 2007) comprises a media perspective, a genre perspective, and a learning perspective, to allow for a multiperspectival take on e-learning in the workplace based on context, culture, and community. These three perspectives are further aligned along an *adaptability continuum*: 'media' at one extreme (which considers workplace context); 'genre' (which takes into account user communities in the workplace); and finally, 'learning' (which concerns notions of culture and how people learn differently). When taken together as a continuum, these perspectives represent an interconnected, mutually symbiotic, multiperspectival framework as a socially responsible methodology that potentially provides

better support in dealing with workplace learning and the challenges of a global workforce that remain unrecognized by current (mechanistic) approaches to e-learning.

Context, Learning, and a Media Perspective

Existing 'e-learning as hardware' approaches answer to the trend in the homogenizing of jobs in the workplace, but not necessarily to the contexts surrounding these jobs. These approaches effect the supplanting of face-to-face workplace learning by hardware (Remtulla, 2007). The premise is straightforward: greater variety and functionality in hardware for distribution and access of information equates to better workplace learning, regardless of context. Terms like 'computer-based instruction' and 'Web-based training' indicate the format of the content and the mode of its availability. By ignoring context, the focus stays on access and information systems and the storage and retrieval of information. Decisions about e-learning and workplace learning now have more to do with investment in and/or deployment of hardware and less to do with the learning needs of a diverse, multifaceted, global workforce.

A media perspective increases e-learning adaptability by neutralizing the *homogenizing* effect of hardware-only approaches to e-learning for workplace learning. This perspective goes beyond hardware-only approaches by placing e-learning in context. It prevents the misperception that e-learning is nothing more than distribution and access to information; a challenge readily addressed through expenditure on more hardware. A media perspective first looks to context, and then to what channels or formats may be made available for distribution and access given this context. In other words, this perspective assesses e-learning adaptability as complementary to contexts in the workplace, rather than implementing hardware as a substitute for them.

Communities, Learning, and a Genre Perspective

Current 'e-learning as software' approaches speak to the normalizing of skills and competencies in the knowledge-based economy, but not necessarily the multitude of communities that individuals interact with at work. These approaches bring about the erasing of difference between jobs through commercial and off-the-shelf software and applications solutions (Remtulla, 2007). Again, the formula is straightforward: greater standardization in software and applications equates to better workplace learning. This happens with standardized, one-size-fits-all software applications as a prescription for predetermined knowledge gaps.

In any organization, it is not uncommon to have many user communities. As this multifaceted, global workforce grows, the likelihood of individuals affiliating and associating with different communities at work will also likely increase. On the other hand, the e-learning software in question is likely to be more *generic* than is actually needed by the user groups and may not be entirely responsive for the particular gender, race, age, and/or other personal and professional communal needs of the users, especially when dealing with a global workforce. Decisions about e-learning now become more about obtaining the most cost-efficient software and less about the learning needs of a diverse, multifaceted, global workforce.

A genre perspective increases e-learning adaptability by countering the *normalizing* effect of software-only approaches. 'Genre' of software involves the intended users and *their* relation to one another (Bezemer & Kress, 2008). This perspective shifts the spotlight away from the media and hardware, and onto software and applications to determine which user communities will ultimately benefit from e-learning for workplace learning and why.

A genre perspective offers additional advantages to and appends a media perspective when pondering e-learning adaptability for workplace learning. It acknowledges the existence of different user groups and their competing requests and circumstances (Graham, 2004; Munro & Rice-Munro, 2004), whereas the media discussion limits the entire e-learning adaptability debate to a discussion about context. A genre point of view also accepts the fragmentation and partitions within communities of users in the workplace. In other words, this perspective assesses e-learning adaptability as fostering cross-cultural communication, community building, and interaction among user groups, rather than installing standardized software as a substitute for them.

Culture, Learning, and a 'Learning' Perspective

A 'learning' perspective on e-learning considers pedagogy—the principles and practices of instruction that make workplace learning possible. When it comes to the global workforce and workplace changes, this viewpoint may be most relevant to assessing e-learning adaptability because it, in fact, undergirds even the media and genre perspectives. It encompasses notions of knowledge and circumstances, and of *how and why* people come to learn things.

This perspective exposes the *universalizing* paradigm of present 'instructional design only' approaches. This universalized worldview is based on five implicit assumptions common to modern workplace learning programs and practices (Johansen & McLean, 2006; McLean, 2006):

(1) Western views and values of learning apply to all workers.

(2) The content and method of teaching are optimal when consistent.
(3) Learning is a personal, solitary, and cognitive undertaking.
(4) All workers are equal when it comes to access and capacity to learn.
(5) Learning must align with economic goals.

All this seems to ignore almost entirely the workplace learning needs and motivations of the non-Western workers who will populate more and more of the global workforce in the future.

The advantage that a learning perspective has over both media and genre perspectives when it comes to e-learning adaptability is that culture is brought squarely into the conversation. At the same time, it does not disregard either context or community, but goes beyond these to look at culture—that is *learning and the learners.* In other words, this perspective assesses e-learning adaptability as enabling a culture of organizational learning (Jensen & Markussen, 2007) and knowledge-building among workers, across contexts and communities, and for a global workforce, rather than using universalized instructional design as a substitute for them.

A Socially Responsible Definition for E-Learning

As such, this chapter now proposes the following definition of e-learning that includes acknowledgment of the needs of the global workforce and the implementation of e-learning through a socially responsible methodology: *E-learning is a process of workplace learning that utilizes information and communications technologies to promote competencies and skills for a diverse workforce in an adaptive manner that is sensitive to context, community, and culture in the workplace.*

FUTURE TRENDS

Organizational stakeholders need to be more vigilant in gaining a better grasp over the needs and complexities of workplace learning for a global workforce and workplace changes when envisioning the future of e-learning. The focus of attention must move away from hardware, software, and instructional design, and towards the global workforce and their contexts, communities, and cultures in the workplace. More powerful software and hardware is not the whole answer. They do not necessarily translate into learning or accomplishing social responsibility while global workers' needs go unresolved.

As such, further research is also needed on e-learning adaptability from a standpoint that incorporates multiple perspectives (i.e., media, genre, and learning) to bring about workplace learning. Additional innovation in assessment criteria and measurement tools and methods that link e-learning adaptability with organizational governance and fair organizational practices are also recommended. E-learning adaptability will become even more imperative through a growing, global workforce that is increasingly diverse; that may not be reflecting workplace priorities, accountabilities, performance, and productivity; and that may be *not learning* despite intensive investment in e-learning and extensive assessments of hardware, software, or instructional design.

CONCLUSION

Current approaches to assessing e-learning in the workplace focus on hardware, software, or instructional design. They speak to homogenizing, normalizing, and universalizing trends in the workplace when it comes to work, skills, and competencies in the knowledge-based economy. Hardware is not a substitute for context. Software cannot take the place of community. Instructional design cannot replace culture.

Given the global workforce and workplace changes, a multiperspectival framework to look at e-learning adaptability—one that brings context, community, and culture together with e-learning for workplace learning—now becomes essential. The e-learning adaptability framework comprises a continuum of three perspectives on e-learning adaptability: (a) a media perspective, which assesses e-learning adaptability as complementary to the contexts of the workplace; (b) a genre perspective, which assesses e-learning adaptability as fostering cross-cultural communication, community building, and interaction of user groups; and (c) a learning perspective, which assesses e-learning adaptability as enabling a culture of organizational learning and knowledge building among workers. When taken together as an interconnected, mutually symbiotic, and multiperspectival methodology, these perspectives represent a socially responsible framework that potentially provides better support in clarifying the workplace learning implications of a global workforce from e-learning, and vice versa.

KEY TERMS

Community: The numerous professional, bureaucratic, social, gendered, racial, cultural, and other groups that individuals affiliate and associate with in the workplace.

Context: The shifting and overlapping political, social, technological, and environmental spaces that individuals occupy in the workplace.

Culture: The common values and paradigms that individuals share with each other across the various communities and contexts they encounter in the workplace.

E-Learning Adaptability Framework: A multiperspectival framework for assessing e-learning for a global workforce based on a continuum of three perspectives: media, genre, and learning.

Homogenizing: To make uniform and constant in function and intention.

Knowledge-Based Economy: "An expression coined to describe trends in advanced economies towards greater dependence on knowledge, information and high skill levels, and the increasing need for ready access to all of these by the business and public sectors" (OECD, 2005, para. 71). Also called *knowledge economy.*

Normalizing: To conform to a standard or widely accepted norm.

Universalizing: To generalize to all people, circumstances, and situations.

Workplace Learning: The skills and competencies that individuals gain knowledge of for work through higher and tertiary education and (re)certification; through workplace learning interventions, both formally organized or informally through coaching and mentoring between coworkers; or by means of other self-directed efforts both inside and outside of the workplace.

Electronic Government and Integrated Library Systems

Yukiko Inoue
University of Guam, Guam

INTRODUCTION

Twenty First Century Government is enabled by technology—policy is inspired by it, business change is delivered by it, customer and corporate services are dependent on it, and democratic engagement is exploring it. Technology alone does not transform government, but government cannot transform to meet modern citizens' expectations without it (Cabinet Office, 2005, p. 3).

According to the E-Government Readiness Ranking Report (United Nations, 2005), in 2005 the United States was the world leader followed by Denmark, Sweden, and the United Kingdom; and in 2004 the Republic of Korea, Singapore, Estonia, Malta, and Chile were also among the top 25 "e-ready" countries. The Ranking Report further emphasizes that 55 countries, out of 179, which maintained a government Web site, encouraged citizens to participate in discussing key issues of importance, and that most developing country governments around the world are promoting citizen awareness about policies, programs, approaches, and strategies on their Web sites—thus making an effort to engage multi-stakeholders in participatory decision-making.

Indeed, one of the significant innovations in information technology (IT) in the digital age has been the creation and ongoing development of the Internet—Internet technology has changed rules about *how* information is managed, collected, and disseminated in commercial, government, and private domains. Internet technology also increases communication flexibility while reducing cost by permitting the exchange of large amounts of data instantaneously regardless of geographic distance (McNeal, Tolbert, Mossberger, & Dotterweich, 2003). In Hirsch's (2006) words, "The Internet has finally achieved the convergence dream of the 1970s and everything that can be canned in digital form is traveling the Net" (p.3).

BACKGROUND

For hundreds of years, American government agencies have collected and provided data and information (such as statutes and regulations, court decisions, votes by Congress, and the records of hearings) for both citizens and government. In fact, American Federal Government has adapted progressive computer and telecommunication technologies both operationally and in policy to harness computing power to improve government performance and enhance citizen access to government and other information services and resources since the development of Internet technology—from the initial steps to establish the Internet in the late 1960s (originally ARPANET) to the establishment of the National Information Infrastructure (NII) and National Performance Review (NPR) initiatives in 1993 (Aldrich, Bertot, & McClure, 2000).

In the early 1990s, city governments began to use e-mail, listserv, and the World Wide Web (WWW or Web) to deliver information and services; and by the end of the 1990s, Web-based services were already an integral and significant part of Electronic Government (e-government) (Ho, 2002). E-government, simply defined as utilizing the Internet and Web for delivering government information and services to citizens, refers to the use by government agencies of IT (such as Wide Area Networks, the Internet, and mobile computing) that have the ability to transform relations with citizens, businesses, and other arms of government (AOEMA, 2006). In essence, e-government could enable citizens to interact and receive services from the federal, state, or local government "24 hours a day," "7 days a week"; it has taken promising steps to deploy e-government services, but much remains to be done, both in implementing e-government services and in developing new technologies and concepts (AOEMA, 2006). All the government activities essentially arise from a mixture of motives intertwined, principally in the interests of *efficiency*, *information access and provision*, and *democracy* (Hirst & Norton, 1999).

And in the electronic information age, the traditional roles of the Federal Depository Library Program (FDLP) libraries in selecting, acquiring, organizing, and providing access to and services for government information are more important than ever (Jacobs, Jacobs, & Yeo, 2005).

ELECTRONIC GOVERNMENT

Key Dimensions

E-government incorporates four key dimensions that reflect the functions of government itself, but the last dimension

is oftentimes slighted because it is mostly invisible to the public (Dawes, 2002): (1) *e-service* (the electronic delivery of government information, programs, and services often over the Internet); (2) *e-democracy* (the use of electronic communications to increase citizen participation in the public decision-making process); (3) *e-commerce* (the electronic exchange of money for goods and services, such as citizens paying taxes and utility bills, and renewing vehicle registration); and (4) *e-management* (the use of IT to improve the management of government from streamlining business processes to maintaining electronic records to improving the flow and integration of information). According to Dawes (2002), New York City is clearly in the first tier of jurisdictions in its development of e-government (NYC.gov). Also the city's Web site has been recognized nationally for its design and usability; especially after "September 11" (that is, "the 2001 terrorist attack on America"), the website has been used with great resourcefulness and flexibility to provide New Yorkers with the best information available.

Objectives/Innovations

Using information and communication technologies (ICTs), e-government promotes more *efficient* and *effective* government, but it is not a shortcut to economic development, budget savings, or efficient government. E-government is a *process* (thus called "e-volution") and often a struggle that presents costs and risks, both financial and political (AOEMA, 2006). However, e-government is not simply the process of moving existing government functions to an electronic platform but calls for "re-thinking" the way government functions are carried out today to improve some processes, involving four objectives/innovations (AOEMA, 2006) (see Table 1).

In addition to the above objectives/innovations, the Department of Labor (DOL), for instance, ensures that federal employees with disabilities are able to use IT to do their jobs, and that members of the public with disabilities who interact with DOL will be able to use IT to access information on equal footing with people who do not have disabilities, in reference to Sections 504 and 508 of the Rehabilitation Act of 1973 (as amended) and published standards (DOL, n.d.).

Security and Privacy

Through the Internet and Web revolution, more effective, convenient, and flexible e-government services are happening, yet *security* and *privacy* are the two critical issues in e-government. Building secure e-government systems requires a careful balancing between providing convenient access and appropriately monitoring permission and, in reality, technology-based solutions are still at their infancy and the existing alternatives consist essentially of enforcing privacy by law or self-regulation of operational practices ("Security and privacy," 2002).

Successfully implementing e-government does require a level of trust on the part of all transacting parties, and e-government security and privacy protection activities address the protection of the government assets involved in e-government. For example, DOL (n.d.) has developed a comprehensive cyber security program in accordance with the Federal Legislation and Policies, which include the Federal Information Security Management Act of 2002 and Privacy Act of 1974. Accomplishments by DOL include: (1) developing system security plans for major applications, general support systems, and financial systems; (2) developing an enhanced computer security awareness training

Table 1. E-government objectives/innovations

Government To Citizen (G2C):
- Providing one-stop, online access to information and services to individuals (citizens should be able to find what they need quickly and easily)
- Disintermediation of civil service staff—delivering services directly to citizens

Government To Business (G2B):
- Reduced burdens on business by providing one-stop access to information to facilitate business development
- Skilled, IT-literate, and flexible citizens for the labor market

Government To Employee (G2E):
- The ability to easily gather information from the field
- Access to important applications and content

Government To Government (G2G):
- Reducing the fractured nature of individual department and agencies, and moving towards "joined-up" government
- Changing the culture of the civil service from reactive to proactive

plan; and (3) issuing the systems development life-cycle methodology integrated IT security into each phase of the project's life cycle.

INTEGRATED LIBRARY SYSTEMS

In the United States, there are deeply rooted values that a democracy requires of an informed citizenry, that government must be accountable to its citizens, and that citizens must have full, free, and easy access to information about the activities of their government; therefore, these "values" have led to the creation of the Government Printing Office (GPO) and FDLP (Jacobs et al., 2005). GPO began operations in accordance with Congressional Joint Resolution 25 of June 23, 1860 as part of the legislative branch of the Federal Government, and it operates under the authority of the Public Printing and Documents Chapters of Title 44 of the U.S. Code (GPO, 2003). To organize, manage, and disseminate the Federal Government's information, the Depository Library Act of 1962 established FDLP, which is an important "partnership" between government and libraries to link the public with government information and resources.

New Online Catalog

According to GPO (2006), *Franklin* (franklin.gpo.gov)—the new online catalog for the National Bibliography of American Government Publications (a comprehensive index of public documents from all three branches of the Federal Government)—is being prepared for its official launch: *Franklin*, which is a component of a modernization plan to replace older legacy systems with GPO's recently acquired state-of-the-art integrated library system, will contain more than 500,000 records dating from July 1976 to the present and will become more far reaching in the future. Through the office of information dissemination programs, GPO disseminates the largest volume of American government publications and information in the world (*GPO Access*, 2005). In the future, GPO will first focus on digitizing legislative and regulatory material that expands the coverage of the most popular *GPO Access* databases (GPO, 2006).

Free Online Access

The traditional mission of GPO (that is, printing, and selling publications) is being made increasingly irrelevant by technological change (Jacobs et al., 2005). GPO was therefore required to disseminate government information with the passage of the GPO Electronic Information Access Enhancement Act of 1993; after this Act became law, the amount of electronic information in the program grew rapidly; in 1995, Public Law 103-40 authorized *GPO Access*—a free online access point to many government databases (Finchum, 2004). In 1993, Congress mandated that the Congressional Record and the Federal Register be made available online for free; as a consequence, there are about one million downloads per day from the Federal Register (Drake, 2006). As Drake further notes, 92% of all Federal Government documents are available online, and the remaining 8% represent specialized publications such as large maps; in 2005, 50% of all government publications were born "digital" and will never be printed by the Federal Government; however, there are now questions about the best way to keep them in perpetuity.

Additionally, the Library of Congress is midway through its ten-year, $100 million National Digital Information Infrastructure and Preservation Project, designed to develop digital preservation strategies; in 2005, the National Archives awarded Lockheed Martin a $308 million contract to develop ways of preserving diverse e-government records (Manes, 2006).

FUTUTE TRENDS

Information Society in 2015

E-government programs, indeed, affect the social, political, and economic fabric of a country, and national e-government programs have progressed steadily around the world since 2001; despite numerous creative initiatives, however, most national e-government programs still focus on *information*, rather than interactive services (International Telecommunication Union or ITU, 2006). Concerning the information society in 2015, ITU predicts as follows:

The next decade will witness innovation and growing convergence between the largely unregulated computing and consumer electronic industries and the more heavily regulated communications and media industries, posing new challenges for policy design and regulation. "The information society in 2015 initiative" considers future scenarios for technological convergence, the desegregation of sector-specific infrastructure from services and content, and the impact of global connectivity, content, and service providers. This initiative, based on possible scenarios, will consider how national, regional, and international policy and regulatory frameworks need to adapt. It will also consider whether shifts in further policy and regulatory regimes are likely to be led by individual users, industry groups or by government mandate—or by a combination of approaches (p. 2).

Moreover, by improving service delivery and associated costs, and by enhancing communication between citizens and government, e-government enables constituents to access information and services from home, which reduces traffic flow, and improves the environment. Sources of government

information are thus rapidly transitioning from paper format to electronic format. It should be noted, however, that e-government and regulatory policy making capabilities are only beginning to emerge and, in the future, it can be expected to fall within the four main areas (i.e., IT, agency management of rule making, public involvement in the rulemaking process, and regulatory compliance); these areas of the research can be enhanced through coordinated research efforts that involve perspectives from both social sciences and information sciences (Coglianese, 2004). Further, there has been a growing appreciation for the importance of doing interdisciplinary research—thus involving ecology, economics, sociology, psychology, political science, public policy, and urban design and planning (Waddell & Borning, 2004). Finally, five challenges identified by Dawes (2002) may continuously hold the future of e-government: (1) comprehensive strategy; (2) integration of information and services; (3) privacy and data sharing; (4) dynamic use of the Web; and (5) partnerships and other organizational networks.

The Once and Future FDLP

The mission of FDLP is to disseminate information about the government activities to over 1,250 Federal Depository Libraries in the 50 states, the District of Columbia, and U.S. territories (*GPO Access*, 2005). The shift to digital production of government information does not change the need for FDLP libraries and five criteria are those that FDLP has been meeting for decades and will be meeting for the future (Jacobs et al., 2005, p. 201): (1) information is available and fully functional to all without charge; (2) information is easy to find and use; (3) information is verifiably authentic; (4) information is preserved for future access and use in a distributed system of digital depository libraries; and (5) privacy of information users is ensured so that citizens can freely use government information without concern that what they read will be subject to disclosure or examination. To access the electronic information, and to make information easy to find and use, librarians must remain current with computer and Internet skills, in addition to knowledge of the legal system and the legislative process (Yang, 2002); thus "libraries must act as expert service providers, rather than warehousing physical collections" (James, 2003, p. 19).

In order to achieve a government information system including the aforementioned five criteria, each of the following stakeholders has to play a significant role (Jacobs et al., 2005): "government agencies" have obligation to collect and compile information for the public; "GPO" should be able to help an agency conform to preservation and dissemination standards and facilitate the creation of metadata; "Congress" should adequately fund the dissemination of information and avoid redundancy and inefficiency; "FDLP libraries" should be able to select government information, acquire digital files, preserve them, and organize them through integration into collections of other information—thus providing access to and service for that information; the role of the "National Archives and Records Administration" is long-term preservation of the record of government; and the "private sector" adds value to government information by re-packaging, re-organizing, and re-distributing the information.

CONCLUSION

Modern governments with serious transformational intent see technology as a "strategic asset" and not just a tool. The real challenge ahead is not just to "do IT better" in the context of the past models for delivery of pubic services; it is also about "doing IT differently" to support the next phase of public service reform—building services which are *more* joined-up, *more* personalized, *more* efficient, and *more* effective in terms of policy outcome (Cabinet Office, 2005).

More and more people are turning to the Internet for information, and there is an increasing emphasis on electronic dissemination of government information. At the same time, electronic information must be preserved against corruption and loss, and there must be ways of ensuring that information created today can be used tomorrow (Jacobs et al., 2005). Another important issue is related to the fact that the Internet's open nature remains an ideal arena for dissemination of misinformation. The question is how to deal with false information on the Web and how to decide whether a source is reliable, even though each individual is ultimately responsible for his or her use of technology and for decisions taken based on information gathered from the Web.

In summary, *power*, *control*, *security*, and *regulation* are the pieces of the "newborn" paradigm in the electronic information age of today (Hirsch, 2006). Certainly, more than ever, each country needs a strategy to position itself in the new economy and define the regulatory framework of e-government applications in accordance with its own goals. That is why Hirsch's inquiry is so important: What will be the copyright enforcement criteria in the Internet era?

KEY TERMS

ARPANET: Advanced research projects agency network that the Internet has roots in, developed by the Department of Defense.

Electronic Information Access Enhancement Act: *GPO Access* is a free service funded by the Federal Depository Library Program and has grown out of Public Law 103-40, known as the Government Printing Office Electronic Information Enhancement Act of 1993.

Information Age: The current era, characterized by the shirt from an industrial economy to an information economy and the convergence of computer and communication technology.

Information and Communication Technologies (ICT): Includes telecommunications technologies (such as telephony, cable, satellite, and radio) and digital technologies (such as computers, information networks, and software).

Internet: World's largest network, a worldwide collection of networks that link together millions of businesses, governments, educational institutions, and individuals using modems, telephone lines, and other communications devices and media. Also called the Net.

Listserv: An automatic mailing list server developed by Eric Thomas for BITNET in 1986, and a program that automatically sends messages to multiple e-mail addresses on a mailing list.

National Information Infrastructure (NII): A futuristic network of high-speed data communications links that eventually will connect virtually every facet of our society.

National Performance Review (NPR): A management reform initiatives established by the national administration to identify ways to make the government work better and cost less.

Wide Area Networks (WAN): A network that extends over a long distance. Each network site is a node on the network. The largest WAN in existence is the Internet.

World Wide Web (WWW): Worldwide collection of electronic documents on the Internet that have built-in hyperlinks to other related documents. Also called the Web.

Electronic Marketplace Support for B2B Business Transactions

Norm Archer
McMaster University, Canada

INTRODUCTION

Information systems that link businesses for the purpose of inter-organizational transfer of business transaction information (inter-organizational information systems or IOIS) have been in use since the 1970s (Lankford & Riggs, 1996). Early systems relied on private networks using *electronic data interchange* (EDI) or *United Nations* EDIFACT standards for format and content of transaction messages. Due to their cost and complexity, the use of these systems was confined primarily to large companies, but low cost Internet commercialization has led to much more widespread adoption of IOIS. Systems using the Internet and the *World Wide Web* are commonly referred to as B2B (business to business) systems, supporting B2B electronic commerce.

Technological innovations have led to several forms of B2B Internet implementations, often in the form of online exchanges or electronic marketplaces (Wang et al., 2005). These are virtual marketplaces where buyers and sellers exchange information about prices, products, and service offerings, and negotiate business transactions. They are major components of the supply chains that they support. In addition to substituting proprietary lines of communication, emerging technologies and public networks have also facilitated new business models and new forms of interaction and collaboration in areas such as collaborative product engineering or joint offerings of complex, modularized products. During the years 1999-2001, a number of online exchanges were introduced, but many of these failed (Gallaugher & Ramanathan, 2002) due mainly to an inability to attract participating business partners, but also because potential participants and their business partners did not perceive enough value added through the significant investment they required. Those that have survived are often owned by companies or consortia that are also exchange customers or suppliers.

The objective of this overview is to describe the evolution and the characteristics of B2B Internet implementations, and to discuss management considerations, the evaluation, and adoption of B2B applications, and the technical infrastructure supporting these systems. We also indicate some of the open issues that remain as the technology and its adoption continues to evolve.

BACKGROUND

Although there are many classification schemes available for B2B online exchanges (Choudhury 1997; Kaplan & Sawhney 2000), we will use a more generic and functional focus, with three categories: sell-side, buy-side, and neutral/market-type applications (Archer & Gebauer, 2001). Early B2B sell-side applications featured online catalogs, made available to the Internet community by distributors and manufacturers, often complemented by features such as shopping baskets and payment functionality. Many now provide customized and secure views of the data, based on business rules from contract agreements with individual customers. In some cases, buying processes of the customers are supported, including features such as approval routing and reporting. While sophisticated applications exist to support collaborative functionalities among the participating organizations, such as forecasting or configuration of complex products, many sell-side systems handle only the simpler transactions such as maintenance, repair, and operation (MRO) supplies. Recently, features that support collaboration have become more widely available through both the "vertical" links of supply chain management and the "horizontal" links of buying groups that can represent suppliers or buyers (Wang & Archer 2007a).

Buy-side applications support procurement, moving order processes closer to the end user, and alleviating structured workloads in functional departments such as purchasing and accounts payable. For smaller companies, an affordable alternative is to work through hosted solutions using Internet browsers to access procurement functionality provided by a third party vendor or application service provider (ASP). Functionalities beyond the automation of highly structured procurement processes include production tendering and multi-step generation requests for proposals, as they are relevant for the procurement of freelance and management services. Interfacing purchasing systems to internal systems such as enterprise resource planning systems (ERP) makes it possible to automate commonly used transactions, thus greatly increasing processing speed and reducing costs. Buy-side solutions that involve long-term inter-organizational relationships are typically set up by the purchasing organization, which then controls catalog content, data format, and backend system functionality. Benefits include

a reduction in maverick buying, and freeing purchasing and accounts payable personnel from clerical work to handle more strategic tasks. Suppliers typically benefit from long-term relationships, and in many cases, the relationships between the buyer and its suppliers were in place long before online operations commenced.

The third group of applications, often referred to as B2B electronic marketplaces or hubs, can either bring together multiple buyers and sellers on an ad hoc basis involving various types of auctions, for example, or support more permanent relationships (a many-to-many equivalent to IOIS) (Wang & Archer, 2004). Those that have been more successful are likely to have been sponsored by a consortium (e.g., *GlobalNetXchange*, in the retail industry, sponsored by buying organizations, and *Global Healthcare Exchange* in the healthcare industry, sponsored by selling organizations). They may feature auctions, electronic catalogs, collaborative functionalities, and auxiliary value added functions such as industry news and online forums. The initiator typically controls the catalog content, aggregates supplier input, and provides additional functionality and standardized data access to buyers (Wang & Archer, 2007). These marketplaces may eliminate the need for market participants to link directly to their business partners, circumventing costly value added EDI network services. Their business models typically include service charges based on transaction volume and setup costs. They provide a standard for suppliers to deliver catalog content, increase flexibility if they support access to suppliers and customers outside pre-established relationships, and create customer value through competitive pressure. Participation in such marketplace solutions may also provide a low cost alternative for SMEs (small and medium enterprises), but SME adoption of such solutions is typically driven by their larger business partners who wield significant market power (Archer et al., 2003).

MANAGEMENT CONSIDERATIONS

A market assumes an intermediary role that supports trade between buyers and suppliers, including (Bailey & Bakos, 1997): (a) matching buyers and sellers, (b) ensuring trust among participants by maintaining a neutral position, (c) facilitating market operations by supporting certain transaction phases, and (d) aggregating buyer demand and seller information. Supporting the marketplace through an electronic exchange has characteristics of (Bakos, 1991): (1) cost reductions, (2) benefits increase with the number of participants, (3) potential switching costs, (4) capital investments but economies of scale and scope, and (5) significant uncertainties in benefits. Many of the management issues of B2B electronic commerce systems relate to the need to coordinate decisions and processes among multiple firms, often through differences in business processes, information systems, business models, and organizational cultures.

Early transaction cost theory recognized markets and hierarchies as the two main methods of governance for coordinating flows of goods and services. Markets such as stock exchanges coordinate the flow through supply and demand forces with price as the main coordination vehicle. Hierarchies such as production networks consist of predetermined relationships among customers and suppliers, and rely on managerial decisions to coordinate flows. There are many intermediate forms of governance such as network organizations and strategic alliances (Gulati, 1998). A common theme among all these governance structures is collaboration among the participants, but the level of collaboration varies. These levels can be described as cooperation, coordination, and collaboration (Winer & Ray, 1994). In cooperation, there is little sharing of goods, services, or expertise; coordination requires mutual planning and open communication among participants, who share resources; collaboration involves deeply synergistic efforts that benefit all parties. Collaboration at different levels between buyers and sellers are emphasized by online exchanges, but this can also take place separately among buyers and among sellers (Wang & Archer, 2004b). A recent survey of 89 online exchanges that offer collaboration services identified a range of collaboration functionalities, including "vertical" supply chain collaboration through collaborative fulfillment, private catalogues, product life cycle management, and supply chain coordination and integration. Additionally, "horizontal" functionalities may be offered in the form of buying groups, which can be classified as dealer-type, exchange-catalogue, exchange-negotiation, supplier-initiated, and buyer initiated (Wang et al., 2007b).

The growth of outsourcing arrangements and more cooperative, integrated long-term inter-organizational relationships with a relatively small number of preferred suppliers can be termed a "move to the middle" (Clemons et al., 1993). This can result in the adoption of collaborative functionalities such as CPFR (collaborative planning, forecasting, and replenishment), which may be used to support joint initiatives between large retail customers and suppliers (Holmstrom et al., 2002; Wang et al., 2004a). Distribution of market power is often an overriding factor. For example, auto manufacturers, as theirs is a concentrated industry, are likely to adopt an approach that involves long-term collaborative relationships among business partners rather than the short-term market-driven relationships that traditionally characterized this industry. On the other hand, relationships among companies in fragmented industries such as construction are typically short-term, with low levels of trust, and transactions such as online procurement are more likely to be through B2B tendering and auctions (Stein et al., 2003).

EVALUATION AND ADOPTION

The task of evaluating an electronic exchange becomes difficult when network effects are taken into account (benefits from participating are usually positively related to the number of participants). As a result of complications such as strategic necessity, dependence on the commitment of business partners, additional risk, external effects etc., the evaluation of electronic exchange adoption is much more complex than for systems deployed within organizations (Gebauer & Buxmann, 2000). B2B market mechanisms focus on four factors that favor one market mechanism over another: degree of fragmentation, asset specificity, complexity of product description, and complexity of value assessment (Mahadevan, 2003). These have a significant impact on the choice of an appropriate market mechanism for B2B interactions.

From the organizational perspective of setting up a successful B2B application, there are initiators and (potential) participants. Initiators bear the majority of the cost and risk, but on the other hand also enjoy the majority of the benefits, and they typically decide on technology infrastructure, type of systems used, corporate identity, representation of partners, and selection of participants. Success of the system depends on the participation of a critical mass of business partners. Supplier participation considerations in a buy-side solution, for example, include investments necessary to prepare and upload catalog data, integration with backend systems, training of staff, and adjustments of business processes. Depending on individual arrangements, benefits include reduced time and costs for order processing, improved customer service, increased customer reach in a globalized marketplace, and an increase in revenues from long-term and trusted customer relationships. Neutral intermediaries in such markets face a difficult balancing task, as they have to be careful to satisfy suppliers as well as buyers, and a business model must be chosen that will attract the desired participants.

Although B2B electronic marketplaces or exchanges have received a great deal of attention by researchers, their rate of adoption by business has not been high. While their aggregate transaction growth rate is growing, they were (in 2004) outranked by at least a factor of 10 in transaction volume by EDI installations, which are still firmly in place in many large corporations (Jakovljevic, 2004). By utilizing EDI over the Internet, companies and organizations also benefit from the ability to facilitate seamless bridging between XML and EDI that can now co-exist on the same infrastructure, and use common protocols to handle electronic procurement, invoicing, and logistics information. With the need to electronically exchange volume-intensive catalogue and product specification information, organizations can reduce significantly the high cost of this exchange by using Internet EDI. In addition, major system vendors (e.g., *IBM, SAP, Oracle*), that already provide enterprise systems to their long-standing corporate clients, compete with electronic marketplaces by providing an array of specialty software-based services that support supply chain and customer relation management interactions between business partners. These proprietary systems can represent obstacles to the development of effective IOIS between companies, but this problem is slowly being reduced due to consolidation of former vendor rivals, and more attention to system interfaces among these competitors.

SMEs can and often do handle B2B transactions through ecommerce solutions without fully automated transaction management systems, through hosted procurement applications. Supply side solutions with Web access can also be used as parallel and partially automated channels for larger businesses that wish to deal with small suppliers or customers. In practice, SMEs execute small numbers of transactions and may not wish to make the investment in resources, training, and internal integration required to link to their business partners (Archer et al., 2003). New technologies are beginning to make affordable solutions available to an increasing number of small and medium sized businesses and thus facilitate their integration in global supply chains. This opens a new range of possibilities for tracing product origins along the supply chain, resulting in improved logistics, better product security, and reduced health, safety and security threats (e.g., in food supply and distribution).

Motivations for joining online exchanges include (Gebauer & Raupp 2000): (a) coercion (through market power), (b) long-term commitment to business relationships and reduction of associated uncertainty, (c) subsidies to support system installations for potential business partners, and (d) general system improvements that result in improved efficiencies and effectiveness. SMEs that link to online exchanges are most likely to be motivated through pressure from their larger partners and by long-term commitments. Many use alternative interactions utilizing a combination of manual and online functions. For example, a medium-sized value-added retailer might use ad hoc purchasing procedures such as searching the Web for catalogue information on major suppliers, and then use the telephone to negotiate prices and delivery schedules (Archer et al., 2003).

TECHNICAL INFRASTRUCTURE

Software products to support B2B interactions are continuing to mature as more complex functions are added such as collaborative planning, forecasting, and replenishment, negotiation and decision support, and procurement and asset management of complex and highly customizable items and systems (Lamont, 2005; Paul et al., 2003). Linking data from many different sources, including legacy systems, through Web services (Iyer et al., 2003) has had many successes supported by the diffusion of extensible markup language

(XML). These two technologies can help to reduce start up and transaction costs as compared to traditional EDI systems. Based on XML and Web technology, a variety of standards have emerged on a more general or sectoral basis, that may assist in: automated recognition of supported business transactions, negotiation, contracting and processing of the deal, creating online dispute resolution mechanisms, signing and encrypting the contents transmitted using the Web, and more general issues such as Internet governance. The relevant international standards are being created through the *ebXML*[1] association. Technical issues are complicated by the critical role of security and confidentiality in inter-organizational settings, particularly when using public networks such as the Internet as compared to the private networks that were traditionally used for EDI implementations. This is further complicated if transactions involve international trade, unless the organizations involved subscribe to internationally recognized standards. Overcoming these obstacles may require significant investments in software, training, business process reengineering, technical support, and time, all of which favor larger corporations.

Transaction complexity is important in the adoption decision, and is determined by factors such as the number of sub-processes and organizational units that are involved, as well as their possible interactions, interdependencies, and relationships with the process environment (Gebauer et al., 2000). This in turn depends on the type of goods or services. Acquiring indirect or non-production supplies and services is the least complex type of transaction, followed by direct goods, and capital goods and other types of ad hoc purchases tends to be the most complex. A high degree of automation is economically viable only for high volume, less complex transactions. As complexity increases and volume decreases, human intervention is more likely to be needed to handle exceptions and ad hoc transactions.

B2B applications can have major impacts on inter-organizational business processes, depending on the level of IOIS integration required (Stelzer, 2001). After planning and designing the system business model and infrastructure, a careful plan of how to implement it, how to train employees, and how to adapt business processes, is the next step towards a successful project (Archer et al., 2001). Business partner adoption, catalog management, and integration with a heterogeneous system of backend applications are frequently listed as major stumbling blocks. For example, an organization could start out by reengineering and then automating a formerly inefficient process that causes long lead times and possibly frequent complaints, such as management approval of end user requests. As a next step, putting together an online catalog that contains the offerings of preferred suppliers can be useful as a first step to reduce "maverick" buying outside pre-established contracts. While the exact steps will depend on the situation within the individual firm, the stepwise approach will also allow frequent adjustments during the project planning and implementation process, including the addition of new requirements. The adoption of a B2B eCommerce solution is a strategic company decision and it is important to evaluate the potential overall impact of this innovation on the firm before proceeding (Warkentin & Bajaj, 2003), since it may require substantial reengineering to become effective (Barnes et al., 2004).

FUTURE TRENDS

There is little doubt that rapid growth will continue in the relative value of B2B transactions handled through electronic commerce solutions, especially as they become less costly and easier to implement in SMEs. However, most of the growth in such offerings is likely to be in sell-side or buy-side online exchanges, supported by infrastructures provided by major system vendors. There has been significant supplier resistance to participating in neutral market-type exchanges. Although these exchanges offer the greatest theoretical benefit because of the potential for standardized linkages among participating companies, and the collaborative functionalities offered by such systems, this does not outweigh resistance from suppliers who see declining profit margins due to transaction cost payments and competitive price bidding. Meanwhile, EDI systems continue to link many large companies, due to their reluctance to give up related investments or to change business processes to accommodate the newer solutions.

CONCLUSION

A clear understanding of the possibilities of emerging technologies is crucial to take advantage of new opportunities in the B2B marketplace. There have been failures in this environment due to a lack of consideration of the wide range of technical, managerial, and economic issues involved. No widely adopted frameworks have been developed to assist in the choice of level of integration or in reengineering boundary spanning business processes. Although technology continues to develop, it is still immature in many areas. In particular, the integration with current IT infrastructures is often extremely complex and difficult to justify for medium to low transaction rates. Meanwhile, B2B applications continue to evolve, changing the rules of the game in subtle ways, but providing fruitful areas for new development and related research.

KEY TERMS

Application Service Provider (ASP): An ASP is a service company that can support and relieve a firm from the daunting challenges of finding, hiring, inspiring, and training technical personnel to manage an application in-house. An ASP provides software applications on a pay-per-use or service basis via the Internet and leased lines.

Collaborative Planning, Forecasting, and Replenishment (CPFR): CPFR is a global, open, and neutral business process standard for value chain partners to coordinate the various activities of purchasing, production planning, demand forecasting, and inventory replenishment, in order to reduce the variance between supply and demand and share the benefits of a more efficient and effective supply chain.

Electronic Data Interchange (EDI): A standard used to govern the formatting and transfer of transaction data between different companies, using networks such as the Internet. As more companies are linking to the Internet, EDI is becoming increasingly important as an easy mechanism for companies to share transaction information on buying, selling, and trading. ANSI (American National Standards Institute) has approved a set of EDI standards known as the X12 standards. Due to the growing influence of international trade, EDIFACT, a standard developed by the United Nations and used primarily in non-North American countries, is being merged with X12 into a worldwide standard.

Enterprise Resource Planning (ERP): A business management system that can integrate all facets of the business, including planning, manufacturing, sales, and marketing, through a common database. As the ERP methodology has become more popular, software applications have been developed to help business managers implement ERP in business activities such as inventory control, order tracking, customer service, finance and human resources.

Extensible Markup Language (XML): Document type definitions that can be used to specify or describe various types of objects. When a set of these is used on the Web to describe product information, it is referred to as cXML or commerce XML. It works as a meta-language that defines necessary information about a product, and standards are being developed for cXML in a number of industries, performing a function similar to that of EDI for non-Web-based systems. ebXML is a set of international standards being developed through the international organization OASIS (organization for the advancement of structured information standards), recognized by the UN. It standardizes the exchange of Web catalog content and defines request/response processes for secure electronic transactions over the Internet. The processes include purchase orders, change orders, acknowledgments, status updates, ship notifications and payment transactions.

Inter-Organizational Information System (IOIS): (Sometimes referred to as an IOS). An automated information system, built around computer and communication technology, that is shared by two or more companies. It facilitates the creation, storage, transformation, and transmission of information across a company's organizational boundaries to its business partners.

Maintenance, Repair, and Operations (MRO): Supplies and services purchased for use internally in the company, often referred to as indirect or non-production supplies and services (such as office supplies, computer equipment and repairs, cleaning supplies, etc.) These tend to be low unit cost, low volume, off-the-shelf purchases.

Small and Medium Enterprise (SME): The definition of small and medium enterprises varies from country to country. If the definition is based on number of employees, SMEs in the U.S. have from 1 to 499 employees. The dividing line between a small and medium business is variously defined as being either 50 or 100 employees.

INTRODUCTION

Money has two main forms nowadays: the fiduciary money (coins, banknotes…) and the scriptural one (electronic or virtual). To pay goods, both are used. The electronic money, one specific form of the scripting money, is more and more used everywhere in the world. Electronic payment has many particularities: specific infrastructure, equipment, and software, new forms of regulations, technical agreements, normalizations, fraud limitations…

The objective of this chapter is to present a general overview of electronic payment. The background section presents its historical evolution. In the main thrust, the chapter focuses first on the general architecture of electronic payment. Second, different authorization mechanisms for the processing of the banking transaction and for fraud prevention are detailed. Future trends stress the different research topics that should be investigated, especially concerning the SEPA program (Single Euro Payments Area), which will harmonize bank payment systems in Europe through 2012.

Figure 1. Exchange of goods

BACKGROUND

Exchanging goods is the basis of commerce. From the origin with barter (Menger, 1892) to the introduction of a valuable commodity to give the goods a value, men managed to build a trustful organization, creating the money, and later the banks and laws, to protect this new financial structure.

Paper money has been developed since the 17th century as an object without any real value but with a financial value given by trust in the emitter: the bank (see Figure 3).

Nowadays, money is often dematerialized in the payment process (Schafer, Konstan, J.A., Riedl, 2001). This can particularly happen (see Figure 4):

- when the purchase is done: an electronic payment occurs between the customer and the merchant ;
- when banks want to clear the positions they have between each other.

E-payment allows exchanging scriptural money electronically, by the use of an "identifier" that can be associated not

Figure 2. Transaction using social money

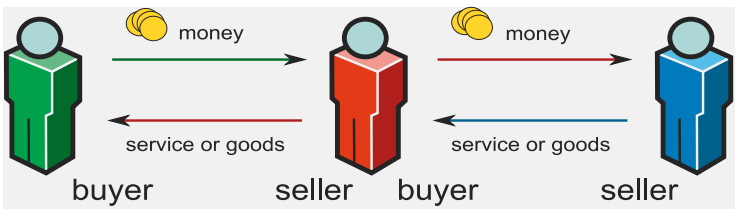

Figure 3. Transaction using paper money

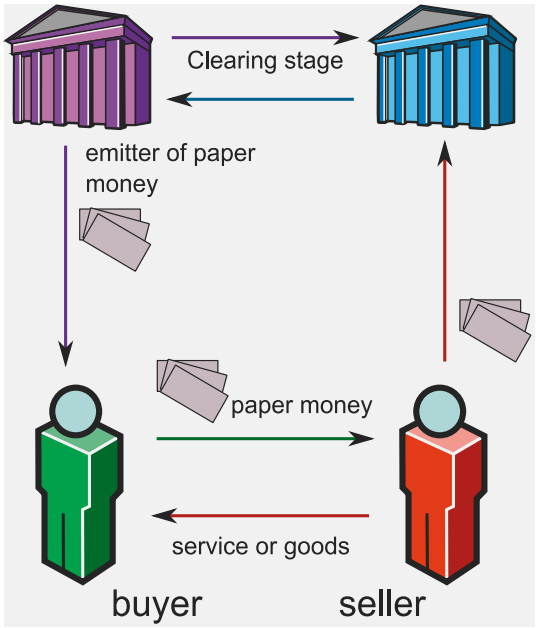

Figure 4. Transaction by electronic payment

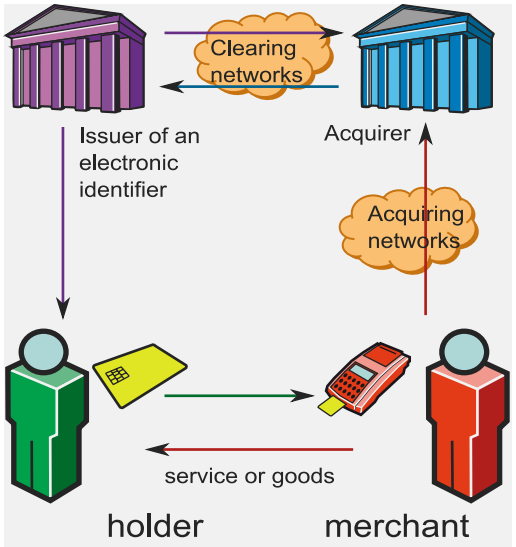


only with a bank user or a fidelity account, but also with an electronic purse (off-line or online) or an anonymous account.

The most common media is a plastic card that includes different technologies (magnetic stripe, microprocessor chip, contactless…) allowing different services and security levels. Other objects and technologies can be used, such as customer's fingerprint, thanks to biometrics.

E-payment can be divided into two families:

- Face-to-face payment, where the customer and the merchant are physically in the same place ;
- Distant payment, where the two participants do not meet each other (mail orders, phone orders, and now electronic commerce via Internet) (see Figure 5).

With the development of recent communication technologies, new payment channels have been developed. Multimodality has become a bet for all participants in the payment process, from banks, merchants, to communication network operators.

Gradually, payment cards are allowing more services than their initial function. Open card development platforms (GlobalPlatform, 2006) of specific card specification, such as EMV (**Europay MasterCard and Visa**), are vectors of development of multiapplications cards. That brings new difficulties to solve, like the need of imperviousness between the applications embedded in a smartcard.

Historically, technical and functional payments architectures have mostly been driven by needs and industries. Some are "open" to allow different implementations to be interoperable:

- ISO/IEC norms, such as 8583 (ISO 8583) for message format or 7816 for smartcards (ISO/IEC 7816) ;
- Open specification, such as EMV specification (EMVco, 2006) that proposed an international specification for payment and multiapplication cards.

Others are kept private, to be used only by a restricted number of participants, such as:

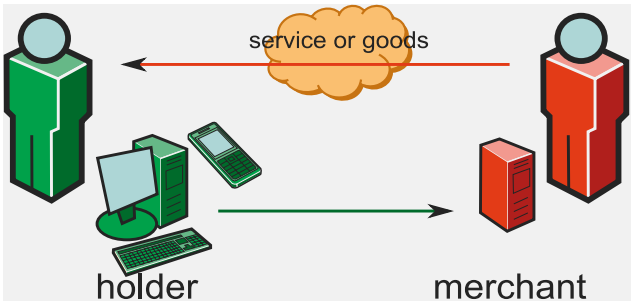
- Communication protocols between servers and terminals ;
- French smartcards specification (B4/B0') ;

However, results coming from research have allowed many evolutions. For example, electronic payment is possible thanks to cryptographic advances: the security aspects of payment are very important to accept the way the transaction is concluded. From the elementary algorithm of Lühn allowing checking the validity of card number to DES, RSA (Rivest, Shamir, & Adleman, 1978), or elliptic curves security algorithms, all aspects are interesting in the payment domain.

MAIN FOCUS OF THE CHAPTER

This section presents the state of the art on the way we can create and settle a transaction nowadays. The first part sets out the necessary exchanges for a full electronic transaction between the actors of the transaction. The second section

Figure 5. Distant payment



focuses on the authorization mechanism. The following part deals with the treatment of the transaction in a bank computer system, pointing out two schemes of transaction. Fraud prevention is the topic of the last section.

- Structure of the electronic transactions exchange

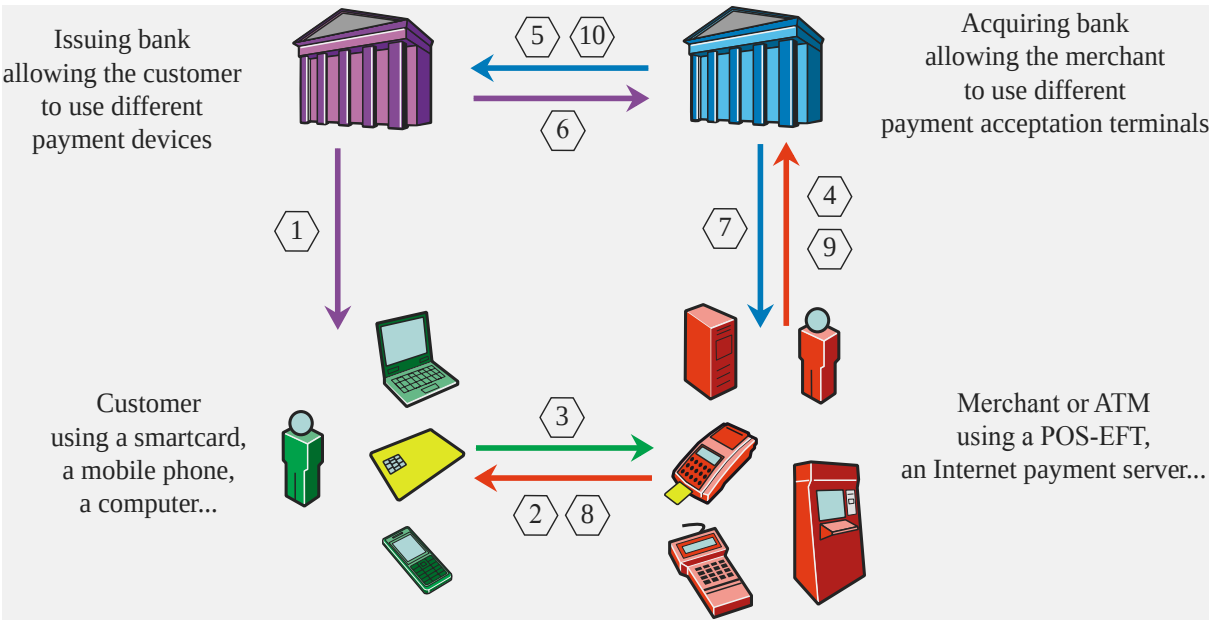
The technical mechanism of an electronic transaction is built on an old financial scheme: the trade. This involves many actors, as shown in Figure 6.

The issuing and the acquiring banks are, respectively, the banks that own the account of the customer and the merchant. Whatever is the relationship between the customer and the merchant (buying in a shop or ordering via the Internet), the scheme is always the same.

The different steps followed during a transaction are:

1. All the banks mainly propose to their account holders the use of an alternative way of payment like debit or credit card, NFC mobile phone... Thus, the first step is when the bank puts an electronic payment device at its customer's disposal;
2. Once the customer decided to buy something, the merchant starts the transaction using its point of sale or its payment server for a distant transaction;
3. The payment device is presented to the terminal that should accept this way of payment;
4. According to the type of device and terminal, each of them tries to authenticate the other. To carry out this authentication, the terminal can ask for an authorization

Figure 6. Electronic payment model



of the transaction. In many countries, this authorization is not automatically required. The authorization request is sent to the acquiring bank, which routes the message to the issuing bank;
5. The issuing bank is the only one able to make the decision to approve or refuse the transaction. The authorization request can travel through private, national, or international financial networks;
6. The issuing bank verifies the authentication of the electronic device holder (verification of the PIN code). Then, it consults all the information it owns about the accounts, the device, and the holder. Thus, the bank decides to accept or reject the transaction;
7. The answer to the authorization is sent back to the point of sale terminal. If the authorization is rejected, the transaction simply ends uncompleted;
8. With a positive answer, the transaction can be fully completed, giving the customer a receipt of the transaction;
9. Next step is the daily collection of all the transactions stored in the memory of the point-of-sale terminal;
10. Final steps are the clearing and the settlement of the transactions between the banks. The accounts of the customer and the merchant are debited and credited of the right amount.

This scheme can be shown as an off-line electronic transaction, except the authorization request, which is not compulsory. The cash withdrawal with ATM is a slightly different electronic transaction. Indeed, the ATM is online, so the authorization is compulsory and the transaction is instantaneously sent to the acquiring bank.

Authorization Mechanism

The authorization has mainly two interests during an electronic transaction:

1. By requesting an authorization, the acquiring bank makes sure that the transaction will be cleared properly;
2. The second interest is to verify that the electronic device and its holder are reliable. Regarding the EMV specification for an electronic transaction (EMVco, 2006), we can simply notice that the authorization is an online request. By this mechanism, we remove some of the weaknesses of the off-line process. Many sensible data (card number, encrypted PIN block…) join the authorization request. Thus, the issuing bank is fully able to verify all those data in order to strengthen its decision about the transaction.

As told previously, the electronic transaction is an off-line process, and requesting an authorization is not compulsory. It is the role of the electronic payment device (smartcard, NFC device…), the merchant, and the point-of-sale terminal to decide if the authorization is necessary for a specific transaction:

- The merchant, by pressing a specific key on its terminal, can decide to request an authorization;
- The electronic payment device has several data to make a decision:
  1. At random;
  2. On deviation from "standard" buying patterns calculated by the processor;
  3. According to internal parameters (floor and ceiling values);
  4. According to a specific programmed behavior (some chips are set up for compulsory authorization on every transaction).
- The point-of-sale terminal receives parameters each time it collects its transactions. Those parameters are used to decide if an authorization is necessary. By this means, the acquiring bank is able to supervise the activity of the merchant.

The authorization can also be compulsory for some specific actions like the cash withdrawal or Internet EMV payment (Van Herreweghen & Wille, 2000).

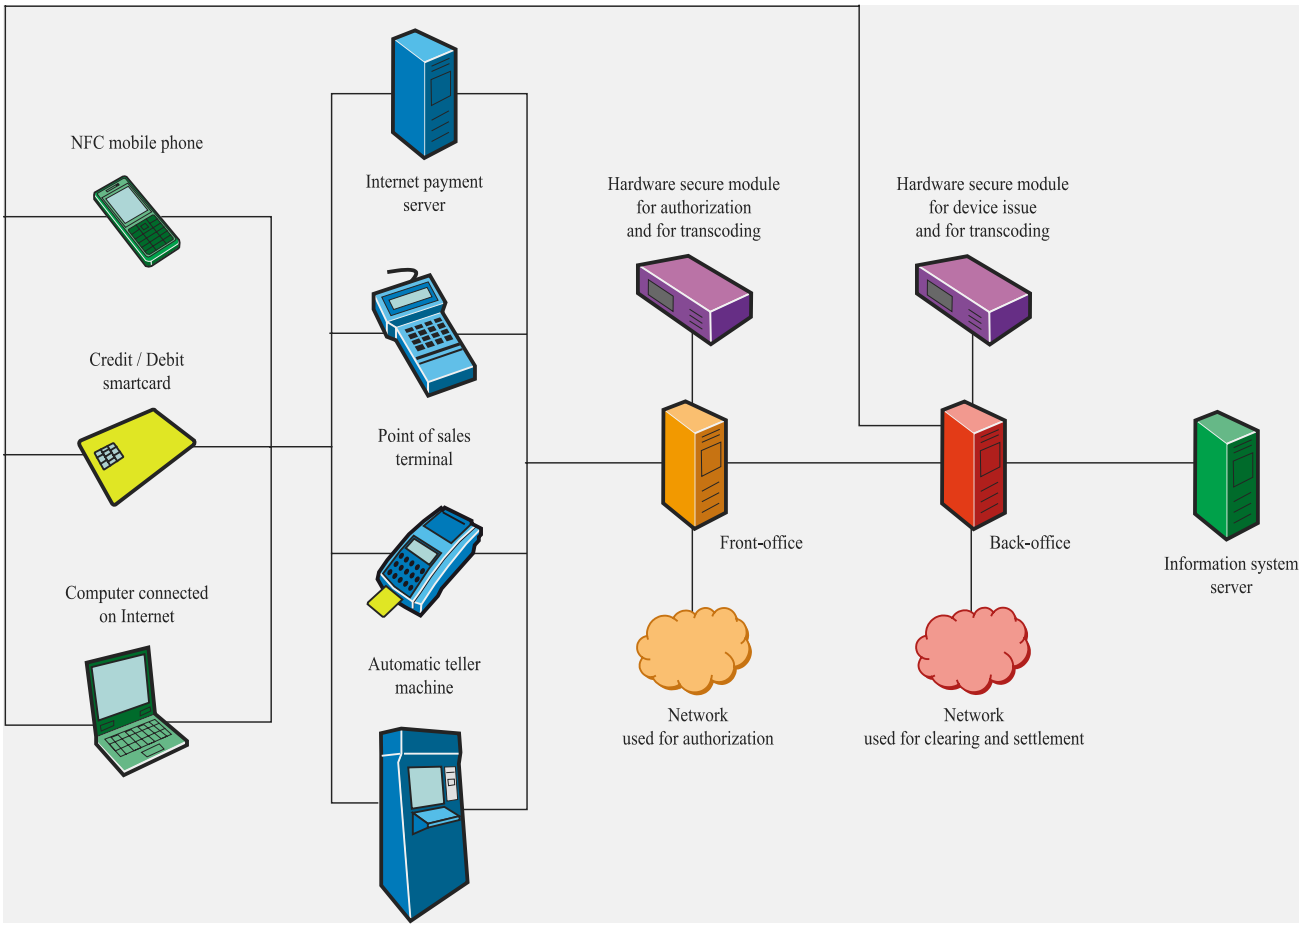
How to Watch Over and Prevent the Fraud?

Electronic commerce is a point of interest for fraud. Obviously, fraud can happen on every single part of the electronic commerce architecture (networks, devices, terminals…). Figure 7 gives an overall illustration of the real infrastructure working in the banks.

In France, an observatory about security for payment cards analyzes, every year, the evolution of the fraud. In its 2006 report (Observatory of the security cards payment, 2007), it is important to notice that the fraud rate in France, for the smartcard payments, is 0.064%. This includes many types of fraud. Most of them are absolutely not technical frauds (the use of stolen or lost cards, the use of non-upstart cards, or the use of stolen card numbers, especially for Internet payments). Only 18% of the fraud is made with falsified or counterfeited cards.

France is an interesting country because the debit smartcard is now used for more than 13 years. It is observed that the fraud rate is nearly divided by three as soon as a country widely uses smartcards for payments and cash withdrawal. For example, the United Kingdom reduced its fraud rate from 0.33 % in 1991 to 0.095 % in 2006, mainly by using EMV smartcards (APACS, the UK payments association 2007). That is one of the elements that decided the SEPA project to choose the use of the EMV specification for the

Figure 7. Technical bank infrastructure



electronic payment devices in its area (EMVco, 2005, European Payments Council, 2006). Many industrial answers to this problem are available. The first element is the setting of opposition lists. In those lists, either the authorized devices or the unauthorized ones are referenced. The main problem is the limitation of the size of the memory in the terminal and thus, the limitation of the size of the stored opposition list.

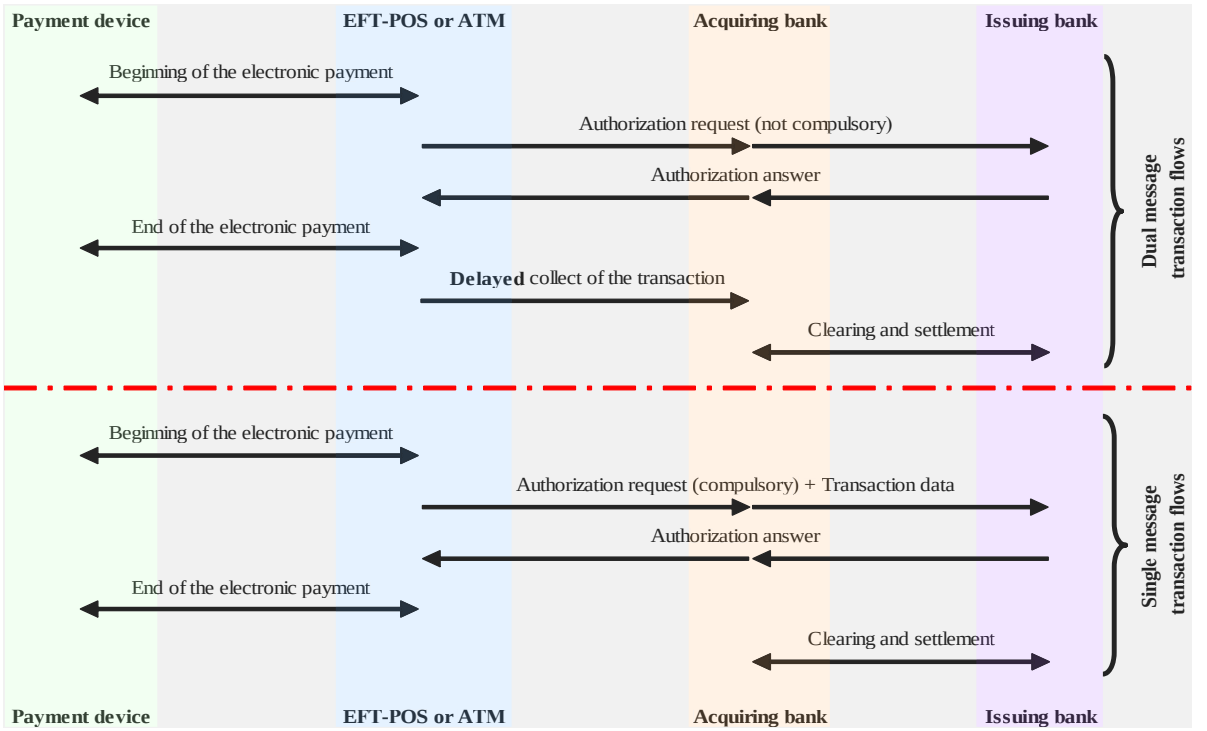
The opposition function is not enough to prevent frauds. It is also necessary to evolve the transaction treatment by decreasing the time taken for the treatment. This time lag let spaces for many frauds to happen. What seems to be a better solution is to have a full online and real-time treatment. Of course, this real-time treatment needs new structures:

- Low-cost networks accessible to the merchant to keep its terminal online;
- Compulsory authorization;
- Full treatment of the authorization (no use of delegation);
- Real-time collection of the transaction;
- Fraud control servers able to analyze, as best as possible, each transaction in real time (so it will be possible to stop a fraudulent transaction before it is ended). As for example, SAS and HSBC recently implemented a solution of real-time fraud management that is able to monitor 100% of the banks credit card transactions from more than 30 million accounts in real time. The fraud detection time is less than 30 milliseconds.

Visa (Visa Debits Processing Service, 2007) and MasterCard use, for cash withdrawal in some countries and with some banks, a function called "single message," in opposition to the "dual message" used in the architecture exposed in the former sections (see Figure 8). The principle consists in sending only one message, including all the data necessary for the authorization, the clearing, and the settlement of the transaction. Thus, there is no need to collect the transaction afterwards, which can be treated in real time just after the payment is finished.

Steve Mott (Mott, 2005), a former MasterCard executive and Norman G. Litell (Litell, 2005), a former vice president

Figure 8. Single and dual message transaction flows



of strategic planning at Visa USA, disagree about the use of the real time. Norman Litell thinks that we first should try to widely use the best secured payment solution available now, like EMV smartcards for proximity payments, and solutions like Verified by Visa or MasterCard SecureCode for distant payments (MasterCard SecureCode 2007, Verified by Visa, 2007) before choosing a full real-time architecture; certainly harder to set up and more expensive. He also pointed out that it is more important to focus on four points to well manage a financial transaction:

- Authenticating the party making the transaction;
- Assuring that proper authorization has been received from that party;
- Assuring the accuracy of all data elements required for the transaction (account number...);
- Assuring that funds will be available in the target account to settle the transaction once it clears.

FUTURE TRENDS

If the banking terminals evolved little during the last 10 years, this evolution is accelerating rapidly in many directions, and the electronic payment will be very different in 10 years from today, mainly in Europe, carried on by the SEPA.

The SEPA is a project founded by the EPC (European Payments Council) and the ECB (European Central Bank). The purpose of the SEPA is to set up a payment architecture allowing all the organizations and private individuals of the European zone unified to carry out payments within this zone, and that with all the advantages of a domestic payment (speed, low cost, and safety of the transaction). This initiative is justified with an economic aim: indeed, the strong costs of the European country-to-country transactions constituted a barrier to the development of a European banking market (European Payments Council, 2006). In particular, it did not allow a nondistorted and free competition, such as the Europe Council recommends. In the long-term, there will be no more distinction between national payments and cross-border payments. The working program will proceed from January 1, 2008 to December 31, 2012, end of deployment of SEPA in all Europe.

These will be the main changes compared to the previous situations:

- The generalization of the use of smartcards (EMV compliant);
- The replacement of the TLV messages (protocol ISO 8583), by XML messages (protocol UNIFI ISO, 20022) for all the exchanges;
- The creation of new point of interaction adapted to the new services (payment of invoice on ATM, GSM

recharging on POS…) and integrated in new networks (IPV6 for ATM, ADSL for POS, GSM for both…);

- The contactless payments with two main supports: contactless smartcards and NFC mobile phone. These devices are much more practical for consumers, and are particularly adapted in purchase environments, where the speed is essential, like in fast food, gas station, small trade supermarkets, and cinemas. The contactless smartcard and the NFC mobile phone become: transport tickets, access badge, payment system (Chanson & Cheung, 2002).
- The development of the biometric authentication. The increase of calculation and storage capacities makes it possible to consider that biometric data processing is now possible with a single chip, placed on a smartcard. Associated with contactless technology, one can imagine a growing use of biometrics for the individual authentication (Jain & Pankanti, 2006): local access control, or network access control (Hyeonjoon & Taekyoung, 2007).

CONCLUSION

The electronic payment is a young technique of only 30 years, but that technique allows everybody to realize a payment everywhere in the world with a secure process and with a very low risk of fraud. For example, even if there exist three big markets: US, Europe, and Asia, and if the three are little different in term of services (debit, credit, smartcard…), a cardholder can realize a transaction in one area with his account located in another area.

It is possible to consider electronic payment as a universal service like Internet, telephone… ; where the role of two big international actors is very important: the card schemes MasterCard and Visa. Those two companies represent the banks, and have a major impact on the electronic payment field in terms of: regulation, technical agreements, normalization, architecture, fraud fight… , but the individual banks have a very important role, in particular, in terms of development of new services. The researchers are so involved in the future trends because that sector knows a very quick evolution.

For the banking sector, the investments were, and continue to be, very high to fight against the fraud and to develop new services for customers (distant payment for e-commerce, bill payments on ATM, contactless payment…). The electronic payments will continue to grow to become, in a short term, the major system of payment in the world, before the cash.

KEY TERMS

Acquirer: A financial institution having a business relationship with merchants, retailers, and other service provides to process their plastic card transactions.

Authorization: The process whereby a merchant requests permission for the card to be used for a particular transaction amount.

Automated Teller Machine (ATM): A computerized self-service device permitting the cardholder to withdraw cash from their account and access other banking services.

Card Issuer: A bank issuing payment or credit cards to its customers.

Card Scheme(s): Card schemes set the business rules that govern the issue of the payment cards that carry their logo. (Examples: Visa, MasterCard, American Express, Diners Club.)

Counterfeit Card: A device or instrument that has been printed, embossed, or encoded so as to purport to be a legitimate card, but which is not genuine.

Electronic Commerce: Transactions that are conducted over an electronic network where the buyer and merchant are not at the same physical location.

Europay MasterCard and Visa (EMV): The internationally agreed standards for chip payment cards. EMV standards are maintained by EMVCo.

E-Libraries and Distance Learning

Merilyn Burke
University of South Florida-Tampa Library, USA

INTRODUCTION

With the explosion of distance learning, academic libraries have had to change to meet the needs of their faculty, staff, and students. The ACRL (Association of College & Research Libraries) presented guidelines to help librarians manage these changes. The proliferation of articles on this topic points to the rapid acceptance of this form of education. This rapid expansion has offered interesting challenges such as providing equitable services for all students, and greater assistance to faculty in supporting their classes. How libraries respond to these challenges will impact the success or the failures of these programs.

BACKGROUND

Historically, distance learning or distance education began as little more than "correspondence courses," which promised an education in one's own home as early as 1728 (Distance Learning, 2002). By the 1800's the concept of distance education can be found in England, Germany, and Japan (ASHE Reader on Distance Education, 2002).

In 1933, the world's first educational television programs were broadcast from the University of Iowa and in 1982, teleconferencing began, (Oregon Community Colleges for Distance Learning, 1997) often using videotaped lectures, taped-for-television programs and live programming, adding a human dimension. Students and faculty were now able to interact with each other in real time; enhancing the learning process by allowing student access to teachers across distances.

By 2006, e-learning is incredibly mainstream, no longer relegated to a sideline position in higher education; e-learning earned its own berth in U.S. News & World Report with an annual guide not unlike the college & university edition. (U.S. News & World Report, October 16, 2006). Not only has learning gone online, so have the textbooks and other information sources. Libraries must respond to the pressures and needs of these students or become irrelevant.

ACADEMIC LIBRARIES AND DISTANCE LEARNING

Distance learning can be defined by the fact that the student and the instructor are separated by space. The issue of time is moot considering the technologies that have evolved allowing real time access. Today, universities around the world use various methods of reaching their remote students. With the use of technology, access becomes possible, whether it is from campuses to remote sites, or to individuals located in their own homes or even the dorms on campus.

The development of course instruction, delivered through a variety of distance learning methods (e.g., including Web-based synchronous and asynchronous communication, e-mail, and audio/video technology) has attracted major university participation (Burke, Levin, & Hanson, 2003). These electronic learning environment initiatives increase the number of courses and undergraduate/graduate degree programs being offered without increasing the need for additional facilities.

During the 2000-2001 academic year, the NCES (National Center for Education Statistics) estimated in the United States alone there were 3,077,000 enrollments in all distance education courses offered by 2-year and 4-year institutions with an estimated 2,876,000 enrollments in college-level, credit-granting distance education courses, with 82% of these at the undergraduate level. (Watts, Lewis, & Greene, 2003, p. 4). Further, the NCES reported that 55% of all 2-year and 4-year U.S. institutions offered college-level, credit-granting distance education courses, with 48% of all institutions offering undergraduate courses, and 22% of all institutions at the graduate level (ibid, p. 4). It is clear that distance education has become an increasingly important component in many colleges and universities, not only in the United States, but also worldwide.

Although educational institutions create courses and programs for distance learners, they often omit the support component that librarians and accrediting organizations consider critical. It is recommended that courses be designed to ensure that students have "reasonable and adequate access to the range of student services appropriate to support their learning" (WICHE, Western Interstate Commission for Higher Education). Further, course should incorporate

information literacy skills within the course or in class assignments to ensure skills for lifelong learning (American Library Association, 1989; Bruce, 1997). In addition, the Association of College & Research Libraries, ACRL, issued guidelines for distance learning library services that were approved in June, 2004 that update various guidelines that were developed beginning in 1963 for "extension students" (Guidelines for Distance Learning Library Services, ALA 2006.)

Distance learning (DL) students are unlikely to walk into the university's library for instruction on how to use the resources, from print to electronic journals, as well as services such as electronic reserves and interlibrary loan. The elements of any successful distance-learning program must include consideration of the instructors and the students, both of whom have needs that must be examined and served.

With imaginative use of technology, libraries have created "chat" sessions, which allow 24/7 access to librarians who direct students to the resources that are available online or through interlibrary loan. In addition, librarians assist faculty in placing materials on electronic reserve so that their students can access the materials as needed. Libraries have become willing to provide mail services and desktop delivery of electronic articles to their distance learning students and, when that is not possible, refer their students to local libraries to take advantage of the interlibrary loan system. Online tutorials have been created to help students learn how to access these resources, while other libraries have specific departments that assist their distance education students and faculty. The role of the library in this process is one of support, both for the students and the faculty.

Of all of the "traditional" library functions such as materials provision, electronic resources, and reciprocal borrowing available to the distance learner, there remains a significant gap in service, that of reference. Although chat lines and other 24/7 services are available, these services simply do not provide the DL student the same quality of service that the on-campus student gets when he or she consults with a librarian in person. Newer versions of distance learning course software provide external links to resources, but do not yet include reference service by email and live chat sessions with librarians in their basic packages. It will continue be the responsibility of the library to make these services easily available and known to the distant learner whose contact to the institution may not include information about the library and its resources. Proactive planning by the library with those who are responsible for distance education can ensure that the students are made aware of what is available for them in the library.

Recently, libraries have been looking at e-commerce business models as a functional way to serve their clientele in reference services, as today's "customers" are savvier and businesses have become more sophisticated in responding to customer's needs. Libraries can use these models to provide the service for DL's whose level of skills has risen with the increased use of the Internet. Coffman (2001) discusses the adaptation of such business tools as customer relations' management (CRM) software such as the Virtual Reference Desk, Webline, NetAgent, and LivePerson. These programs are based upon the "call center model," which can queue and route Web queries to the next available librarian. A quick visit to the LSSI Web site (Library Systems and Services, L.L.C, http://www.lssi.com) allows a look into the philosophy of offering "live, real-time reference services." LSSI's "virtual reference desk" allows librarians to "push" Web pages to their patron's browser, escort patrons around the Web, and search databases together, all while communicating with them by chat or phone" (www.lssi.com). Many of these systems provide the capability to build a "knowledge base" that can track and handle a diverse range and volume of questions. These collaborative efforts, with a multitude of libraries inputting the questions asked of them and creating FAQs (frequently asked questions lists), provide another level of service for the distance learner (Wells & Hanson, 2003).

These systems have great potential, and while they show tremendous possibilities, they need more work to make them more functional for library use. Chat sessions are problematic when the patron is using his or her phone line to connect to the computer, and libraries must look to the emerging technology to find solutions to such issues to prevent becoming obsolete.

Another direction is the development of "virtual reference centers," which would not necessarily have to be located in any particular physical library. Current collaboratives among universities have created consortial reference centers accessible anywhere and anytime. The reference center librarian could direct the student to the nearest physical resource or to an online full-text database based upon the student's educational profile (e.g., university, student status, and geographic location). Although the physical library may indeed become a repository for books and physical items, the reference component may no longer be housed within that particular building.

An example of support is Toronto's Ryerson Polytechnic University (Lowe & Malinski, 2000) infrastructure, which is based upon the concept that, in order to provide effective distance education programs and resources, there must be a high level of cooperation between the university, the departments involved, and the library. At Ryerson, the continuing education department studied what types of support the students needed and identified technical, administrative, and academic help as three major areas of concern. Technical help was assigned to the university's computing services, administrative help was available on the Web and through telephone access, and academic help included writing centers, study skill programs, and library services. Ryerson's philosophy encompassed the concept that synchronization of all these components would assist in making the student's

experience richer and give the student a higher degree of success. Their report shows an interesting view of librarians working to redefine their roles and participate in an important and exciting reference service to their distance learning population. (http://www.ryerson.ca/continuing/distance/)

The library and the distance education unit worked to provide connectivity to resources that were important to the classes being taught online or at-a-distance. It is these types of library involvement that can make distance learning an even more successful and enriching experience. When a university system, as a whole, embraces a collaboration of all its components, both the students and the university reap the rewards.

FUTURE TRENDS

As distance learning continues to flourish, research will be needed to examine the effective implementation and ongoing management of distance education. While several issues emerge as salient such as the social aspects of communication in the networked environment, and the integrity of Web-based course resources, it is the role of libraries in support of distance education that must be considered. Recent advances in groupware technologies have enhanced an individual's ability to stay connected for both work and social exchange through the use of synchronous and asynchronous remote communication and the previous concern of isolation has been all but forgotten (Li, 1998; Watson, Fritz et al., 1998). However, the increased use of technology suggests that formal and extensive training on both distance technology and team communications are necessary (Venkatesh & Speier, 2000).

Libraries, often overlooked in this process, are working to be far more assertive in the distance learning process. Libraries can be a center of technical and administrative help along with the traditional academic role that they have normally held. The growing DL field allows librarians to re-define their roles, and request monies for advanced technological necessary to become as "virtual" as the classes being taught. In addition, to serve the ever-increasing DL population, library education must now include the course work that will provide future librarians the training necessary to serve this ever-expanding population.

CONCLUSION

Distance education will continue to grow. In order to support this educational initiative, academic libraries must establish a supporting framework and commitment to those services traditionally provided by libraries such as lending books and answering reference questions in person or by telephone, plus new services such as "live chat" and desk top delivery of articles that are unique to the virtual environment. Faculty and students in distance learning courses should be able to depend on the academic library for their resources and services, and the library must be able to deliver materials to students or assist them in finding alternate sources in a timely manner, otherwise the students and faculty will seek other sources of materials. Libraries need to be able to identify and assist their DL students. Help desks, chat rooms, blogs, email programs, and live reference all contribute to the support of the distance learning programs. Since DL students may never visit a library's physical facility, it is important to provide information on how best to access the library virtually.

Faculty members also require library support for their courses. For example, materials may be scanned or digitized and placed on the Web, in a content management program, or videos may be "streamed" for online access. In order to digitize and make these items accessible, faculty members need information on the correct use of copyrighted materials. It is also important to put into place an action plan to implement a program for distance learning and a method for assessing that program once it is in place.

KEY TERMS

Asynchronous Communication: Is when messages are exchanged during different time intervals (e.g., e-mail).

Blog: A blog is a Web site where entries are made in journal style and displayed in areverse chronological order. Blogs often provide commentary or news on a particular subject. A typical blog combines text, images, and links to other blogs, Web pages, and other media related to its topic. The ability for readers to leave comments in an interactive format is an important part of many blogs. Most blogs are primarily textual although some focus on photographs, videos, or audio (podcasting), and are part of a wider network of social media.The term "blog" is derived from "Web log." "Blog" can also be used as a verb, meaning to maintain or add content to a blog.

Chat: A realtime conferencing capability, which uses text by typing on the keyboard, not speaking. Generally, between two or more users on a local area network (LAN), on the Internet, or via a bulletin board service (BBS).

CRM (Customer Relationship Management): This term refers to how a company interacts with its customers, gathers information about them (needs, preferences, past transactions), and shares this data within marketing, sales, and service functions.

Desktop Delivery: Using electronic formats to send articles to users.

Distance Learning/Distance Education: Taking courses by teleconferencing or using the Internet (together with e-mail) as the primary method of communication.

Electronic Reserves: The electronic storage and transmission of course-related information distributed by local area networks (LANs) or the Internet. Also known as e-reserves, in addition to displaying items on a screen, printing to paper, and saving to disk are often allowed.

Internet: A worldwide information network connecting millions of computers. Also called the Net.

Link-Rot: The name given to a link that leads to a Web page or site that has either moved or no longer exists.

Next Generation Internet (NGI): Currently known as Abilene, the next generation Internet refers to the next level of protocols developed for bandwidth capacity, quality of service (QOS), and resource utilization.

Real-Time: Communication, which is simultaneous; see Synchronous.

Social Aspects of Communication: A social process using language as a means of transferring information from one person to another, the generation of knowledge among individuals or groups, and creating relationships among persons.

Streaming Video: A technique for transferring data as a steady and continuous stream. A browser or plug-in can start displaying the data before the entire file has been transmitted. Synchronous and asynchronous communication: Synchronous communication is when messages are exchanged during the same time interval (e.g., Instant Messenger™).

Virtual Library: More than just a means of collocating electronic resources (full-text materials, databases, media, and catalogues), a virtual library also provides user assistance services such as reference, interlibrary loan, technical assistance, etc.

Voice Over Internet protocol (VoIP): A protocol that enables people to use the Internet as the transmission medium for telephone calls.

Web (World Wide Web): A global system of networks that allows transmission of images, documents, multimedia using the Internet.

E-Logistics: The Slowly Evolving Platform Undrepinning E-Business

Kim Hassall
University of Melbourne, Australia

INTRODUCTION

By 1998, arguably some four years after the Internet's general user beginnings, many commentators did not doubt that Internet based home shopping was on its way to revolutionize our lives. At the margin, it certainly allowed us another purchasing channel and for many retailers some 5% to 12% of differing goods is now done through an "e-store" or "e-marketplace". (Visser & Hassall, 2005). However, by 2001 a range of major e-business summits, perhaps very notable being the 44 nation OECD hosted e-transport and e-logistics summit in Paris (June, 2001), was beginning to demolish the euphoria of B2C. In its basic state, B2C was a very marginal business. But what of B2B? Yes, it is a bigger sector but how were the business rules and logistics strategies shaping up for network design, e-marketplace use, and logistic fulfilment changing when compared to the rapidly evolving B2C environment? The ICT sector rapidly began to assemble a host of B2B applications for Supply Chain Management and despite the "tech wreck" occurring towards the end of 2001, these highly expensive suites of products found some traction over the next three to four years. So, initially, the development of large logistics software packages such as I2, Baan, Descartes, and so forth, were offerings that the B2B sectors availed themselves of. However, besides the ICT developments in the B2B space, the evolution of new logistics strategies would prove themselves to be good, bad, and various shades in between, when examining the full end to end (E2E) e-business operations. Since 2001, a tide of interest has turned towards the adoption of fit for purpose e-logistic models to support the end to end functionality of e-business. Hassall (2003) describes a detailed survey for the international Postal Authorities as to what new e-logistics and e-business strategies should be developed. These ranged from new householder delivery choices, to global e-marketplaces being developed. Why this survey was important was because the global postal authorities are the largest combined B2C operator and also a growing B2B logistics supplier.

The Tools of E-Logistics

The staple of the world's logistics is activated by orders generated by the use of the phone and the fax machine. This is true for small/medium enterprises (SMEs), small

Table 1. The tools for e-logistics

E-logistics Tool	Description
e-ordering	Via Web, e-market, auction, collaborative system, etc.
EDI Requirements	Optional – dependent on contract requirement
Activated order/Shipment number	Usually an imperative requirement. Various Generators
Activation of Logistics services -order/pick/pack -despatch -transport, etc.	Activation of a specific set or single operation from warehouse, transport operator, delivery agent etc through shipper, broker, customs agent, and/or sub-contractor or own fleet
Barcode or RFID scan	Optional – dependent on requirement
Track and Trace capability	Optional – dependent on requirement
Call Centre CRM ability	Optional – dependent on requirement
Automatic Logistic Performance calculator	A rare but powerful tool. Can save many hours per week in evaluating if functionality is available.
Client Accounting	Commonly an e-market and portal offering,
Quarterly reporting	Specified financials/service performance or customers, etc.

Source: Hassall (2005)

office/home office (SOHOs) and Medium Enterprises (MEs) involved in B2C, b2b (small business to small business) or b2B (small business to large business). In many ways it will be the customer requirements that eventually force the smaller enterprises into adopting the use of further enhanced Web based products so that the information flow and reporting of their product orders or dispatches can feed customer or client information systems. B2B logistic contracts will often have a predefined set of software systems in place for reporting, monitoring, and accounting. Usually these will be more expensive than the suite of systems that the SMEs, SOHOs, and so forth, will have at their disposal.

The above list of e-logistic options is a list of capabilities that either the customer may require, or the logistics supplier offers. It would be quite unusual for many major 3PLs (Third Party Logistic Providers) to supply all of these capabilities unless directed to, usually by the decree of a major client. However, a subset of these strategies ought to be examined by the supplier or the e-logistics provider fulfilling the service.

The Evolution in B2C Logistics

The evolution of B2C from the Christmas mishaps in 1999 to now has been to achieve a cheap and successful delivery by the delivery agent. This statement is true but another dimension to the home delivery is trying to minimize the problems associated with product returns, and products being taken back to the delivery depot. That is, home delivery is also aware of the problems of "reverse logistics," which range from 2% returns for household chemicals to 50% returns for magazines. (Bayles, 2001). Reverse logistics is a large cost burden and, in fact, integral to the physical and environmental cost of the B2C operation. (Sarkis, Meade, & Talluri, 2004). Generally, the full planning and operational capability required for reverse logistics has even spawned several specialist providers in this area. (Poirier & Bauer , 2001). However, is a better way to minimize the reverse logistic operations to have the customer pick up the item? This may minimize some aspects of reverse logistics, but it may not be a winner in the area of customer satisfaction. Certainly delivering to a retail agent is a large cost benefit for the delivery agent. One drop of a hundred parcels to a retail agent is a lot cheaper than attempting delivery to one hundred households. But perhaps the delivery dump at the retail partner is not the choicest alternative for the majority of customers.

New strategies outlined in Table 2 are, for example, the electronic home parcel box (Number 2) which is just progressing beyond the R&D stage. In Europe this method of delivery is being discussed in regard to new planning regulations and this strategy may be a significant strategy within ten years. One way retailers are experimenting with loading for household delivery is directly out of their normal retail premises, not from a distribution centre. This Strategy (Number 8) is employed by such retailers as Tesco. This strategy may negate the need for a separate loading centre but what happens when 100 commercial vehicles arrive to load at the same time slot? Answer: Severe queuing and a valuable loss of time for the delivery agents.

However, for a wholesaler with a diverse enough range of products, an entire retail operation could, in theory, be by-passed in a home shopping environment. The wholesaler takes orders, picks the orders from a central warehouse, then undertakes the delivery of these orders directly to households from the warehouse. The benefits to customers could see a substitute to a retail price which would be now made up of a wholesale price, plus a transport cost, and a small margin. This could be cheaper than the retail purchase price. Many major retailers, however, offer both services to span both the customer shopping and home delivery requirements.

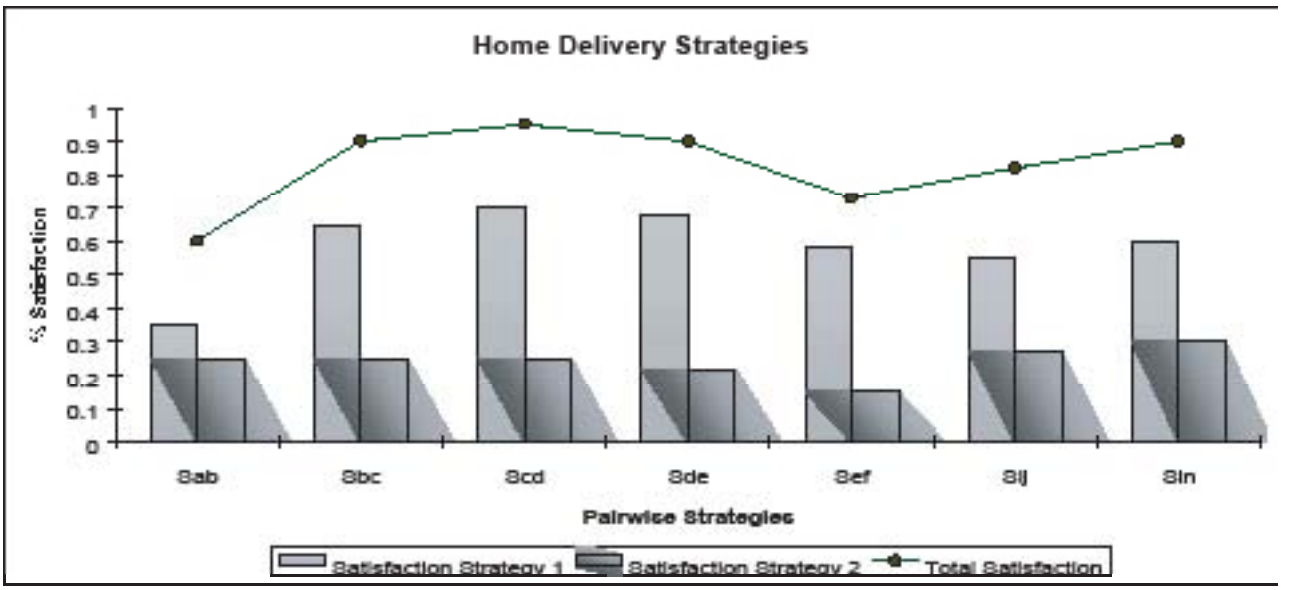
Customer Fit in the New B2C Pairwise Strategy Models

Some of these new strategies, listed in Table 2, are geared towards a high degree of cost minimization for the delivery operator. This inherently may not be a bad thing, however, where does the customer rate in the strategy? More importantly, customer response surveys may indicate exactly what proportion of the customers are happy and unhappy with the offered delivery strategies. If the surveyed service response rating exceeds 85% or 90%, then that one strategy may be worth keeping for that delivery agent for that class of home-shopping products. One survey conducted in 1998 (Hassall, 2000) suggested that about 12% of electronic order forms allowed for alternative delivery instructions. Limiting alternative delivery strategies will hardly reflect a high level of customer satisfaction. However, allowing a limited set of delivery options may add significantly to the home shoppers' level of satisfaction.

Figure 1 suggests that the combination of "hypothetical generic pairs" of strategies will give at least an equivalent level of cumulative satisfaction. Seven pairs of strategies are hypothetically displayed. For any particular retailer and delivery agent it is a matter of examining what pairwise options are feasible and customer friendly. It may only be that two single and two pairwise options are feasible. Perhaps even one direct hop strategy and one pairwise strategy is feasible for the particular commodity purchased, but it is certainly part of the operation that the retailer is aware of the customers' highest preferences for the particular delivery options either offered or not offered. For example, the delivery of backyard furniture may very much limit the feasibility of selecting from at most a small number of the 13 options listed in Table 2.

Why are pairwise delivery strategies important? As stated above pairwise strategies can reflect higher levels of customer

Figure 1. Pairwise home delivery strategies and satisfaction ratings



(Source: Hassall, 2001b)

satisfaction, but also they can be used to lower the marginal delivery cost of a single strategy. Another benefit for pairwise delivery strategies is that they can add a considerable level of security for particular commodities. For example, a business consultant takes advantage of a discount sale on a new desktop computer model. Instructions are to attempt after hours home delivery on a particular evening. If a computer agent sent the computer to the domestic householder upon nobody at home it will be returned to a safe storage site for customer pickup. For small items, a return to a local 24-hour convenience retail agent, or to a retail agent near a day office may be an alternative. However, boxed computers are not a small item, they are valuable as well, and a small retail agent may not wish to store such a large single cubic consignment. This pairwise strategy, therefore, is performed at smaller cost than attempting second delivery, or telephoning to arrange a second delivery.

One recent international survey of B2C delivery strategies across 16 countries suggested that the offering of a diversity of delivery options was the second most important strategic issue facing incumbent B2C operators (Hassall, 2003).

Reynolds (2004) describes six e-fulfilment models, however, when compared to Table 2, these are somewhat more macro in their descriptions.

B2B Fulfillment and the Appropriate E-Logistic Solutions

B2B is simple in concept but the sub-classifications of B2B are quite large. Many B2B transactions do not generate freight *per se* and this is why generally e-logistics is far more relevant to e-business generating physical product.

At the OECD/ECMT e-transport and e-logistics Summit (Paris, 2001), Nemoto, Visser, & Yoshimoto (2001) described B2B as "too big" a concept for the logistical requirements of B2B. Instead classifications such a G=Government, S=Shippers, L=Logistics Operators should be subsets of the B2B space. The only classification to have become recognized in its own rite is the Governmental category G. In fact the e-business of Government has become a specialist study area in its own rite.

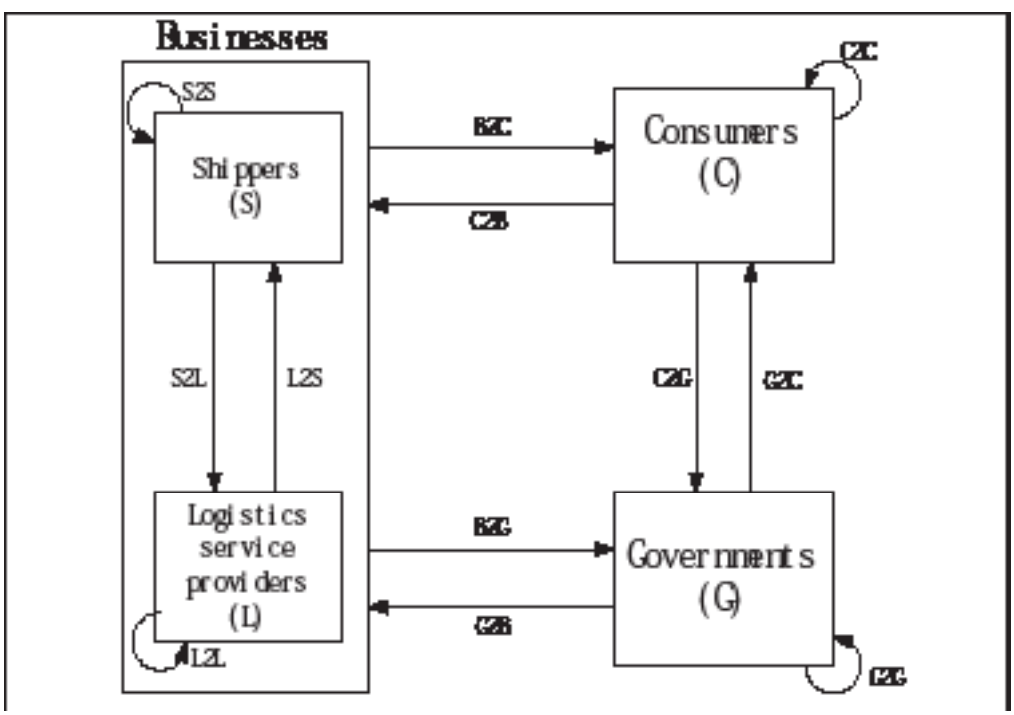
The logistic fulfilment for B2B is most often performed as a well defined set of pre-arranged business rules that are implemented between the customer and the 3PL or fulfilment agent. That is, the software requirements, service performance level, reporting levels, and invoicing are all covered by contractual arrangements. Enterprise Requirements Planning systems have been designed for the B2B space (Reynolds, 2001) but many are exceedingly costly. It will be interesting as to whether smaller "best of breed" technologies will

Table 2. B2C householder delivery strategies

13 STRATEGIES for Household delivery	
1.	Attempt 1st delivery, phone follow up for 2nd attempt.
2.	Attempt delivery to a home parcel box.
3.	Attempt home delivery, failure redirected to retail agent for customer pick up.
4.	Continual household attempt at delivery.
5.	Customer pick up from retail key-hole or kiosk site.
6.	Customer pick up from secure depot storage or common parcel box.
7.	Delivery agent to retail agent by direct drop.
8.	Delivery agents loads orders direct from retail site not a specialized distribution hub.
9.	Delivery to public provider parcel delivery box.
10.	Initial delivery to preferred post office of choice.
11.	Optional flexible delivery strategies as stated on the customer order form.
12.	Phone booking for initial delivery slot.
13.	Slotted after hours delivery.

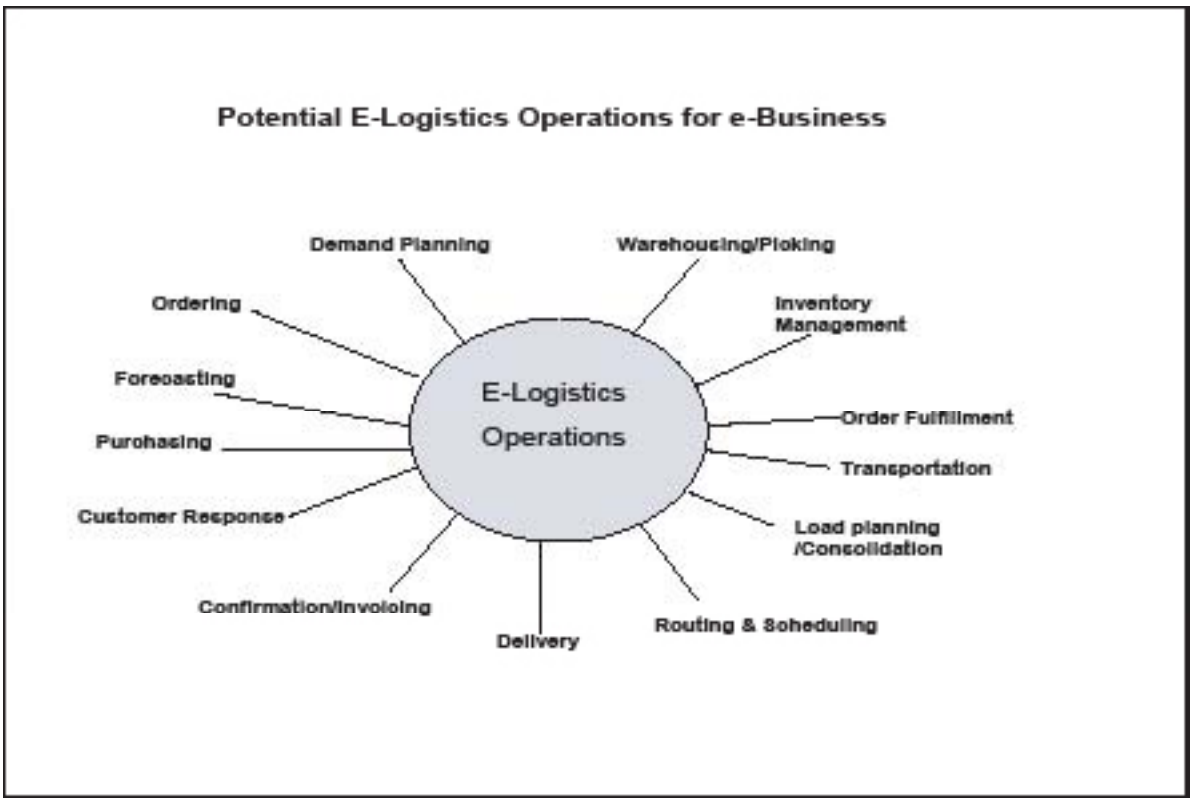
(Source: Hassall, 2002, revised.)

Figure 2. The proposed expanded B2B and B2C environments



(Source: Nemoto, Visser,& Yoshimoto, 2001)

Figure 3. Potential operational components of e-logistics



(Source: Hassall, 2001a)

replace these mega ERP systems that were being developed some five years ago. This is especially true as the requirement for many e-logistic applications such as Radio Frequency Identification (RFID), Track and Trace, Barcode reading, vehicle routing optimization and fleet management were often not part of these mega systems.

In fact, the build to scale E2E (end–to-end) solutions, or assembly of a suite of smaller "best of breed" solutions for MEs (Medium Enterprises), will be an attractive applications business space over the next five years for logistics operators to buy from.

Figure 3 depicts the several of the dozen or more end-to-end logistics and supply chain functions that can be streamlined through either individual or aggregated Web based e-logistic applications and platforms, through which e-business can be supported and fulfilled.

E-Logistics: Is it all about Visibility, Validation, and Verification? The New Question

What makes the difference between traditional logistics and e-logistics? This is a crucial question which may be better understood from examining the several definitions of e-logistics. Current definitions refer to logistics support for Web ordering. However, it may be suggested that true "e-logistics" operations are generated from Web based/electronic applications that are activated by the order, guided through the process stages until fulfilment, invoicing, payment, and reporting occurs. If one or more electronic logistic tools are invoked across the order to delivery, then there are the three properties of visibility, validation, and verification that can be seen as the electronic "value adds" for the e-logistics chain

as opposed to the "phone/fax" orders and delivery used by traditional logistics. In fact the property of Visibility is the most significant difference between e-logistics and traditional logistics, at least according to this author.

What Does the Crystal Ball Hold?

Around June 2001, somewhat coincidentally, when the OECD hosted a 44 country summit on "e-transport and e-logistics", a wave of reality was emerging such that the business models for the fulfilment of e-business had to be rethought. E-stores and e-markets were proving that they were not very "logistics savvy." The area of Business to Consumer (B2C) was very much a high focal point and is arguably still, in France, the Netherlands, Germany, Italy, and many other European countries. B2C was "doing it tough with very low, or negative, profit margins" even though over a dozen fulfilment strategies had evolved in the B2C space. The bigger Business to Business (B2B) brother, although it was seen as being several factors larger in volume and value than B2C operations, when viewed from an e-logistics perspective, it was somewhat harder to enunciate the generalised logistics activities.

However, B2B in one perspective looks after itself. If the customer requires specific levels of service, reporting, software collaboration, and so forth, then the logistics supplier has a choice, either develop, or link into the capability, or risk losing the contract. The customer needs also to be aware what, specifically, the logistical services from a third party, or own fulfilment divisions, involve, and at what cost they can be provided. Many B2B relationships may just be coming to grips with a few of the available e-logistic tools and how to both price and leverage off their use. However, many major B2B relationships are still totally supported phone and facsimile machines. It is more than possible that the future evolution of very cheap public domain software for planning, routing, reporting, and for performing even "track and trace" through various mechanisms, will encourage not only the Medium Enterprise (ME) logistics operators, but even quite large 3PLs, the opportunity to offer a much larger suite of e-logistic functionality to their clients at very cheap prices.

CONCLUSION

The absolute difference between e-logistics and traditional logistics is the electronic "visibility" of particular steps in the chain, from order to confirmation of delivery and onward to invoice payment. The electronic logistic audit trail also lends itself to "verification and validation" of orders, pick pack instructions, standards of delivery services, and any alternative delivery instructions. In fact, the full range of services taken up in the e-logistics chain can be a very powerful input activity subset into the Activity Based Costing models (ABC) for that particular chain. This also assists what many logistic companies, B2C or B2B, are not fully cogniscent of, and that is their full attributable activity-based chain costs. A comprehensive knowledge of impact of these operationally based costs can very much make the difference between profit and failure.

This difference between traditional and e-logistics has not been widely examined in any a more meaningful way than by suggesting that e-logistics "may" be highly Web and applications enabled, unlike traditional logistics. But traditional logistics offerings that might only depend on the phone and facsimile machine may also be supported by very good databases, service response teams, and accounting and business systems. These systems may be very functional and successful. The differences between the streams of e-logistics and traditional logistics, is a fertile ground for future research which should also canvass the opinions of the actual logistic and transport operators.

KEY TERMS

3PL (IIIPL): Third party logistics provider. A diversified provider of logistics services that may include: warehousing, freight forwarding, longhaul and shorthaul transport , storage, inventory management, returns, tracking, performance monitoring, selected documentation, and so forth.

Electronic Data Interchange (EDI): Computer to computer interchange between two or more companies so such entities can enter a range of standard forms such as purchase orders, bills of lading, invoices, forward orders, stock replenishment, and so forth.

E-Logistics: The following definitions are variations on the theme that e-logistics utilises Web based tools in the support of e-business. Some definitions are fuller than others. The timing in the emergence of these definitions is also relevant.

1. **Finnish (translation)**
   E-logistics can be defined as the application of Internet based technologies to traditional logistics processes.
2. **German: (Translation)**
   E-Logistics: Web based applications and services dealing with the efficient transport, distribution, and storage of products along the supply and demand chain.
3. **French: (Translation)**
   E-Logistics: A collection of the new logistic management practices for the Internet.
4. **Forbes:** "E-logistics" describes three core back-end processes required to get an order from the "buy" button to the bottom line: warehousing, delivery, and transportation, and customer interaction (usually handled through a call center where customers can ask questions, place orders, check on order status, and arrange for returns). In many cases, a different vendor handles each of these three separate functions. Managing them all successfully and simultaneously requires an in-depth understanding of each discipline. Integrating them with one another and with a corporation's existing systems is even tougher. Source: www.forbes.com/specialsections/elogistics.
5. "The electronic activation of a set of physical logistic activities with associated electronic information flows that support e-Business." (Hassall, 2005) (presentation) http://www.smartsupplychain.com.au/seminars.cfm.

ICT: Information and Communication Technology.

IV PL (4PL™): Fourth Party Logistics Provider. The operation of end-to-end coordination and management of a logistics chain by direction to 3PL operators and often including the use of large scale IT systems that drive management, reporting, and scheduling activities. IV PL operators need not operate any 3PL activities themselves.

Radio Frequency Identification: Active or passive tag or print based "label" that can be pre-programmed with specific data input fields. These fields emit data from active tags or can reflect embedded data for inactive tags when pulsed with specific electronic signals.

Reverse Logistics: The process of collecting, moving, storing used, damaged, or outdated products and/or packaging from end users.

Tecso Model: Strategy for replenishment of grocery orders for delivery from existing supermarket stores rather than from a specialized, non retain pick/pack urban depots. Used by Tesco stores.

Emergence Index in Image Databases

Sagarmay Deb
Southern Cross University, Australia

INTRODUCTION

Images are generated everywhere from various sources. It could be satellite pictures, biomedical, scientific, entertainment, sports and many more, generated through video camera, ordinary camera, x-ray machine, and so on. These images are stored in image databases. Content-based image retrieval (CBIR) technique is being applied to access these vast volumes of images from databases efficiently. Some of the areas, where CBIR is applied, include weather forecasting, scientific database management, art galleries, law enforcement, and fashion design.

Initially image representation was based on various attributes of the image like height, length, angle and was accessed using those attributes extracted manually and managed within the framework of conventional database management systems. Queries are specified using these attributes. This entails a high-level of image abstraction (Chen, Li & Wang, 2004). Also there was feature-based object-recognition approach where the process was automated to extract images based on color, shape, texture, and spatial relations among various objects of the image.

Recently combining these two approaches, efficient image representation and query-processing algorithms, have been developed to access image databases. Recent CBIR research tries to combine both of these above mentioned approach and has given rise to efficient image representations and data models, query-processing algorithms, intelligent query interfaces and domain-independent system architecture.

As we mentioned, image retrieval can be based on low-level visual features such as color (Antani, Rodney Long & Thoma, 2004; Deb & Kulkarni, 2007; Deb & Kulkarni, 2007a; Ritter & Cooper, 2007; Srisuk & Kurutach, 2002; Sural, Qian & Pramanik, 2002; Traina, Traina, Jr., Bueno, & Chino, 2003; Verma & Kulkarni, 2004), texture (Antani et al., 2004; Deb & Kulkarni, 2007a; Zhou, Feng & Shi, 2001), shape (Ritter & Cooper, 2007; Safar, Shahabi & Sun, 2000; Shahabi & Safar, 1999; Tao & Grosky, 1999), high-level semantics (Forsyth et al., 1996), or both (Zhao & Grosky, 2001).

But most of the works done so far are based on the analysis of explicit meanings of images. But image has implicit meanings as well, which give more and different meanings than only explicit analysis provides. In this paper we provide the concepts of emergence index and analysis of the implicit meanings of the image which we believe should be taken into account in analysis of images of image or multimedia databases.

BACKGROUND

Concepts of Emergence

A feature of an image which is not explicit would be emergent feature if it can be made explicit. There are three types of emergence: computational emergence, thermodynamic emergence and emergence relative to a model (Cariani, 1992). We would use the latter one in our chapter.

Whenever we shift our focus on an existing shape, in other words an image, new shape emerges. The representation of the new shape is based upon our view of the original shape. The new shape emerges as we change our view of the original shape. This is the most important idea of emergence. Two classes of shape emergence have been identified: embedded shape emergence and illusory shape emergence (Gero, year unknown; Gero & Maher, 1994). These procedures could be based on geometrical, topological, or dimensional studies of the original shape.

Model of Emergence

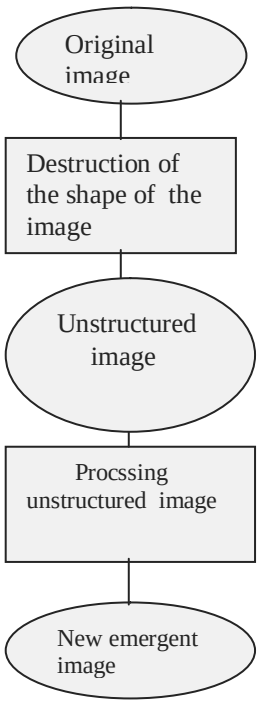
To extract emergent shape from an image, first we have to destroy the original shape of the image. This would give us an unstructured image. Now we take the unstructured image and find out the extra or implicit meaning out of it, in addition to the original meaning, and this process gives rise to emergent image with implicit meaning making explicit and emergent image would be generated. This can be defined in a model as follows (Gero & Yan, 1994):

Definition of Emergence Index

Image retrieval where the hidden or emergence meanings of the images are studied and based on those hidden meanings as well as explicit meanings, where there is no hidden meaning at all, an index of search is defined to retrieve images is called emergence index.

When images are retrieved based on textual information then various parameters and descriptions might define the input and the images of the database. Whenever there would

Figure 1 . Model of emergence



be symmetry of parameters and descriptions, the image could be retrieved. As mentioned earlier, in CBIR, color, texture, and shape are widely used as index to retrieve images. But in our studies, we can find the hidden meanings of the images and whenever those hidden meanings match with the input given, although the original image may not match at all with the input, we can retrieve that image.

When an input would come in the form of an image, the image could be studied based on features, constraints, variables and domains and converted into parametric form. Then the image database would be accessed and each image would be interpreted considering the items mentioned earlier, and also emergence and converted into parametric form like the input image. Whenever there would be a match between parameters of the input and the images of the database, these records would be selected. In other words, indexing would be decided by the outcome of emergence which means more meaningful images could be found hidden in an image which would otherwise not be understood.

Many images of the database may not have any apparent similarities with the input, but emergence could bring out the hidden meaning of the image and could establish similarities with the input image. So emergence outcomes of the images would form the index structure of the search.

Analyses of Works Done

Attempts have been made to give rise to symbolic representation of shape where shape is defined as

$$S = \{N; \text{Constraints}\}$$

where N is the cardinality, that is, the number of infinite maximal lines constituting shape S and the constraints limit the behaviors or properties resulting from the infinite maximal lines, based upon which particular shape is defined. Lines have been defined as Ik, Ij, and so on with their intersection as Ikj. Then topological, geometric, and dimensional properties are defined (Gero, 1992). Also symmetry has been found through the corresponding relevant positions of the lines and coordinates of one shape with that of the other and in the process, emergence of the shapes are studied (Jun, 1994).

There is no direct approach to solve the problem of emergent index other than the ones mentioned earlier. Only there is an indirect approach where this conception has been applied. In a model named Copycat involving computer programs, the program makes all possible sets of consistent combinations of pairings once all plausible pairings have been made. In other words, it gives rise to something explicit which were implicit earlier which is the essential feature of emergence phenomenon (Mitchell & Hofstadter, 1994).

MAIN FOCUS OF THE CHAPTER

We attempt to study the problem of image query where a query made would be searched through the database to select those records where a similar shape has been found. But in addition to that we pick up records based on the emergence phenomena where the query input may not have an apparent match in a particular image of the database, but emergence phenomena could give rise to a similar structure in the same image and as such this image should be selected as a query result. For example, a square with single diagonal can be observed as two triangles. So whenever search intends to find a triangle this image which apparently is much different than triangle would be selected because of emergence.

We calculate emergence index of images of image databases based on features, constraints, variables, domains, and emergence.

Various mathematical tools that could be used in the definition of the image:

- Geometric property
- Topological property
- Dimensional property
- Statistical properties

Structure of Emergence Index

Emergence indexes can be defined out of five factors

$$EI = f(D,F,V,C,E)$$

Where EI stands for emergence index, D for domain where the image belongs, F for features, V for variables which can define the feature's constraints under which the features are defined, C for constraints and E for emergence characteristics of images.

We believe any image, static or in motion, could be expressed semantically in terms of the above mentioned five parameters (Deb & Zhang, 2001).

Application of Emergence Index in Geographic Location

If we have a map of a geographic location like the one below, then we find there are three streets, namely, STREET1, STREET2 and STREET3. There is a park between STREET1 and STREET2 and HOUSE1, HOUSE2, HOUSE3, HOUSE4 are four houses on STREET2.

We also notice that STREET1, STREET2 and STREET3 form a triangle surrounding PARK. In normal map interpretation this may not surface. But when hidden shape is searched we get a triangle. This is the emergence outcome of the search. This would help us to locate the places more accurately by referring to the triangle in the map. Also if there is an input in the form of a triangle, then this image, although a map, would be selected because of emergence.

FUTURE TRENDS

Quite a few models of CBIR are now commercially available like QBIC, Virage, Excalibur, Attrasoft, and others. Noncommercial models developed by universities and research institutions are also available. But they do approximate matches between inputs and objects of image database. A query in most of the currently available CBIR systems is submitted in the form of an image and images similar to this particular image are selected and retrieved from the image database based on color, texture, shape, and spatial locations. Thorough and meaningful image segmentation, which is essential for accurate image retrieval, is still a problem. Also finding the semantic meanings out of an image from low-level features like color, shape, texture, and spatial locations and connect it to high-level features like chair, table, car, house, and so on is also another unresolved problem.

As far as CBIR based on emergence index is concerned, we have conducted preliminary experiments to show how it works (Deb & Kulkarni, 2007). We developed algorithms for retrieval of images from image database based on a given input image using emergence index. We plan to conduct more experiments based on automated image segmentation and retrieval from a query image by finding the semantic and hidden meanings of the target image in the database.

CONCLUSION

Emergence is a phenomenon where we study the implicit or hidden meaning of an image. We introduced this concept in image database access and retrieval of images using this as an index for retrieval. This would give an entirely different search outcome than ordinary search where emergence is not considered as consideration of hidden meanings could change the index of search. We discussed emergence, emergence index and approach as to how to apply this concept in image retrieval and preliminary experiments to retrieve images based on emergence index in this chapter.

KEY TERMS

Computational Emergence: Here it is assumed computational interactions can generate different features or behaviors. This is one of the approaches in the field of artificial life.

Content-Based Image Retrieval: In this kind of retrieval, symmetry between input image and images of database are established based on contents of the images under consideration.

Embedded Shape Emergence: In embedded shape emergence, all the emergent shapes can be identified by set theory kind of procedures on the original shape under consideration. For example, in a set S= {a,b,c,d,e}, we can find subsets like S1={a,b,c}, S2={c,d,e}, S3={a,c,e}, and so on.

Emergence Index: Image retrieval where the hidden or emergence meanings of the images are studied and based on those hidden meanings as well as explicit meanings, where there is no hidden meaning at all, an index of search is defined to retrieve images is called emergence index.

Emergence Relative to a Model: In this case, deviation of the behavior from the original model gives rise to emergence.

Illusory Shape Emergence: In illusory shape emergence, where contours defining a shape are perceived even though no contours are physically present. Here set theory procedures are not enough and more effective procedures have to be applied to find these hidden shapes.

Thermodynamic Emergence: This is of the view that new stable features or behaviors can arise from equilibrium through the use of thermodynamic theory.

Emerging Online E-Payment and Issues of Adoption

Qile He
University of Bedfordshire Business School, UK

Yanqing Duan
University of Bedfordshire Business School, UK

INTRODUCTION

Due to the rapid growth of e-commerce, the physical boundaries between parties in business transaction have been eliminated by the fast and convenient network connection. Nevertheless, most payment still has to be carried out offline by conventional methods. Over the last decade, a large number of online payment solutions have been developed, but many are still remained at the trial stage; while others are competing with each other; some even failed to reach a customer acceptance stage before developers quit the business. Reasons of slow acceptance are technological, but more importantly, societal. Developers are struggling in pushing increasingly secure and convenient technological solutions to the public. On the other side, users are seeking the balance between benefits and the risks of using online e-payment, which prolongs the process of wider acceptance. This article offers a brief introduction to typical online e-payment instruments and classifications of existing payment systems. It intends to provide researchers and developers with a clearer view on e-payment by comparing various existing systems. The article also attempts to shed light on the issue of social acceptance and adoption of online e-payment.

BACKGROUND

Online e-payment refers to the process of finance or payment mainly using Internet as a medium. Making payment electronically is not new. Long before online e-payment has been introduced, financial institutions had established Automated Clearing House (ACH) to clear money transfers electronically. The electronic financial infrastructure has promoted introduction of various Electronic Fund Transfer (EFT) solutions. In a broader sense, electronic payment includes those based on private networks, such as ATM, credit card payment, POS (point-of-sale) and other payment over proprietary networks. The rapid development of B2B, B2C and C2C e-commerce gave rise to the development of new payment solutions over the open network. Thanks to the rapid development of ICTs and e-commerce, a vast number of online e-payment solutions have been introduced. Conventional payment methods and concepts like credit card and cheque have been extended and modified to incorporate online transactions. New schemes of payment like electronic currency and smart cards have been introduced for online payment. Many e-payment systems share similar characteristics or developed upon similar protocols or payment infrastructures. Despite numerous attempts aimed at offering innovative alternatives, credit and debit cards payment based on the existing payment network and procedures remains the main payment instrument for online transactions. For instance, a report showed that in the UK some 90% of online purchases are made by credit card and debit card, although the amount only represents 3% of all card payments (Allen, 2003).

Many have realized that the limited acceptance of online e-payment is by and large a chicken and egg problem. Diffusion of online e-payment is limited by the unavailability of payment solutions accepted by wide range of transactions. Moreover, the lack of market-wide diffusion limited development of more integrated online payment solution (Allen, 2003). The phenomenon has attracted attention of researchers to investigate the factors hinder the wider acceptance of online e-payment (Abrazhevich, 2001b; He, Duan, Fu, & Li, 2006). To have a better understanding of the issue of acceptance, the characteristics of different online payment systems, and technological and social issues associated with their implementation need to be clarified.

EMERGING ONLINE E-PAYMENT TECHNOLOGIES

In response to the rapid development of e-commerce and the security requirements of the online e-payment, research groups, financial institutions and commercial firms have developed a number of online e-payment solutions since the last decade. Table 1 provides a list of some typical online e-payment methods with examples.

Table 1. Various online e-payment systems

Type of Payment	Example	Advantages	Disadvantages
Credit/Debit card	SET (Cyber Cash)	Card information not transmitted; Multiple-layer authentication.	Complexity
	SSL	Simplicity; Easy to setup; Using existing financial infrastructure.	Non-anonymity; Transaction cost relatively high.
Electronic Cheque	FSTC E-check	Able to handle large value payment.	Extra infrastructure needed; Need hardware devices to store electronic chequebook.
	NetBill	Simplicity; Able to handle small amount payment; Payer remains unknown to the payee.	Reliance on a central server; Server load limits number of participants.
	NetCheque	Choices of various NetCheque servers; Scalability.	Need to establish a hierarchy of servers.
Electronic Currency	Ecash	Payer anonymity remained.	Rely on single Ecash bank; Large database needed to store serial numbers.
	NetCash	Different currency servers allowed; Scalability.	Limited anonymity to users; Large database needed to prevent double spending.
	Millicent	Capable of handling micropayment; Communication efficiency; Low transaction cost.	Limited customer anonymity; Broker and vendor need to be trusted.
Smart Card Payment	Mondex	Portability; Anonymity; Secured fund transfer.	Need extra hardware devices.
	NACHA ISAP	Simplicity; Using existing financial infrastructure.	Need extra hardware devices; Non-anonymity.
Centralized Account System	Yahoo!Direct; PayPal; First Virtual; Nochex; iTransact	Double blind system; Payer and payee remain unknown to each other.	Lack of integrated system; Users need to register with various accounts.

Credit Card and Debit Card Payment

Extended from the conventional MOTO (Mail Order Telephone Order) transaction, credit and debit card as means of online e-payment has been widely explored. Thanks to the already developed payment schemes and established public acceptance, credit and debit card payment systems are most widely used online payment methods at present. Because cardholders need to provide card details on the Internet, which is subjected to attacks from hackers and fraudsters, security of the credit and debit card payment over the Internet is a common concern. To ensure the security, two major Internet standards have been introduced, namely SET and SSL.

The basic principal of SET (Secured Electronic Transaction) is to use digital certificate consists of a **private key** for encrypting data or documents and a corresponding **public key** for reading the data, so that the information is transmitted to the identified parties and is secured from external parties. SET creates secured dialogue between cardholder, merchant, and acquiring bank using digital certificates, which substitute credit card number during the transaction. However, the problem with SET is the complexity of the system, in that the transaction parties have to install independent pieces of software working together to accept the certificate and ensure the authentication of each party. SET also needs the support of a complex certification authority hierarchy, and requires the cardholders to go through a registration process in order to be issued with a certificate.

SSL (Secure Socket Layer) uses encryption technology to secure any dialogue taking place between buyer and

merchant across a "socket" interprocess communication mechanism. SSL allows encrypted traffic between a Web server and client using public key and private key technology. Due to its simplicity (only the merchant's Web server needs to be authenticated through a once-off and straightforward procedure, and the client remains unauthenticated), SSL is now widely used by online banks and online retail stores. However, there is no protection over the amount of the transaction, number of transactions, the legitimacy of the cardholder, or the creditworthiness of the card. It also can't prevent merchant from examining or tampering with payer's information.

Electronic Cheque

An **electronic cheque** is a document containing fields identical to those on a paper cheque with appropriate digital signatures being added when the cheque is first issued by the payer and also when it is endorsed by the payee. The **digital signature** is a piece of electronically recorded data representing fingerprint, which is then encrypted using a secret key. The digital signature can be signed only by the holder of the secrete key. Parties want to verify the digital signature can use the public-key to testify the validity of the fingerprint. The basic idea of electronic cheque is that payer who possesses an electronic chequebook signs the cheque with digital signature and passes it through secure e-mail or SSL enabled communication to the payee, who will then endorse and send the cheque to the payer bank to be settled for payment transfer.

The wide acceptance of the digital signature depends on the establishment of a network of cooperating certification authorities and bodies referred to as Public-key Infrastructure (PKI) (Li & Wang, 2003). Moreover, to handle e-cheque payments, banks need to provide some new infrastructures from existing systems. All these implementation rules inevitably increase the complexity of the system and its rapid adoption. However, compared with other online payment instruments, e-cheque is considered to be suitable to B2B and B2G **e-commerce**, as the electronic cheque has the potential to handle larger amount transactions.

Electronic Currency

Compared to credit card or cheque, conventional cash has the advantages of wider acceptability, guaranteed payment, no transaction charges, and anonymity (O'Mahony, Peirce, & Tewari, 2001). To resemble these advantages of cash, electronic currency was invented. **Electronic currency** was defined as "pre-paid products, in which a record of the funds or value available to a consumer is stored on an electronic device in the consumer's possession" (BIS, 2001, p. 1). To use e-currency, a payer has to prepay the fund in stored value card or in prepaid wallet software in order to issue a certificate. Once issued the electronic money represents the value, which may be spent with merchants who deposit the certificates in their own accounts or spend the currency elsewhere. Early trials of electronic currency include Ecash launched by DigiCash Inc. and NetCash developed by USC-ISI. The former employs Ecash wallet software to sore electronic coins issued by the same Ecash bank. The later allows payer and payee to use different currency servers to obtain or verify electronic coins. Another typical electronic currency called Millicent was developed by Compaq in the late 1990s to handle micropayment for information products over the Internet. Under the Millicent system, the customer purchases electronic currency called "broker scrip" from a broker which will be exchanged into "vendor scrip" when the customer decides to purchase a product from a vendor.

Smart Card Payment

Smart card is regarded as an ideal form of e-payment device, given its massive information storage capability and the embedded security function. Mondex is one of the typical smart card payment instruments owned by MasterCard and NatWest Bank of UK. Because the encryption software is stored in the smart card and authentication techniques are used, no central processing is required. Only two participants' cards are involved in the transaction. Consequently, no central records can be kept or interrogated, and the anonymity is maintained. Because the transaction cost by smart card is relatively low, this makes it suitable for small value payment online. Another typical smart card-based payment called Internet Secure ATM Payments (ISAP) is piloted by NACHA (a nonprofit electronic payment trade organization representing a large number of financial institutions) in late 2000 (O'Mahony et al., 2001). ISAP payment uses debit card embedded with smart card chip to store secret signing key. Instead of using a PIN number to authenticate the card payment, payers use digital signature, which is to be verified by the bank. The problem with both these systems is the need to have a card reader device installed to the user's computer, which increases the setting up cost of both payment methods.

Centralized Account Systems

The basic idea of **centralized account system** (also known as Third Party Handled System) is that a payer stores credit to the centralized account operated by an independent company. A payer who has been authenticated online notifies the centralized account system to make payment from its online account. The payee will receive verifications from the centralized account system and will notify the receipt of payment. Communications between payer, centralized

account system, payee and bank are normally secured by SSL protocols. In such a way, the centralized account system serves as a bridge between parties to allow payer spending credits from the online account to pay for goods and services to the merchants or individual payee. Typical examples of centralized account systems are PayPal and Yahoo!Direct.

For commercial vendors, the basic model of centralized account systems is less efficient because the payee has to verify the payment for each transaction. Therefore, to handle larger amount of transactions, Application Programming Interfaces (APIs) are introduced to integrate payment system with the merchant's Web site. APIs redirect customer from merchant Web site to the centralized account system server, which settles the payment and makes notifications to the merchant. Typical examples of such systems are Nochex and iTransact, which allow merchants to accept online credit card payment from customers, without bearing the cost and complexity of setting up online credit card payment system. Centralized account system is highlighted because the account information of both payer and payee remains unknown to each other during the transaction. However, because such instrument requires users to have an account with the same payment system, payers and payees need to have several accounts with different systems.

CLASSIFICATIONS OF ONLINE E-PAYMENT

Online vs. Off-Line

One of the classification criteria is whether the authorization server is involved during the payment process (Asokan, Janson, Steiner, & Waidner, 1997). The system is online when it involves an authorization server (usually as part of the issuer or acquirer) in each payment. On the other hand, off-line payments involve only payer and payee during the payment process. Compared to off-line payment systems, online payment systems are considered to be more secure, because an authorization party is involved in validating and monitoring the payment process. However, the increased communication also increases the complexity and commutation cost of the system. Typical examples of online payment systems include First Virtual, NetCheque, NetBill, Ecash, NetCash, and PayPal. Millicent and Mondex are two examples of off-line payment systems.

Specific Hardware vs. General-Purpose Hardware

Online e-payment systems could also be classified by specific hardware-based and general-purpose hardware-based (Ferreira & Dahab, 1997). Specific hardware refers to e-payment systems, in which users need the support of certain hardware during the payment process. FSTC E-check and smart card-based systems fall into this category, as payers need to have either a chequebook storing device or card reader device to make the payment. On the other hand, the general-purpose hardware payment system relies on the common computer to complete the payment, although some complementary software might be required to complete the payment. Examples are SSL, NetBill, NetCheque, Ecash, NetCash, Millicent, and PayPal.

Macropayments vs. Micropayments

Under the online payment scenario the value of payment could be very small, say one tenth of a cent to buy a single Web content. Thus, payment by macropayment systems, such as credit/debit card-based instruments, FSTC E-check, NetCash, and centralized account systems could be very cost ineffective. Therefore, micropayment systems are needed to carry out small value payments. Some payment instruments are designed particularly for micropayments, such as Millicent. There are also payment systems capable of handling small value payment, such as Mondex and NetBill.

Token-Based vs. Account-based

Despite the above-mentioned features, the role of financial institutions in the process of online payment is also an important issue. Currently, financial institutions are still the most important intermediaries for fund storage, clearing and transfer in most payment systems. Therefore, how bank accounts are incorporated into payment systems is an important characteristic to differentiate online e-payment systems. According to Abrazhevich (2001a), online e-payment could be classified as token-based or account-based. Account-based systems refer to payment systems in which money are represented by numbers in bank accounts and these numbers are transferred between parties in an electronic manner over computer networks. Accordingly, most credit and debit card-based systems, as well as electronic cheque payment and centralized account systems, fall into this category. Token-based systems are those that allow participants to exchange electronic tokens in the transaction, as the payment instrument itself carries the value. Most electronic currency systems, such as Ecash, NetCash, and Millicent, as well as some of the smart card based system, such as Mondex, fall into the category of token-based systems.

ONLINE E-PAYMENT ADOPTION AND FUTURE DEVELOPMENT

Among most of the emerging online e-payment solutions, security and reliability are of greater concern to developers. Many systems have sacrificed the simplicity for security purposes. Consequently, complex authentication procedures are introduced, more parties are involved, and more infrastructures are established. The intention is to reduce security bugs and to provide more complete and feasible online payment solutions. Nevertheless, the success of any online e-payment is not determined by perfection of the system but by wide market acceptance. Adoption of online e-payment is a more critical issue to be faced by vendors and developers.

Table 2. Requirements of merchants and customers over online e-payment

Requirements	Merchants	Customers
Security	√	√
Integrity	√	√
Low operational cost	√	
Compatibility to existing system	√	√
Reliability	√	√
Information richness	√	
Privacy	√	√
Flexibility		√
Convenience		√
Speed of settlement	√	√
User-friendly/ease of Use		√

Table 3. Possible risks of using online e-payment

Risks	Merchants	Customers
Security deficiencies	√	√
Lack of integrity	√	√
Overly dependent on system providers	√	
Sunk cost involved in implementation	√	
Lack of compatibility to existing system	√	
Lack of reliability	√	√
Losing privacy		√

Table 4. Barriers to online e-payment adoption

Internal Barriers		External Barriers	
Merchants	Customers	E-payment providers	Legal
Security concerns	Security concerns	Lack of cooperation	Lack of legal infrastructure
Reluctant to give up old system	Risk perceptions	Lack of interoperability between schemes	Too much restrictions
Lack of adequate HR	No access to services	Lack of standardization	
Inadequate technology infrastructure	Inadequate skills	Too many immature competing systems	
Financial resources constraints	Lack of bank account		

Due to the fast development of ICTs and increasingly integrated financial infrastructures, technology is no longer the main obstacle to online e-payment development. Nowadays, customers and merchants are facing the choice of many competing payment solutions. Developers need to be aware that the wide acceptance of online e-payment is more importantly a societal issue, which involves entities such as merchants, customers, system providers, financial institutions, and regulation bodies. Given users are ultimate forces determining the success of any e-payment systems, their behaviors and attitudes need to be examined more carefully before complicated systems are introduced (Hayashi & Klee, 2003; Lawson & Todd, 2003). In various e-commerce, merchants and customers are the most important entities and direct users. Their expectations and requirements are shaping the development and social acceptance of online e-payment (see table 2).

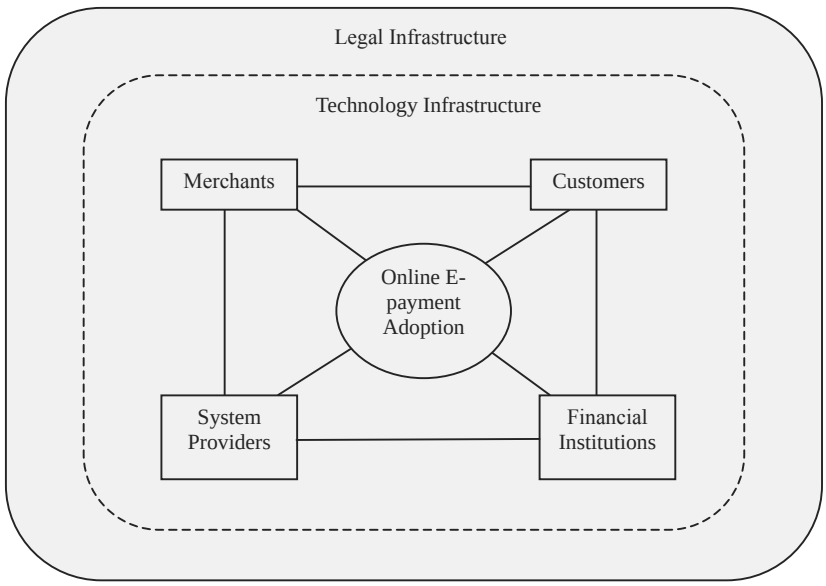
Expectations of both groups, however, are not the same, and sometimes are even conflicting to each other. For instance, merchants' expectation of acquiring more customer information is contradicting with customer's need of privacy (Heng, 2004). Such unbalanced expectations impose extra complexity to the development of online e-payment. At the early stage of e-payment adoption, the confidence of users is quite vulnerable (Thomas, 2003). Developers need to be aware that if the expectations of both business users and customers are not met, the benefits e-payment promised could easily turn into risks (see table 3). To meet the expectations of users, developers need to seek balance between various requirements of users. For example, developers need to be careful whether simplicity should be sacrificed to meet the high reliability and security standards.

Within barriers of adoption arise from internal and external of potential users (see table 4), collaboration of e-payment providers is a critical issue (ePSO, 2006). Plenty of evidence shows that too many competing payment systems damaged users' loyalty to e-payment and slowed down the adoption (Trombly, 2002). E-payment providers are suggested to cooperate more to improve the interoperability of different systems and the standardization of technologies (Allen, 2003). Moreover, a moderate legal framework is also needed to not only provide protection to e-payment users, but also give the market enough freedom for further development.

Obviously, the issue of successful development and adoption of online e-payment is too complex to be handled by a single entity. As shown in Figure 1, the wide acceptance of online e-payment needs the social wide collaboration from all parities involved, that is, system providers, financial institutions, merchants, customers, and regulation bodies. Moreover, successful development is bounded and also supported by technological and legal infrastructures. To overcome barriers to wider acceptance, e-payment developers need to have a more comprehensive view to the issue and seek more social wide collaboration.

Specifically, to avoid the vicious circle from occurring, in which merchants would not offer e-payment schemes if few customers use them, while customers would not use e-payments if few merchants accept them, developers are suggested to provide secure, simpler and more robust

Figure 1. Conceptual model of online e-payment adoption



payment solutions, which bridge various payment schemes to allow for the interoperatability of systems. It is worth noting that payment systems which use a maximum of the existing financial as well as technology infrastructures, are more likely to succeed.

CONCLUSION

This article introduced the emerging online e-payment. Different payment systems were classified according to various criteria. These classifications could be used as guidelines for both users and developers to have a better understanding of existing online payment solutions, and also the possible trend of future development. This article suggested that successful deployment and acceptance of online e-payment is not only a technological issue, but also a social issue. Behaviors and attitudes of both consumers and merchants need to be fully understood. Moreover, collaborations between various parities are needed to promote wider acceptance and further development of online e-payment.

KEY TERMS

Electronic Cheque: Cheque like electronic payment technologies using digital signature and certification technology to authorize and endorse the payment.

Electronic Currency: Prepaid product resembles the conventional cash, in which a record of the funds or value is stored on an electronic device in the consumer's possession.

Online E-Payment: Electronic payment technologies which allow money to be transferred over the open network, such as the Internet.

Public-Key Cryptography: An asymmetric encryption technology designed to secure communication between individual entities. The sender encrypts the message using public-key of the intended receiver, and the receiver then decrypts the message using its secret key.

Secure Socket Layer (SSL): An encryption technology based on public-key and private-key cryptography, which ensures secured dialogue between payer and merchant over the Internet.

Secured Electronic Transaction (SET): A set of technology protocols based on digital certificates, which identifies the parties involved in the payment transaction and protects the dialogue between parties.

Smart Card: A plastic card with an integrated circus chip securely embedded in the card. It can store 100 times more information than traditional magnetic cards in a form that cannot be copied.

INTRODUCTION

In this fast moving global working environment, negotiators are benefiting from the pervasive application of computers and networks in the workplace. There is an increasing usage of E-negotiation Support Systems (ENS) in both internal and external negotiations. ENS are computer systems that help negotiators achieve better agreements by enhancing their information processing capabilities and communication with other parties. Recent empirical research on ENS has shown that the employment of ENS facilitates the improvement of the negotiation process and outcome (e.g., Delaney, Foroughi, & Perkins, 1997; Goh, Teo, Wu, &Wei, 2000; Rangaswamy & Shell, 1997). This article identifies the key areas of ENS research, the corresponding constructs, findings and challenges. Finally, it proposes an integrative framework of ENS research for future research.

BACKGROUND

Negotiation

Despite being a common task for managers, negotiation is challenging, complex and effort demanding. Negotiations have been studied from many perspectives including sociology, psychology, political science, economics, applied mathematics, computer science and artificial intelligence. Negotiation is "a process in the public domain where two parties, with supporters of various kinds, attempt to reach a joint decision on issues in dispute" (Gulliver, 1979, p. 79). It is a special form of communication that centers on perceived incompatibilities and focuses on reaching mutually acceptable agreements (Putnam & Roloff, 1992). Through a negotiation, two or more parties can resolve conflicts and enter into contracts (Walters, Stuhlmacher, & Meyer, 1998).

Theoretical Perspectives of Negotiation

In the literature of negotiation research, the descriptive model and the prescriptive model form two major schools. While the descriptive model focuses on the process of negotiation, the prescriptive model emphasizes the outcomes of negotiation.

The descriptive model of negotiation is widely studied in social behavior science, sociology, and psychology. Based on sociological and psychological theories of learning and joint decision-making, the descriptive model seeks to describe what actually happens in a negotiation process (Weigand, Schoop, de Moor, & Dignum, 2003). Researchers within this stream focus on individual differences (Hausken, 1997), contextual characteristics of negotiation, situational determinants (Pruitt & Rubin, 1986), and cognitive processes of judgment, behavior, and outcomes in negotiation (Thompson, 1990).

The prescriptive model of negotiation, in contrast, stems from the studies of Game Theory, social psychology and organizational behavior. Its fundamental assumption is axiomatic rationality, where participants will always choose the options that are in their best interests according to the particular quality measurement instrument chosen. It is normative in the sense that it prescribes what negotiators should do to achieve the desired results (Weigand et al., 2003). While the theoretical objective of the prescriptive model is to predict the processes and outcomes of negotiation, the practical goal is to help people negotiate more effectively (Raiffa, 1982).

E-Negotiation Support Systems

Since the 1960s, when computer models were first employed for the support of individual negotiation, interest has been growing on the possibility of using computer technology and information systems to support negotiations (DeSanctis & Gallupe 1987). Today, a number of decision-aiding techniques

are employed by the decision support component, such as information control component for data storage and retrieval, representational aids, decision aiding techniques and models, and inference capabilities. The development of the Internet and multimedia benefited ENS as various communication channels could be deployed to enhance information exchange in the negotiation.

The types of ENS vary from no computer mediation assistance at all to fully automated computer arbitration. Based on the fundamental differences in the design and functionality of ENS, ENS can be classified into two categories (Rangaswamy & Starke, 2000): (1) preparation and evaluation systems, which provide negotiation decision support before or during a negotiation; (2) process support systems, which provide the negotiators with the means to communicate with each other, and computer mediation or arbitration mechanisms.

KEY AREAS OF ENS RESEARCH

To guide future research, there is a need to build a broader theoretical framework of ENS (Bui, 1994). In order to formulate the ENS research framework, this article reviews the following four major research areas:

1. The *e-negotiation support systems*; specifically, the system components.
2. The negotiation *process*; specifically, the interaction and cognition process.
3. The negotiation *outcomes*; specifically, the contract-related outcomes and process-related outcomes.
4. The *context* of ENS negotiation; specifically, the negotiator characteristics, the task nature and the culture.

E-Negotiation Support Systems

Conceptually, ENS consist of two subcomponents (Lim & Benbasat, 1993): the decision support systems (DSS) component and the electronic communication component. *DSS* help to refine the negotiators' objectives and enhance the capability of information processing and complex problem analyses, so that more efficient and balanced outcomes may be achieved. The use of the *electronic communication channel* increases the level of perceived commitment and trust in the other party. As a consequence, agreements may be reached with less time and effort spent.

In addition to the traditional ENS mentioned above, the autonomous *negotiation agent* is becoming popular (Beam & Segev, 1997). Instead of human negotiators, negotiation agents prepare and negotiate on behalf of their human "clients," especially in cases where the negotiation tasks are well-structured. Governed by computational rules, these agents may include a concession model with general strategies of concession in multiple-issue negotiations (Matwin, Szapiro, & Haigh, 1991), a case-based reasoning to plan and support negotiations (Sycara, 1990), and a genetic algorithm-based learning technique (Oliver, 1997). Negotiation agents could bring significant benefits, such as time savings, avoiding unnecessary cognitive limitations, lowering transaction costs, and increasing the efficiency of settlements (Rangaswamy & Starke, 2000).

Negotiation Process

Interaction Process-Communication

Negotiation, after all, is a special kind of communication (Putnam & Roloff, 1992). It is a dynamic process characterized by information exchange, persuasion, and joint problem solving. Communication in negotiation serves four primary functions (Tutzauer, 1989): (1) a vehicle for transmitting and accepting offers; (2) a means for conveying information; (3) a mechanism for shaping the relationship between the bargainers via argumentations; and (4) a lens for uncovering outcomes.

Research on communication in negotiation has followed two lines (Neale & Northcraft, 1991). One group studies the effects of communication on outcomes, specifically the content and style; while the other group investigates the determinants of communication tactical choices. In the context of facilitated negotiation using ENS, visual and audio channels are proposed to support the communication process. Media richness, synchronicity of the communication channels, and multilingual support are popular research areas.

Interaction Process-Negotiation Strategies

One of the important findings in negotiation strategy research is the Dual Concern Model (Pruitt & Rubin, 1986). This predicts that bargaining outcomes depend on the negotiator's concern for self profits (assertiveness) and concern for the opponent's welfares (cooperativeness). Table 1 presents the summary of the negotiation strategy and outcome predicted by this model.

The Dual Concern Model provides insights to the question of how to achieve a more effective negotiating tactic. This model suggests that successful integrative bargaining requires both high concerns for the value of one's own outcome as well as for the other's welfare. However, in real life, negotiators may fail to achieve that due to human limitations and resource constraints. These potential problems could be solved with the assistance of ENS.

Cognitive Process

Negotiator cognitions research focuses on what goes on in the mind of a negotiator. Negotiator cognitions can be classified into three classes (Neale & Northcraft, 1991):

Table 1. The dual concern model: Strategy and outcome

	High self concern		Low self concern	
	Strategy	**Joint Outcome**	**Strategy**	**Joint Outcome**
High other concern	Problem solving (Collaborative)	High	Yielding (Accommodating)	Low
Low other concern	Contending (Competitive)	Moderate	Inaction (Avoiding)	Low

negotiation planning, information processing, and affect. *Negotiation planning* refers to how an individual identifies systematic mechanisms for developing and implementing bargaining strategies. In the literature, proposed antecedents of planning include level of aspiration, integrative potential, role, and so forth. *Information Processing* refers to how an individual intakes and compiles the environmental inputs in order to make sense of the negotiation context. The identified information processing strategies include framing, anchoring and adjustment, overconfidence, and reactive devaluation. *Affect* refers to the ways an individual expresses his or her emotion and needs in a negotiation.

Negotiation Outcomes

Contract-Related Outcomes

Joint outcome or joint utility measures the efficiency of a negotiation. It is measured by the sum of total multi-attribute utility scores of negotiators from all parties for the final agreement. It hence provides a measure of the total utility of a negotiated settlement. It serves the same purpose as the efficient frontier.

Contract balance measures the fairness of the negotiation outcome. It is computed by the absolute value of the differences between the total utility scores achieved by each negotiation party. The agreement is balanced, if the score equals zero. It serves the same purpose as the Nash solution.

Process-Related Outcomes

Satisfaction is an important measure of negotiation outcomes (King & Hinson, 1994). It is essential that negotiators are satisfied enough with the negotiation process and outcomes to warrant further business. Good performance in a negotiation, improved relationship with opponents, and an enjoyable interacting process are ways to increase the negotiators' satisfaction.

Perceived control refers to the sense of ownership in the negotiation process. When negotiators are able to reach consensus, they prefer to do it by themselves rather than by relying on external assistance (Hiltrop & Rubin, 1982). Jones (1988) found that in high-conflict treatments, bargainers tended to ignore the computer suggestions in favor of their own solutions, even though they were often not as good as the options suggested by computer systems.

Negotiation Context

Negotiator Characteristics

Almost every negotiation involves people, thus it is essential to understand negotiator characteristics in the study of ENS. In the negotiation literature, gender (King & Hinson, 1994), personalities (Ford, 1983), intelligence, negotiation experience, communication style (Simintiras & Thomas, 1998) are the noted factors shaping the negotiation process and outcome (Lewicki, Saunders, & Minton, 2003).

Negotiation Task

The bargaining orientation of a negotiation task is an essential input to formulate strategies and tactics in the negotiation process (Kersten, 2001). A negotiation task can be distinguished through the dimensions of integrative and distributive tasks (Walton & McKersie, 1965). Distributive tasks are win-lose situations (Fisher & Ury, 1981) that lead negotiators to focus on "slicing the pie" (Thompson, 2000). In contrast, integrative tasks provide an opportunity for the negotiation parties to integrate their interests. Negotiators might achieve a win-win agreement by expanding the pie.

Nearly every negotiation is conducted under certain time limitations. *Time pressure* influences people's behaviors (Druskat & Kayes, 2000). The time allocated in the negotiation is defined as either relatively short (high pressure) or long (low pressure). Researchers have categorized response processes due to time pressure into three types (Stuhlmacher & Champagne, 2000): (1) the process toward agreement

would be accelerated due to the strong time pressures in the form of fixed deadlines (Druckman, 1994; Maule & Mackie, 1990); (2) negotiators may process information selectively with time pressure (Svenson & Edland, 1987); and (3) differential combination of information would be generated as well.

Structural Factors

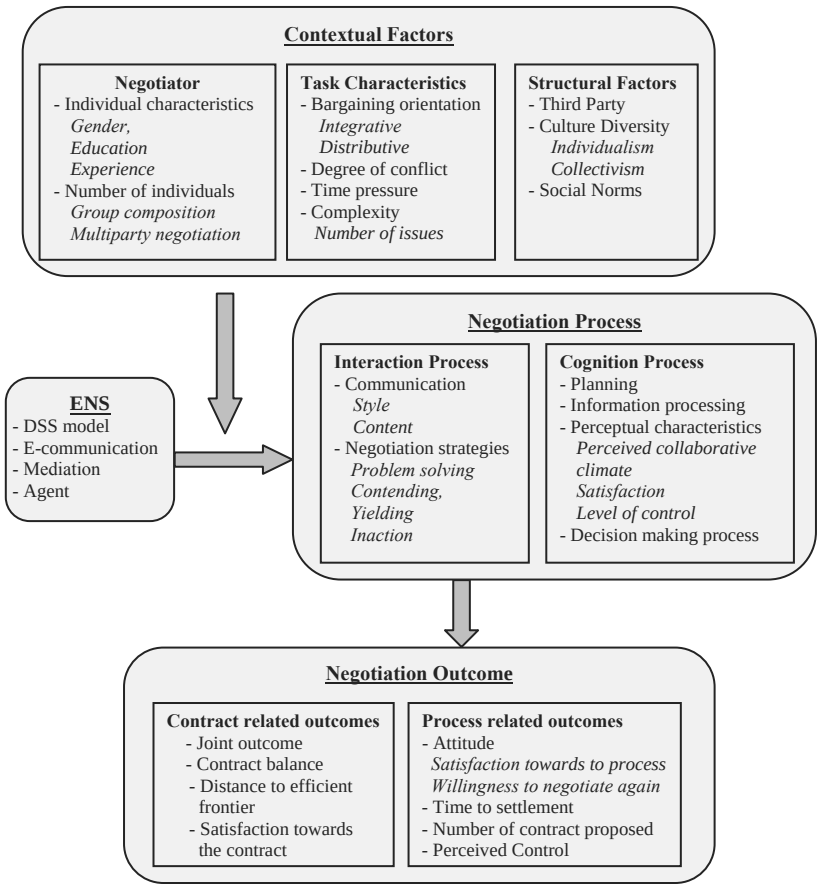
The *availability of third parties* may be another source that influences the negotiation process and outcome (Wall & Blum, 1991). In most of the cases, the third party would resolve the dispute in the negotiation, if the negotiating parties fail to do so. However, the third party may also have his or her own objectives (Zartman & Touval, 1985). Research has shown that negotiators alter their behavior with the presence of a third party (e.g., Neale, 1984). This effect would vary depending on the types and behavior of third parties. Third parties can be grouped into four basic types: mediator, arbitrator, conciliator and consultant (Fisher, 1990).

Culture can be defined as an entity consisting of interrelated parts, such as knowledge, beliefs, art, morals, customs and any other capabilities acquired by members of a society. A negotiator can only behave according to his or her cultural background and experiences. One conceptual dimension of culture is collectivism and individualism (Hofstede, 1991). This dimension refers to the extent to which a culture fosters its people to promote a group's well-being and to endorse the desire of self over a group. It reflects the relationship between an individual and his/her fellows. Thus, collectivists have norms and focuses about negotiation outcomes that are different from individualists (Wall & Blum, 1991). These norms and focuses are likely to influence the negotiation processes.

Research Framework for ENS

Figure 1 presents a proposed framework of ENS by integrating both prescriptive and descriptive perspectives of negotiation research. It summarizes the four categories reviewed above. Under each category, key variables are identified. This framework may provide researchers with a direction for future ENS research.

Figure 1. Proposed framework of e-negotiation support systems research



FUTURE TRENDS

E-Negotiation Technology

ENS can provide different levels of support to negotiators, such as DSS only, e-communication only, or full support. Researchers from the fields of computer science, engineering and economics might develop new algorithms and processing models of DSS to enhance the effectiveness and efficiency of ENS. Continuous effort on examining the variants of the e-communication component, such as video conferencing, is another direction (Yuan, Head, & Du, 2003). Although research on negotiation agents is still at the exploratory stage, its potential growth is both empirically and practically valuable. There is a need to develop an infrastructure and a negotiating protocol in which negotiators, DSS, and agents can work together for value creation (Lo & Kersten, 1999). Moreover, the role of ENS in a negotiation forms another interesting research direction. In addition, developing user-friendly interfaces by incorporating the findings of negotiator characteristics is another direction in the research domain of human computer interaction.

Interactive and Cognitive Behavior in Negotiation Process

Negotiation is a dynamic process characterized by information exchange, persuasion, and joint problem solving. There are two important components in the negotiation process: interaction process and cognition process. More studies are needed to reveal the dynamic between these two types of behavior. This helps to understand how a person's internal cognition leads to his or hers interaction behavior in negotiation.

In the ENS context, more effort is required to open the "black box" of negotiation process by exploring the negotiators' communication style and negotiation strategy. With greater knowledge in this area, researchers and designers might improve the ENS to better facilitate information exchange, increase the possibility to close a deal, and promote a collaborative negotiation atmosphere. The study of negotiation strategies could also contribute toward developing the concession model for negotiation agents and the design of negotiation training courses.

Contextual Factors in Negotiation Research

In the literature of information systems, social-psychology, computer science, and human computer interaction, three groups of contextual factors have been identified: negotiator characteristics, task characteristics and structural factors. These contextual factors are likely to moderate the effects of ENS on the negotiation process. There are a few studies that have visited these factors, specifically negotiator characteristics. More research is needed to understand the role of contextual factors in ENS facilitated negotiation. Potential findings can help system designers to better customize the ENS to satisfy different needs and fit varying situations. Nonetheless, group negotiation is prevalent in today's business world. The impacts of group formation, culture diversity, and third parties are areas that require more investigation.

Negotiation Outcomes

Contract-related outcomes are the measures reflecting the effectiveness and efficiency of the final agreement. Most empirical studies of ENS have examined these factors, such as joint outcome, contract balance, and the distance to efficient frontier. However, process-related outcomes have not been sufficiently studied; examples include perceived commitment of opponent, perceived collaborative atmosphere, and perceived control. These factors are essential to understand negotiator satisfaction and could consequently contribute to the knowledge of ENS adoption and diffusion. Case studies and longitudinal research are needed to understand these issues.

CONCLUSION

Having reviewed the influential theories and models in negotiation literature, we propose a framework for ENS research by synthesizing the research from both descriptive and prescriptive perspectives. These two theoretical perspectives are not mutually exclusive, but complementary. Together, they represent a holistic negotiation picture, which enables researchers to better understand the causes, processes and outcomes of negotiation. Four areas of interests are discussed: negotiation support systems, the negotiation process, contextual factors and the negotiation outcome. We also provide a list of important variables for each area. Some potential research directions and managerial implications are drawn from the proposed framework.

This article has some limitations as well. Firstly, the variables listed here are not exhaustive, but we aim to suggest a direction for research. Secondly, some of the variables proposed may be difficult to measure, for instance, communication content. Thirdly, in this framework, we have used constructs together with variables. This may lead to confusion. However, there is always a trade-off between the simplicity and the concreteness of a framework. When we try to provide a more complete view, we tend to include more variables. Thus, to simplify the framework, we used

some constructs instead. Lastly, we did not elucidate in detail all the relationships among the variables due to the page limit.

KEY TERMS

Cognitive Information Processing: Refers to how an individual absorbs and compiles the environmental inputs in order to make sense of the negotiation context.

Contract Balance: Is the absolute value of differences between the total utility scores achieved by each negotiation party.

Descriptive Model of Negotiation Research: A research stream focusing on the process of negotiation.

E-Negotiation Support Systems (ENS): Are computer systems that enable negotiators to achieve better agreement by enhancing the negotiators' information processing capability and communication with the other party.

Joint Outcome: Refers to the efficiency of the negotiation. It is measured by the sum of the total multi-attribute utility scores from all the negotiators in the final agreement.

Negotiation: Is a process where two or more parties attempt to reach a joint decision on issues in dispute.

Negotiation Planning: Refers to a process where an individual identifies systematic mechanisms for developing and implementing bargaining strategies.

Prescriptive Model of Negotiation Research: A research stream focusing on the outcomes of negotiation.

Energy Management in Wireless Networked Embedded Systems

G. Manimaran
Iowa State University, USA

INTRODUCTION

Real-time systems have undergone an evolution in the last several years in terms of their number and variety of applications, as well as in complexity. A natural result of these advances, coupled with those in sensor techniques and networking, have led to the rise of a new class of applications that fall into the distributed real-time embedded systems category (Loyall, Schantz, Corman, Paunicka, & Fernandez, 2005; Report, 2006). Recent technological advancements in device scaling have been instrumental in enabling the mass production of such devices at reduced costs. As a result, applications with a number of internetworked embedded systems have become prominent. At the same time, there has been a need to move from stand-alone real-time unit into a network of units that collaborate to achieve a real-time functionality. Extensive research has been carried out to achieve real-time guarantees over a set of nodes distributed over wired networks (Siva Ram Murthy & Manimaran, 2001). However, there exist a number of real-time applications in domains, such as industrial processing, military, robotics and tracking, that require the nodes to communicate over the wireless medium where the application dynamics prevent the existence of a wired communication infrastructure. These applications present challenges beyond those of traditional embedded or networked systems, since they involve many heterogeneous nodes and links, shared and constrained resources, and are deployed in dynamic environments where resource contention is dynamic and communication channel is noisy (Report, 2006, Loyall et al., 2005). Hence, resource management in embedded real-time networks requires efficient algorithms and strategies that achieve competing requirements, such as time sensitive energy-efficient reliable message delivery. In what follows, we discuss some applications in this category, and discuss their requirements and the research challenges.

Safety-critical mobile applications running on resource-constrained embedded systems will play an increasingly important role in domains such as automotive systems, space, robotics, and avionics. The core controlling module in such mission critical applications is an embedded system consisting of a number of autonomous components. These components form a wireless (ad hoc) network for cooperatively communicating with each other to achieve the desired functionality. In these applications, a failure or violation of deadlines can be disastrous, leading to loss of life, money, or equipment. Hence, there arises a need to coordinate and operate within stringent timing constraints, overcoming the limitations of the wireless network. For example, robots used in urban search and rescue missions cooperate together and with humans in overlapping workspaces. For this working environment to remain safe and secure, not only must internal computations of robots meet their deadlines, but timely coordination of robots behavior is also required (Report, 2006). Other such medium-scale distributed real-time embedded applications include target tracking systems that perform surveillance, detection, and tracking of time critical targets (Loyall et al., 2005), or a mobile robotics application where a team of autonomous robots cooperate in achieving a common goal such as using sensor feeds to locate trapped humans in a building on fire. Other more passive applications include the use of networked embedded systems to monitor critical infrastructure such as electric grids (Leon, Vittal, & Manimaran, 2007). These applications need to meet certain real-time constraints in response to transient events, such as fast-moving targets, where the time to detect and respond to events is shortened significantly. In surveillance systems, for example, communication delays within sensing and actuating loops directly affect the quality of tracking. While providing real-time guarantees is the primary requirement in these applications, mechanisms need to exist to meet other crucial system needs such as energy consumption and accuracy (Rusu, Melhem & Mosse, 2003). In most cases, there are tradeoffs involved in balancing these competing requirements.

BACKGROUND

The typical architecture in a distributed real-time embedded system consists of several processor-controlled nodes interconnected through one or more interconnection networks. The system software running on each node enables the execution of one or more concurrent tasks that are activated by the arrival of triggering events generated by the external environment, a timer, or arrival of a message from another task. A response to an event generally involves several tasks to be executed on different nodes, and several messages to be

exchanged in the network. The tasks on the same node may share data and resources using synchronization mechanisms present in shared memory systems, and also interact with tasks on other nodes by exchanging messages using the services provided by the communication subsystem. For the proper functioning of the whole system, each individual task, as well as all the messages exchanged, need to be completed before specified deadlines.

The workload in the majority of the distributed embedded real-time applications is similar to those found in traditional real-time systems comprising of periodic and aperiodic tasks. Periodic tasks form the base load invoked at regular intervals, while aperiodic tasks include the transient load generated in response to alarm or an external environment stimuli. However, one can expect stronger cooperation between the internetworked units in more dynamic and complex systems inducing richer communication patterns than simple periodic messages. For distributed real-time embedded system, the primary requirement is that there is an end-to-end timing requirement that needs to be met. This implies that there exists a set of messages with complex precedence constraints that need to be exchanged between the networked nodes before some deadline. Hence, one needs to characterize the different message communications and computations that are possible, and perform a preruntime analysis to guarantee, a priori, that all the task deadlines will be met. Moreover, in a distributed real-time system, the ability to meet task deadlines largely depends on the underlying task allocation, and hence, we need a preruntime task allocation algorithm that takes into consideration the real-time constraints. Intertask communication significantly influences the response time of these distributed applications and hence, the design needs to account for the effect of delays imposed by the communication network and precedence constraints imposed by the communicating tasks during task allocation. Since the inherent nature of many of the discussed applications precludes the use of wired networks, wireless networks are commonly used in such applications.

The wireless medium is inherently unreliable due to characteristics such as fading and interference. Hence, to guarantee that tasks should meet timing constraints, it becomes necessary to develop techniques that characterize the unreliability in the network channel, and take them into account while making transmission scheduling decisions. Energy management is another crucial aspect for internetworked embedded devices. These devices contain not only radio and computer components, but also complete system functionalities, such as networking functions across all levels of the protocol stack. Energy savings and allocation among these modules will affect the life time of these battery-powered devices. Energy management also needs to be considered, together with other constraints in size, real-time requirements, functionalities, and network connectivity.

In summary, the combination of temporal requirements, limited resources and power, networked system architectures, time-varying wireless channel, and high reliability requirements presents unique challenges

(Loyall et al., 2005; Report 2006).The end goal of most of the research in this area is to devise efficient resource management algorithms for energy-constrained and highly dynamic wireless networks in order to support end-to-end system requirements that are comparable to their wireline counterparts.

MAIN FOCUS OF THE CHAPTER

Energy management is one of the key issues in the design and operation of networked embedded systems, which involves energy management at the system level considering both computing and communication subsystems. For embedded computing, there are well known techniques, such as dynamic voltage scaling (DVS) (Aydin, Melhem, Mosse, & Alvarez, 2004; Shin, Kim, & Lee, 2005) and dynamic power adaptation (DPM), that have been exploited by intertask and intratask scheduling algorithms. For wireless communication, techniques such as dynamic modulation scaling (DMS) (Raghunathan, Schurgers, Park, & Srivastava, 2002), dynamic code scaling (DCS), power adaptation (Raghunathan, Pereira, Srivastava, & Gupta, 2005), and adaptive duty cycling have been employed for minimizing energy consumption. These techniques essentially provide energy-time tradeoff, that is, the lesser the time taken for execution of tasks or transmission of messages, the higher the energy consumed.

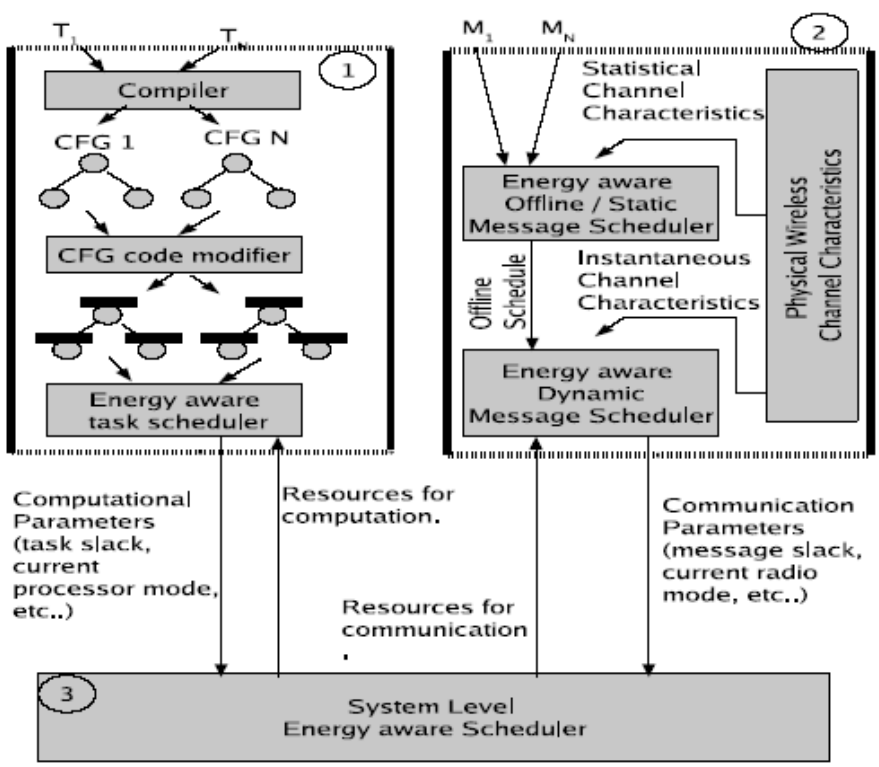
Our research contributions are in the design of a comprehensive energy management framework, with associated off-line and online scheduling algorithms, for networked embedded systems. In system-level energy management (Kumar, Sudha & Manimaran, 2007; Unsal & Koren, 2003), the fundamental question to be answered is how much of the available slack be allocated to each of task execution and message transmission. In general, the computation energy (for a CPU cycle) consumed is much lesser than the communication energy (for a bit of data transmission) for currently available technologies. Therefore, allocating as much slack as possible for communication energy optimization sounds appealing on the surface. However, our analysis shows that there is a diminishing return when the transmission time is increased beyond a certain threshold, with coding taken into account (Kumar et al., 2007). Therefore, the slack should be allocated in a balanced manner between computing and communication subsystems, considering current energy levels of tasks and messages and the channel condition. In our research, we considered DVS and DMS for energy

optimizations in computing and communication subsystems, respectively.

The major challenge in performing energy management in networked embedded systems lies in estimating the exact workload required by the application. The exact workload determines the least power mode that the device can operate at, while meeting the deadlines. In case of local computation, the workload refers to the task execution times, which exhibit a wide variation from their worst-case estimates. Most of the existing research speculates the task execution times. On the other hand, in the case of messages, the workload refers to the number of retransmissions required over a wireless link for a successful transmission. In our research, we consider both real-time constraints and channel conditions (reliability) while achieving energy efficiency of the networked embedded system. The proposed energy-aware resource management approach, shown in Figure 1, has the following three key components: computing subsystem energy management, communication subsystem energy management, and system-level energy management.

Energy Management at Computing Subsystem: This deals with the energy-aware real-time scheduling of tasks on a local node. Specifically, the goal is to minimize the processor energy consumption while meeting all the task deadlines. Specifically, we have designed cross-layer task scheduling algorithms that exploit intratask information, such as path locality information (if available) and run-time branching information, at the intertask scheduling level. We have designed a generic scheme, called *early basic block execution,* that aims at minimizing the energy consumption by reducing the nondeterminism in the workload; this is achieved by exploiting the control flow graph (CFG) of each task at the intertask level. The basic idea is as follows (Kumar, Sudha & Manimaran, 2006): "whenever the current task generates a slack due to a shorter branch execution, the early execution algorithm uses this slack to execute the basic blocks of the other ready tasks rather than using the entire available slack for slowing down the processor for the current task, with the objective of knowing other tasks' branching decisions which would otherwise be known at a later point of time." By performing such early execution of the basic blocks, the proposed algorithm builds a better picture of the workload at an earlier point in time. This will be exploited to scale the voltage/frequency appropriately across tasks, as opposed to within a task. This approach can acquire a much better idea of the future workload (branching decisions) than

Figure 1. Schematic of system-level energy management with computing and communication subsystems



a crude speculation, and hence, has the potential to offer significantly higher energy savings. These algorithms can be employed in networked as well as stand-alone embedded systems. The performance of such an algorithm depends on the nature of the workload and the overhead incurred by the algorithm itself.

Energy Management at Communication Subsystem: This deals with the energy-aware real-time scheduling of the internode messages over the wireless medium that is prone to phenomenon, such as fading, noise, and interference. Specifically, given a set of messages, each with a source and a destination, the goal is to transmit them, with the objective of minimizing the energy consumption of the communication subsystem while meeting all the message deadlines with a given probability of success. Due to the fading and noisy nature of the wireless channel, it is not feasible to guarantee 100% reliability.

We propose to estimate the channel condition using past feedback from the receivers, and based on the channel condition estimation/prediction, design efficient message transmission strategies, namely determining appropriate power level, modulation format, and coding scheme, for a given set of messages, such that they are successfully transmitted by the deadlines with maximum energy efficiency. We propose to include error-control coding in the energy consumption consideration, in addition to the modulation adaptation, as in DMS and power adaptation. By first quantifying the reliability (i.e., message success probability) using error-exponent and outage probability, we study the problem of allocating available slacks for communication among the messages in a way that maximizes the energy reduction.

Energy Management at the Networked System Level: In a typical networked embedded application, each node performs some local computation (task), and communicates the results (message) to a remote node in the network. Both task and message deadlines must be guaranteed in order to provide end-to-end deadline guarantees. In order to minimize the total energy consumption while guaranteeing the deadlines, the algorithm needs to optimally distribute the available slack among different tasks and messages. Task utilizes the slack to perform DVS, while the message uses the slack to perform DMS, or any other similar technique that trades off time for energy. In general, the computation energy is much less than the communication energy. Therefore, allocating maximum slack to communication subsystem sounds appealing on the surface. However, as can be seen from a more refined analysis, with coding taken into account, there is diminishing returns when the transmission time is increased beyond a certain threshold. Therefore, there should be a balance between the computing subsystem and the communication subsystem in slack distribution. For specific instances of the problem, we have validated such tradeoffs through theoretical analysis, considering the transmission time, wireless channel condition, and different overheads encountered in practice. Based on the results of our analysis, we have designed efficient energy-aware slack distribution algorithms that consider related tasks and messages in an integrated manner (Kumar et al., 2007). The challenge is to design distributed algorithms for slack distribution.

The optimization metric for the system-level energy-management algorithm depends on the requirements of the underlying application. Sample metrics include minimizing the total energy of the entire system, minimizing the maximum energy of the nodes in the system; at a higher level, metrics include maximizing the life time of the networked embedded system satisfying the coverage, connectivity, real-time, and/or reliability properties. The resource management consists of static and dynamic scheduling of tasks and messages. In static scheduling, the workload is periodic and the schedule is constructed off-line for the given workload on the target system platform. There are two options here: (1) construct an energy optimized feasible schedule using energy unoptimized feasible schedule as the input; (2) construct an energy optimized feasible schedule using the workload and target networked platform as inputs. While the first problem assumes a feasible schedule is produced by an existing distributing real-time scheduling algorithm, the second problem does not rely on such a schedule and hence, is a harder problem than the first one. In dynamic scheduling, two options exist: (1) reclaim both static and dynamic slacks and use them for energy optimization through a dynamic slack distribution algorithm. The static slacks are the ones that were left in the schedule as "holes," and the dynamic slacks are the ones that are created due to situations such as when the actual computation time of a task is less than its scheduled worst-case computation time, or when the actual transmission time (including retransmissions) is less than the worst-case transmission time of a message. In dynamic scheduling, efficient means to keeping track of the slack is critical for achieving high energy performance, and moreover, dynamic slack reclamation and distribution should be done in a distributed manner (with less or no coordination among nodes) without leading to any deadline violation anomalies.

FUTURE TRENDS

This work opens up several avenues for further research in the emerging area of networked embedded systems, which include the following: (1) Real-time networked embedded system architectures and resource management algorithms: (2) Cross-layer algorithms for compute-communication energy management; (3) Cross-layer algorithms for sense-compute-communication energy management; (4) Implementation of such architectures and algorithms for real-world applications; (5) Specific research on energy-management algorithms include: (a) designing static system-level energy-

aware scheduling algorithms taking task set and the network architecture as inputs, as opposed to taking a given feasible schedule as input; (b) studying the tradeoff involving other energy optimization techniques (e.g., DPM vs. DMS, DVS vs. DMS+DCS), and designing static and dynamic slack allocation algorithms for these specific instances; (c) addressing all these research problems in the context of multihop networks with structured topologies (e.g., tree and mesh) and arbitrary topologies.

CONCLUSION

Real-time embedded systems play a prominent role in a variety of applications ranging from medical sensors in the human body to signaling sensors in war fields. The consumer domain of the embedded devices is large and ever increasing. A natural result of this trend coupled with those in sensor technologies and wireless communications have led to the rise of a new class of systems, called the networked embedded systems. Energy management is of the key issues in the design and operation of such systems, which involves energy management at the system level considering both computing and communication subsystems. This chapter advocated cross-layer algorithms for energy-aware resource management in networked embedded systems, considering an integrated workload of tasks and messages and their respective power management techniques. The fundamental question to be answered is how much of the available slack be allocated to each of task execution and message transmission. The answer lies in analyzing the characteristics of tasks and messages, considering their current energy levels, deadlines, and the channel condition. The research highlighted in this chapter opens up several research directions in wireless networked embedded systems.

KEY TERMS

Cross-Layer Algorithms: Two or more layers of the system (e.g., computing and communication layers) work synergistically to achieve the stated objective of the system.

Embedded System: Computing system that is a core part of a large system to achieve sense, process, and actuation capabilities.

Energy-Aware Resource Management: The goal of minimizing energy consumption in the system.

Energy-Time Tradeoffs: This refers to the tradeoff involving time to execute a task or to transmit a message vs.

the amount of energy consumed. Lesser the time taken for execution of tasks or transmission of messages, the higher the energy consumed.

Real-Time Workload: The workload consists of a set of tasks and messages that have precedence relations among themselves, and each task/message has specific deadline before which the execution/transmission must be completed.

System-Level Resource Management: The goal of achieving system-level resource management objectives as opposed to making subsystem level optimizations.

Wireless Embedded Network: A set of embedded nodes connected through a wireless network; the wireless channel is time-variant.

Enhancing Workplaces with Constructive Online Recreation

Jo Ann Oravec
University of Wisconsin-Whitewater, USA

INTRODUCTION

Organizations have become more permeable— integrating more influences from the outside world— as participants engage in such online diversions as trading stocks, engaging in multiplayer games, or viewing images of their children in daycare. Ready availability of these activities has brought the potential for abuse but also new opportunities. Constructive uses of online recreation and play can enhance many workplaces (especially high-tech and information-saturated ones) and perhaps ultimately make them more productive. This article proposes that these complex issues be resolved through participatory approaches, involving workgroups in discussions as to what constitutes "constructive recreation" as well as in development and dissemination of effective and fair policies. This discourse can also ultimately increase levels of trust among team members and between employees and management.

BACKGROUND

Issues concerning the boundaries between work and play have provided continuing struggles for managers and employees. Workplaces have become more "porous" and permeable— integrating more influences from the outside world— as individuals engage in such online diversions as trading stocks, playing games, or viewing images of their children in daycare. Everyday workplace life is becoming more diverse and chaotic. Although many organizational roles today demand high levels of creativity and mental flexibility, they can also fail to provide the means through which individuals can gain fresh perspectives. In the "information age," playful, exploratory, and spontaneous interaction can also facilitate the exchange of ideas for tackling workplace problems. Managers who expect employees not to use the Internet for some amount of off-task activity severely misjudge the nature of workplace life— which is solidly infused in online interaction. Depriving employees of opportunities for Internet recreation in some cases excludes the possibility of nearly any form of diversion from assigned responsibilities.

Workplace use of the Internet for activities that are not directly authorized by management is often considered as the "theft" of human and computer resources, while construed as a just reward by employees (Lim, 2002). Even though many managers consider the personal use of the Internet as an ethical lapse (Greengard, 2000), the "moral high ground" concerning these issues is not entirely clear. Much of the rhetoric and advertising copy associated with workplace computing incorporates recreational imageries and motifs, which can send misleading signals to employees. A number of individuals have already had significant experience combining work with online recreation; convincing them that hard work cannot be combined with online play is thus a tough sell. Telecommuters returning to organizational settings are often not entrusted with the autonomy to engage in online breaks at appropriate times— latitude they take for granted when doing the same tasks in their home offices. Many young people became comfortable with computing through video games and online interpersonal interaction and took online breaks during their demanding college studies (Colkin & George, 2002). Individuals must find ways to cope psychologically with increased pressures on the job (Weil & Rosen, 1997) and management should explore creative but feasible ways to assist them in these efforts.

Wireless Internet applications add more complexities, further increasing the porousness of organizations and making employees' access to recreation less dependent on systems controlled by their managers. Daniels (2000) reports how wireless technologies (such as PDAs with Internet access) are used within meetings to amuse and distract participants, often resulting in productivity losses. Since wireless technologies are still in the early stages of adoption in many organizational contexts, placing severe restrictions on their use (and penalties for misuse) could be counter-productive. Personal computers became familiar workplace additions in the 1980s in part because of their use for gaming, an activity that encouraged employees of a variety of ages and backgrounds to explore the various dimensions of the devices and to become more comfortable with them.

If engaged in constructively, online recreation can aid in awakening creativity and increasing wellbeing, just as appropriate and timely face-to-face diversions have restored employees' energies over the past decades. However, some individuals may not be able to deal with online recreation constructively. They indeed will use it in ways that affect their organizations and themselves negatively, just as some

individuals cannot perform adequately on the job for other reasons. Forms of "positive discipline" can be utilized if employees choose to exceed reasonable, agreed-upon limits; implementing such discipline "requires that the supervisor and employee work together to correct the problem behavior" (Guffey & Helms, 2001). Managers and employees should strive together to harness online recreation toward positive ends, rather than condemning or seeking to stifle it completely.

WHAT IS "CONSTRUCTIVE RECREATION"?

Online recreation has already served many supportive purposes in organizations; games can be used to help decrease computer anxiety as well as encourage experimentation and the early stages of learning (Kendall & Webster, 1997; Oravec, 1999; Webster & Martocchio, 1992). What would make online recreation optimally beneficial to individuals, project teams, and the organization as a whole? To start the discussion: recreation is "constructive" when it is in synch with pending work responsibilities, allowing individuals to use time not consumed by workplace demands in ways that equip them to face future tasks with greater energy and expanded perspectives. Constructive recreation is also in keeping with technological constraints, as exemplified by the organizations that allow online recreation but place limits during certain hours to avoid system overload (Verton, 2000). Policies established are developed in participatory ways, and are disseminated broadly. Constructing ways of assigning tasks and evaluating employees so that significant and meaningful measures of productivity are involved can lessen an emphasis on the "surface" behavior of employees. Other characteristics of constructive recreation initiatives include:

- ***fostering flexibility:*** A major impetus behind constructive recreation initiatives is facilitating the rapid adaptation of individuals to changing circumstances. Constructive recreation affords individuals the means to maintain their flexibility in workplace environments that place increasing demands on their capacities to withstand change.
- ***manifesting sensitivity to cultural concerns:*** Workplace recreation is also "constructive" to the extent in which it is responsive to the overall culture of the organization and sensitive to the needs and values of other organizational participants (including freedom from harassment). Requirements of project team members in terms of scheduling are especially critical to recognize since the synchronization and sustained involvement of everyone are required during critical periods.
- ***providing stimulation and refreshment:*** Along with its other aspects, recreation is constructive if it provides intellectual and psychological stimulation or support, the sustenance often needed to take on tough challenges. "Reclaimed moments" that individuals spend in such activity can allow them to reestablish senses of control in otherwise stressful and constraining contexts. Ability to access such recreation and thus momentarily escape can provide a safety valve for those who face unyielding situations or put in long work hours, thus putting the porousness of today's Internet-supported workplaces to good use.

FUTURE TRENDS

The value of recreation and play in adult realms is not well understood. Play has been given an assortment of definitions in the academic and research literatures (with examinations in the fields of social psychology, philosophy, and anthropology); it is often considered in both its adult and child modes as a "cognitive and symbolic act that is fundamental to the human representational process" (Myers, 1999). Across species as well as cultures, play has been shown to help individuals prepare for the unexpected by presenting varying streams of novel or challenging situations (Spinka, 2001). Play is generally considered as a support for children's intellectual and social development, but its role in adult lives is less clear. Research initiatives on what kinds of recreation and play are most efficacious in different workplace environments—as well as on individual and group "play styles"—could enlighten constructive recreation efforts (although they cannot be expected to provide definitive results).

Simulation is indeed an aspect of play that has some direct implications for employee readiness in the workplace, and it has received some research treatment (Myers, 1999). Michael Schrage's (1999) *Serious Play* examines how simulations expand the intellectual capacities of knowledge workers; forms of online play may equip individuals to utilize an organization's "serious" computer simulations more effectively, thus reinforcing skills applicable in many workplace contexts. Many powerful simulation games with societal or political themes are widely available to the public and have considerable audiences; the Sims series and other popular single- and multiplayer games have been used to entertain and educate in a variety of contexts (Pillay, Brownlee & Wilss, 1999).

Constructive recreation initiatives will also be a part of many organizational efforts to build cohesion. Managers have often used organizationally sanctioned recreation as a perquisite, a bonus for acceptable conduct. It has served as an extension of the workplace, providing a form of "social capital" (part of the "glue" that holds the at-work community together). Through the past century, many organizations

have sponsored picnics and celebrations with the strategy of increasing workplace cohesion (Putnam, 2000).

As employees (including many white collar as well as knowledge workers) telecommute or put in long and irregular hours, the adhesive that binds organizations has been increasingly conveyed through electronic channels. However, it is unclear what kinds of online activity can foster social capital (Uslaner, 2000). Just as human resource experts struggled early in the twentieth century to integrate face-to-face recreation into workplace contexts, organizations should attempt similar feats in online realms, thus making online recreation a shared and open resource rather than a secretive endeavor. Unlike many early human relations experiments, the recreational activities involved should be developed in a participatory (rather than patriarchal) fashion. Whether organization-approved fantasy football, discussion group and collaborative filtering forums, joke-of-the-day contests, or other recreations are ultimately successful will depend on how they fit into everyday working experiences.

CONCLUSION

Can we indeed construct a "level playing field"? As workplaces have evolved, so have the issues that have divided employers and managers. Conflict has ensued for decades on an assortment of matters relating to the quality of worklife, often leading to dysfunctional confrontations. Today, employees who guess wrong about online recreation standards— or choose to violate them— often pay large penalties, even being demoted or fired. Some managers have devised negative sanctions for these infringements far more severe than those applied to comparable face-to-face interaction. Office workers paging through paper catalogues in idle minutes rarely face the harsh penalties that those caught shopping online often encounter.

Hard-line positions against forms of online recreation may be required in some instances and directly related to important organizational goals. For instance, air traffic controllers should be expected to keep focused on landing real airplanes rather than escape into fantasy games during assigned hours. However, some hard-line restrictions can reflect fear or lack of understanding of online realms. Management may assume that online recreation will foster or encourage Internet addiction or related concerns. "Internet addiction" has become a widely identified syndrome, although its medical underpinnings are still in question (Beard, 2002; Oravec, 1996, 2000).

Ambiguities concerning online work and play in virtual realms are increasingly adding complexities to these issues (Broadfoot, 2001). It is often difficult to tell which Web sites are related to business needs and which are recreational; many have dual purposes, combining amusement with news and other serious pursuits. Slashdot.org has humorous material as well as valuable technical commentary, and abcnews.com has stories on upcoming movies as well as current economic results. Helpful intelligent agents (some with cartoon-like manifestations) can add levity to everyday tasks. Surfing the Internet for an answer to a question or fiddling with various programs can interfere with productive effort, as individuals dwell on technological nuances. Managers and employees need to deal not only with recreational concerns but also with broader issues of how to integrate computing into workplaces in ways that are engaging yet productive. However, online recreation should not be exploited as a means to keep individuals glued to workstations for indefinite periods in lieu of reasonable work schedules and functional work-life balances.

Solutions as to how to couple online work and play are emerging in organizations that are tailored to specific workplace contexts. Managers and employees are gaining important experience in resolving these issues as individuals perform activities away from direct supervision via mobile computing or virtual office configurations. Managers are learning how to perform their functions without direct employee surveillance. Employees are learning higher levels of self-discipline and the skills of balancing on-line work and play— just as they have learned to balance face-to-face schmoozing with task orientation in the physical world. Thus setting severe restrictions on online recreation can serve to slow down the process of understanding how to migrate the organization into virtual realms and establish trust. Responsibility and respect for others in these realms can be difficult to acquire, and many employees will indeed need direction.

Allowing for reasonable and humane amounts of online recreation can indeed have considerable advantages, both for the individuals involved and the organization as a whole. It can serve to open blocked creative channels and possibly relieve stress as well. Online recreation can also extend the limits of individuals' working days by providing extra dimensions to workplace activity. Rather than going through the emotional labor of looking busy, employees can utilize spare moments on the job in recharging their mental batteries. Constructive use of recreation will require a number of changes, such as increases in managerial flexibility and employee empowerment (Boswell, Moynihan, Roehling & Cavanaugh, 2001; Kanter, 2002). Organizational participants must learn how to handle the distractions and opportunities of increasingly porous workplaces, with their many external influences. Education and training can be useful in these initiatives: novice employees can be aided to couple work and recreation in ways that increase overall effectiveness. Constructive recreation strategies can bring these complex matters into the open, rather than allow them to be objects of rumor and fear.

Forms of online diversion are already becoming integral elements of everyday workplace life, often serving to human-

ize and enhance organizations. Negotiation and discourse on constructive recreation issues can increase mutual trust and respect concerning online as well as face-to-face activity. With effort on everyone's part, the constructive use of online recreation can help the entire organization work harder and play harder.

KEY TERMS

Flexible Workplace: Organizational settings that can quickly take external and internal changes into account in their processes.

Internet Addiction: Use of the Internet and network resources that undermines the fulfillment of some of an individual's basic human needs.

Organizational Policies: Openly-stated, officially-sanctioned rules for organizational resource usage and other kinds of organization-related conduct.

Participatory Management: Management in which the input of employees as well as managers is thoughtfully taken into account in setting organizational policies and developing organizational structures.

Play: Activities in which individuals and groups engage that stimulate various aspects of personal and social functioning without necessarily being related to particular utilitarian outcomes.

Simulation Games: Games in which important aspects of a system are modeled so that game participants can engage in activities and deal with events that are comparable to those that system participants would encounter.

Social Capital: Social closeness, mutual knowledge, and cohesion that are a product of a wide assortment of different kinds of informal, volunteer, and partially-structured social interactions.

Enterprise Resource Planning (ERP) Maintenance Metrics for Management

Celeste See-pui Ng
Yuan-Ze University, R.O.C.

INTRODUCTION

A typical packaged software lifecycle, from the client-organization perspective, is packaged software selection followed by implementation, installation, training, and maintenance (that includes upgrades). Traditional software maintenance has been acknowledged by many researchers as the longest and most costly phase in the software lifecycle. This fact is no exception in the ERP packaged software maintenance context (Moore, 2005; Whiting, 2006).

According to Ng, Gable, & Chan (2002, pg. 100) ERP maintenance is defined as "post-implementation activities related to the packaged application software undertaken by the client-organization from the time the system goes live (i.e., successfully implemented and transported to the production environment), until it is retired from an organization's production system, to keep the system running; adapt to a changed environment in order to operate well; provide helps to the system users in using the system; realize benefits from the system (best business processes, enhanced system integration, cost reduction); and keep the system a supported-version and meet the vendor's requirements for standard code. These activities include: implementing internal change-requests (initiated by an ERP-using organization's system users and IT-staff); responding or handling user-support requests (initiated by an ERP-using organization's system users); upgrading to new versions/releases (introduced by the vendor); and performing patches (support provided by the vendor)."

In order to achieve the abovementioned maintenance objectives of keeping the ERP system running, adapting the system to a new operating environment, and ensuring the system up to the vendor's requirement for standard code; and realizing benefits such as competitive advantages from the system, the IT department staff has to collect some metrics or relevant data on patches and modifications done to the ERP system so that they can know or can tell the status and the performance of their maintenance activities. The authors in Fenton (1991), Fenton & Pfleeger (1997), and Florac (1992), agree that software maintenance data are useful for planning, assessment, tracking, and predictions on software maintenance. Although, there is a lot of literature on ERP, we find almost no literature on ERP maintenance metrics. Thus, this text is meant to provide some fundamental metrics on ERP patches and modifications which could be useful for ERP maintenance management in order to answer questions on the state of their ERP system, their patch implementation costs, and the ongoing maintenance costs for their previous modification or custom development.

BACKGROUND: METRIC

The *IEEE Standard Glossary of Software Engineering Terminology* (1990) defines a metric as a "quantitative measure of the degree to which a system, component, or process possesses a given attribute." Based on the definition, this text interprets a metric as being derived from data, and as quantifiable, meaningful, and used for strategic, tactical and/or operational purposes. Data (or data item), in turn, is defined as a quantitative indication of the extent, amount, dimension, capacity, size, or characteristic of particular attributes of a task or activity in a process. It can be collected using forms (e.g., change request form, change report, software engineering report), interviews (with the users, testers, programmers, analysts, managers), and via computerized systems (e.g., the in-built change management system in ERP, change request database). A goal/question/metric (GQM) paradigm is a systematic way of collecting predefined data, with intended goal(s), and the associated sets of predetermined questions, in order to derive the anticipated measurable metrics. Basili and Weiss (1984) advocate this methodology for collecting valid data. In GQM, which is also known as the top-down approach, the timing (in terms of the software life cycle or activity), interviewees, and reasons for collection are all predetermined.

The literature reports that successful use of measurement/metric program avoids recurring errors (Ebert, Dumke, Bundschuh, & Schmietendorf, 2005), improves software maintenance processes at Burrough Corporation (Rombach & Ulery, 1989), and Motorola (Smith, 1993), and improves product quality at AT&T (Fenton & Pfleeger, 1997).

On the flip side, a known metric – together with the context for its interpretation – can determine what data might be collected (Rombach & Ulery, 1989). There are three main purposes of metrics: assessment, prediction, and control.

Table 1. Main characteristics and purpose of three main metric categories

Metric category	Main characteristic	Purpose	Example of ERP maintenance metric
Assessment	Informative (about person, process, object); may be used in decision making or for controlling purposes	Retain knowledge	Programmer ID, problem description, description of changes, issues of consideration, patch ID
Prediction or decision-making	Conclusive; most likely derived from the assessment and control metrics; usually describes what should be done	Make decision, planning and estimation	Estimated maintenance time, quotation for a maintenance request, action to be taken, maintenance request type, projected availability
Control	Indicative (indicating that something needs to be done); most likely used to pinpoint that a particular decision needs to be made; usually requires data to be collected over a period of time; usually has some attached baseline value	Monitor performance, track progress, identify problem	Problem status, approved by, accepted by, maintenance request ID, time of problem occurrence, resolution impact

Table 2. Application of software metrics in practice

Purpose	Case name	Metrics used	Goal
Assessment	Hewlett-Packard (Wood, 2003).	Event chronology, problem symptoms, diagnostic information, release version information	Problem analysis and resolution
Decision-making	NASA's Mission Operations Directorate (Stark, Durst, & Vowell, 1994)	Previous project delivery rate	Estimate a test schedule
	Hewlett-Packard to (Grady, 1994).	Defect trend	Determine time to release a product
Control and monitoring	NASA's Mission Operations Directorate (Stark, et al., 1994)	Earned value management technique: project cost and schedule	Monitor project cost and schedule performance
		Defect density	Track quality in subsystem, efficiency in testing, and backlog of fault
	Hewlett-Packard (Grady, 1994)	Code size and time	Monitor project progress
	Bull's Arizona (Weller, 1994)	Effort, resources, product size, estimated completion date and defect detected	Manage project and improve project planning
	Siemens (Paulish & Carleton, 1994)	Defect rate (i.e. number of defect/ product size)	Measure performance
		Product size and effort (i.e. product size/effort)	Project productivity
		Productivity gain, error detection rate, and reduction in time to market	Measure software process improvement

Table 1 shows the main characteristics and objectives of these three metric categories. In addition to this, their application in practice is provided in Table 2.

APPLYING METRICS IN THE ERP MAINTENANCE (AND UPGRADE) CONTEXT: AN IMPLICATION FOR MANAGEMENT

The following discussion focuses on the practical application of the data items or software metrics. As stated earlier, metrics are derived from the data items collected from the activities that produce them. The metrics covered in this section are: (1) the state of the current system relative to the vendor's expectation, (2) the number of modifications or custom developments likely to be affected by each patch implementation, (3) patch implementation costs, (4) effort needed to reapply a previous modification or custom development, and (5) ongoing maintenance costs for modification requests. As shown later, these metrics are developed by manipulating (summation, division, multiplication, etc.) simple data items that are directly collected. Maintenance managers can use these metrics to manage maintenance activities for tactical and operational management decision-making. Table 3 provides the notations used in the abovementioned five metrics.

In addressing the manager question of: How up-to-date is my ERP system compared to my vendor's standard code?

With the aim of achieving economies-of-scale, many organizations "batch" the patches instead of implementing them as they arrive. Thus, in order to measure how up-to-date or state-of-the-art an installed ERP system is relative to the vendor's patch introduction for a given version, one needs to know how many patches have already been implemented, that is:

$$\textit{State-of-the-art} = \frac{R_A}{R_P} \text{X } 100\% \quad (1)$$

In addressing the manager question of: On average, how many modifications are affected by a patch implementation and what does it cost to implement a patch?

Table 3. Notations for metrics

Context	Notation	Metrics description	How it is measured?
User organization	k	Probability that a modification or custom development will be affected by future patch implementation	Done by studying the 'description of changes', 'related changes' and 'issues of consideration' related to that modification
	L	Labor rate	[a direct data item]
Previous modification	M	Number of modifications and/or custom developments	Summing up all the previous modifications based on previous record on it
	T_I	Effort required to conduct impact analysis for a modification	[a direct data item]
	T_R	Effort required to reapply a modification	[a direct data item]
	$T_{A\&T}$	Effort required to apply and conduct complete testing for a modification	[a direct data item]
Patch	N	Number of patch projects	Summing up all the previous patch projects based on previous record on it
	p_i	Number of patches in the *i*-th project	Each project may have different number of patched implemented at a time. This is usually depending on economy-of-scales and/or urgency of some patches
	T_{Pi}	Average effort required to implement a patch in the *i*-th project	Dividing the total effort in the *i*-th project by the total number of patches in the *i*-th project
	R_P	Patch introduction rate	Number of patches introduced by the vendor per year
	R_A	Patch implementation/application rate	Number of patches implemented by the client-organization per year

The *IEEE 1219 – Standard for Software Maintenance* (1998) suggests that cost and benefit analysis is required in order to determine the feasibility of a maintenance request, and to quantify the long-term or ongoing cost of a maintenance request. Patch implementation effort is believed to increase, to some degree, depending on the number of modifications already made to an ERP system (Ng, 2001). Patch implementation involves replacing some portion of the existing customized ERP code with the vendor's standard code. It can overwrite existing modifications or custom developments. However, not all modifications or custom developments are necessarily affected by each patch implementation. It is observed in a study by Ng (2001) based on an upgrade experience that only certain portion of them are affected. (Note that although a patch implementation is a small scale of an upgrade implementation, both of them could have overwritten effects on modifications done on existing system.) Therefore, the number of previous modifications or custom developments probably affected by each patch implementation, *m*, is:

$$m = k \text{ X } M \tag{2}$$

As a result,

Patch implementation costs = average number of patches per project X *average effort per patch* X *labor rate* + *effort required to reapply previous modifications* X *labor rate, or:*

$$= \frac{\sum_{i=1}^{N} p_i}{N} \text{ X } \frac{\sum_{i=1}^{N} T_{P_i} \text{ x } p_i}{\sum_{i=1}^{N} p_i} \text{ X } L + \sum_{i=1}^{m} T_R \text{ x } L \tag{3}$$

In addressing the manager question of: How much efforts is needed to reapply previous modification, and what are the ongoing maintenance costs for a modification request?

As modifications or custom developments may be overwritten during patch implementation, extra effort is needed in order to check whether such overwriting has occurred. If the affected modifications and custom developments are still needed, they may have to be reapplied to ensure that they can operate as they did before the patch(es) were implemented. Although activities such as analysis, design, and coding do not need to be repeated, complete testing (involving integration, validation, and system testing) for the previous modifications is required. These additional efforts generate the so-called ongoing maintenance costs for modification request. Hence, the major effort to reapply a single previous modification or custom development, T_R, is:

$$T_R = \quad T_I \quad + \quad T_{A\&T} \tag{4}$$

The greater the number of patch projects that must be carried out in an existing system, the greater the likelihood of ongoing maintenance costs associated with a modification in that system. Assuming that all modifications and custom developments will be affected by the patch and that the vendor will incorporate these modifications and custom developments into the new version. they are no longer needed after the upgrade. A simple formula for ongoing maintenance costs for a modification is as follows:

Ongoing maintenance costs = Number of patch project X *effort to reapply the modification* X *labor rate*

$$= \quad N \text{ X } T_R \text{ X } L \tag{5}$$

Thus, with these metrics, maintenance manager will be in a better position to charge the ongoing maintenance cost of the modification to the respective user department. Alternatively, this information can be used to convince the system user department to delay or forego the maintenance, based on a more accurate assessment of total perceived benefits and estimated costs.

FUTURE TRENDS

Many organizations start to recognize the importance of collecting ERP system's performance metrics such as inventory level, operational costs, schedule compliance, and on-time delivery (Jutras, 2007). Like other software systems, ERP system is not a panacea for all. ERP is built to be generic in order to meet a wide range of clients needs. Thus, while some clients try to change their business processes, some change the standard code in order to incorporate their unique business processes where they perceive critical for competitive advantages. Also, although ERP software provides a comprehensive set of business applications that can serve different departments under a single system, most companies still maintain their idiosyncrasy legacy systems and some buy best-of-breed packaged software from different vendors. These are because of unwillingness or resistance to replace a system that is still working, and the packaged software does not meet their requirements or is simply not good enough. Besides, there could also be owing to economy slowdown, wanting to avoid vendor lock-in, waiting for the Web-application (erpwire.com, 2006b) and mobile-application (erpwire.com, 2006a) to mature, and so forth. However, multi-system leads to integration problem. As a consequence, time and effort need to be invested in order to make disparate systems talk to each other. Some perceive that the answer to this is the Web and mobile application. But, as far as Web application is concerned, there are a number of issues yet to consider and address, that is, cost, benefit, network bandwidth and

infrastructure, threats and risks, security, and ethics. Also, developing mobile ERP application can be very complicated due to non-standardization in mobile devices (e.g., various sizes and shapes), and small screen display; it's not simply the broadband or bandwidth boost issue. Moreover, in light of growing customer base of the ERP system, it is valuable to investigate how ERP maintenance and upgrade could be better managed. How patches implementation can be better queued and implemented to achieve economy-of-scale? What and how process model will best describe activities in ERP maintenance and upgrade?

KEY TERMS

ERP Modification: A type of maintenance request which results in changes being made to the existing ERP (standard) code and custom objects being created.

ERP Software Maintenance Data (or Data Item): ERP software maintenance quantitative indication of the extent, amount, dimension, capacity, size, or characteristic of particular attributes of a task or activity in a process.

ERP Software Maintenance Metric: ERP software maintenance measure that is derived from data, and is quantifiable, meaningful and used for strategic, tactical, and/or operational purposes.

ERP Vendor's Standard Code: Program code that is

without any modification or custom development at all.

ERP Vendor's Supported-Version: An ERP version that is still supported by the ERP vendor. This means that the vendor will provide patches for bug fixes and minor enhancements for this version.

Ongoing Maintenance Costs: Additional costs, besides the initial implementation costs, incurred as a result of upkeeping some software code or objects created in previous maintenance request.

Patch Implementation Costs: Costs incurred in implementing (usually) a batch of patches provided by the ERP vendor. As custom code or previous modifications may be overwritten while implementing the patches, usually these costs also include the costs of reapplying previous modifications.

Enterprise Resource Planning and Integration

Karl Kurbel
European University - Frankfurt (Oder), Germany

INTRODUCTION

Enterprise resource planning (ERP) is a state-of-the-art approach to running organizations with the help of comprehensive information systems, providing support for key business processes and more general, for electronic business (e-business). ERP has evolved from earlier approaches, in particular, materials requirement planning (MRP) and manufacturing resource planning (called MRP II) in the 1980s. The focus of MRP and MRP II was on manufacturing firms. The essential problem that MRP attacked was to determine suitable quantities of all parts and materials needed to produce a given master production schedule (also called a "production program"), plus the dates and times when those quantities had to be available. Application packages for MRP have been available from the 1960s on. In the beginning, they were mostly provided by hardware vendors like IBM, Honeywell Bull, Digital Equipment, Siemens, etc. MRP was later expanded to *closed-loop MRP* to include capacity planning, shop floor control, and purchasing, because as Oliver Wight (1884) puts it: "Knowing what material was needed was fine, but if the capacity wasn't available, the proper material couldn't be produced" (p. 48).

The next step in the evolution was *MRP II (manufacturing resource planning)*. According to the father of MRP II, Oliver Wight, top management involvement in the planning is indispensable. Therefore, MRP II expands closed-loop MRP "to include the financial numbers that management needs to run the business and a simulation capability" (Wight, 1984, p. 54).

Enterprise resource planning (ERP) has its roots in the earlier MRP II concepts, but it extends those concepts substantially into two directions. ERP takes into account that other types of enterprises than those producing physical goods need comprehensive information system (IS) support as well, and even in the manufacturing industry, there are more areas than those directly related to the production of goods that are critical for the success of a business.

BACKGROUND OF ERP

The key issue of ERP is integration (Langenwalter, 1999). While stand-alone solutions—sometimes quite sophisticated information systems—for various areas of a business have been available before, ERP takes a holistic approach. Instead of isolated views—on procurement, on manufacturing, on sales and distribution, on accounting, etc.—the focus is now on integrating those functional areas (Scheer & Habermann, 2000). The need for integrated systems has been recognized by many, but Germany-based SAP AG was the first to put them into reality. SAP's early success as worldwide market leader comes largely from the fact that this company actually designed and implemented business-wide integrated information systems. The lack of integration of information systems has created a variety of problems. The most serious ones are the following:

- Redundancy (i.e., the same information is stored and maintained several times)
- Inconsistency (i.e., information about the same entity stored in different places is not the same)
- Lack of integrity (i.e., databases where such information is stored are not correct)

Mistakes, wrong decisions, and additional work are some of the consequences resulting from these problems. Consider, for example, data about customers. Such data are often entered and maintained in a sales and distribution information system (customer orders), then again in the dispatching system (delivery orders), and perhaps once more in a financial accounting system (invoices). Not only is this redundant and means additional work, but also the same attributes may even stand for different things. For example, an "address" field in the sales and distribution system may represent the address of the customer's procurement department, whereas "address" in the dispatching system is the place where the goods have to be delivered.

Integration of information systems can be considered from several perspectives: from the data, the functions, the operations, the processes, the methods, and the software perspectives. The most important aspects are data integration, operations integration, process integration, and software integration:

- **Integration** of *data* means that data models and databases are unified so that all departments of an enterprise use the same data entities, with the same values.

- **Integration** of *operations* requires connecting individual operations, or steps of a business process, with preceding or succeeding operations, respectively.
- **Integration** of *processes* means that interfaces between different business processes are explicitly considered (e.g., connections between order processing and flow of material control).
- **Integration** of *software* means that different programs (e.g., information systems for different business functions, can run together and use each other's data and operations.

Those aspects of integration have always been considered important requirements for effective business information processing, but how does one actually obtain enterprise-wide integrated information systems?

Because most organizations have been using information systems in various business areas for quite some time, one way is to integrate those stand-alone systems subsequently. This approach has been discussed and practiced under the concept of "software reengineering," often related to the term "legacy systems" for the information systems to be integrated (Miller, 1997; Seacord et al., 2003).

The other approach to obtain integrated information systems is obviously to start developing them from scratch. In such a situation, information structures can be modelled and designed on the drawing board in an enterprise-wide manner, at least in theory. Practical experiences have shown that developing comprehensive information systems for all areas of a business is a giant task. That is why such systems have rarely been developed as individual solutions. Not only is the investment needed very high, but also manpower and know-how to develop such systems are often beyond the means of a single company. Therefore, comprehensive integrated information systems have mostly been developed by dedicated software and consulting companies. In the 1970s and 1980s, those systems were named with rather general terms, like standard packages or integrated business information systems, until the terms "enterprise resource planning" and "ERP system" emerged in the 1990s. In fact, the term "enterprise resource planning" has been coined by the software industry and not by academia.

Today there is a common understanding of what the term stands for. The definition used in this article is as follows: An enterprise resource planning system (ERP system) is a comprehensive information system that collects, processes, and provides information about all parts of an enterprise, automating business processes and business rules within and across business functions partly or completely.

Alternatively, an ERP system may be defined as a set of integrated information systems rather than as one system. This depends on the perspective of the viewer. For the user, an ideal ERP system will behave like one enterprise-wide information system, with one database, and one common user interface. Nevertheless, such a system may be composed of many subsystems and many databases, as long as they are well integrated.

COMPONENTS OF AN ERP SYSTEM

Horizontal and Vertical Views of Enterprise Resource Planning

An ERP system integrates information, processes, functions, and people into one coherent system (Brady et al., 2001). Such a system supports all horizontal business functions and all vertical levels of a business (operational, tactical, and strategic). Figure 1 illustrates this view in a simplified information systems pyramid. Each component may be seen as a functional subsystem. In a horizontal perspective, systems are integrated along the value chain. The vertical direction asks for integration of operative systems with their corresponding value-oriented accounting systems; reporting and controlling systems; analysis and management information systems; and long-term planning and decision support systems (Scheer, 1994, p. 5).

A typical ERP system provides components like the ones shown in Figure 1, arranged and extended in one way or another. As an example of integrated information systems, the mySAP ERP system is described subsequently.

An Example: SAP ERP

SAP ERP has evolved from SAP R/3 which is still the most frequently installed ERP system. SAP ERP is based on SAP NetWeaver as technology platform (SAP, 2006b). Encompassing all levels of the pyramid, SAP ERP is logically structured into the following modules (short descriptions are taken from SAP, 2006a, 2006b):

Analytics

- Strategic enterprise management—Supports the top level of the pyramid in Figure 1: integrated strategic planning, performance monitoring, business consolidation, and stakeholder communication; provides tools for planning and executing the strategies: balanced scorecard, value-based management, financial statement planning, risk management, investment planning, and more
- Business analytics (financial, operations, workforce analytics)—Supports managers with methods and tools for financial and management reporting, financial planning, budgeting and forecasting, profitability management, product and service cost management,

Figure 1. Integrated business information systems (Scheer, 1994, p. 5)

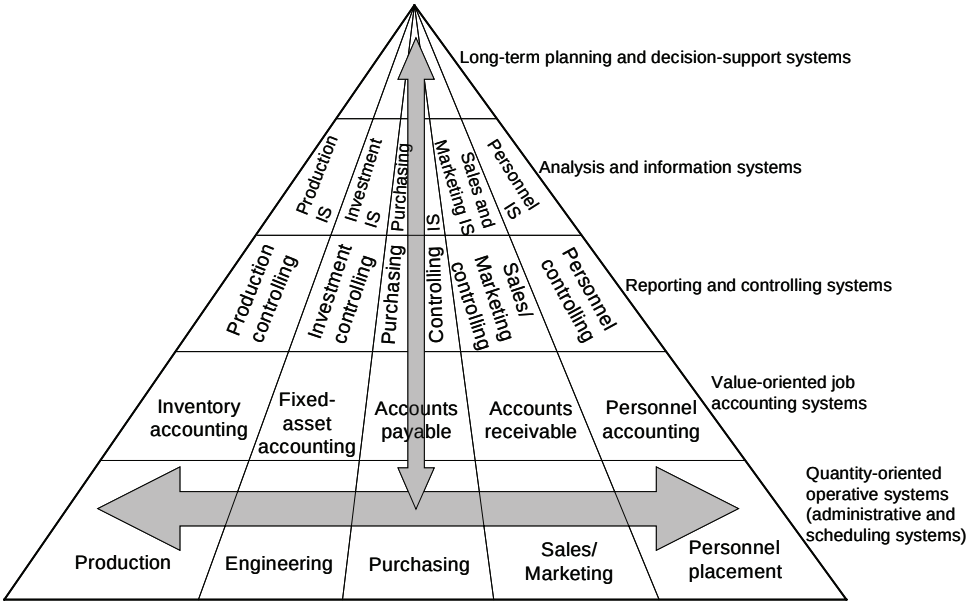

Figure 2. Application domains and modules of SAP ERP (SAP, 2006b)

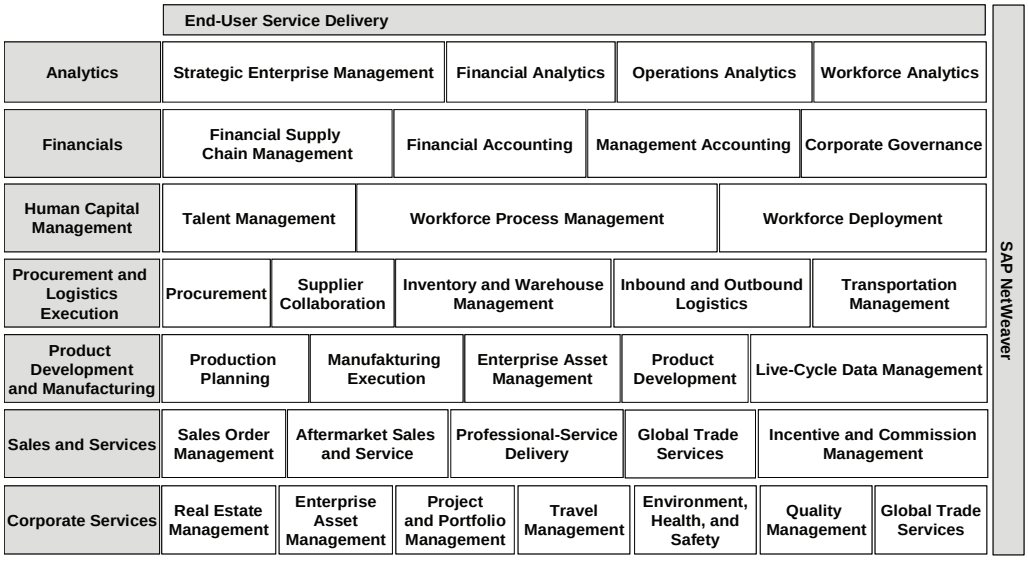

overhead cost management, working capital and cash-flow management, etc.; provides analytical functions for procurement, inventory and warehouse management, manufacturing, transport, sales, customer service, quality management, enterprise asset management, program and project management, and more. [In Figure 1, those functions, tools, and methods belong mostly to levels 2 (analysis and information systems) and 3 (reporting and controlling information systems).]

Financials

The Financials module supports several application areas that are located on level 4 of the pyramid:

- **Financial accounting:** Processing of incoming and outgoing payments, cash flows; provides general ledger, accounts receivable, accounts payable, fixed assets accounting, inventory accounting, tax accounting, financial statements, and more; helps to monitor financial transactions; supports business analysis through combined planning, reporting, and analysis of competitive measures
- **Managerial accounting:** Provides profit center accounting, cost center and internal order accounting, project accounting, product cost accounting, profitability accounting; supports investment management, revenue and cost planning, transfer pricing, etc.
- **Financial supply chain management:** Supports financial collaboration within the enterprise and its business networks; provides credit management, cash and liquidity management, treasury and risk management, and more
- **Corporate governance:** Helps to ensure that the objectives, rules and regulations under which the corporation is directed and controlled are being followed and met.

Human Resources

The human resources module is comprehensive, including functionalities of the operative, administrative level (level 5) and the value-oriented level (level 4).

- **Talent management:** Supports recruiting and talent management, performance management, compensation management for various modes (e.g., performance- and competency-based pay)
- **Workforce process management:** Provides the central repository for employee data; integrates the information with other SAP business applications, especially Financials and Operations; supports time and attendance processing (planning, managing, and evaluating the working times and activities of internal and external employees); handles working-time provisions determined by companies themselves, by standard agreements, or required by law; handles all payroll processes, supports current legal regulations and collective agreement specifications, and ensures compliance with regulatory changes
- **Workforce deployment:** Provides project resource planning, resource and program management (i.e., resource management, project portfolio management, project execution, and skills management) and specific solutions for retail personnel and call centers.

Procurement and Logistics Execution

This module supports the bottom level of the pyramid through quantity-oriented operative subsystems for daily operations, including support for planning and execution.

- **Purchase order management:** Provides conversion from demands to purchase orders, issuance, and confirmation of purchase orders; supports purchasing of materials and services (for example, subcontracting for components)
- **Supplier cooperation:** Helps to streamline information supply and communication with and among suppliers
- **Inventory and warehouse management:** Comprises warehousing and storing (warehouse-internal movements and storage of materials) and managing physical inventory for the company's own stocks (periodic, continous, etc.)
- **Inbound and outbound logistics:** Supports inbound processing (all the steps of an external procurement process that occur when the goods are received) and outbound processing (all steps to p**repare and ship goods to their destination)**
- **Transportation management:** Provides transportation planning (routing, carrier selection, etc.) and execution (shipment orders), freight costing, and legal services

Product Development and Manufacturing

With the help of this module, engineering and design, creating relevant product data, and planning and executing manufacturing operations are supported.

- **Product planning:** Provides typical MRP (materials requirement planning) functionality: computing quantities and due dates for production orders and purchase requisitions through lead-time scheduling,

depending on buffers, operation times, lot-sizing rules and so on

- **Manufacturing execution:** Supports the process of capturing actual production information from the shop floor to support production control and costing processes; supports a variety of concepts: make-to-order, repetitive manufacturing, flow manufacturing, shop-floor manufacturing, lean manufacturing, process manufacturing, and batch manufacturing
- **Product development and life-cycle management:** Cover the life-cycle of product related master data such as product structures, routings and documents from invention to phase-out. Provide document management, product structure management (including bills of materials), recipe management, integration of CAD (computer-aided design), PDM (product data management), and GIS (geographical information system) data, and more.

Sales and Services

The Sales and service module addresses the customer focusing processes like selling products and services and providing aftermarket services.

- **Sales order management:** Supports quotation and order management (creating and processing orders, including pricing and scheduling orders for fulfillment) including inquiries and follow-up orders; provides mobile-sales, billing, and contract-management functionalities
- **Aftermarket sales end service:** Helps to manage a customer's product configuration (installation and configuration management, including definition of the product hierarchy, management of serial numbers, measurements, document management, and engineering change management), service contracts, planned services, warranties, and so on
- **Professional-service delivery:** Provides capabilities for selling, planning, delivering and billing project-based services
- **Incentive and commission management:** Helps to design incentive compensation plans, calculate variable compensation (e.g., direct sales commissions), carry out evaluations of performance and cost results, and more.

Corporate Services

The Corporate Services module provides comprehensive support for resource-intensive corporate functions including the following:

- **Real estate management:** Provides tools to support real-estate property acquisition and disposal, property portfolios, functions to help users lease and manage the real estate portfolio, etc.
- **Project and portfolio:** Provides functions for project (project structures, costs, budgets, workforce and resource planning, scheduling activities, etc.), project execution (monitoring project progress analysis/earned value analysis, progress tracking, etc.)
- **Travel management:** Provides functions for travel request and pre-trip approval, travel planning and online booking, travel expense management, services for mobile staff, and more
- **Environment, health, and safety:** Supports a variety of functions for product safety, handling of hazardous substances, transportation of dangerous goods, waste management, etc.; allows companies to take preventive care of their employees' health; schedules medical examinations and testing for workers; manages emissions for air, water, and soil; monitors and controls plant emission sources.
- **Quality management:** Supports quality engineering according to the ISO 9000 standard, quality assurance and control (quality inspections, statistical process control, traceability, etc.), quality improvement (audit management according to ISO 19011, problem/complaint management, corrective and preventive action, etc.)

This overview of components of the SAP ERP system illustrates the wide range of functions that support ERP nowadays. The reader interested in details of ERP functionality is encouraged to study the products' Web sites. Descriptions of the above functions can be found in SAP's electronic and printed documentation (e.g., SAP, 2006a, 2006b). Other vendors' ERP systems are outlined below.

THE MARKET FOR ERP

ERP systems have been around for about two decades now. All large and medium-size companies use such systems today, and more small companies are catching up. Well-known ERP systems in use include R/3 Enterprise, and SAP ERP (by SAP AG, Germany), Oracle's E-Business Suite (by Oracle, USA), Microsoft Dynamics, and infor: COM (by Infor Global Solutions, formerly Germany, now USA). Well-known ERP systems such as iBaan Enterprise, J.D. Edwards, PeopleSoft, Navision and many more have disappeared, either bought by competitors or gone up into other systems of the vendor.

Names and vendors are changing, as there is plenty of dynamic in the ERP market. Mergers and acquisitions and an ongoing market concentration can be observed year by year.

Although there is still a fairly large number of ERP vendors, a handful of them dominate the ERP market worldwide. The global market leader by far is SAP AG from Walldorf (Germany). Followers are Oracle, Microsoft, Infor, and Sage.

FUTURE TRENDS

While ERP continues to be the core of any integrated business software, the focus has shifted toward advanced user support, like Business Intelligence (Biere, 2003) and Knowledge Management (Davenport et al., 1998; Earl, 2001), and inter-organizational support of electronic business, in particular, supply chain management and customer relationship management. As those areas are closely related to ERP, all major vendors have extended their systems to support them as well. *Customer Relationship Management (CRM)* is an approach to develop a coherent, integrated view of all relationships a firm maintains with its existing andpotential customers (Laudon, 2007, p. 59). Nowadays, many channels are available for enterprises and customers to be in contact with each other: retail stores, telephone, e-mail, electronic shopping on the Web, mobile devices, etc. CRM systems try to consolidate customer information from all those channels and integrate the firm's diverse customer-related processes.

The major focus of ERP is to support the internal business processes of an organization. However, business activities do not end at the limits of one's own company. A natural extension of ERP is, therefore, s*upply chain management* (SCM; Ayers, 2001). SCM looks at the organization's business partners, in particular at the suppliers and their suppliers. In addition, many methodological and technical shortcomings of ERP have been removed or at least improved in SCM. Those improvements have been discussed in the literature under "Advanced Planning and Scheduling" (e.g., Meyr et al., 2002) and were implemented in SCM solutions by SCM vendors.

One example of such improvements is the use of optimization methods, like linear programming, mixed- integer programming, constraint propagation, and heuristics like genetic algorithms to solve production and distribution planning problems. Another example is pegging, i.e., creating, maintaining, and evaluating relationships between purchasing orders, production orders, transportation orders, and customer orders across entire supply networks worldwide.

CONCLUSION

ERP is a comprehensive approach to running organizations with the help of computer-based information systems. Such systems, so-called ERP systems, support all major areas of a business. ERP systems are integrated systems, with respect to information, processes, functions, and people. Usually, those systems are very large, developed by specialized software firms. The worldwide market leader is, by far, Germany-based SAP AG, with its current systems R/3 Enterprise and SAP ERP. Except for small enterprises, almost all of today's companies use ERP systems for their ongoing business.

Extensions of ERP systems can be observed at the former limits of ERP: in CRM, the focus is on dedicated customer support; the focus of SCM is to help organizations plan worldwide supplier–buyer networks and to act successfully within such networks; business intelligence enables enterprises to behave in an "intelligent" way (e.g., addressing the most promising customers well-aimed); knowledge management helps to formalize and preserve important knowledge in an organization; and information system support for key areas, like the before-mentioned areas, is provided both by ERP vendors and by specialized software and consulting firms

KEY TERMS

Data Integration: Unifying data models and databases so that all departments of an enterprise use the same data entities, with the same values.

Enterprise Resource Planning (ERP): The current state-of-the-art approach to running organizations with the help of information systems that provide support for key business processes and, more general, for electronic business (e-business).

ERP System (Enterprise Resource Planning System): A comprehensive information system that collects, processes, and provides information about all parts of an enterprise, automating business processes and business rules within and across business functions, partly or completely.

Operations Integration: Creating logical connections of individual operations, or steps of a business process, with preceding or succeeding operations, respectively.

Process Integration: Defining and automating interfaces between different business processes explicitly.

SAP: Software company based in Walldorf (Germany); market leader in ERP software worldwide. SAP is an abbreviation of the company's German name "Systeme, Anwendungen, Produkte in der Datenverarbeitung" (systems, applications, products in data processing).

Software Integration: Connecting different programs so that they can run together and use each other's data and operations.

Entrepreneurship in the Internet

Christian Serarols-Tarrés
Universitat Autònoma de Barcelona, Spain

INTRODUCTION

The increasing development of information technologies (IT) has significantly affected both firms and markets. IT is currently changing the world in a more permanent and far-reaching way than any other technology in the history of mankind (Carrier, Raymond, & Eltaief, 2004). A new economy, where knowledge is the most important strategic resource, is forcing firms to review their traditional routines and take advantage of the tools able to create new value.

Nowadays, there are two types of firms using this new IT. On the one hand, firms with physical presence (traditional companies) use the Internet as a new distribution channel or alternatively as a logical extension of their traditional business. On the other hand, there are dotcoms, Internet start-ups, or *cybertraders* (European Commission, 1997), which have been specifically conceived to operate in this new environment.

A number of scholars have attempted to explain the creation of new ventures from many different theoretical perspectives (economics, psychology, and population ecology among others) and have also offered frameworks for exploring the characteristics of the creation process (Bhave, 1994; Carter, Gartner, & Reynolds, 1996; Gartner, 1985; Shook, Priem, & McGee, 2003; Veciana, 1988; Vesper, 1990; Webster, 1976). However, despite the growing literature in this area, few studies have explored the process of venture creation in dotcom firms.

Cyberentrepreneurship is still in its emergent phase, and there is more to know about the phenomenon and the elements of the venture creation process (Carrier et al., 2004; Jiwa, Lavelle, & Rose, 2004; Martin & Wright, 2005). What are the stages they follow to create their firms? This article attempts to answer this question. First, we analyse the entrepreneurial process of a new firm's creation. Second, we shed some light on how this process is applied by cyberentrepreneurs in starting their businesses based on an in-depth, multiple case study of eight entrepreneurs in Spain.

BACKGROUND

Process of New Venture Creation

A framework for describing new venture creation integrates four major perspectives in entrepreneurship, for Gartner (1985): (1) the individuals involved in the creation of the new venture, (2) the activities undertaken by those individuals during the creation process, (3) the organisational structure and strategy of the new venture, and (4) the environment surrounding the new venture.

According to Gatewood, Shaver, and Gartner (1995) the *venture creation process* is defined as "the process that takes place between the intention to start a business and making the first sale"(p. 374). Much of the research on process of venture creation has assumed a linear, unitary process, composed of a set of activities, beginning with the recognition of a business opportunity and culminating with the first sale (Galbraith, 1982; Kazanjain & Drazin, 1990; Liao, Welsch, & Tan, 2005; Shane & Venkataraman, 2000). However, other authors have included activities occurring after the founding of the venture or its first sales (Bhave, 1994; Shook et al., 2003; Veciana, 2005; among others). For example, Veciana (1988, 2005) includes a consolidation stage where the entrepreneur squeezes out undesirable partners to establish his leadership and guarantee the survival of the firm. Another typical approach to study the process of venture creation is to examine the activities, key milestones, the frequency, and time of those activities (Carter et al., 1996; Gatewood et al., 1995; Kaulio, 2003). Empirical explorations (Hansen & Bird, 1997; Reynolds & Miller, 1992) have found that no one pattern or sequence of events is common to all emerging organisations. Despite this evidence, a recent exploratory study on the entrepreneurial process of creating a firm on the Internet (Carrier et al., 2004) has revealed that the cyberentrepreneurs had gone through basically the same stages, though they belonged to different industries.

According to Baker, Miner, and Eesley (2003) there are two approaches when studying the founding process in entrepreneurship research. First, a design-then-execution framework that assumes a mainly linear process in which start-up intentions and gestation typically lead to the creation of a plan. We refer to this model as *design-precedes-execution* (DPE). In contrast to this model they describe an improvisation framework, where design and execution of the start-up converge. In this case, founders may plunge into the start-up process, designing the firm as they create it.

Figure 1. Comparing the core stages in the start-up process

Pre-venture stage	Organisation stage	Financial jeopardy	Introduction of the product	Squeezing out partners	Outcome stage
Venture idea	Set up operations	Prototypes and channels established	Produce the product	Gain control by the entrepreneur	Survival

Webster (1976)

Proof of principle	Prototype	Model-shop	Start-up
Create a solution: configuration of the business idea	Refine developed technology	Produce and test a number of models	Produce the product (volume production)
Develop nascent proprietary technology	Produce the first prototypes		First sales

Galbraith (1982)

Gestation	Creation	Launching	Consolidation
Childhood	Look for a business opportunity	Create a team	Survival
Antecedents and professional knowledge	Create a solution: configuration of the business idea	Obtain and organise the means	Squeezing out partners
Incubator	Evaluate this opportunity	Develop the product/service	All under control
Precipitation condition	Write the business plan	Find out financial aid	
Decision of creating a new venture	Formal/legal constitution of the firm	Launch the product/service	

Veciana (1988, 2005)

Opportunity recognition	Technical set-up and organisation creation stage	Exchange stage
Business idea	Garner resources	Market feedback

Bhave (1994)

Entrepreneurial intent	Opportunity search	Decision to exploit	Explotation
Individual intent to create a venture based on perceptions of feasibility and desirability, and propensity to act upon opportunities	Search the business opportunity based on individual's alertness to new opportunities and past experiences	Decision to exploit based on risk propensity, motives and attitudes	Finding the resources, planning, networking, selling

Shook et al. (2003)

Business idea	Market needs	Identification business opportunity	Feasibility	Search for support	Venture creation
The initial vision or idea is generated	Determine the needs of different potential customers for the products	Identify opportunities, propose innovative solutions to market needs	Develop prototypes, write a business plan, or find contracts	Gather all the needed resources	Formal/legal constitution of the firm and first sales

Carrier et al. (2004)

Models of Venture Creation, a Sequence of Events

A number of scholars have offered numerous stage models of venture creation process. This approach implies that an additive combination of events will lead to the creation of a new firm. Yet there is little empirical evidence that either validate or fail to validate the linear model (Liao et al., 2005). An in-depth revision of the different stage models in the literature review reveals some similarities that should be noticed (see Figure 1). We can summarise all different stages in the aforementioned *stage models* in just three main steps:

1. *Concept (or gestation) stage* is where the idea of the new venture is set up. This stage is influenced by entrepreneur's background, and it culminates with the identification of a business opportunity. The precipitation condition, the business opportunity, and the incubator play a principal role in this stage.
2. *Planning stage* is where a sequence of steps is essential to coordinate in detail what resources will be needed to produce a product or to offer a service. Once the entrepreneur has detected the business opportunity and has refined it, the next step is to plan how he/she is going to carry on with the idea. This is the stage where the entrepreneur has to transfer what he/she has "in mind" to a plan. The business plan plays a major role in this stage.
3. *Implementation stage* is when the business begins to run. In this stage, all the plans are ready, and the firm begins to operate. Whatever has been planned is now being put into practice. The team is created, resources are gathered, financial aid is obtained, and the product or service is launched.

It is important to notice that these models vary from one author to another, stressing the step they consider most important. However, there are common features that make one able to find a core process. In fact, these stages are not quite well differentiated, with one step usually ending before the other begins.

Table 1. Technical specifications of the study

Sample segmentation criteria
1. Proportion of sales turned over on Internet > 95%.
2. Age of operation: > 3 years to ensure that they had all moved through basic start-up phases.
3. Belongs to already-existing business group: subsidiaries of already-existing groups were eliminated.
4. Main activity of firm: attempt to include widest range of activities, at most one firm per activity.

DISCUSSION

Via multiple case studies, it was hoped to provide an in-depth exploration of each cyberentrepreneur and give rich insights into the entrepreneurial process in such firms. Four sample segmentation criteria were used (see Table 1), and it was done a Web site analysis of the preselected firms.

The cyberentrepreneurs in the sample were asked to provide a detailed history of the process of venture creation. This process involved the activities from the time they first had the intention to start a business until they finally launched the firm and had the first sales. The information was coded, analysed, and the process was reconstructed.

Gestation Stage

It was interesting that most of the entrepreneurs had in mind the idea to create a firm but they had not detected an opportunity first. Yet, they actively began to search for a business opportunity when the Internet became widespread for commercial purposes in Spain in the late 1990s. They all realised that this new distribution channel had many advantages in comparison to others, they would not need big investments nor high operation costs to create and run a venture. Another factor that helped them to detect an opportunity was the fact that they were all aware of the potential offered by the Internet by either working in the field of IT, or doing research on the topic.

The approaches for the opportunity detection process took different forms in all cases. First, there is a wide group of cyberentrepreneurs that tried to combine their hobbies with the potential of the Internet. For example, A.com detected a gap in the Spanish digital photography retailer's market on the Internet. This type of photography was emerging, thus there was the need for a Web site that could aggregate the offer and the demand for these products. The owner of H.com was really interested in the cultural industry, especially in theatre and concerts. He had a broad network of friends working in this industry and he detected a gap in the market for selling last-minute seats at low cost.

Second, there are a couple of cyberentrepreneurs that were struck by a signal from the market, namely the need to facilitate the access to information. This eventually evolved in the possibility of developing software that would, automatically and in real time, help to match the offer and demand for a certain type of content. The owner of G.com invented the first software platform for content aggregation purposes.

Planning Stage

We identify a set of firms that were not founded through a process involving design or planning followed by execution. In these founding processes, the design of the new business occurred at the same time that the first implementation steps were being taken. We have labelled these founding processes as *improvisational*. For example, the owner of B.com did not conduct any attempt to design his business before beginning its execution, neither formally nor informally, nor did he systematically survey the potential market for his products. Instead, he began by legally constituting his firm and launched his Web site, intending to test it with real customers.

Secondly, there is a group of cyberentrepreneurs that spent a lot of time identifying market needs and the industrial structure of the product/service they were planning to sell. Their approaches to clearly define these business opportunities took different forms in all cases: market surveys, brainstorming, and order studies to marketing research companies, research with universities, and so forth. For example, the owner of C.com extensively researched the off-line market for holiday tourist rentals because there was hardly anything on the Internet at that time. He surveyed many of the existing Catalan tourist housing renting agencies offering them to take part in his booking platform. He was able to collect information about margins, tour operators, distribution channels, and so forth. He also went to the tourist faculty at a university to gather information about the customers and the sector. He ended up with a very good notion of the market needs and the structure of the industry.

Implementation Stage

In this stage, three main behaviours are identified. First, there is a group of entrepreneurs that essentially provided all the resources by themselves, both financial and labour. The owner of F.com went straight into the business with his own resources and only after 3 years of operation, he detected the need to write a business plan. In his opinion, the creation of the firm was a sort of prototype to test its success in the market.

Another group of entrepreneurs decided to involve other people or other entrepreneurs in their projects when they searched for support. This venture creation process could be labelled as *team founding*. C.com had to find partners to fund the business, and to design and execute his technological platform. He gave them some shares of the company in exchange for their contributions. The owner of D.com also had to involve some key partners from the organisation he was currently working for Centro Superior de Investigaciones Científicas (CSIC). This case is somehow unique in comparison to the rest, because D.com had been using facilities and knowledge from CSIC to develop his products. All this, and the fact that CSIC is a public research centre, provoked the involvement of CSIC in the project. Thereby D.com can be considered as a spin-off from the CSIC.

Finally, although E.com can not be considered as a team founding because the firm was already created, the owner also had to enter into a partnership agreement with a technological firm to design and execute his e-commerce portal. In exchange of this portal the owner of E.com gave 35% of the shares to this new partner.

Redefinition Stage

Based on the analysis of the data from the selected case studies, a new phase, called *redefinition stage*, has been detected. In this stage, the firm is already operating, sales are being conducted, and a lot of effort is put on receiving feedback from the market. This phase begins with the first sales and culminates with the redefinition of business opportunity and the adjustments that need to be done to the organisation for its survival. While reviewing stage models literature, we hardly find a redefinition stage. Serarols, Del Aguila, and Padilla (forthcoming) stress the importance of a redefinition stage in digital firms. Based on case studies, they observed that those entrepreneurs who had not redefined their businesses rapidly had many difficulties in surviving and some even died. The cyberentrepreneurs questioned for this study present different behaviours in this stage.

First, there is a group of cyberentrepreneurs that had to redefine their business opportunity because their current products/services did not match customer's needs or customers were not willing to pay for them. For example, D.com had to deal with the conceived idea that Spanish software is lesser quality than foreign software. Moreover, D.com was developing technology that was too advanced for the current Spanish market. Therefore, they had to put off their initial idea of focusing on developing advanced artificial intelligence (AI) software in favour of providing technological consultant services to generate revenues. The owner of G.com realised that advertisers were not investing their money in the Internet after the widely publicised failure of new e-businesses in late 2000/early 2001 so he had to adapt his initial idea of providing a customised e-paper to end users. The founding team of G.com adapted their developed technology and offered online press-clipping, professional services to businesses. Yet, this change enabled the firm to survive. Both enterprises were able to successfully adapt their business models and obtained financial aid from venture capital which led them to grow in sales and size.

A second group of two cyberentrepreneurs has achieved a considerable success, but as the Spanish market was not as big as to generate a critical demand for their products they had to diversify their products to grow. For H.com, selling low-fare tickets for concerts and the theatre was a way to penetrate the market. Soon after their first sales, they introduced

new complementary services based on customer's needs. Those services were budget flights, restaurants vouchers, hotel booking services, and last minute holiday packages. Three years after its foundation, H.com was selling over 10 million euros per year.

Appendix A presents a new venture creation model that reflects how each phase was applied by the cyberentrepreneurs studied. This model does not pretend to be a linear, unitary process because our analysis suggests at least two different patterns approaching new venture creation process in cyberentrepreneurships. First, there is a group of cyberentrepreneurs (B.com, E.com, and F.com) that have followed the following sequence: concept—implementation—planning/redefinition. Another group (A.com, D.com, G.com, and H.com) have followed this pattern: concept—planning—implementation—redefinition.

FUTURE TRENDS

This study has also generated several future research opportunities. First, future research should examine the conditions in which potential entrepreneurs discover opportunities without an active search. The Austrian School considers search unnecessary while some scholars view opportunity search as a natural activity of entrepreneurs (Shane, 2000). Our results suggest that some of the cyberentrepreneurs have created their firms without an active search for an opportunity while others have extensively searched for an opportunity. More work needs to be done on the exploration process that precedes and generates formal recognition of an Internet-based business opportunity. This type of information will certainly be of interest to researchers working on business idea exploration, and to entrepreneurship trainers.

Second, focus may be directed to the nature of start-ups and how it affects the venture creation process. For example, are there real differences in the process of start-ups according to the type of firm being created? It can also be useful to investigate how the venture creation process differs across technology-based and nontechnology-based firms, as well as to detect whether industry characteristics influence them.

Finally, future research should aim to investigate whether the environment could have influenced the redefinition stage. We have to bear in mind that many of these entrepreneurs lived the failure of new e-businesses in late 2000/2001.

CONCLUSION

The results of this research throw some interesting light on a new entrepreneurial form (cyberentrepreneurship) that is likely to become much more widespread with the advent of the new economy. The most important contribution of the paper certainly lies in its observation of the cyberentrepreneurship and the process that guides the creation of dotcom firms and its proposed model incorporating the practices observed.

The process of starting a new venture can be studied stressing a sequence of different steps to follow, or without a structured step-by-step sequence focussing on the key milestones that influence the process. When studying the process as a sequence of events, some similarities come up among different authors. Those similarities help us classify those stages into just three: (1) concept, (2) planning, and (3) implementation. Although a clear sequence of events does not exist one after the other.

While analysing the process of new venture creation in cyberspace, an additional stage is detected: redefinition. This stage begins with the first sales and culminates with the redefinition of business opportunity and the adjustments that need to be done to the organisation for its survival.

Overall, our results suggest that venture creation processes are exceedingly more complex and fluid than we have presumed. Venture creation is more than an orderly, unitary, and progressive path that consists of an accumulating series of events. Although the cyberentrepreneurs appear to have gone through similar stages, many different sequences might be observed. In the proposed model, at least two different patterns approaching new venture creation process can be identified.

KEY TERMS

Cyberentrepreneurs: The individual that creates a firm that is essentially founded upon e-commerce, and whose main activities are based on the exploiting networks using Internet, intranets, and extranets.

Cybertraders (dot-coms): These are companies without significant physical presence, which exclusively operate on the Internet. Using IT, they specialise in a market niche or in cost reduction. Most of them are small companies, and they are only known because of their Webs, though others (Amazon, Cdnow, etc.) have turned into companies of recognized prestige.

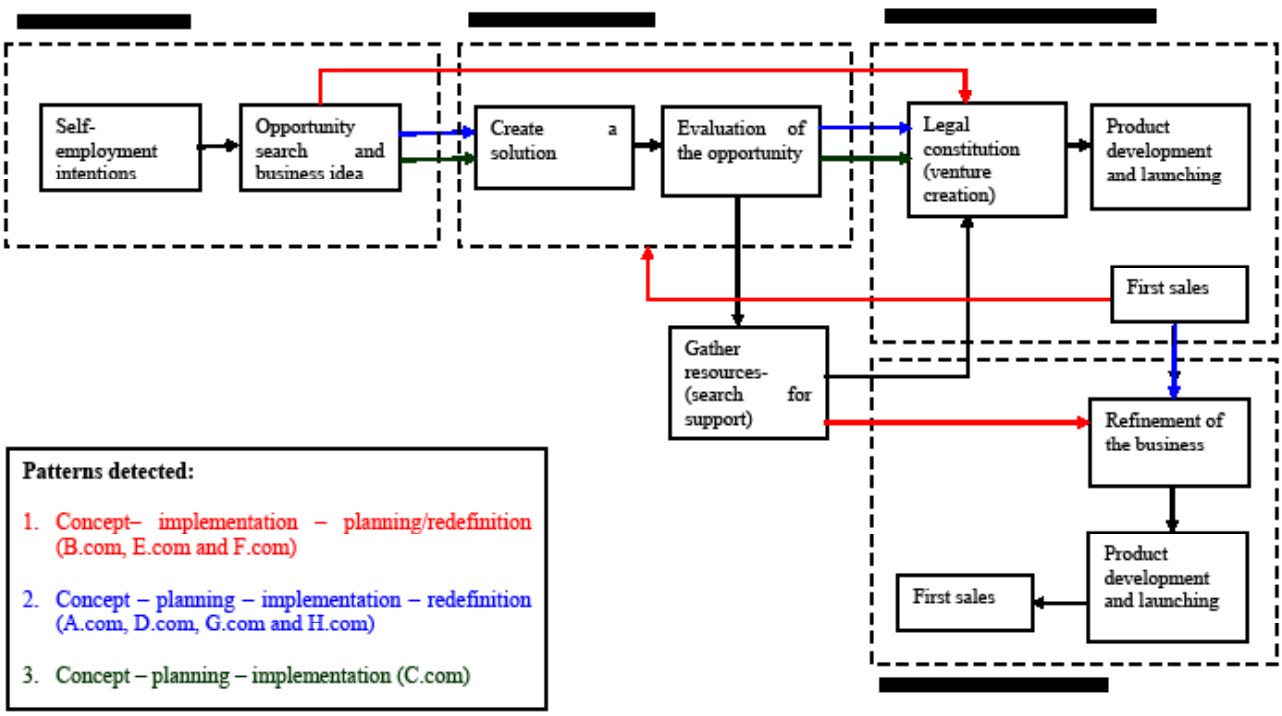
Redefinition Stage: This stage begins with the first sales and culminates with the redefinition of business opportunity and the adjustments that need to be done to the organisation for its survival.

Stage Model: A linear sequence or steps involved in the starting-up through the establishment of a chain of events, cause-and-effect phenomenon that should be followed to create the business.

Web Aggregator: Web aggregator is an entity that can transparently collect and analyse information from multiple Web data sources.

Venture Creation Process: The process that takes place between the intention to start a business and making the first sale.

APPENDIX A.



Patterns detected:

1. Concept– implementation – planning/redefinition (B.com, E.com and F.com)
2. Concept – planning – implementation – redefinition (A.com, D.com, G.com and H.com)
3. Concept – planning – implementation (C.com)

Envisaging Business Integration in the Insurance Sector

Silvina Santana
Universidade de Aveiro, Portugal

Vítor Amorim
I2S Informática-Sistemas e Serviços, Portugal

INTRODUCTION

Data, information and knowledge are the heart of the insurance business. Each policy is composed of a set of data that can vary substantially. Risk management is a complex process that implies the availability of rich and accurate information and knowledge. In our fast moving world, connectivity and articulation between insurance industry players is therefore mandatory. Information and communication systems and technology (ICST) can provide this connectivity, allowing insurance partners to become closer and able to reach better negotiation, reducing response time and costs and probably creating new business opportunities (Strazewski, 2001).

Insurance intermediaries (brokers and agents) are important players in this scenario. They act as consultants operating independently from insurance companies, being specialists in providing services to their clients, gathering the best solutions thanks to their vast knowledge of insurance companies' products. Consequently, they achieve the best insurance contracts at the least cost (APROSE, 2005a, 2005b).

Being a great value-adding activity, insurance mediation is also very complex. To operate in an effective and efficient way, intermediaries need to establish a good connection with all entities in the industry and electronic business can help insurance intermediaries' business model in both business-to-business (B2B) and business-to-consumer (B2C) dimensions. In B2B, intermediaries establish relations with insurance companies, agents, banks and official entities. In B2C, intermediaries establish relations with their clients, giving them all the necessary assistance in a customized and fast way, since the first contact and during the policy's whole life cycle, offering the best solutions according to their needs.

However, in spite of all the apparent and potential benefits, intermediaries are not grasping all the advantages that electronic business can provide. This definitely relates to a very important issue, the integration level between the different players' information systems.

Analysing the situation from the intermediary perspective, this article exposes the problems faced by intermediaries and insurance companies all over the world when trying to integrate their business electronically and how these can be overcome so that partners can fully benefit from the opportunities here identified. The methodology used includes a deep case study involving a Portuguese intermediary having a significant level of integration with an insurance company. Results are compared with situations reported in other countries, leading to the conclusion that most of the problems and barriers here identified are being experienced worldwide. Conclusions bring significant implications for information science and technology (IS&T) and add important contribution and knowledge to research in this area.

BACKGROUND

This case study involves three entities: an insurance intermediary, an insurance company and a software house specialized in the development of technological solutions for the insurance industry.

A deep study of the software house clients highlighted the case of an insurance intermediary having a significant level of integration with an insurance company. Interviews with representatives from the different companies have shown that in spite of strong and continued technological and financial efforts the parties were still far from having reached a satisfactory solution. Legal, technical and organizational issues seem to be burdening the integration process, maintaining an inefficient status quo and preventing the parties from grasping the desired benefits. It was then decided to deepen the analysis in order to foster knowledge in the area and assist in the development of proper solutions.

The intermediary in our case study uses GIS® Agents & Brokers (developed by I2S Informática-Sistemas e Serviços SA: www.i2s.pt) for managing its own business, but also to transfer data to/from the insurance company Web site. Any break in the electronic data flow, internally or between parties, adds additional costs at several levels. Information systems must support the integration of processes across the extended value chain.

The insurance company in this study has an Internet public site which allows the intermediary and the general public to make online proposals and product simulations and knowing available products. A username and a password allow partners to access a restricted area where they can find, for example, product manuals and rates, proposal forms and products' general conditions. In the same area, the same username and password give access to a new restricted area of the extranet named Broker Information System, where it is possible, among other operations, to view online several brokers' portfolio data (clients, policies and claims) and to access a file transfer area.

This file transfer area allows the intermediary to receive/send data from/to the insurance company on a periodic basis (might be daily). The application GIS® Agents & Brokers includes a set of data transfer modules that, according to the insurance company format, can integrate data from the files received into the GIS® Agents & Brokers database and generate new ones from this database.

Besides communicating with the insurance company, GIS® Agents & Brokers can also import/export files from/to banks and export data to agents. When the intermediary needs to integrate data with some defined clients, it is possible to develop a customized application. In spite of sending/receiving data to/from the ISP (Instituto de Seguros de Portugal (Portuguese Insurance Institute): www.isp.pt), a regulatory body, there is no data exchange that interacts directly with GIS® Agents & Brokers.

The study revealed the existence of an additional integration module used exclusively between the insurance company and some of its brokers using GIS® Agents & Brokers. Data concern claims and only flow from the insurance company to the intermediary, without integrating with GIS® Agents & Brokers. The claims module processes data sent by the insurance company and allows data browsing by means of an Internet browser.

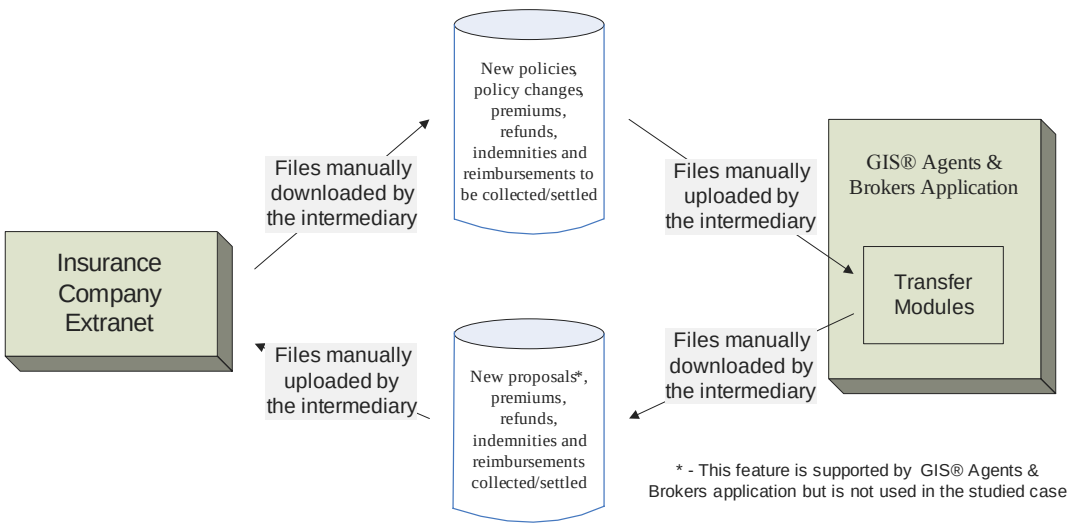
For detailed information and technical aspects, impossible to address here due to space restrictions, please refer to Amorim and Santana (2007) where you may find diagrams representing processes of interaction between the several entities and the electronic business platforms; data flow to/from the several transfer modules which integrate the application GIS® Agents & Brokers; and business terminology.

ELECTRONIC DATA EXCHANGE AND INTEGRATION VIA THE INTERMEDIARY APPLICATION

GIS® Agents & Brokers includes a set of modules which allow data to be integrated to and extracted from the intermediary information system. As depicted in Figure 1, by means of file manipulation each transfer module integrates data supplied by the several entities or extracts data to be supplied to them. The exchanged files are composed of plain text formatted in columns. There is no use for XML. Initially, files were supplied to/by the several modules in floppy disks. Nowadays, there are alternatives, namely the use of e-mail or data download/upload from/to a private extranet area.

The several modules correspond to mediation process data needs and their functioning can be summarized as follows:

Figure 1. Data exchange supported by GIS® Agents & Brokers between an insurance company and an intermediary



- **Extraction of new proposals:** If the intermediary enters new proposals in the system, a module will extract data to be supplied to the insurance company system. In the case under analysis, this module is not being used because the insurance company system cannot store the proposal number sent by the intermediary system or because the intermediary sends proposals that do not match the validation rules of the insurance company. Because frequently partners do not have the same calculation and validation rules, the insurance company may have to adjust some values so that the proposal is in conformity with the products being sold.
- **Integration of new policies:** After analyzing and accepting proposals, the insurance company issues the corresponding policies. Policies' data would be integrated in the intermediary system by a specific module, but in this situation such is not possible. As the insurance company system cannot integrate the proposal number produced by GIS® Agents & Brokers, the proposal and the policy numbers are different and the policy data supplied to the intermediary system cannot be integrated straightforwardly. Data is received by a different module that organizes it in order to be manually checked and integrated. Furthermore, it may happen that some changes have been made by the insurance company to some of the data fields provided in the proposal (such as to the number of characters allowed) and that these changes are not according to the intermediary rules. In such cases, the intermediary may opt to ignore the changes and preserving the data already available in its database. To establish the necessary correspondence, there is a module with a functionality named matching that allows, for each policy of the insurance company, to select the intermediary proposals that might correspond to that policy based on a data set (e.g., the policyholder name, the insurance start date or the sum insured). Manually, the intermediary matches the policy to the corresponding proposal. If proposals have not yet been entered in the intermediary system, he or she can directly accept the data to be integrated. However, if the intermediary does not enter the proposals in the system, then he or she will have to manage them manually (in paper, for example) and there is one situation where this can be quite complicated and inefficient: when the intermediary works with several sellers/agents. Without registering commercial data, the intermediary cannot properly control the production of each seller or agent. Besides that, when the proposal is sent to the insurance company, there is no indication of who has produced it. There is only indication that the proposal has been originated in this intermediary. As there are no proposals registered in the intermediary's system, after policy integration the intermediary has to manually introduce data related to the seller/agent that had produced each proposal. With proposals entered directly in the system, the intermediary does not have to care with this aspect, as commercial data has already been properly registered.
- **Integration of policy changes:** When there are changes to policies (e.g., changes to the address or to the sum insured), the insurance company system supplies the corresponding data to be integrated.
- **Integration of transactions:** Data concerning transactions (premiums, refunds, indemnities and reimbursements) to be collected/settled by the intermediary are supplied by the insurance company. This way, the intermediary can address the policyholders in order to receive/pay what is necessary. If the policyholders go to the insurance company branches instead of addressing the intermediary to pay/receive what is necessary, the insurance company system supplies the resulting data to the intermediary to be integrated. This avoids double collection or payment by the intermediary.
- **Extraction of transactions:** Besides other elements, there is a module that extracts data from transactions collected/settled by the intermediary to be supplied to the insurance company.

When a claim occurs, the insurance company system supplies the corresponding data to be processed by the intermediary claims module so that the intermediary can follow its development. This module is specific to the insurance company studied and does not integrate with GIS® Agents & Brokers.

In some particular situations, intermediary clients may need to supply or receive, in electronic format, a large volume of data. These cases can lead to the development of customized transfer modules.

If the intermediary collects premiums by bank debit, he or she can use another module which allows bank file extraction and integration. If the intermediary works with agents, there is a module that extracts data concerning premiums, refunds, indemnities and reimbursements that agents can collect/settle. If the agents have GIS® Agents & Brokers, then, with another module, they can integrate the data supplied by the intermediary module; otherwise, the agent system must have a functionality that can integrate the data received.

In this case, the intermediary does not exchange electronic data with banks, agents or the ISP. The intermediary also does not use the extranet (GIS® Web) which is part of GIS® Agents & Brokers, and that would allow an integrated view of the contract by the intermediary clients and agents. The product is not being used because the intermediary did not know about its existence.

Every module receiving data from the insurance company has functionalities which allow testing data quality before integrating it in the intermediary application. It is possible to simulate data integration to avoid abnormal data entry. The integration process has the same validation features as the simulation process. In both simulation and integration, the modules produce error printings and indicate what data would be/were loaded successfully. The simulation stage is optional and must be manually selected by the intermediary.

Intermediaries also have to download manually from the insurance company Web site the files that are to be loaded into their systems by the integration modules and have to upload manually the files that were produced by their systems and are to be integrated into the insurance company system.

Several barriers to the adhesion to electronic business have been identified:

- the intermediary and the insurance company have their own visions of business, organizing their own products in a particular and perhaps unique way;
- the integration of data between systems becomes more complex, time-consuming and prone to mistakes due to the lack of normalization, forcing data conversion so that the parties can dialog;
- lapses in data handling, the lack of validation rules and delays in data extraction decrease data quality and, in the limit, can make electronic integration unfeasible;
- parties implement only business facets presenting the best cost/benefit relation;
- some of the processes require manual intervention of the intermediary, originating breaks in the data flow; and
- paper is used in varied circumstances of this business, be it for legal impositions, or due to data validation/checking procedures, hampering complete dematerialization of business.

However, there are many advantages in the adhesion to electronic business in this industry, clearly assumed by the parties involved. These can be found in the following aspects:

- the intermediary becomes much more autonomous from the insurance company;
- the client/agent becomes much more autonomous from the intermediary;
- all benefit from the possibility of using up-to-date forms;
- manual data entry is minimized, with consequent reduction of human mistakes;
- the automatic processing of huge volumes of data in reduced time becomes possible;
- normally, cost reduction is attained;
- partners will be able to provide a better service to the final client.

FUTURE TRENDS

In the insurance industry, the key to electronic business evolution at electronic data integration level consists in the development of a normalized structure where the insurance companies' products can be published. Besides defining data representations, such a structure must also define the rules that relate and validate them. Data could then flow between systems because the rules that support them are the same, avoiding situations where valid data for one entity is not valid to another.

For some time now, the insurance industry has used several Service-oriented Architecture (SOA) approaches to enable electronic business. SOA "is a technical framework that allows faster, lower cost sharing of data and processing power across a heterogeneous IT infrastructure" and "is platform-neutral and uses standard data types, structured text-based messages, and open transport protocols" (Celent & Sun, 2006, p. 3). These text messages are typically written in Extensible Markup Language (XML) and SOA can be used both internally, over an internal TCP/IP network, or externally, over the Internet, in which case it is often referred to as a "Web service" (Celent & Sun, 2006, p. 3).

Web services technology has been advertised as an industry-transforming means of enabling communications among insurers, their business partners and end-customers (O'Donnel, 2004, p. 1). Even if security, performance and standards issues have led to cautious adoption of Web services, the technology brought many benefits for insurers working to integrate applications within the enterprise.

However, in spite of the effort put in the definition of standards, several national standards still prevail (Chesher & Kaura, 1998; CEN, 2003). Not even the problems raised in the past due to the existence of different standards for Electronic Data Interchange (EDI) have prevented the most recent developments at technological level from originating a number of standards that, directly or indirectly, compete with each other. Taking XML as an example, there are several standards competing to ebXML which is a standard developed by the Organization for the Advancement of Structured Information Standards (OASIS) and the United Nations Centre for Trade Facilitation and Electronic Business (UN/CEFACT).

Many efforts are being made to overcome the situation. In 1983, 21 insurance companies in the United States founded an organization named Insurance Value Added Network Services (IVANS) that operates as a communications network for the insurance industry aiming at using technology to increase sales and improve support to clients (IVANS, 2007a).

In 2000, in partnership with a software house from the insurance area, IVANS began the development of a solution for real-time communications between insurance companies and intermediaries named Transformation Station™ (Applied Systems, 2005). This solution is based on the standards defined by the Association for Cooperative Operations Research and Development (ACORD) and supplies, through the Internet, a Web Services communication infrastructure between intermediaries and insurance companies. Intermediaries now have access to a functionality named Single-Entry, Multiple-Company Interface (SEMCI), meaning that through a single data entrance point, they are able to interact with the interfaces of multiple insurance companies. For some types of products, they can, in real time, get the prices, view policies' data and even perform some processing, like claim handling (Fitzpatrick, 2005; IVANS, 2004, 2007b; McKenna, 2005).

Currently, the Council of Insurance Agents & Brokers (CIAB), along with several industry partners, is working on a new "groundbreaking electronic insurance exchange that will give brokers and agents the ability to consolidate their account information, enter the data once and send all material—or parts of it—to a variety of insurers" (CIAB, 2007, p. 15). This exchange is expected to be operational in 2008 (CIAB, 2007).

According to Speer (2007, p. 1), "the exchange takes the real-time, comparative rating, single-entry, multiple-company interface idea a step further." Along with providing producers of all sizes with the ability to perform "once and done" transactions with any number of carriers simultaneously, it works as a content aggregator, making exchange participants' data available in a variety of forms to subscribers. Many believe that this new approach will overcome past failures (Arvidson, 2006; Chordas, 2007; Maciag, 2006), and succeed because it is broker-oriented and broker-driven (Arvidson, 2006).

SEMCI has been the Holy Grail for the brokerage industry (Fitzpatrick, 2005) that intermediaries have waited for more than 20 years (Yates, 2004). The results of the 2006 ACORD-User Groups Information Exchange (AUGIE)-Agency Technology Survey that involved more than 7,500 agency, brokerage and wholesaler professionals show how important SEMCI is in the industry (AUGIE 2006). From the respondents, 48.9% answered that "learning and using various company proprietary systems" was their greatest challenge in supporting automation, while 46.6% quoted "duplicate data entry" as their major automation time waster in doing business today. For 70.6% of the respondents, in the 2 previous years, ease of doing business with a carrier has become an increasingly important factor in the decision to place business with that carrier.

However, despite all technological promises, finding systems that work well for all involved has proved difficult (Chordas, 2007, p. 1). There are still too many proprietary insurer forms and Web sites (Maciag, 2006), and examples of failed implementations abound. In 2006, six leading Lloyd's underwriters came together to develop the system Kinnect to transfer data and documents electronically. "With the loss of 70 million [pounds sterling] (about U.S. $137 million), the project disbanded after Lloyd's withdrew its support, saying the approach was no longer suited to the market" (Chordas, 2007, p. 1). The G6 initiative, that joins six Lloyd's insurers (known as managing agents), followed on the heels of Lloyd's unsuccessful electronic communications system. This system uses ACORD data standards (Chordas, 2007).

Overall, the results seem short from expectations. "The reality of most carriers is that critical costumer and product information is spread across disparate systems," "key channels for serving costumers cannot act in a coordinated fashion, and many core processes are still performed manually." It seems that "existing IT architectures are one of the biggest roadblocks to enhanced efficiency within the industry" (Tulloch, 2005, p. 1).

The insurers' ability to react to the industry fast changes is being hindered by the industry's preponderance of aging core legacy systems. Mainframe systems have run the business and undergone massive investment over decades, but it is now clear that they present many challenges for companies, namely increasing difficulty of integration to new applications, inhibiting data mastery and re-use and impeding reengineering and improvement of process and workflows (Itemfield, 2005).

Most large and mid-size insurers are moving forward by extending the use of critical legacy systems, while adopting ACORD industry document and transaction standards. The results from Celent's third annual survey of senior IT executives, conducted in the fall of 2005, reveals that insurers are now "more inclined to believe an acceptable solution is available in the marketplace. Most large firms are still inclined to assemble best-of-breed components, while many smaller companies prefer end-to-end solutions" (Celent, 2005). It is clear that insurers are making selective investments in new applications for the back and front office and specific core functions; however, it seems that integration issues still lag behind.

Maintaining legacy systems while trying to cope with industry transaction standards can be difficult, taking into consideration current solutions. Legacy systems must be prepared to support new front ends, information exchange with a wide range of internal applications and XML for Internet-based applications, such as with business partners or online services. On the other hand, companies adopting ACORD XML standards must decide for the use of an external data exchange service such as IVANS or in-house solutions. In-house solutions need to address a number of problems, namely due to frequent changes and implementation issues with ACORD XML. "While versions are intended to be backwards compatible, real world complexities such as data

elements being renamed or deprecated between versions, or proprietary implementations make use of current fixed parsers for ACORD cumbersome and expensive. Further complicating use of ACORD is the need to detect versions of ACORD XML and determine how to handle data elements that are not consistent across versions, for example, mapping from a higher to a lower version of the standard." Managing data quality issues in these environments becomes "costly and often limits the usefulness of enterprise data" (Itemfield, 2005, p. 2).

Several players are positioning themselves in this promising market, offering SOA solutions. SOA can improve access to legacy systems, integrate multiple sales channels and improve insurers' clients self-service, among other things. However, the industry is still in the early phases of adopting SOA and the internal efforts have led to some frustration. Tulloch (2005), reporting the results of a study, refers that "nearly one-third of companies polled believe service-oriented architectures are not performing as well as expected. Of those, almost a quarter actually believe that SOA has increased the complexity of their IT systems" (p. 2). Tulloch (2005) defends that "this has more to do with the approach taken, and internal skills that organizations have at their disposal, than with the results that can be realized from a well-designed and implemented SOA," but also recognizes that "with the modularity of a component-based approach, functionality to impact business can be delivered next quarter, not next year" (p. 2).

Fortunately, the industry now understands that "the big-bang, all-at-once approach to SOA implementation has been largely ineffective" (Conz, 2007, p. 1). It seems that the insurers that are seeing the most encouraging returns on their SOA efforts are those that took an incremental approach. New endeavours will certainly benefit from best practices regarding implementation and organization. A recent report published by Celent (2007) claims that large insurers have already realized integration efficiencies ranging from 10% to 49% from their investments in SOA.

Insurance business processes are complex and contract data may be very different from one insurance product to another. It is possible to reach a limit where certain contracts are unique, that is, they are completely different from any other, leading to data that is merely descriptive and can only be interpreted by humans. Setting aside these cases, insurance electronic data format normalization will be an important evolution to electronic business because the computer system of each intermediary will only need to know how to import and export data based on a format common to all insurance companies.

Besides that, with sufficient trust in exchanged data, intermediary and insurance company businesses' integration would be superior by discarding the manual validation stage. Data could freely flow from one system to another without human intervention. In addition, the absence of human intervention could lead to frequent or even real time data integration. However, the file exchange process must be more automated.

In the ideal situation, manual data entry would be done in only one system, and data would be sent automatically to the other system to be integrated. A new proposal could be entered in the intermediary system and later be electronically integrated in the insurance company system. Working with only one interface that would be their own systems, the intermediaries could manage data right from the beginning and the insurance company or the intermediaries themselves would not have to replicate the previous manual work. This way, all parties (client, intermediary and insurance company) could grasp the productivity gains attained through single-entry, multiple-company interface.

Alternatively, if the insurance company does not have means to electronically integrate the intermediary's data, then the intermediary could directly enter the data into the insurance company system (because it is the intermediary who has the data) and, automatically, these data would be sent to the intermediary system to be electronically integrated. Any delay in sending or integrating will be harmful to the intermediaries because the data they need to run their business is not in their systems. However, with this alternative, the intermediaries have the inconvenience of having different data entry interfaces according to the several insurance companies they work with, increasing the potential for human error.

In either of the suggested hypothesis data integration must evolve in a way to support an increasing data flow between the intermediary and the insurance company until total business integration is reached.

The first step toward overall business integration is the national adoption, by the insurance industry, of one data exchange standard like the one developed by the e-business Expert Group for the Insurance Industry (eEG7), that is part of the Centre Européen de Normalisation and Information Society Standardization System (CEN/ISSS), or the one developed by ACORD, for example. XML and a Service-oriented Architecture based on Web Services should be used to integrate all insurance players. XML is currently being widely adopted by data exchange standards and Web Services can provide an interface that simplifies integration between several systems.

Yet, the evolution cannot be restricted to the integration of data between intermediary and insurance company. Data integration between intermediary and agents must be substantially improved so that both systems are completely synchronized in all business data without data entry replication. On the other hand, the intermediary application must support electronic data extraction to regulatory bodies in the required formats, avoiding the manual process currently

performed by the intermediary. It is also fundamental to bet heavily on extranets, both in insurance companies and intermediaries.

CONCLUSION

To operate in an effective and efficient way, intermediaries need to achieve great connectivity and articulation with all insurance business entities. Electronic business can provide this connectivity and articulation, bringing the different parties together, reducing response time and costs, serving clients better and creating new business opportunities.

In spite of being relatively advanced in this domain, the intermediary and the insurance company here analysed still operate low dematerialized processes in which paper, manual data entry and validation routines are a daily reality.

This situation is due to different visions of the business, to the lack of normalization and poor data quality, to some specificities of the insurance company information system, to the unfavourable cost/benefit relation, to the existence of manual processes and to the continued use of paper.

However, there are many advantages in the adhesion to electronic business in this industry, clearly assumed by the parties. Manual data entry is minimized, with consequent reduction of human mistakes. The automatic processing of huge volumes of data becomes possible in a short time. The intermediary becomes much more autonomous from the insurance company, the client/agent becomes much more autonomous from the intermediary and all benefit from the possibility of using up-to-date forms. Cost reduction is normally attained and partners become able to provide a better service to the final client.

KEY TERMS

Association for Cooperative Operations Research and Development (ACORD): ACORD (Association for Cooperative Operations Research and Development) is a global, nonprofit insurance association whose mission is to facilitate the development and use of standards for the insurance, reinsurance and related financial services industries.

Electronic Business: The electronic business concept is used to describe business conducted by electronic means, often over the Internet. It may be understood as a combination of business strategies and distributed processes that use technology to manage the electronic transfer of data and information between business partners. It may concern the exchange of structured and unstructured data and information.

eXtensible Markup Language (XML): XML is a set of standards that specify how to structure a text-based document for communication between two computers for any number of purposes. It allows incorporating metadata in the message to be exchanged, so the data may be transmitted and understood by the receiving party.

Insurance E-Business Expert Group (EG7): eEG7 is the European forum for the development of e-business standards for electronic communication in the insurance sector. It is one of the e-business Board for European Standardization (eBES) groups. eEG7 aims at facilitating the transfer of information between policyholders, professional intermediaries (agents, brokers), insurers and other involved parties. Its standards support the placing and administration of insurance contracts, claims handling and accounting.

Insurance Intermediary or Insurance Broker: Insurance brokerage is a remunerated activity whose main goals are to facilitate the settling of insurance contracts and assist them over their lifecycles. An insurance intermediary or insurance broker is a consultant operating in the insurance sector, independently from any insurance company. He specialises in providing services to their clients, and gathering the best solutions thanks to their vast knowledge of insurance companies' products.

Service-Oriented Architecture (SOA): The Service-oriented Architecture (SOA) is an approach to Enterprise Architecture where each major element is presented as a "service." A SOA solution materializes in a distributed computer environment with a high level of interoperability between the existing systems and eased integration of new functionalities. It allows combining and recombining software components, which is expected to reflect on business processes' flexibility.

Single-Entry Multiple Company Interface (SEMCI): Single Entry Multiple Company Interface (SEMCI) is a computer system based on service-oriented architecture (SOA). SEMCI acts as an interface which connects the agent information system to the information systems of multiple insurance companies.

ERP and the Best-of-Breed Alternative

Joseph Bradley
University of Idaho, USA

INTRODUCTION

Enterprise resource planning (ERP) systems are off-the-shelf software systems that claim to meet the information needs of organizations. These systems are usually adopted to replace hard-to-maintain legacy systems developed by IS departments or older off-the-shelf packages that often provided only piecemeal solutions to the organization's information needs. ERP systems evolved in the 1990s from material requirements planning (MRP) systems developed in the 1970s and manufacturing resources planning (MRPII) systems developed in the 1980s. ERP systems serve the entire organization, not just material or manufacturing planning. One advantage of ERP is that it integrates all the information for the entire organization into a single database.

Implementation of ERP systems has proven expensive and time consuming. Failed and abandoned projects have been well publicized in the business press. ERP systems are "expensive and difficult to implement, often imposing their own logic on a company's strategy and existing culture" (Pozzebon, 2000, p. 105).

Most firms utilize a single software vendor for the complete ERP system throughout their organizations. The integrated nature of ERP software favors this single-vendor approach. An alternative strategy adopted by some firms is the best-of-breed approach, where the adopting organization picks and chooses ERP functional modules from the vendor whose software best supports its business processes. Organizations adopting best of breed believe that this approach will create a better fit with existing or required business processes,

Table 1. Some functions available in SAP R/3 (Source: Davenport, 1998)

Financials	**Operations and Logistics**
Accounts receivable and payable	Inventory management
Asset accounting	Material requirements planning
Cash management and forecasting	Plant maintenance
Cost element and cost center accounting	Production planning
Executive information systems	Project management
Financial consolidations	Purchasing
General ledger	Quality management
Product-cost accounting	Routing management
Profitability analysis	Shipping
Profit-center accounting	Vendor evaluation
Standard and period-related costing	
Human Resources	**Sales and Marketing**
Human resources time accounting	Order management
Payroll	Pricing
Personnel planning	Sales management
Travel expenses	Sales planning

reduce or eliminate the need to customize a single-vendor solution, and reduce user resistance. Jones and Young (2006) found that 18% of companies used this approach to select ERP software packages.

This article examines what the best-of-breed strategy is, when it is used, what advantage adopting companies seek, examples of best-of-breed implementations, and differences in implementation methods.

BACKGROUND

ERP implementation projects can be distinguished from other IT projects by three characteristics (Somers, Ragowsky, Nelson, & Stern, 2001). First, ERP systems are "profoundly complex pieces of software, and installing them requires large investments in money, time and expertise" (Davenport, 1998, p. 122). Second, ERP packages may require the user to change business processes and procedures, may require customization, and may leave the firm dependent on a vendor for support and updates (Lucas, Walton, & Ginsberg, 1988). Finally, adopting firms are usually required to reengineer their business processes. Implementation projects must be managed as broad programs of organizational change rather than a software implementation (Markus & Tanis, 2000; Somers et al., 2001).

ERP systems include functionality for basic business processes based on the vendor's interpretation of best practices. However, the selected functionalities do not generally match the existing business processes of all organizations and may not be the best practices for a particular organization.

Typical ERP functions from SAP R/3, a major ERP vendor, are shown in Table 1. SAP R/3 modules provide a wide range of functional solutions, however, with the wide range of potential ERP customers, some organizations may not be a good fit. With the best-of-breed strategy, organizations can pick and choose the ERP modules from whichever vendor provides the best fit with their business processes and possibly reduce the amount of reengineering of business processes required, hence reducing the level of employee resistance.

BEST OF BREED IN INFORMATION SYSTEMS

The term *best of breed* was originally used in information systems literature to describe a situation where individual departments are allowed to install systems that best meet their needs rather than adhere to a corporate standard.

Acquisition costs are lower when all departments use the same software systems because of joint-purchase benefits such as volume discounts and other economies of scale. However, other costs may offset these savings. Unit document costs may be higher on a single-vendor approach compared to best of breed. Costs to translate and reformat data may be excessive. Switching costs may differ depending on the system chosen (Dewan, Seidmann, & Sunderesan, 1995).

BEST-OF-BREED ERP

ERP vendors design systems that are "purported to represent best practice and a more competitive business model." However, organizations interested in adopting ERP argue that "ERP software functionality is often lacking, the implicit business model does not represent their own and therefore reengineering business processes in line with this presents major difficulties" (Light & Holland, 2001, p. 217).

Single-vendor packages seem to have strengths in a particular functional area. PeopleSoft is known for exceptional human resource modules and Oracle has a reputation for exceptional financial modules.

Best-of-breed solutions provide an alternative strategy to enable organizations to implement ERP when a single vendor may not provide the functionality that the adopter requires or when modules from different vendors may provide a better match with existing or required business processes than a single-vendor solution. Lack of feature-function fit may be due to the design of most ERP systems for discrete manufacturing. Many organizations have specialized business processes common to their industry that may not be solved by the best practices embedded into single-vendor ERP systems. Various modules may not support process manufacturing industries, such as food processing and paper manufacturing; project industries, such as aerospace; or industries that manufacture products with dimensionality, such a clothing or footwear (Markus & Tanis, 2000).

While providing the additional needed functionalities, the best-of-breed approach complicates integration. With a single-vendor ERP system, "the whole package is designed for data compatibility" (Grant & Tu, 2005). With best-of-breed implementations, middleware is usually needed to link the various modules and databases: "The chance of being able to arrive at the same levels of integration as with an ERP system is very low, but this may be worth accepting as a means of saving the cost and pain associated with ERP implementation" (Payne, 2002).

Although most firms select a single vendor, a survey of Fortune 1000 firms found that 18% of the respondents chose ERP packages based on best-of-breed criteria; 32% of respondents used a combination of packages, such as SAP, PeopleSoft, Oracle, Baan, JD Edwards, Lawson, Adage, and SSA/CT (Jones & Young, 2006).

Although little empirical research has been done on best-of-breed ERP implementations, the information shown

Table 2. Best of breed vs. single-vendor ERP (Source: adapted from Light, Holland, & Wills, 2001)

BEST OF BREED	SINGLE-VENDOR ERP
Organization requirements determine functionality	Vendor determines functionality
Context approach to business process reengineering (BPR)	Clean-slate approach to BPR
Good flexibility in process redesign due to choice of components	Limited flexibility on process redesign
Reliance on numerous vendors distributes risk	Single vendor may increase risks
IT department requires multiple skills sets to deal with multiple software sources	Single skills set required in IT
Capabilities may be retained or enhanced with unique combinations of vendor packages and custom components	Distinctive capabilities may be impacted in common business process throughout industry
Need for flexibility and competitiveness is acknowledged up front	Flexibility and competitiveness may be constrained
Integration of applications may be time consuming and upgrades can be complicated	Integration of applications is precoded into system and maintained in upgrades

in Table 2 is the result of a single case study of a business referred to as Global Entertainment (Light & Holland, 2001). The best-of-breed approach clearly gives the adopting organization the ability to determine functionality rather than accepting a single vendor's determination of best practices. The adopting organization can select packages that best support its existing or desired business processes.

The adoption of a single-vendor ERP may cause the loss of competitive advantage. The single-vendor software may require the adopting organization to abandon its existing business processes, which may have created competitive advantage for the organization in favor of ERP-vendor-defined best practices. The organization's competitors may have also adopted these vendor-defined best practices, leaving the organization without a competitive advantage.

The best-of-breed approach may also spread the risk of the failure of an ERP vendor. If a vendor drops out of the ERP market for any reason, only a part of the system will be affected, not the entire system.

On the negative side, the best-of-breed approach requires more knowledge and skills in the adopting firm's IT department to support multiple packages. IT staff must be trained to support software from multiple vendors and maintain integration software as packages are upgraded.

Integration of modules from more than one vendor may be time consuming and costly. Upgrades to any of the vendor packages can cause complexities not encountered with a single-vendor approach.

EXAMPLES OF BEST OF BREED

Examples of best-of-breed selection and implementation projects may provide insight into the reasons best of breed remains a viable option for firms selecting ERP systems. Example 1 is a simple best-of-breed project with only two vendors. Example 2 represents a more complex best-of-breed project involving five different vendor packages.

Example 1

This example presents a relatively simple use of a best-of-breed solution. In 1995, a Houston-based energy services company embarked on a major systems effort. Legacy systems were accounting oriented and provided little operating information. Y2K (year 2000) problems were the catalyst for proceeding with the project.

With extensive help from the consultants on the project, Oracle was selected for the financial part of the new system. Oracle was considerably less expensive than other systems the company considered and the majority owner of the company implemented Oracle several years earlier. The decision was complicated by the lack of an Oracle module to support process manufacturing.

To resolve Oracle's inability at the time to support process manufacturing, the company adopted a process manufactur-

ing package from Datalogix called Global Enterprise Manufacturing Management Systems (GEMMS). The interface software between Oracle and GEMMS presented many technical implementation problems, which were resolved by the vendors and implementation consultants. While these technical integration problems caused some delay, they were not major issues from the point of view of the company.

During the course of the implementation project, a risk of the best-of-breed strategy occurred. Oracle acquired Datalogix in the midst of the project. Instead of helping resolve any problems by consolidating the software in one vendor, the acquisition exacerbated the problem because of a postacquisition exodus of Datalogix personnel.

The best-of-breed approach did not significantly contribute to cost overruns or delays in implementation. Overall, the project is regarded as a success. The problems caused in the integration of the two vendor solutions impacted mainly the software vendors and consultants, although company personnel had to coordinate the parties in reaching solutions. Project success can be attributed to the existence of a champion, training, and use of a project manager with both ERP and project management experience (Bradley, 2005).

Example 2

This example involves three divisions of a major defense contractor based in southern California. A series of acquisitions had left it with several nonintegrated mainframe systems supplemented by personal computer based point solutions. Prior to the ERP project, each division was pursuing different approaches to its information systems needs. One division was in the process of implementing an out-of-the-box Baan ERP system, the second division was using a heavily customized WDS system, and the third had no IT infrastructure. The corporate parent of these divisions wanted a single solution to control costs and leverage its purchasing power on the purchase of the software. This goal was complicated because the divisions had been highly independent of parent control and no single vendor offered a solution that met the needs of all three divisions. Standard packages failed to meet the needs of the bulk of their business. The parent was faced with balancing the benefits, cost savings, and standardization with the flexibility and independence of the divisions.

In 1996, when the project started, no single vendor provided a solution to the company's needs. A joint oversight team from the three divisions selected WDS (now Manugistics) as the core, but incorporated best-of-breed solutions such as PeopleSoft for human resource management, Oracle for financials, TIP QA for quality control, and Matrix One for product data management.

The best-of-breed approach did not cause significant problems according to the project manager; however, this project was his first ERP implementation, so he had little basis for comparison. The project was completed 6 months late and was $2 million over budget, although a contingency budget had addressed possible overruns.

FUTURE TRENDS

The Gartner Group coined the term *ERP II* to describe the shift in ERP from an enterprise information base focusing on back-office transaction processing within one organization to moving information across the supply chain ("Taking the Pulse of ERP," 2001). Others refer to this process as extended enterprise systems. ERP II or extended enterprise systems include customer relationship management (CRM) applications that accumulate information to better serve customers, supply chain management (SCM) applications that manage materials and services from acquisition to delivery to the customer, and e-business applications to enable the organization to reach customers over the Internet. Davenport and Brooks (2004) refer to basic ERP as infrastructural capability and SCM modules as strategic capabilities, raising the question of "whether to implement the infrastructural capabilities first, strategic capabilities first, or both simultaneously." They believe that while the infrastructural capabilities of ERP "provide very little in the way of real business value…they are critical to long-term internal and external integration." What they lack are short-term cost savings and competitive advantage. SCM and other extended enterprise systems modules have a payoff in terms of competitive advantage.

Best-of-breed terminology, while originally used for ERP software, is also applied to ERP II software. Major ERP vendors have concentrated on the transaction processing or back-office procedures in ERP. Independent vendors have concentrated on the add-ons that constitute ERP II. Davenport and Brooks (2004) point out that this situation is changing. Mainstream ERP vendors are adding SCM and other functionalities to their packages, avoiding some of the integration issues, but smaller vendors "have the edge in state-of-the-art functionality." This observation means that the best-of-breed strategy will continue to be a viable ERP II strategy choice.

CONCLUSION

The best-of-breed strategy will continue to be a viable option in both ERP and ERP II for organizations that attempt to create competitive advantage by assembling a custom ERP system rather than adopting the same off-the-shelf, "vanilla" ERP systems adopted by their competitors. While most adopting organizations will stick with the full integration of a single-vendor package, firms willing to take risks to obtain competitive advantage will assemble a best-of-breed solution that enhances their ability to serve their customers.

Example 1 demonstrates how a best-of-breed strategy can compensate for the lack of a desired functionality in one vendor's package by supplementing it with a second package. Example 2 shows how the strategy can blend together the diverse needs of three operating divisions to arrive at a solution acceptable to all parties. While one of these examples was clearly successful and the other had overruns in both cost and time, the best-of-breed option did not seriously hamper either of these implementations.

Both implementation strategies will continue to be complex and costly. Best of breed may provide an avenue to reduce the reengineering required at the cost of increased integration problems. The single-vendor approach may result in more reengineering of business processes but avoids the integration issues.

The best-of-breed implementation strategy is an area of ERP systems that has not been fully explored. More research of this promising alternative implementation strategy is needed.

KEY TERMS

Best of Breed: It is a combination of ERP software provided by more than one vendor and legacy systems designed to meet the needs of an organization in a manner superior to the single-vendor ERP approach.

Business Processes: "A business process is a set of business events that together enable the creation and delivery of an organization's products or services to its customers" (Gelinas, Sutton, & Fedorowicz, 2004).

Customer Relationship Management (CRM): These are software packages that enable a business to develop knowledge of their customers' needs and buying patterns. These systems "focus on the integration of externally based customer data for the organization to pursue more customer-oriented activities like targeted advertising, one-on-one marketing, customer retention and building a real-time integrated view of the customer" (Pan, 2005).

Enterprise Resource Planning (ERP) System: An off-the-shelf accounting-oriented information system that is designed to meet the information needs of most organizations. ERP systems enable an organization to procure, process, and deliver customer goods or services in a timely, predictable manner. These systems are complex and expensive information tools that have proven difficult and time consuming to implement.

ERP II or Extended Enterprise Systems: ERP II opens ERP systems beyond the enterprise level to exchange information with supply chain partners and customers. ERP II extends beyond the four walls of the business to trading partners. Typically, ERP II includes CRM packages, SCM packages, and e-business packages.

Integration: Integration is generally defined as "the bringing together of related components to form a unified whole….The primary concern of integration is 'oneness' and 'harmony' between user, technology, and the environment" (Grant & Tu, 2005, p. 8). Grant and Tu propose a taxonomy of ERP integration ranging from the lowest level, system specification integration, to global integration, which deals with "issues of language, time difference, culture, politics, customs, management style." Their proposed Level II deals with system-user integration at both the ergonomic and cognitive level. Level III deals with the integration of islands of technology throughout the firm.

Legacy Systems: They are transaction processing systems designed to perform specific tasks, or systems that have become outdated as business needs change and the hardware and software available in the marketplace have improved.

Manufacturing Resources Planning (MRPII): MRPII extends MRP by addressing all resources in addition to inventory. MRPII links material requirements planning with capacity requirements planning avoiding over- and under-shop-loading typical with MRP.

Material Requirements Planning (MRP) Systems: They are processes that use bills of materials, inventory data, and a master productions schedule to time-phase material requirements, releasing inventory purchases in a manner that reduces inventory investment yet meets customer requirements.

Supply Chain Management (SCM): These software packages exchange information with supply chain partners to order and track the procurement of goods and services. SCM can be viewed in four basic categories (Davenport & Brooks, 2004): supply planning tools, demand planning tools, plant scheduling tools, and logistics systems. A newer functionality in SCM is collaborative planning, forecasting, and replenishment (CPFR). In CPFR, "supply chain partners exchange not only orders and shipment notices, but sales plans and production forecasts with each other, so that they can synchronize their respective processes more fully."

ERP Systems' Life Cycle: An Extended Version

Cesar Alexandre de Souza
University of São Paulo – Brazil, Brazil

Ronaldo Zwicker
University of São Paulo – Brazil, Brazil

INTRODUCTION

The 1990's witnessed an impressive growth of Enterprise Resource Planning (ERP) systems in the market of corporate IT solutions, and now they are an important component of IT architecture in many companies. The ERP systems are introduced in companies following well-defined stages, namely the stages of decision, selection, implementation, stabilization and utilization. This last stage (utilization) is also characterized by the development of an organized effort to continuously ensure that the ERP system meets business needs regarding functionality, performance, availability, and to control operation costs, at the ERP management stage. This chapter presents aspects involved in each stage of this life cycle, based on the referenced bibliography.

BACKGROUND

Enterprise Resource Planning (ERP) systems are integrated information systems acquired as commercial software packages that aim supporting most of the operations of a company. Markus and Tanis (2000) define them as commercial packages that enable the integration of data coming from transactions-oriented information systems and from the various business processes throughout the entire organization. Examples of ERP systems found on the market are the SAP ERP of the German company SAP and Oracle Applications of the American Oracle. Some authors present and describe characteristics that allow differentiating ERP systems from systems developed within the companies and from other types of commercial packages (Markus & Tanis, 2000; Souza & Zwicker, 2001). These characteristics may be summarized as:

- ERP systems are commercial software packages;
- They include standard models of business processes;
- They are integrated information systems and use a corporate data base;
- They have a large functional scope;
- They require adjustment procedures to be used in a given company.

When deciding to use ERP systems, companies hope to achieve manifold benefits, like business processes integration, increased of control of operations, technological updating, IT cost reduction and access to information in real time for decision making. However, there are also problems to be considered, with implementation failures being reported (Barker & Frolick, 2003). Table 1 synthesizes benefits and difficulties of ERP systems mentioned by many authors (Bancroft, Seip & Sprengel, 1998; Davenport, 1998), and relates them to ERP systems' characteristics.

Although the initial focus of ERP systems was the integration of the internal value chain of large industrial companies, they are now evolving to a wider scope, including interenterprise integration features (McGhaughey & Gunasekaran, 2007). In many cases, the ERP systems became the basis upon which companies begun to develop other initiatives such as: customer relationship management (CRM), supply chain management (SCM) and business intelligence (BI). ERP systems are also now present in a growing number of companies in financial and service sectors and several vendors are now focusing small and medium companies as their target for market expansion.

ERP SYSTEMS LIFE CYCLE MODEL

The life cycle of information systems represents the various stages through which a project of development and utilization of information systems passes through. In its traditional form, the systems development life cycle encompasses project definition, system study, design, programming, installation, and post-implementation stages.

In the case of use of commercial software packages, these stages may differ. For instance, in the system study stage the focus is not on obtaining a detailed system specification from the users for programming the system, but instead, verifying the functionality of the many choices available from vendors, against a set of requisites from the users that will guide system adaptation or customization.

Like any commercial software package, ERP systems exhibit differences in their life cycle regarding traditional systems development projects. But because of their large functional scope and the integration between its various

Table 1. ERP systems benefits and difficulties

Characteristics	*Benefits Sought*	*Possible Difficulties*
Commercial Package	- IT costs reduction - Focus on company's core activities - Technological updating - Backlog reduction	- Supplier dependence - Lack of knowledge on the package - Loss of previous systems functionalities
Best Practice Business Models	- Knowledge on best practices - Access to other companies' experiences	- Need to adjust the company to the package - Need to change business procedures - Need of consulting for implementation
Integrated Information System	- Greater control on the company's operation - Real time access to data and information - Elimination of interfaces between isolated systems - Improvement of information quality - Synchronization between activities of the value chain	- High implementation complexity and costs - Difficulty to update the system as it requires agreement among various departments - One module not available may interrupt the functioning of the others - Resistance due to increase of demands to the areas responsible for data input
Corporate Data Base	- Standardization of information and data definitions - Elimination of discrepancies between information of different departments - Information quality improvement - Access to information for the whole company	- Cultural change of the view of "owner of the information" to that of "responsible for the information" may cause resistance to change - Responsibilities attribution on files shared between areas - Overload of the data base causing performance problems
Great Functional Scope	- Maintenance elimination of multiple systems - Standardization of practices - Reduction of training costs - Interaction with a single supplier	- Dependence upon a single supplier - If the system fails the entire company may stop - Support difficulties in the stabilization phase

modules, these differences are deepened. Some authors present models for the ERP systems' life cycle (Esteves & Pastor, 1999; Markus & Tanis, 2000; Souza & Zwicker, 2001). The main features of these many models are summarized in Figure 1, which includes the stages of decision and selection, implementation, stabilization, and utilization. The ERP management stage is included as an addition to the utilization stage and as an extension to the traditional ERP life cycle model, and is described next, along with the other stages.

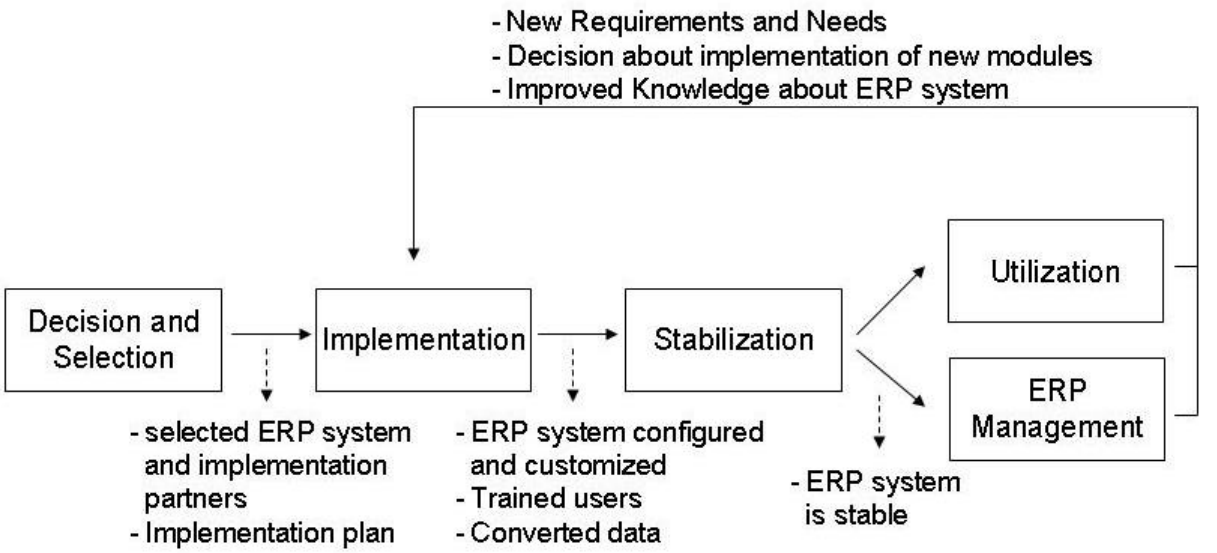
ERP Systems Decision and Selection

At the decision and selection stage the company decides to implement an ERP system as an IT solution and chooses the vendor. A series of issues must be taken into account at this stage. For instance, Davenport (1998) analyzes the decision from the point of view of the compatibility between the organization and the characteristics of the ERP systems. Hecht (1997) presents criteria that may help in this choice: adjustment of the package's functionality to the requisites of the company, technical architecture of the product, implementation costs, quality of post-sales support, and financial health of the vendor and its vision for the future of the package. The main product of this stage is a detailed implementation plan, where the modules to be implemented, the implementation approach, the project schedule, the implementation team and responsibilities are defined. Also, it is very common to hire a consulting company during the implementation project, for tasks that range from development of customizations to full responsibility for project management, depending on the case and the knowledge available in the company.

ERP Systems Implementation

Implementation comprises the second stage of the ERP systems' life cycle. The implementation of an ERP system may be defined as the process by which the system's modules

Figure 1. ERP systems life cycle model (adapted from Souza & Zwicker, 2001)



are put into operation within a company. Implementation entails adjustment of the business process to the system, configuration and eventual customizing of the system, loading or conversion of initial data, hardware and software configuration and training of users and managers. This stage encompasses the tasks ranging from the end of implementation plan's concept to the beginning of the operation.

The implementation stage is reported to be the most critical of all (Bingi, Sharma & Godla, 1999). Difficulties are mainly due to organizational changes that imply in changes of tasks and responsibilities of individuals and departments and transformations in the relationships between different departments. In an ERP system implementation it is generally pursued the optimization of the global processes of the company, which may cause as a counterpart changes in the activities in most of the departments involved. The need of intense participation and commitment of the company's top management and the requirement of permanent communication among the involved units is brought about by the size and complexity of this change and of the conflicts it may generate among those involved.

Adjusting the ERP system to company's processes is part of the implementation stage and is achieved by adjustment of parameters (configuration) or software customization (development of programs to modify or complement existing functions). At the implementation stage, the decision on how to start the operation of the ERP system (the "go-live") is also important. All modules may start operating in all divisions or plants of the company simultaneously (*big bang)* or in one division or plant after the other (*small bangs)*. The start may also occur in *phases* (one or some modules start operating in one division or plant after the other, also called *roll-out*). The approach used to start the ERP system operation is an important decision in its implementation project as it greatly affects the configuration of the system, the allocation of resources and the management of the project and its risks. It also plays a decisive role at all stages of ERP system's life cycle.

ERP systems' integration entails difficulties for the ERP systems implementation stage. These difficulties are related to three types of changes in the way people do their work (Souza & Zwicker, 2001):

(1) The integration transfers to departments that produce the information the responsibility to insert it properly. This includes data used by other departments only (for instance, typing of an accounting bill in a production entry) and as a consequence the users feel that their tasks are increased.
(2) Information must be inserted into the system at the best-suited moment for the process and not at the best-suited moment for a specific department. Thus, there is a need to change the way which tasks are carried out and other departments begin to demand the information they rely upon.
(3) The activities of a department become transparent to all others and this has the inconvenience to require "explanations" for everything it does.

Training of end users for working with an integrated system is an important consideration for the success of the implementation process.

Stabilization

In the first moments after the beginning of the ERP system operation there is a critical stage for the project's success: the stabilization. At this moment, the ERP system, that until then was only an abstraction, gains reality and starts to be part of company's and people's daily lives. This is when the highest amount of energy, be it managerial or technical, is required. It is a stage in which problems that could not have been easily detected at the implementation stage become apparent. This is a particularly critical stage, as the company is already relying upon the system for its activities and which causes major pressure for quick solution of problems. The length of this period depends on the company and takes about eight weeks (Zwicker & Souza, 2004).

The exact characterization of this stage is related to the operation starting mode chosen by the company. If operation of the ERP system started by means of a *big bang*, the stage of stabilization can be clearly distinguished from those of implementation and utilization. However, in companies that implement the modules in phases, or even in *small-bangs*, the stabilization stage is less characterized and merges with the implementation stage of the remaining modules. It can be stated that the stabilization stage in the case of implementation by phases starts with the operation of the first module and ends only when the last module implemented, in the last locality of the company, becomes stabilized. This longer implementation and stabilization time in general entails loss of focus of the project and may be viewed as a risk factor for the implementation in phases (for further details on the influence of ERP *go-live* approach on its life cycle, see Zwicker & Souza, 2004).

Utilization

Finally, at the fourth stage the system starts to belong to day-by-day operations. This does not mean that all its possibilities of usage are already known, nor that they are properly equated. Orlikovski and Hofman (1997) report on the difficulty within a company to know beforehand all use possibilities of the new information technologies. This knowledge is only achieved after a certain period of continued use of the technology, through the ideas that emerge during the utilization process. Therefore, the stage of utilization feeds back the stage of implementation with new possibilities and needs that may be solved through new modules, parameter adjustments or software customizing. In the case of implementation in phases, the already implemented modules may impose restrictions upon new modules caused by already defined parameters or customizations. Markus and Tanis (2000) point out that it is only in this stage that the organization is finally able to ascertain the benefits (if any) of its investment in the ERP system, due to continuous business improvement, additional user skill building, and post implementation benefits assessment. Also at this point, companies begin to consolidate their process reviews and effectively employ a model of integrated process management.

This stage can also be viewed as an evolutionary process. For instance, Botta-Genoulaz and Millet (2005) present a model to asses the ERP use maturity in three stages: mastery of the software, it is, the acquisition of the technical and operational knowledge about the ERP system; improvement, when the company has enough knowledge to effectively use the ERP systems for processes redesign and integration; and evolution, when it is possible to effectively align the ERP use to business strategies.

ERP Management

After its implementation, the ERP system becomes a critical component of the integrated management of diverse company areas and of supply chain management, which demands compliance with extreme availability and performance requirements. According to Zwicker and Souza (2006), ERP management encompasses the set of actions undertaken to ensure meeting the business needs, the performance, availability and control of the maintenance and operation costs. ERP systems management includes the activities of development (implementation and evolution of the system), operation (keep the system operation within the specified parameters of performance and availability), support (user services) and planning. Many of these tasks may be performed by the IT staff in cooperation with users (for example, the first instance of problem resolution may be done by users with good knowledge of the ERP system), as well as with outsourced personnel and consultants.

Esteves and Pastor (1999) also point out an interesting phase of the life cycle of ERP systems, the "retirement" stage, in which the ERP system would be substituted for other solution or solutions. What is being observed is that companies go through great efforts and costs each time a new version upgrade is needed (McMahon, 2004). Every time the decision to upgrade or not is posed to the organization it is also an opportunity to analyzing other ERP vendors or technologies (Kremers & van Dissel, 2000).

FUTURE TRENDS

The ERP Market has changed considerably since the 1990's. After a period of huge expansion based on sales for new clients who were manly large companies, the market stabilized and a series of mergers and acquisitions occurred. Vendors are now looking for new ways of increasing their revenues. Although the idea of one single system for the whole enterprise has not been reached yet, ERP vendors are incorporating new functionalities that comprise front-office and external integration tasks in their systems. Also,

companies in sectors not traditionally related to ERP, like finance, services and universities are beginning to implement it (McGhaughey & Gunasekaran, 2007). Another trend is the focus on the small and medium enterprise (SME) market. The implementation of whole ERP systems in these companies poses great challenges to vendors, due to the lack of financial, human and knowledge resources these companies usually present. Vendors are also struggling to innovate and incorporate new technologies and trends, like collaboration, business process management, service-oriented architectures (SOA), and business intelligence (Wailgum, 2007).

There are also challenges related to the management of IT in an ERP system context. An important option many ERP users are adopting is participating in user groups. This can be understood as an alternative strategy to obtain the knowledge needed to keep the ERP system up to date and better aligned with business needs.

CONCLUSION

This chapter presented an extended model for ERP systems life cycle that tries to encompass the complexities involved in implementing ERP systems in companies. To achieve this purpose, several aspects relating to the decision and selection, implementation, stabilization, utilization, and ERP management stages were presented.

The recommendation for companies that are deciding for ERP systems utilization and for companies that are already in the implementation stage is the careful analysis of the difficulties associated which each ERP systems' life cycle stage. With a better knowledge about these difficulties, the process can be improved though better planning and better action on the inherent difficulties of such an organizational change. One critical factor for success is to avoid it to be handled as an IT project (Willcocks & Sykes, 2000). Dedication and involvement of top management, strong participation of users and change management were aspects considered essential for the success of ERP systems implementation projects (Bingi, Sharma & Godla, 1999).

KEY TERMS

ERP Systems: Integrated information systems purchased as commercial software packages with the aim of supporting most operations of a company.

System Development Life Cycle: The various stages through which a project of development and utilization of information systems passes.

ERP Systems' Life Cycle: The various stages through which a project of introducing an ERP system in a company passes through.

ERP Decision and Selection Stage: Stage at which the company decides to implement an ERP system and chooses the supplier.

ERP Implementation Stage: Stage of an ERP project at which the ERP system's modules are put into operation.

ERP Stabilization Stage: The first weeks after the beginning of an ERP system operation in the company.

ERP Utilization Stage: Stage of an ERP project at which the system starts to belong to the day-by-day operations of the company.

ERP Management: The group of actions carried out to ensure the fulfillment of business requirements, the performance, the availability and the control of maintenance and operation activities of ERP systems.

Big-Bang Approach: Implementing all modules of an ERP system in all locations or plants of the company simultaneously.

Phased Approach: Implementing the modules on an ERP system in sequential steps, comprising one or more modules in one or more locations or plants, until the system is completely installed. It is also called roll out.

Establishing the Credibility of Social Web Applications

Pankaj Kamthan
Concordia University, Canada

INTRODUCTION

In recent years, there has been a steady shift in the *nature* of Web applications. The vehicle of this transition of Web applications is *us*, the people. The ability to post photographs or videos, exchange music snippets with peers, and annotate a piece of information, are but a few exemplars of this phenomenon. Indeed, the pseudonym Web 2.0 (O'Reilly, 2005) has been used to describe the apparent "socialization" of the Web.

In spite of the significant prospects offered by human-centric Web applications, the mere fact that virtually *anyone* can set up such applications claiming to sell products and services or upload/post unscrutinized information on a topic as being "definitive," raises the issues of credibility from a consumers' viewpoint. Therefore, establishing credibility is essential for an organization's reputation and for building consumers' trust.

The rest of the article is organized as follows. We first provide the background necessary for later discussion. This is followed by the introduction of a framework within which different types of credibility in the context of human-centric Web applications can be systematically addressed and thereby improved. Next, challenges and directions for future research are outlined. Finally, concluding remarks are given.

BACKGROUND

In this section, we present the fundamental concepts underlying credibility and present the motivation and related work for addressing credibility within the context of Web applications.

Basic Concepts of Credibility of Web Applications

For the purposes of this article, we will consider credibility to be synonymous to (and therefore interchangeable with) believability (Fogg & Tseng, 1999).

The concept of credibility can be classified based upon the types of user interactions with a Web application. A user could consider a Web application to be credible based upon direct interaction with the application (*active credibility*), or consider it to be credible in absence of any direct interaction but based on certain pre-determined notions (*passive credibility*). There can be two types of *active credibility*, namely *surface credibility*, which describes how much the user believes the Web application based on simple inspection, and *experienced credibility*, which describes how much the user believes the Web application based on first-hand experience in the past. There can be two types of *passive credibility*, namely *presumed credibility*, which describes how much the user believes the Web application because of general assumptions that the user holds, and *reputed credibility*, which describes how much the user believes the Web application because of a reference from a third party.

Related Work on Credibility of Web Applications

The issue of the credibility of Web applications has garnered attention in recent years from diverse viewpoints and this has lead to theoretical (Fogg, 2003; Metzger, 2005) and empirical (Consumer Reports WebWatch, 2005) studies pertaining to the credibility of both commercial and non-commercial Web applications.

There have been some partial efforts in addressing the credibility of Web applications. A set of guidelines for improving the credibility of Web applications have been presented (Fogg, 2003). However, these guidelines are stated in such a fashion that they can be open to broad interpretation, do not always present the relationships among them, and are stated at such a high-level that they may not always be practical or may be difficult to realize by a novice user.

A general framework for addressing the credibility of Web applications has been proposed previously (Kamthan, 2007; Kamthan, 2008). This article presents an adaptation as well as a modest extension of these works.

A SYSTEMATIC APPROACH TOWARDS THE CREDIBILITY OF WEB APPLICATIONS

In this section, we consider approaches for understanding and improving active and passive credibility.

Stakeholders and Credibility of Web Applications

We identify two broad classes of stakeholders with respect to their *roles* in relationship to a Web application: a *producer* (such as the provider or an engineer) is the one who owns, finances, develops, deploys, or maintains the Web application, and a *consumer* (such as a novice or expert user) is the one who uses the Web application for some purpose.

We then assert that credibility is a *perceived* quality attribute with respect to the stakeholders of a Web application. Indeed, we view credibility as a *contract* between a producer and a consumer. This contract can have ethical, legal, and/or moral implications.

Addressing Active Credibility of Web Applications

We consider a Web application to be an interactive information system and adopt semiotics (Shanks, 1999; Stamper, 1992) as the theoretical basis for communication of information. The active credibility of Web applications is viewed as a qualitative aspect and is addressed indirectly from the perspective of semiotics (Table 1).

We now discuss each of the components of Table 1 in detail.

Identification of Semiotic Levels

The first column of Table 1 addresses semiotic levels. We are particularly interested in the communicative properties of the representations of a Web application, which in semiotics we can view on six interrelated levels: physical, empirical, syntactic, semantic, pragmatic, and social.

We focus only on the quality concerns at the last two levels: at the *pragmatic level* the interest is in the utility of the representations to its stakeholders, while at the *social level* the interest is in the manifestations of social interaction among stakeholders with respect to the representations.

Decomposition of Semiotic Levels and Assignment of Quality Attributes

The second column of Table 1 draws the relationship between semiotic levels and corresponding quality attributes.

Since each semiotic level is rather high to be tackled directly, we decompose it further into quality attributes that are widely-known and relevant. Not all attributes corresponding to a semiotic level are on the same echelon, and therefore they are placed at different tiers. We contend that the quality attributes included are necessary but make no claim of their sufficiency. Also, the quality attributes are not necessarily mutually exclusive, and this dependency can be either favorable or unfavorable (Wiegers, 2003). We note that some of the quality attributes are classical and relevant in a desktop environment but they get amplified, and in certain cases exacerbated, in a networked environment.

Specifically, credibility belongs to the social level and depends on the layers beneath it. The quality attributes aesthetics (presentation), legality, privacy, security, and transparency (of the producer) also at the social level depend upon the quality attributes accessibility and usability at the pragmatic level, which in turn depend upon the quality attributes comprehensibility, interoperability, performance, readability, reliability, and robustness also at the pragmatic level.

We discuss only the entries in the social level in some detail. The sensitivity part of visual perception is strongly related to aesthetics as it is close to human senses. The artistic expression plays an important role in making a Web application "attractive" to its customers beyond simply the functionality it provides. It is critical that the Web application be legal (for example, is legal in the jurisdiction it operates and all components it makes use of are legal); takes steps to respect user's privacy (for example, does not abuse or share user-supplied information without permission); takes steps to secure itself (for example, in situations where financial transactions are made). The provider must take all steps to be transparent with respect to the user (for example, not include misleading information such as the features of products or services offered, clearly label promotional

Table 1. A semiotic framework for active credibility of Web applications

<table>
<tr><th>Semiotic Level</th><th>Quality Attributes</th><th colspan="2">Means for Assurance and Evaluation</th><th>Decision Support</th></tr>

</table>

content, make available their contact information including physical address, policies regarding returning/exchanging products, and so on).

Next, we separate the semiotic quality attributes and the means for addressing those.

Means for Active Credibility Assurance and Evaluation

The third column of Table 1 lists the means for assuring and evaluating active credibility. We note that the mapping between the aforementioned pragmatic and social quality attributes and the means for addressing them is many-to-many.

We now briefly discuss two product-oriented means, namely training and guidance for assuring the active credibility of a Web application.

Training

Often, the courses related to the Web offered at institutions tend to focus primarily on the manipulations of the "popular" (and moving target) client- and/or server-side technologies-of-the-day. The result is that the students tend to learn more about "technology hacks" rather than the fundamentals of analysis and design necessary towards a *systematic* approach to the large-scale development of Web applications.

Apart from an exposure to a comprehensive technical background in Web engineering (Mendes & Mosley, 2006), the toolbox of a prospective professional Web engineer should include several other aspects: means of precisely identifying user classes, user preferences, and their needs; understanding of quality attributes specific to the domain of the Web application and their social manifestations; appropriate use of standards for both the process and the product; ability of journalistic writing, including the ability of balancing information with other types of media (related to marketing such as advertisements); training in informed and balanced decision making in order to analyze the trade-offs and decide amongst different design approaches, or between the use of early and established technologies; basic knowledge of issues related to legal issues such as those related to intellectual property rights (IPR) and licensing; and basic knowledge of financial issues (such as those related to merchant accounts and payment systems) in the lieu of support for commercial transactions.

Guidance

We consider guidelines and patterns as two "bodies of knowledge" based on past experience and expertise that can serve as aids for structured guidance.

The guidelines encourage the use of conventions and good practice. They could serve as a checklist with respect to which an application could be heuristically and, to certain extent, automatically evaluated. There are guidelines available for addressing accessibility (Chisholm, Vanderheiden, & Jacobs, 1999) and usability (Nielsen, 2000) of Web applications. However, guidelines suffer from certain limitations: they may seem rather general at times, often do not discuss trade-offs as a consequence of their application or relationships among them, and tend to assume a certain level of knowledge of the domain and therefore are more suitable for an expert than for a novice.

A pattern provides a conceptually reusable and proven solution to a recurring problem in a given context. It has been pointed out (Friedman, 2005) that identifying patterns for the design of Web applications could be useful towards improving the credibility of these applications. Indeed, patterns for Web applications have begun to appear (Van Duyne, Landay, & Hong, 2003), and a judicious use of patterns can tackle many of the pragmatic and social quality attributes in Table 1. However, there are certain caveats in the adoption of patterns: there is an evident cost involved in adaptation of patterns to new contexts; since the mapping between patterns and quality attributes is many-to-many, their selection may not be trivial; and there is always a distinct possibility that for a given problem, there simply may not be any suitable pattern available.

We next briefly discuss two process-oriented means, namely inspections and testing for evaluating the active credibility of a Web application.

Inspections

Inspections are a rigorous form of auditing based upon peer review that, when practiced well, can help evaluating some of the quality attributes at both pragmatic and social levels in Web applications. These are aesthetics, comprehensibility, legality, privacy, readability, and transparency. Inspections could, for example, assess if the presentation of information appears "professional", determine "sufficiency" of contact information, or decide what information is/is not considered "promotional."

Since inspections is a means for *static* verification, it can evaluate in rather limited form (if at all) the quality attributes that by necessity require some form of "dynamism" or real-world use. These include accessibility, interoperability, performance, reliability, robustness, security, and usability.

In spite of the usefulness of inspections in early defect detection, adoption can depend on the level of organizational process maturity, their effectiveness lies strongly on the reading technique deployed, and entail an initial cost overhead of training each participant in the structured review process followed by the logistics of checklists, forms, and reports involved.

Testing

Testing is a means for *dynamic* verification and is usually supported by most Web application development processes. The attributes of accessibility, interoperability, performance,

reliability, robustness, security, and usability can to a large extent be tested (semi-)automatically using tools or with the help of actual users.

However, not all quality attributes at either pragmatic or social levels in a Web application can be tested automatically. For example, it is not possible to completely test a Web application for aesthetics, comprehensibility, legality, privacy, readability, or transparency (like producer's intent) using tools; human inspection would be necessary for checking and determining the level of support of these quality attributes. Thus, inspections and testing do not replace but *complement* each other.

Tools

There are various tools that can help improve quality concerns at technical and social levels, manually, semi-automatically, or automatically. For example, they can help us detect security breaches, inform us of absence of privacy metadata, report violations of accessibility guidelines, or suggest image sizes favorable to the performance on the Web.

However, state-of-the-art tools can be expensive, although this situation is changing with the rise of open source software (OSS). They also may not always be applicable.

Decision Support

The last column of Table 1 acknowledges that the activities of assurance and/or evaluation must be realizable in practice.

The providers of Web applications take into account organizational constraints of time and resources (personnel, infrastructure, budget, and so on) and external forces (market value, competitors, and so on), which compels them to make quality related decisions that, apart from being sensitive to credibility, must also be feasible. For example, an a priori guarantee that a Web application will be credible to *all* users at *all* times in situations that they can find themselves in, is simply impractical.

The feasibility analysis is evidently related to decision making and could be a part of the overall Web application project planning activity. Further discussion of this aspect is beyond the scope of this article.

Addressing Passive Credibility of Web Applications

In this section, we briefly look into the case of passive credibility, specifically reputed credibility.

Like in the real-world contexts, Web applications could be audited for quality in general and credibility in particular. Indeed, WebTrust and TRUSTe are two relevant initiatives in the direction of addressing reputed credibility.

We acknowledge that the perceptions related to presumed credibility may be one of the most difficult to tackle. There are no absolute guarantees but the following could be helpful for presumed credibility assurance of a Web application: personalizing the application to user context, making organizational policies explicit, and appropriately labeling the nature of content as per the requirements of the Internet Content Rating Association (ICRA).

Scope of Credibility of Web Applications

We note that credibility is not a "universal" concern. The credibility of a Web application is a concern to a user if there is an associated cost (say, in terms of lost time, effort, or money) that is outright unacceptable to the user.

That the credibility of a Web application is a concern may also depend on the purpose of the interaction and the role played by the user. For example, credibility may be a lesser concern to a user if (s)he is casually browsing a gossip column on a movie artist than if (s)he is filling out an annual tax return form.

We also note that credibility is *not* a quality attribute that is absolute with respect to users or with respect to the Web application itself. We contend that for a Web application to be labeled as non-credible there must exist at least a part of it that is labeled non-credible based on the aforementioned classification by at least one user at some point in time. For example, a user may question the credibility of information on a specific product displayed on a specific "Web page" within a Web application.

FUTURE TRENDS

The work presented in this article can be extended in a few different directions, which we now briefly discuss.

It is known that, when applied judiciously, standards can contribute towards quality improvement. Indeed, credibility has recently been a topic of interest in standards for Web applications such as the IEEE Standard 2001-2002. However, awareness and broad use of these standards among engineers is yet to be seen.

Due to the unique nature of Web applications, any initiative towards addressing the credibility of Web applications should take place within the auspices of a development process that is that is sufficiently *agile*. This would require that the current agile methodologies for the development of Web applications evolve to provide support for credibility in general and for pragmatic and social quality attributes discussed in this article in particular.

The semantic Web has recently emerged as an extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning (Hendler, Lassila, & Berners-Lee, 2001). At the highest level of this infrastructure is the issue of trust. For

example, ontologies are central to the semantic Web and their development and subsequent use is based on mutual trust among the stakeholders. For the sustainability of the Web architecture, it is critical that the social Web and the semantic Web co-exist and evolve harmoniously. However, the "human" aspects of the semantic Web remain largely unaddressed. A natural extension of the discussion on credibility of the preceding section could be within the context of semantic Web applications.

CONCLUSION

By shifting from a collective of computers towards a community of people, the Web is becoming a symbiotic means of contribution, participation, and collaboration. The consumer concerns of credibility and the extent to which they are addressed will remain a key determinant towards the success of this paradigm.

Although there have been many advances towards enabling the technological infrastructure of the Web in the past decade, there is much to be done in addressing the social challenges, including user perceptions and expectations.

In conclusion, if credibility is important to an organization, it needs to be considered as a *first-class* concern, rather than an afterthought, from inception to conclusion of a Web application development process. Addressing the credibility in a systematic and feasible manner is one step in that direction.

KEY TERMS

Credibility Engineering: The discipline of ensuring that a system will be perceived as credible by its stakeholders, and doing so throughout the life cycle of the system.

Delivery Context: A set of attributes that characterizes the capabilities of the access mechanism, the preferences of the user, and other aspects of the context into which a resource is to be delivered.

Quality: The totality of features and characteristics of a product or a service that bear on its ability to satisfy stated or implied needs.

Quality Model: A set of characteristics and the relationships between them that provide the basis for specifying quality requirements and evaluating quality of an entity.

Semantic Web: An extension of the current Web that adds technological infrastructure for better knowledge representation, interpretation, and reasoning.

Semiotics: The field of study of signs and the communicative properties of their representations.

Web Application: A specific to a domain Web site that behaves more like an interactive software system rather than a catalog: it will in general require programmatic ability on the server-side and may integrate/deploy additional software for some purpose (such as dynamic delivery of resources).

Web Engineering: A discipline concerned with the establishment and use of sound scientific, engineering and management principles and systematic approaches to the successful development, deployment, and maintenance of high-quality Web applications.

E-Technology Challenges to Information Privacy

Edward J. Szewczak
Canisius College, USA

INTRODUCTION

The collection of personal information by electronic technology (e-technology) and the possibility of misuse of that information are primary reasons why people limit their use of the Internet and are even limiting the success of e-commerce (Szewczak, 2004). Various uses of e-technology that collect and/or disseminate personal information include corporate and government databases, e-mail, wireless communications, clickstream tracking, and PC software. The main challenge to personal information privacy is *the surreptitious monitoring of user behavior on the Internet without the user's consent and the possible misuse of the collected information resulting in financial and personal harm to the user*. Our focus is primarily on Internet use in the United States of America, though clearly e-technology is global in nature and poses challenges and issues for societies around the world.

BACKGROUND

Concerns about the collection of personal information are ongoing. The results of a 1998 survey conducted by Louis Harris & Associates, Inc. revealed that worries about protecting personal information ranked as the top reason people generally are avoiding the Web (Hammonds, 1998). The misuse of credit card data for activities such as identity theft is a major concern (Stop thieves from stealing you, 2003; www.Truste.org/articles/holiday_shopping.php). A survey of 1068 consumers conducted by primary monitor Truste found that many people were skeptical of giving their personal information to online businesses. Seventy-five percent of respondents reported not liking to register at Web sites they visit. Fifteen percent of respondents refused to register at all. Forty-three percent of respondents stated they did not trust companies to not share their personal information. Of those respondents who did share personal information, 25% said they were less than impressed with the return on the information they provided (www.Truste.org/articles/quarterly_index1.php). A 2005 California HealthCare Foundation and the Health Privacy Project Poll found that 67% of national respondents are concerned about the privacy of their personal medical records (www.epic.org/privacy/medical/polls.html).

Dhillon and Moores (2001) reported that the selling of personal information by companies to third parties was the top privacy issue as identified by IS executives. However, failed Internet companies such as Boo.com, Toysmart.com, and CraftShop.com have either sold or have tried to sell customer data that may include phone numbers, credit card numbers, home address, and statistics on shopping habits, even though they had previously met Internet privacy monitor Truste's criteria for safeguarding customer information privacy. The rationale for the selling was to appease creditors (Sandoval, 2000). Even financially healthy companies realize there are advantages to be gained in the selling of collected customer information. Buyers include other businesses as well as the U.S. government. The Departments of Justice, State, and Homeland Security spend millions of dollars annually to buy commercial databases that track American citizens' finances, phone numbers, and biographical data. Often these data are accepted at face value without further evaluation for accuracy (Woellent & Kopecki, 2006). Companies such as Amazon, Ebay, and Google have opened up access to their databases to other companies for free in hopes these companies will develop new products and services that are organized around their database systems (Schonfeld, 2005).

In his excellent study on privacy in the information age, Cate (1997) adopted the definition of privacy as "the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others" from Westin (1967, p. 7). Westin/Cate's definition is interesting because it allows for flexibility in discussing privacy within the context of the Internet. Whereas many people worry about divulging personal information electronically, other people seem more than willing to give it away, trading their personal information for personal benefits such as free shipping and coupons (Kuchinskas, 2000). Personalized service is the main benefit. A Web site can save a shopper time and money by storing and recalling a user's tastes and buying habits (Baig, Stepanek, & Gross, 1999). ISPs are willing to allow Web users cheaper access to the Internet provided the users are amenable to having their online behavior tracked for marketing purposes by specialized software (Angwin, 2000). If users are not amenable to having their personal information shared among company subsidiaries, at least one company

has warned that discounts for offerings such as high-speed Internet service will be taken away (Lazarus, 2004).

TECHNOLOGICAL CHALLENGES TO PRIVACY

Corporate and Government Databases

The practice of gathering personal information about customers and citizens by corporations and governments is well established. Software is available that is dedicated to analyzing data collected by company Web sites, direct-mail operations, customer service, retail stores, and field sales. Web analysis and marketing software enable Web companies to take data about customers stored in large databases and offer these customers merchandise based on past buying behavior, either actual or inferred. It also enables targeted marketing to individuals using e-mail. Governments routinely collect personal information from official records of births, deaths, marriages, divorces, property sales, business licenses, legal proceedings, and driving records. Many of the databases containing this information are going online (Bott, 2000).

These company and government databases are often not adequately secure against various threats to their integrity. Companies such as Choicepoint, Bank of America, Time Warner, Acxiom, and CardSystems Solutions have experienced breaches of security wherein unauthorized access of customer information such as names, addresses, Social Security numbers, credit and debit card numbers, and driver's license numbers occurred (Carrns, 2005; Perez & Brooks, 2005). Other companies blame checkout software that improperly stored credit card data for security breaches (Bank, 2005). For some companies, the threat to data security is internal rather than external (Yuan, 2005).

The deregulation of the financial services industry has made it possible for banks, insurance companies, and investment companies to begin working together to offer various financial products to consumers. Personal financial information that was kept separate before deregulation can now be aggregated. In fact the ability to mine customer data is one of the driving forces behind the creation of large financial conglomerates. Services can be offered to customers based on their information profiles. Large credit bureaus such as Equifax and Trans Union have traditionally been a source of information about a person's credit worthiness. Their databases contain information such as a person's age, address, and occupation. Credit bureaus have begun to sell personal information to retailers and other businesses (Big browser is watching you!, 2000). Some mutual fund companies have disclosed information such as customer name, home address, and account numbers on a U.S. government Web site in response to a Securities and Exchange Commission regulation, leaving customers vulnerable to identity theft and other crimes (Maremont, 2005).

Like personal financial information, medical information is for most people a very private matter. Despite this fact, there is a wealth of personal medical data in government and institutional databases. As *Consumer Reports* (Who knows your medical secrets, 2000, p. 23) notes, "[t]he federal government maintains electronic files of hundreds of millions of Medicare claims. And every state aggregates medical data on its inhabitants, including registries of births, deaths, immunizations, and communicable diseases. But most states go much further. Thirty-seven mandate collection of electronic records of every hospital discharge. Thirty-nine maintain registries of every newly diagnosed case of cancer. Most of these databases are available to any member of the public who asks for them and can operate the database software required to read and manipulate them."

Much of personal health information that is available to the public is volunteered by individuals themselves, by responding to 800 numbers, coupon offers, rebate offers, and Web site registration. Much of the information is included in commercial databases like Behavior-Bank sponsored by Experian, one of the world's largest direct-mail database companies. This information is sold to clients interested in categories of health problems, such as bladder control or high cholesterol.

E-Mail

In a survey of 840 U.S. companies, 60% said they use some type of software to monitor employees' e-mail activities (Tam, White, Wingfield, & Maher, 2005). Despite the fact that most companies had policies alerting employees that they were subject to monitoring, some had fired employees based on evidence collected during monitoring (Seglin, 2000). Hackers can also be a problem. Programs can be surreptitiously installed that monitor a user's keystrokes. The keystrokes can be sent across the Internet to a computer that logs everything that is typed for later use (Glass, 2000).

Employee's invasion of privacy claims have not been upheld in the United States courts, which argue that, since employers own the computer equipment, they can do whatever they want with it (McCarthy, 2000). However, use of Google's Gmail could present an information privacy issue of another sort. Gmail searches for certain words in a user's incoming messages, then displays text ads related to the words. There is a potential for many messages accumulated on Google's servers to be combined to produce a profile of an individual that could be accessed by, say, a government law enforcement agency or a criminal organization (Jesdanun, 2005; Wildstrom, 2004, 2006).

Wireless Communications

Wireless advertising poses a host of challenges for privacy advocates. Wireless service providers know customers' names, cell phone numbers, home and/or office addresses, and the location from where a customer is calling, as well as the number a customer is calling. Each phone has a unique identifier that can be used to record where in the physical world someone travels while using the cell phone (Petersen, 2000). The Federal Communications Commission requires cell phone service providers to be able to identify the location of a caller who dials 911, the emergency number. Since a cell phone service provider can track the location of a 911 call, it can track the location of any other call as well using global positioning system (GPS) technology. Mobile tracking firm Yora uses Nextel GPS phone software to create "geofences" technology that sets off an alarm at the office when field workers go to off-limit locations (Charny, 2004).

Wi-Fi networks provide ample opportunity for data breaches. Wi-Fi networks access points function as invitations to other wireless devices (such as laptop computers) to hook up and create a session. Because wireless networking is designed to be simple to install and easy to use, the various devices do not automatically distinguish between an authorized user and an unauthorized intruder (Bulkeley, 2004). Even with security systems using keys and encryption, Wi-Fi networks will remain vulnerable to sophisticated hackers (Crockett, 2004).

Radio frequency identification (RFID) systems use microchips (tags) that transmit/receive data to/from a reader device. Tags have been used by railroads and the U.S. Department of Defense to track inventory, in payment cards such as Mastercard PayPass, on individual items at Walmart, in library books, and in U.S. passports. Data collected from multiple tags can be aggregated in a database and associated with an individual using a tracking number (The end of privacy, 2006). RFID systems may also be a security challenge for companies as well. Corporate espionage involving tapping into warehouse readers or scanning goods as they leave a distribution point may constitute a serious security breach (Clayburn, 2004).

Clickstream Tracking

Tracking employee behavior on the Internet has become common practice. Software programs have been specifically designed to monitor when employees use the Internet and which sites they visit (McCarthy, 1999). Internet companies monitor Internet user behavior by a number of means, primarily to gather data about shopping and buying preferences with a view toward developing "user profiles." The primary means is the creation and use of cookies.

Cookies are text files created by a Web server and stored on a user's hard disk. A cookie is a set of fields that a user's computer and a server exchange during a transaction. The server may change or suppress the contents of a cookie it has created. When a user connects to a Web site, the browser checks the cookies on the hard drive. If a cookie matches the site's address, the browser uploads the cookie to the Web site. With the information contained in the cookie, the site can run programs that personalize site offerings and/or track the user's activity while online (www.cnil.fr/traces). Cookies come in two varieties: first party and third party. First party cookies are stored on a user's PC by the actual company site being visited. Third party cookies are stored by an outside company such as a Web analytic firm used by online retailers. A user is viewed as more inclined to trust a first-party cookie since it came from a known source (Kesmodel, 2005).

PC Software

Various kinds of PC software may pose a threat to a user's privacy. Usually the user has not explicitly asked for the software to be downloaded and is not aware the software is actually running on the PC.

Spyware installs itself surreptitiously on computers when a user downloads other programs, then tracks each click the user makes (Hagerty & Berman, 2003). A species of spyware called adware tracks Web surfing or online buying so marketers can send a user targeted ads (which are usually unsolicited). Other spyware may steal user passwords or credit card information (Gutner, 2004).

Phishing uses e-mail to direct unsuspecting users to legitimate-looking Web sites (such as a trusted bank) where the user is asked to provide personal information about themselves such as passwords and account numbers. Phishers team up with international criminal syndicates to fence stolen data (Kay, 2004).

Pharming has succeeded phishing. Users are redirected to an imposter Web page even though the user enters the correct address into a browser. The results may be the same as in phishing (Delaney, 2005).

FUTURE TRENDS

The issue of personal information privacy and the Internet continues to be debated within the community of Internet users. Privacy is a social issue, generally speaking. How the personal information privacy debate is ultimately resolved will be decided by the values inherent in a given society. Since the position of privacy advocates differs so markedly from the position of technology growth advocates, and since privacy issues have been addressed in court and precedents established in state and common law, it seems likely that the personal information privacy debate will be resolved in the world's legislatures and resulting laws enforced in the courts

(Lessig, 1999). The U.S. has seen the passage of the Health Insurance Portability and Accountability Act that prohibits unauthorized disclosures of personal medical information, punishable by a fine up to $250,000 and 10 years in jail (Lueck, 2003). The Identity Theft Penalty Enhancement Act prescribes stiff prison terms for people who use identity theft to commit other crimes (Kay, 2004). Other nations will have to adopt their own measures to ensure the privacy of their citizens' personal information. Since the Internet is a global technology, perhaps a global effort will be needed to adequately address these issues.

CONCLUSIONS

Various uses of e-technology that collect and/or disseminate personal information include corporate and government databases, e-mail, wireless communications, clickstream tracking, and PC software. Clearly the challenges to personal information privacy posed by the various forms of e-technology are not the result of the technology itself. Rather it is the uses of the technology that pose the threat to the integrity of personal information privacy. In particular, the surreptitious monitoring of user behavior without the user's consent and the possible misuse of the collected information pose the biggest threats. The various nations of the world must come to grip with these challenges in their own way, perhaps working in unison. Otherwise the personal information privacy of their citizens will be continuously at risk.

KEY TERMS

Clickstream Tracking: The use of software to monitor when people use the Internet and what sites they visit.

Cookies: Text files created by a Web server and stored on a user's hard disk that contain data about which Web sites have been visited.

Global Positioning System (GPS): A satellite-based data system that works with a computer chip embedded in a cell phone to identify the location of the user anywhere in the world.

Identity Theft: The stealing and use of a person's identity through the acquisition of personal information without that person's knowledge or permission.

Personal Information: Information about, or peculiar to, a certain person or individual.

Pharming: Users are redirected to an imposter Web page, even though the user enters the correct URL into a browser (see **Phishing**).

Phishing: A user's e-mail program is used to direct the user to a legitimate-looking Web site where the user is asked to provide personal information about himself or herself such as passwords and account numbers.

Privacy: The claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others (Westin, 1967).

Radio Frequency Identification (RFID) System: Microchips (tags) are used to wirelessly transmit/receive data to/from a reader device.

Spyware: Software that installs itself on computers when programs are downloaded and that tracks each user click, usually without the user's knowledge or permission.

Ethical Issues in Conducting Online Research

Lynne D. Roberts
University of Western Australia, Australia

Leigh M. Smith
Curtin University of Technology, Australia

Clare M. Pollock
Curtin University of Technology, Australia

INTRODUCTION

The rapid growth of the Internet has been accompanied by a growth in the number and types of virtual environments supporting computer-mediated communication. This was soon followed by interest in using these virtual environments for research purposes: the recruitment of research participants, the conduct of research, and the study of virtual environments. Early research using virtual environments raised a number of ethical issues and debates. As early as 1996 a forum in the *The Information Society* (volume 12, issue 2) was devoted to ethical issues in conducting social science research online. The debate has continued with more recent collaborative attempts to develop guidelines for ethical research online (Ess & AoIR ethics working committee, 2002; Frankel & Siang, 1999). In this article we explore contemporary ethical issues associated with conducting research online.

BACKGROUND

The basic principles of ethical research with humans are integrity, respect, beneficence, and justice (National Health & Medical Research Council, 2006). Based on these principles many professional associations provide ethical guidelines, or codes, for the conduct of research. Guidelines and legislation vary across disciplines and across countries. However, these codes have typically been developed for use in off-line settings, prior to consideration of research being conducted online[1]. While these codes contain guiding principles for research generally, the translation of these principles into actions for conducting research in virtual environments is open to interpretation. The process of translating ethical guidelines into ethical practice online involves a deliberation of the options available to the researcher and the likely impact on research participants, their communities, and the research process. Central concerns in this process are maintaining respect for individuals, their online identities, and the ownership of words.

PUBLIC VS. PRIVATE SPACE

Research online can take place within a range of virtual environments that vary in terms of purpose, synchronicity, access, number of users, and norms. A major issue in developing ethical research procedures for use within a particular virtual environment is determining whether the setting represents a private or public "space." Various attempts have been made to distinguish between the public and the private in virtual environments (see, e.g., Lessig, 1995), but little agreement has been reached. There are currently no clear guidelines for researchers on what constitutes private vs. public space in virtual environments, yet the distinction is important, as it affects the rights of participants to be advised of the research and to give or withhold their informed consent.

The defining of public vs. private space cannot be reduced to the single dimension of accessibility to the virtual environment. Interactions that occur within publicly accessible virtual environments may be perceived by participants to be private. Newsgroups can be accessed without restriction, yet newsgroup postings can be, and frequently are, high in self-disclosure and are perceived by many users to be private (Witmer, 1997). Similarly, support groups on sensitive issues may be conducted in publicly accessible sites with participants adhering to norms of confidentiality and privacy (Elgesem, 2002).

Some ethical codes exempt naturalistic observations and archival research from requiring informed consent where no harm or distress is likely to come to those researched and where their confidentiality is protected. It has been argued that the decision not to inform members of online groups about research conducted on the group has the advantage of the research being "unobtrusive" (Langer & Beckman, 2005). Others, while acknowledging the benefits of naturalistic observation, regard this approach as placing researchers in a position "little better than spies" (Bakardjieva & Feenberg, 2001, p. 234). King (1996) highlighted the potential for psychological harm to members of online groups where research is conducted and published without the prior knowledge and informed consent of participants.

Where there has been the expectation of privacy within a group (however misinformed that expectation may be) the individual may feel violated upon hearing of, or reading, the results of that research.

Where the presumption is made that online communication occurs in public space simply because it is accessible without restriction, an anomaly may result in how research participants are treated in equivalent settings in online and off-line research. For example, research on support groups off-line requires the informed consent of research participants, while similar research online may occur without the knowledge or informed consent of the participants, on the grounds that all postings are public documents (see, e.g., Salem, Bogat, & Reid's 1997 study of a depression support group). Despite the inequities this raises, in a recent review of psychological research conducted online (Skitka & Sargis, 2006) it was noted that "most Institutional Review Boards are concluding that online postings represent the public domain and that researchers do not need to obtain informed consent to use this material" (p. 549).

Table 1 summarizes possible dimensions against which the public/private nature of a virtual environment can be assessed. Virtual environments where all dimensions fall on the left-hand side of the continua may be deemed as public environments for research purposes and subject to guidelines for research in public settings. We recommend virtual environments where all dimensions are on the right be deemed private environments, requiring informed consent from research participants. The difficulty arises with the majority of settings that do not fall clearly into public or private spaces. Researchers do not have the right to define virtual environments as public or private to meet their own research needs (Waskul & Douglass, 1996). Rather, account should be taken of the size and nature of the online forum and the intrusiveness of the study. Consideration should be made of the likely effect of the request to conduct research and the research itself on research participants and their communities. The process of requesting consent to research may in itself alter group dynamics (Sixsmith & Murray, 2001).

INFORMED CONSENT

Research conducted in virtual environments that have been conceptualized as private settings requires the informed consent of research participants. Obtaining informed consent in virtual environments is more problematic than in off-line research, as participants are frequently geographically dispersed. In addition, research participants may be reluctant to divulge details of off-line identities required for the signing of consent forms. Further, it is difficult to verify factors that may affect an individual's ability to provide informed consent, such as age, mental competency, and comprehension of risk (Skitka & Sargis, 2006).

A range of options has been suggested for obtaining informed consent in online research (Bruckman, 1997; Flicker, Haans, & Skinner, 2004; Jacobson, 1999; Kralik, Warren, Price, Koch, & Pignone, 2005; Roberts, Smith, & Pollock, 2004; Smith & Leigh, 1997), and these have been summarized in Table 2. Selection of a method for obtaining informed consent will necessarily be dependent upon the type of virtual environment, the level of anonymity required by research participants, and their access to high-level computing facilities. Regardless of the method used, the information about the research should be presented in a format that the research participants can keep and refer back to at any time before, during, or after their research participation.

Table 1. Dimensions of public and private space in virtual environments

Accessibility:	Accessible to all	→	Restricted membership
Users' perceptions:	Public	→	Private
Community statement:	Research permitted	→	Research prohibited
Topic sensitivity:	Low	→	High
Permanency of records:	Public archives	→	Private logs only

Table 2. Methods of obtaining informed consent in online research

	Format of information	***How consent obtained***
Signed consent:	Hard copy or electronic	Post, fax, or e-mail
Implied consent:	Electronic	Gateway WWW page E-mail consent Logging of consent Use of password protected site

Table 3. Factors that decrease the anonymity afforded by pseudonyms

• Use of name, derivation of name, or nickname
• Use of same pseudonym across virtual environments with differing requirements for identification
• Self-disclosure
• Active seeking of identifying information by others

Table 4. Levels of anonymity (site, pseudonym, and quotations)

• Identify site, use online pseudonym, and directly quote
• Identify site, use pseudonym of online pseudonym, and directly quote
• Identify site, use pseudonym of online pseudonym, and paraphrase
• Do not identify site, use online pseudonym, and directly quote
• Do not identify site, use pseudonym of online pseudonym, and directly quote
• Do not identify site, use pseudonym of online pseudonym, and paraphrase

Skitka and Sargis (2006) reviewed Internet-based psychological research conducted over a two-year period. In almost two thirds (62.5%) of studies reviewed, the researchers clearly obtained informed consent from research participants; 12.5% did not obtain informed consent, and it was unclear in the remaining 25% whether informed consent was obtained or not. Of concern, deception was used in 18% of studies, with less than half indicating that debriefing had been provided to research participants.

Consideration should also be given to seeking the cooperation of community gatekeepers[2] and advising the community of the research being undertaken. Advising communities of a research project requires the public identification of the researcher. In some circumstances, the decision to research within a particular virtual environment may be made after the researcher has been either an active participant or "lurker" within that environment. We recommend that researchers make their researcher status overt as soon as the research process begins. This may include identifying as a researcher in pseudonyms (Roberts et al., 2004), descriptions (Allen, 1996), or objects (Reid, 1996); linking between research and social identities (Roberts et al., 2004); and posting information about the research.

Advising communities of a research project may take ongoing effort in public virtual environments without membership boundaries. Identifying oneself as a researcher once within an online group does not mean that absent or future members of the group are also informed of the researcher's role (Sixsmith & Murray, 2001). There may be a need to re-identify researcher status and restate and clarify the role of the researcher on an ongoing basis.

PROTECTING ANONYMITY AND CONFIDENTIALITY

Individuals typically adopt a pseudonym (or pseudonyms) for use in virtual environments, providing a level of anonymity. Some studies include pseudonyms in reports and publications on the basis that they provide information relevant to the study (Langer & Beckman, 2005). While it has been argued that research involving pseudonymous characters is exempt from regulations governing human subjects as "true" (off-line) identities are not known (Jacobson, 1999), there are often links between the individual and their pseudonyms that decrease the level of anonymity a pseudonym provides (Allen, 1996; Bruckman, 2002; Jacobson, 1996). These are presented in Table 3. The combination of these factors means that researchers cannot assume that pseudonyms provide adequate protection for off-line identities. The degree of anonymity conferred in virtual environments does not reduce the ethical requirements for researchers to protect the anonymity of research participants and virtual interaction settings (Waskul & Douglass, 1996).

Protecting the anonymity[3] of the individual extends to protecting the anonymity of their pseudonym(s), as representations of the individual online. Pseudonyms themselves gain reputations over time (Bruckman, 2002). Researchers can provide varying levels of protection to research participants' anonymity (see Table 4). The practice of replacing existing pseudonyms with other pseudonyms in research materials confers little additional protection to the existing pseudonym when text searches can be used to identify source documents (Allen, 1996) or where the individual has a distinctive, recognisable writing style (Markham, 2005).

Further, other community members may seek to identify disguised identities and may share this information with others (Bruckman, 2002).

In addition to protecting the anonymity of research participants in research reports, the data collected need to be kept secure in order to protect confidentiality. Maintaining the security of data collected in computer-mediated research poses unique difficulties. Confidentiality may be breached at the site of data collection, during transmission of data, or in the storage of data. Sites at which data is collected may not be secure and may be subject to surveillance by gatekeepers, "hackers" (Rhodes, Bowie, & Hergenrather, 2003), other computer users, or others physically present in the location at the time (Kralik et al., 2005). Confidentiality of data may be breached during data transmission where another party intercepts data (Nosek, Banaji, & Greenwald, 2002). This may include the Internet service provider of the research participant or researcher. Employers may also monitor employees' e-mail (Sipior & Ward, 1995; Weisband & Reinig, 1995). Confidentiality of data may be breached during storage by hackers, employers, or as a result of "open records" legislation (Pittenger, 2003).

Online researchers need to provide the most secure forms of data collection, transmission, and storage possible, aiming to minimize the risks of unauthorized persons gaining access to research data at any stage of the research process. The procedures used to ensure this will differ according to the type of virtual media used. Using a "perspective of reasonableness," Kralik et al. (2005) argue that the chances of a breach of security are small and need to be weighed against possible gains from the research.

OWNERSHIP OF WORDS

The ownership of electronic messages has been contested. It is still unclear whether the individual who authored a message, the community to which it was sent, or anyone who has access to the message is the owner of the electronic message. Electronic postings may be considered original works protected by copyright, although this has not yet been legally tested (Sixsmith & Murray, 2001). If informed consent is not obtained to use electronic messages, copyright provisions suggest that they are subject to "fair dealing" for research purposes, and should be attributed to the author (Australian Copyright Council, 2001). Researchers who neither obtain informed consent, nor reference the material they are quoting, risk violating both ethical and copyright standards. With the consent of the research participant, quotes in research may be attributed to the individual, their online pseudonym, or used anonymously. Respect for research participants is demonstrated through asking, and abiding by, their preferences for anonymity, pseudonymity, or identification. However, this is not without its problems. Individual preferences for identification may not be consistent with the norms or wishes of the community. There can be tensions between respecting copyright entitlements of individuals and protecting the privacy of other participants within a virtual environment. Roberts et al. (2004) highlighted the potential for negative impacts on the privacy of other virtual environment members when one research participant's work is fully attributed, including information on the virtual environment.

RETURNING RESEARCH FINDINGS TO THE COMMUNITY

A requirement in some ethical codes is to provide research participants with information about the outcome of the research. In addition to being a requirement, this can demonstrate respect for the individuals who participated in the research. A summary of research findings can be provided to research participants in hardcopy or electronic format. Where research participants are reluctant to provide contact information that may link their online and off-line identities, the summary can be placed on a Web site or sent through the messaging system of the virtual community (Roberts et al., 2004).

FUTURE TRENDS

Rapidly changing technologies will result in the development of an increasing range of virtual environments and tools that may be used for research purposes. The precise characteristics of these new virtual environments and tools may vary greatly from those available today. Concern has already been raised over the potential for participant harm when non-human agents used in the research process evoke negative responses or unwanted arousal (Palomares & Flanagin, 2005). Privacy issues have been raised in relation to Web-cams, which have the potential to capture data from both consenting research participants and other non-consenting individuals in their proximity (Palomares & Flanagin, 2005).

Decisions made regarding research methodologies and designs in virtual environments need to be embedded in the basic principles of ethical research and may require multi-layered considerations. Before conducting research within each new type of environment or with a new type of research tool, researchers will need to address the intrusiveness of the proposed research, the perceived privacy of the research setting, the vulnerability of the community, the potential for harm to individuals and/or the community, and how confidentiality will be maintained and intellectual property rights respected in their research proposals (Eysenbach & Till, 2001). This requires a consideration of the likely impacts of the research on both research participants and the

communities in which the research is conducted. It should be guided by researchers' knowledge and adherence to the "Netiquette" and social norms of the virtual environments concerned. Guided by the principles outlined in their ethical codes, researchers will need to develop ethically defensible strategies that balance the needs of research participants and their online communities, offering protection to both, while providing the validity assurances required by the readers/users of the research.

CONCLUSION

Our approach to the conduct of ethical research in virtual environments is based on a human research perspective, explicitly recognizing that communication online is conducted by individuals who interact via their online identities. Our focus is therefore on individuals rather than texts. We privilege the rights of individuals to make informed consent about whether or not traces of their interaction online (e.g., logs or postings) can be used for research purposes. We believe this approach is consistent with general ethical guidelines for human research in the social sciences. Alternative perspectives to the conduct of ethical research in virtual environments place a stronger emphasis on the cultural production of texts and performance (Bassett & O'Riordan, 2002; White, 2002) reflecting calls for an ethical pluralism in Internet research that recognizes a range of ethical perspectives as legitimate (Ess, 2002).

Regardless of the perspective adopted, all research should comply with the principles of ethical research as outlined in the relevant professional association's code of ethics or by Institutional Review Boards. In the absence of specific guidelines for online research and where review committees are unfamiliar with online research issues (Keller & Lee, 2003), we recommend that researchers be guided by the principles outlined in their code, adapting the guidelines for use in virtual environments as necessary. In addition to protecting the rights of research participations, researchers have a social responsibility to ensure online research is conducted in an ethically defensible manner to maintain the viability of virtual environments as research media (Colvin & Lanigan, 2005).

KEY TERMS

Computer-Mediated Communication: Communication between two or more individuals that occurs via computer networks. Computer-mediated communication may be text, audio, graphics, or video based and occur synchronously (in "real time") or asynchronously (delayed).

Informed Consent: An individual's freely given consent to participate in research based on information provided by the researcher(s) about the research, possible risks associated with the research, and the voluntary nature of participation.

Informed consent must be obtained without coercion or undue influence.

Netiquette: The etiquette, or social rules, associated with communicating online. Netiquette may vary across virtual environments.

Private Space: Off-line, private space refers to geographical areas that are not for general or public use (e.g., your home). Online, the term private space is commonly used to refer to virtual environments, or parts of virtual environments that have restrictions on who may access them.

Pseudonym: The fictitious name adopted for use within a virtual environment. An individual may consistently use the same pseudonym or adopt several pseudonyms for use within and between virtual environments.

Public Space: Off-line, public space refers to geographical areas that are accessible to the general public (e.g., streets). Online, the term public space is commonly used to refer to virtual environments that do not have restrictions on access.

Virtual Identity: Representation of the individual in a virtual environment. The form of representation varies across virtual environments and may range from a pseudonym only (Internet relay chat), a pseudonym combined with a character description (multi-user dimensions), through to graphical representations, or avatars, in graphics-based environments. An individual may have multiple virtual identities.

ENDNOTES

1 Over time as codes are updated, consideration of research conducted online may be included. See, for example, the revised *Ethical Principles of Psychologists and Code of Conduct* (American Psychological Association, 2002).

2 Gatekeepers can ease researchers' access to a virtual community. While gatekeepers can influence the ease of communicating with community members, ultimately each community member has the right to choose whether or not they will participate in research, irrespective of gatekeepers' views.

3 We note, however, that the professional responsibility of the researcher sometimes overrides that of anonymity and confidentiality (e.g., reportable offences or subpoenaed research records).

Ethics of New Technologies

Joe Gilbert
University of Nevada Las Vegas, USA

INTRODUCTION

Information processing has been done through telling stories, drawing on cave walls, writing on parchment, printing books, talking on telephones, sending messages via telegraphs, broadcasting on radio and television, processing data in computers, and now by instantaneous network dissemination. Since the mid-1990's, personal computers have been the instrument of choice for sending and receiving information, and for processing much of it. The technology is the latest in a long series, but social issues involved have not really changed. Issues of content (is it true? obscene?), ownership (whose picture/text/idea? whose parchment/telephone system/computer?), and impact (anti-government, anti-social, harmful to children) appear today just as they did hundreds or thousands of years ago.

BACKGROUND

New technologies enable people to do new things (send 20 copies of a memo at once) or to do old things in new ways, such as storing files (Freeman & Soete, 1997). Improvements in technology that are incremental do not usually introduce major social issues, but radical innovations frequently present new kinds of social opportunities and threats (Brown, 1997). Ethics is the branch of philosophy that studies interpersonal or social values and the rules of conduct that follow from them. Ethics deals with questions of how people should treat each other on a basic level (Berlin, 2000). It considers such issues as rights and duties and fairness or justice. Because ethics concerns itself with fundamental rules, its applications to specific new technologies might require both knowledge of the new technology and reasoning about its possible applications based on established principles of ethics (Burn & Loch, 2001; Halbert & Ingulli, 2002).

Philosophers have pondered and written about issues of ethics for thousands of years. Some of their writings on this subject continue to be read and debated generation after generation (LaFollette, 2000). Three basic approaches have been most common and most accepted in discussions of ethics.

- Utilitarianism maintains that the ethical act is the one that creates the greatest good for the greatest number of people.
- Rights and duties maintain that the ethical act is the one that acknowledges the rights of others and the duties which those rights impose on the actor.
- Fairness and justice hold that the ethical act is the one that treats similarly situated people in similar ways with regard to both process and outcome.

ETHICS AND TECHNOLOGY

John Stuart Mill and Jeremy Bentham are the two philosophers most closely associated with utilitarianism. This view of ethics puts a high value on results, and holds that we must consider whether and to what degree our actions will bring pain or pleasure not only to ourselves but to all others who will be impacted by what we do (Frey, 2000; Mill & Bentham, 1987). A utilitarian would argue that the harm done to many individuals and businesses by viruses and worms far outweighs any happiness brought to their authors, and thus creating and disseminating such code is unethical. Similarly, a utilitarian analysis of music file-sharing would consider whether widespread free file-sharing might result in composers and artists deciding that it is not in their financial interest to continue writing and performing music. If this result occurred, not only the composers and artists but also their listeners would end up suffering harm that might outweigh the good that they enjoy from free file-sharing. Finally, a utilitarian analysis would favor products and policies that increase the spread of computer literacy and availability, since the Internet can bring great good to its users and computer literacy and availability makes such use possible.

Many philosophers have written about rights and duties (Sumner, 1987). The basic idea of this approach is that individuals do have rights, and that these rights are, practically speaking, worthless unless someone or some group has a corresponding duty. Thus, if I have a right to privacy, you have a duty not to monitor my every move (Kelly & Rowland, 2000). There are four basic sources of rights, and we will consider each in turn.

Human rights are possessed by every human, simply by virtue of being human. Among these rights are the right to live (not to be randomly killed), to be told the truth, to own property, and to basic dignity (Ignatieff, 2001). Among these, the one that most often causes confusion is the right to be

told the truth. Humans could not interact with each other in any meaningful way if lying and truth-telling were equally valid. Promises, contracts, and interpersonal relations all depend on the fact that the default setting for conversation is truth-telling. This does not mean that everyone always will or even should tell the whole truth all the time. It does, however, mean that we can and do start with an assumption of truth-telling (Bok, 1999). A right to property, whether physical or intellectual, means that others have a duty not to take or use my goods without compensating me.

Since property rights are human, they apply whether a given country's laws regarding such things as copyright and intellectual property are specific on a given issue or not. Music companies and movie studios, on behalf of individual artists, have a right to control and charge for distribution of their products. This right imposes a duty on individuals not to take such property without paying for it and recognizing the terms of distribution. Similarly, software companies have a right to charge for and control the distribution of their intellectual property. They paid programmers to develop a software product; others have a duty to respect the rights to this intellectual property.

Some rights are given to individuals by law. These citizen rights come by reason of membership in a community (nation, state, county, etc.). The right of citizens of the United States to free speech is not recognized by some other countries. Typically, dictatorships grant few citizen rights to those under their rule. These rights often coincide with human rights (right to live, to property, etc.) but frequently go beyond basic human rights. Copyright, as it exists in the United States, is not recognized equally in all countries. This is why it is important that the basic right to own property is a human right—it is valid whatever the laws of a particular jurisdiction.

A third source of rights is position. Policemen may apprehend and incarcerate suspected criminals. CEO's can speak for their companies on many issues. Purchasing agents can spend a company's money on goods or services within some limits. Managers can set rules for computer usage at work. People have these rights not just because they are human, or because they are particularly wise or knowledgeable, but because of the position they occupy. Since individuals have these rights, others have duties to respect the rights and follow their direction.

The fourth and final basic source of rights is by contract. Individuals or organizations can agree to contractual relations that create rights and impose duties that would not otherwise exist. If I agree to pay a certain amount of money each month in order to use an online service, I have a duty to pay and the service provider has a duty to make the service available to me under the terms of the contract.

The third basic approach to ethics is fairness and justice: it is ethical to be fair and unethical to be unfair. It is not fair that some individuals should purchase software and others obtain it free through sharing or piracy. It is fair for those who invest time, talent and money in producing software to be paid for the products resulting from their efforts and investments by all of those who use them, not just by some. Issues of fairness sometimes arise in the area of using computer technology for purposes of employee monitoring (Alder, 1998). In general terms, fairness involves treating similarly situated people in similar ways with regard to both process and outcome. However, justice is sometimes defined as equality, and at other times, as based on contribution, on needs and abilities, or on maximum freedom (Velasquez, 2002).

An issue that often arises in considering fairness and justice is the question of which individuals or groups are similarly situated. In the sense that all who access the Internet can view unrestricted sites, all who access the Internet are similarly situated. In the sense that some who access the Internet may choose to view pornography and others may choose not to (even inadvertently), we have at least two groups that are not similarly situated. Using this approach, one might argue against unrestricted availability of pornography on the Internet, but in favor of restricted access to Internet pornography. All who receive e-mail might be viewed as similarly situated. Spam reaching all e-mail accounts thus reaches similarly situated people. However, if most individuals who receive e-mail do not wish to receive spam, then this group (the unwilling) might be seen as not similarly situated with those who do wish to receive it. Such an argument could serve as the basis for something like an e-mail equivalent of the do-not-call list recently introduced for telemarketing.

The different approaches to ethics often produce the same result. If we consider the issue of hacking or gaining unauthorized access to another's system, utilitarianism concludes that more harm than good results from this activity. Those whose system is wrongfully accessed are faced with revising controls, checking to see what harm if any has been done, and correcting any problems caused by the hacking. Only the hacker gains. Those who have created or purchased the system have a right to limit access; the hacker has a duty to respect this right. It is not fair or just that some people go through the appropriate authorization to access or use a system while others hack into it. Thus from all three perspectives, hacking as defined can be judged unethical. If one does not accept the basic premises of the prevailing capitalist system, however, a defense of hacking can be devised (Halbert, 1994).

When the three approaches provide different results, rights and duties usually prevails as a way of determining whether an act is ethical, because rights are so basic. However, this is not always the case. In American copyright law, there is a "fair use" provision that allows an individual to make one copy for personal use of a copyrighted article without obtaining permission of the copyright holder. Whether this copy is made from a printed article on a photocopy machine

or downloaded from a computer, the same basic principle applies (Halbert & Ingulli, 2003). A utilitarian analysis suggests that this provision allows the greatest good for the greatest number of people, because single-copy permissions for personal use would involve excessive transaction costs to both users and copyright owners. One could argue from a rights and duties perspective that the copyright owner has a right (and the user a corresponding duty) to payment for each and every copy made of the material, even for a single copy. Fairness and justice would suggest that the "fair use" exception is ethically acceptable as long as each owner and user play by the same rules.

FUTURE TRENDS

Each of the three views can be used to analyze issues regarding new information technology and its applications (Gilbert, 2001). Because information technology has developed so quickly in the last quarter century, and appears to be poised for continued rapid development, a good deal of ethical analysis is and will be needed of specific questions and issues. The basic approaches are clear from a long history of ethical theory. The specific issues are and will be fresh, but those concerned with using information technology ethically can find answers to their questions. The collecting, storing, transmitting and analysis of information will continue to be central to both commerce and society. Issues of ownership, access, privacy and social impact will continue to concern individuals and society.

It seems safe to assume that laws will evolve and court decisions will help to illuminate legal issues involved with information processing technology. Individual managers, technicians and citizens will ponder and debate the ethics of various uses of this technology. Basic philosophical approaches will remain the same; their application to individual situations will continue to require that thoughtful individuals work through the journey from abstract principles to particular applications and decisions.

CONCLUSION

Much of the discussion of right and wrong concerning information technology is based either on personal opinion or on legal interpretations of such topics as intellectual property rights and individual privacy. Philosophers have thought about, discussed, and written about right and wrong for thousands of years. While the history of philosophy has unfolded before the invention of electronic information technology, issues such as privacy, property ownership, truthfulness, and government intrusion on individual liberties have been the subjects of ethical inquiries for well over two thousand years. In attempting to cope with social issues raised by new technologies, the best thoughts of many generations of humans can be usefully brought to bear on current controversies. Doing this requires both knowledge of the discipline of ethics and at least some knowledge of new technologies and their social impacts. The application of such knowledge connects us with our ancestors who wrote on cave walls, told stories over campfires, printed books, and used the other means of processing information described at the beginning of this article.

KEY TERMS

Citizen Rights: Those rights that an individual has by virtue of being a member of a government unit (country, state, province, etc.). They vary from government unit to government unit.

Contract Rights: Those rights that an individual has by reason of a valid contract that imposes duties on the other contracting party or parties. They are enforceable under legal systems, but are not the same as citizen rights.

Duties: The correlative of rights, since rights by their nature impose duties.

Ethics: The study of social or interpersonal values and the rules of conduct that follow from them.

Fairness and Justice: The philosophical view that the moral act is the one that treats similarly situated people in similar ways with regard to both process and outcome.

Human Rights: Those rights that all humans have simply by reason of being human, without regard to an individual government unit's laws.

Philosophy: The study of basic principles including what and how we know, rules for language and reasoning, and the basis for social interaction.

Position Rights: Those rights that an individual has by reason of the position that he or she occupies, such as police officer, chief financial officer, or parent.

Rights and Duties: The philosophical view that the moral act is the one that recognizes the rights of others and the duties that those rights impose on the actor.

Utilitarianism: The philosophical view that the moral act is the one that results in the greatest good or happiness for the greatest number of people.

Evaluating Computer-Supported Learning Initiatives

John B. Nash
Stanford University, USA

Christoph Richter
University of Hannover, Germany

Heidrun Allert
University of Hannover, Germany

INTRODUCTION

The call for the integration of program evaluation into the development of computer-supported learning environments is ever increasing. Pushed not only by demands from policy makers and grant givers for more accountability within lean times, this trend is due also to the fact that outcomes of computer-supported learning environment projects often fall short of the expectations held by the project teams. The discrepancy between the targets set by the project staff and the outcomes achieved suggests there is a need for formative evaluation approaches (versus summative approaches) that facilitate the elicitation of information that can be used to improve a program while it is in its development stage (c.p., Worthen, Sanders & Fitzpatrick, 1997). While the call for formative evaluation as an integral part of projects that aim to develop complex socio-technical systems is widely accepted, we note a lack of theoretical frameworks that reflect the particularities of these kind of systems and the ways they evolve (c.p., Keil-Slawik, 1999). This is of crucial importance, as formative evaluation will only be an accepted and effective part of a project if it provides information useful for the project staff. Below we outline the obstacles evaluation faces with regard to projects that design computer-supported learning environments, and discuss two promising approaches that can be used in complimentary fashion.

BACKGROUND

According to Worthen et al. (1997), evaluation is "the identification, clarification, and application of defensible criteria to determine an evaluation object's value (worth or merit), quality, utility, effectiveness, or significance in relation to those criteria." In this regard evaluation can serve different purposes. Patton (1997) distinguishes between judgment-, knowledge- and improvement-oriented evaluations. We focus on improvement-oriented evaluation approaches. We stress that evaluation can facilitate decision making and reveal information that can be used to improve not only the project itself, but also outcomes within the project's target population. The conceptualization of evaluation as an improvement-oriented and formative activity reveals its proximity to design activities. In fact this kind of evaluative activity is an integral part of any design process, whether it is explicitly mentioned or not. Accordingly it is not the question if one should evaluate, but which evaluation methods generate the most useful information in order to improve the program. This question can only be answered by facing the characteristics and obstacles of designing computer-supported learning environments.

Keil-Slawik (1999) points out that one of the main challenges in evaluating computer-supported learning environments is that some goals and opportunities can spontaneously arise in the course of the development process and are thus not specified in advance. We believe that this is due to the fact that design, in this context, addresses ill-structured and situated problems. The design and implementation of computer-supported learning environments, which can be viewed as a response to a perceived problem, also generates new problems as it is designed. Furthermore every computer-supported learning experience takes place in a unique social context that contributes to the success of an intervention or prevents it. Therefore evaluation requires that designers pay attention to evolutionary and cyclic processes and situational factors. As Weiss notes, "Much evaluation is done by investigating outcomes without much attention to the paths by which they were produced" (1998, p. 55).

For developers designing projects at the intersection of information and communication technology (ICT) and the learning sciences, evaluation is difficult. Evaluation efforts are often subverted by a myriad of confounding variables, leading to a "garbage in, garbage out" effect; the evaluation cannot be better than the parameters that were built in the project from the start (Nash, Plugge & Eurlings, 2001). Leaving key parameters of evaluative thinking out

of computer-supported learning projects is exacerbated by the fact that many investigators lack the tools and expertise necessary to cope with the complexity they face in addressing the field of learning.

We strongly advocate leveraging the innate ability of members of the computer science and engineering communities to engage in "design thinking" and turn this ability into a set of practices that naturally becomes program evaluation, thereby making an assessment of the usefulness of ICT tools for learning a natural occurrence (and a manifest activity) in any computer-supported learning project.

Design-Oriented Evaluation for Computer-Supported Learning Environments

There are two approaches that inherently relate themselves to design as well as to evaluation. Therefore they are useful tools for designers of computer-supported learning initiatives. These two perspectives, discussed below, are scenario-based design and program theory evaluation. Both approaches assume that the ultimate goal of a project should be at the center of the design and evaluation discussion, ensuring a project is not about only developing a usable tool or system, but is about developing a useful tool or system that improves outcomes for the user. Beyond this common ground, these approaches are rather complementary to each other and it is reasonable to use them in conjunction with one another.

Scenario-Based Approaches

Scenario-based approaches are widely used in the fields of software engineering, requirements engineering, human computer interaction, and information systems (Rolland et al., 1996). Scenarios are a method to model the universe of discourse of an application, that is, the environment in which a system, technical or non-technical, will be deployed. A scenario is a concrete story about use of an innovative tool and/or social interactions (Carroll, 2000). Scenarios include protagonists with individual goals or objectives and reflect exemplary sequences of actions and events. They refer to observable behavior as well as mental processes, and also cover situational details assumed to affect the course of actions (Rosson & Carroll, 2002). Additionally it might explicitly refer to the underlying culture, norms, and values (see Bødker & Christiansen, 1997). That said, scenarios usually focus on specific situations, only enlighten some important aspects, and generally do not include every eventuality (e.g., Benner, Feather, Johnson & Zorman, 1993).

Beside their use in the design process, scenarios can also be used for purposes of formative evaluation. First of all, as a means of communication, they are a valuable resource for identifying underlying assumptions regarding the program under development. Stakeholder assumptions might include those related to instructional theories, the learner, the environmental context, and its impact on learning or technical requirements. Underlying assumptions such as these are typically hidden from view of others, but easily developed and strongly held within individuals developing computer-supported learning environments. Scenarios help to reveal the thinking of designers so that others can participate in the design process and questionable assumptions can come under scrutiny. The use of scenarios also allows identification of pros and cons of a certain decision within the design process. In this vein Carroll (2000) suggests employing "claim analysis." Claims are the positive or negative, desirable and undesirable consequences related to a certain characteristic of a scenario. Assuming that every feature of a proposed solution usually will entail both positive and negative effects helps to reflect on the current solution and might provoke alternative proposals. The analysis of claims is thereby not limited to an intuitive ad hoc evaluation, but also can bring forth an explicit hypothesis to be addressed in a subsequent survey.

Program Theory Evaluation

Program theory evaluation, also known as theory-based evaluation, assumes that underlying any initiative or project is an explicit or latent "theory" (or "theories") about how the initiative or project is meant to change outcomes. An evaluator should surface those theories and lay them out in as fine detail as possible, identifying all the assumptions and sub-assumptions built into the program (Weiss, 1995). This approach has been promoted as useful in evaluating computer-supported learning projects (Strömdahl & Langerth-Zetterman, 2000; Nash, Plugge & Eurlings, 2001) where investigators across disciplines find it appealing. For instance, for designers (in mechanical engineering or computer science), program theory evaluation reminds them of their own use of the "design rationale." And among economists, program theory evaluation reminds them of total quality management (TQM). In the program theory approach (Weiss, 1995, 1998; Chen, 1989; Chen & Rossi, 1987), one constructs a project's "theory of change" or "program logic" by asking the various stakeholders, "What is the project designed to accomplish, and how are its components intended to get it there?" The process helps the project stakeholders and the evaluation team to identify and come to consensus on the project's theory of change. By identifying and describing the activities, outcomes, and goals of the program, along with their interrelationships, the stakeholders are then in position to identify quantifiable measures to portray the veracity of the model.

Theory-based evaluation identifies and tests the relationships among a project's inputs or activities and its outcomes via intermediate outcomes. The key advantages

to using theory-based evaluation are (Connel & Kubisch, 1995; Weiss, 1995):

- It asks project practitioners to make their assumptions explicit and to reach consensus with their colleagues about what they are trying to do and why.
- It articulates a theory of change at the outset and gains agreement on it, by all stakeholders reducing problems associated with causal attribution of impact.
- It concentrates evaluation attention and resources on key aspects of the project.
- It facilitates aggregation of evaluation results into a broader context based on theoretical program knowledge.
- The theory of change model identified will facilitate the research design, measurement, data collection, and analysis elements of the evaluation.

Both scenario-based design and program theory stress the importance of the social context while planning computer-supported environments. They also represent means to facilitate the communication among the stakeholders and urge the project team to reflect their underlying assumptions in order to discuss and test them. Furthermore, both approaches are particularly suitable for multidisciplinary project teams. Scenarios and program logic maps are not static artifacts; they are a starting point for discussion and have to be changed when necessary. With these similarities there are also differences in both approaches. The major difference between them is that program theory offers a goal-oriented way to structure a project, while scenario-based design proffers an explorative approach that opens the mind to the complexity of the problem, alternatives, and the diversity of theories that try to explain social and socio-technical process. That is, scenario-based design highlights the divergent aspects of project planning, and evaluation program theory stresses the convergent aspects. Program theory evaluation helps to integrate each scenario, decision, and predefinition into the whole process. Scenarios force users not just to use terms, but to give meaningful descriptions. They force users to state how they actually want to instantiate an abstract theory of learning and teaching. This helps to implement the project within real situations of use, which are complex and ill structured. Program theory helps to focus on core aspects of design and prevent getting 'lost in scenarios'. Scenarios and program theory evaluation can be used in an alternating way. Thereby it is possible to use both approaches and improve the overall development process.

The program theory of an initiative can be a starting point for writing scenarios. Especially the interrelations between the goals and interrelation between ultimate goal and inputs can be described with a scenario. The scenario can help to understand how this interrelation is meant to work and how it will look in a concrete situation. Scenarios on the other hand can be used to create program theory by pointing out main elements of the intended program. They can also be used to complete already existing program theory by presenting alternative situations of use. For developers of computer-supported learning environments, scenario-based design and program theory represent complementary approaches, which when used together or separately, can add strength to the implementation and success of such projects.

FUTURE TRENDS

It is clear that formative evaluation will become more important in the future, and it will be especially crucial to think about how to integrate evaluation into the design process. Essentially, designers will need to answer the question "Why does the program work?" and not just "Did it work?" It becomes obvious that the design of a computer-supported learning environment, like the development of any other complex socio-technical system, is a difficult process. In fact the necessity for changes in the original plan is practically preordained due to the ill-structured and situated nature of the domain. The mere act of engaging in a design process suggests that designers will engage in planned as well as evolutionary, unplanned activities. Therefore it is important that the project designers use methods that support divergent thinking and methods that support convergent processes. While scenario-based design and program-theory evaluation represent complementary views on the design and evaluation of computer-supported learning environments that can facilitate these processes, there is still room for improvement.

CONCLUSION

Formative evaluation is an important means to ensure the quality of an initiative's outcomes. Formative evaluation directed towards improvement of an initiative can be understood as a natural part of any design activity. While this is widely recognized, there is still a lack of program evaluation frameworks that reflect the uniqueness of the design process, the most crucial of which is the inherent ambiguity of design. In spite of great inspiration portrayed by project teams, usually manifested by visions of a certain and sure outcome, no project can be pre-planned completely, and mid-course corrections are a certainty. Scenario-based design and program theory evaluation provide a theoretical foothold for projects in need of collecting and analyzing data for program improvement and judging program success.

In sum, scenario-based design and program theory hold many similarities. The major difference between them is that program theory offers a goal-oriented way to structure a project, while scenario-based design provides an explorative approach that opens the mind to the complexity of the

problem, alternatives, and the diversity of theories that try to explain social and socio-technical process.

Scenario-based design highlights the divergent aspects of project planning, and evaluation program theory stresses the convergent aspects. For developers of computer-supported learning experiences, scenario-based design and program theory represent complementary approaches, which when used together or separately can add strength to the implementation and success of ICT learning projects.

KEY TERMS

Computer-Supported Learning: Learning processes that take place in an environment that includes computer-based tools and/or electronically stored resources. CSCL is one part of this type of learning.

Evaluation: The systematic determination of the merit or worth of an object.

Formative Evaluation: The elicitation of information that can be used to improve a program while it is in the development stage.

Program: A social endeavor to reach some predefined goals and objectives. A program draws on personal, social, and material resources to alter or preserve the context in which it takes place.

Program Theory: A set of assumptions underlying a program that explains why the planned activities should lead to the predefined goals and objectives. The program theory includes activities directly implemented by the program, as well as the activities that are generated as an response to the program by the context in which it takes place.

Scenarios: A narrative description of a sequence of (inter-)actions performed by one or more persons in a particular context. Scenarios include information about goals, plans, interpretations, values, and contextual conditions and events.

Summative Evaluation: The elicitation of information that can be used to determine if a program should be continued or terminated.

E

Evaluating UML Using a Generic Quality Framework

John Krogstie
IDI, NTNU, SINTEF, Norway

INTRODUCTION

According to Booch, Rumbaugh, and Jacobson (2005), developing a model for an industrial strength software system before its construction is increasingly regarded as a necessary activity in information systems development. The use of object-oriented modeling in analysis and design started to become popular in the late 80s, producing a large number of different languages and approaches. Over the last 10 years, UML (OMG, 2006a) has taken a leading position in this area.

In this chapter, we give an overview assessment of UML using a generic evaluation framework. We will first present the evaluation framework. We will then evaluate the language quality of UML before pointing to the future direction and potential of UML.

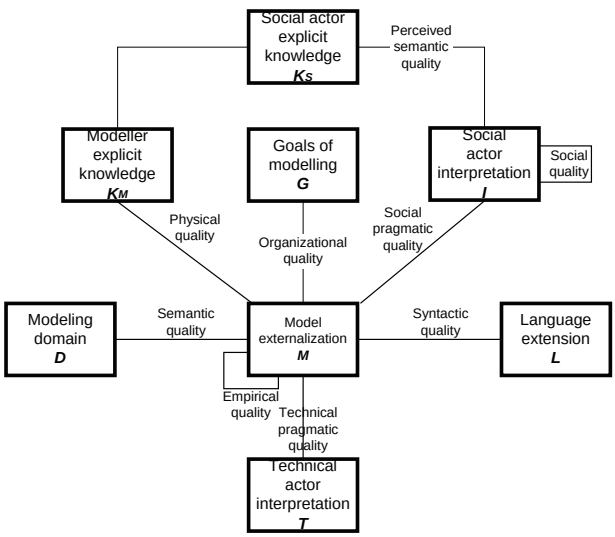
BACKGROUND

Earlier, we developed a framework for understanding and assessing quality of models and modeling languages (Krogstie & Sølvberg, 2003; Krogstie, Sindre, & Jørgensen, 2006).

The main concepts of the framework and their relationships are shown in Figure 1 and are explained next. Quality has been defined referring to the correspondence between statements belonging to the following sets:

- G, the goals of the modeling task
- L, the language extension (i.e., the set of all statements that are possible to make according to the graphemes, vocabulary, and syntax of the modeling languages used)
- D, the domain (i.e., the set of all statements that can be stated about the situation at hand)
- M, the externalized model itself
- Ks, the relevant explicit knowledge of those being involved in modeling. A subset of these is actively involved in modeling, and their explicit knowledge is indicated by K_M.
- I, the social actor interpretation (i.e., the set of all statements that the audience thinks that an externalized model consists of)
- T, the technical actor interpretation (i.e., the statements in the model as "interpreted" by modeling tools)

Figure 1. Framework for discussing the quality of models



The main quality types are indicated by solid lines between the sets and are described briefly next:

- **Physical quality:** The basic quality goals on the physical level is that the knowledge K of the domain D has been externalized, and internalizeability, that the externalized model M is available.
- **Empirical quality** deals with predictable error frequencies when a model is read or written by different users, coding (e.g., shapes of boxes) and HCI-ergonomics for documentation and modeling-tools. For instance, graph layout to avoid crossing lines in a model is a mean to address the empirical quality of a model.
- **Syntactic quality** is the correspondence between the model M and the language extension L.
- **Semantic quality** is the correspondence between the model M and the domain D. This includes validity and completeness.
- **Perceived semantic quality** is the similar correspondence between the audience interpretation I of a model M and his or hers current knowledge K of the domain D.
- **Pragmatic quality** is the correspondence between the model M and the audience's interpretation and application of it (I). We differentiate between social pragmatic quality (to what extent people understand and are able to use the models) and technical pragmatic quality (to what extent tools can be made that interpret the models).

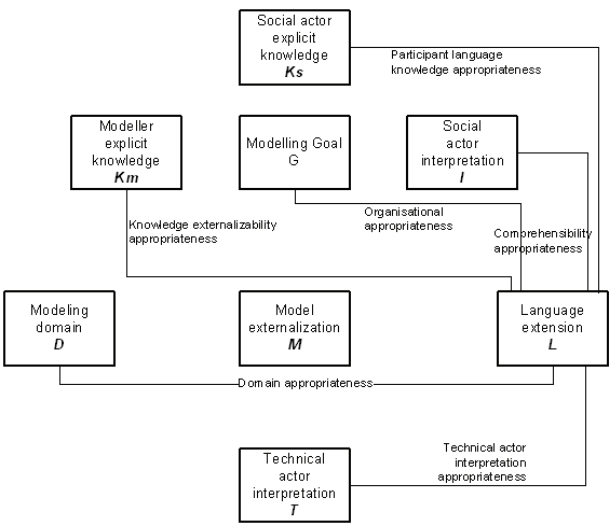
The goal defined for social quality is agreement among audience members' interpretations I.

The organizational quality of the model relates to that all statements in the model contribute to fulfilling the goals of modeling (organizational goal validity), and that all the goals of modeling are addressed through the model (organizational goal completeness).

Language quality relates the modeling language used to the other sets. Six quality areas for language quality are identified with aspects related to both the language metamodel and the notation as illustrated in Figure 2.

- **Domain appropriateness:** This relates the language and the domain. Ideally, the conceptual basis must be powerful enough to express anything in the domain, not having what Wand and Weber (1993) term construct deficit. On the other hand, you should not be able to express things that are not in the domain (i.e., what is termed construct excess) (Wand et al., 1993). Domain appropriateness is primarily a mean to achieve physical quality, and through this, to achieve semantic quality.
- **Participant language knowledge appropriateness** relates the social actors' explicit knowledge to the language. Participant language knowledge appropriateness is primarily a mean to achieve physical and pragmatic quality.
- **Knowledge externalizability appropriateness:** This area relates the language extension to the participant knowledge. The goal is that there are no statements in the explicit knowledge of the modeler that cannot be expressed in the language. Knowledge externalizability appropriateness is primarily a mean to achieve physical quality.

Figure 2. Language quality in the quality framework



- **Comprehensibility appropriateness** relates the language to the social actor interpretation. The goal is that the participants in the modeling effort using the language understand all the possible statements of the language. Comprehensibility appropriateness is primarily a mean to achieve empirical and pragmatic quality.
- **Technical actor interpretation appropriateness** relates the language to the technical audience interpretations. For tool interpretation, it is especially important that the language lend itself to automatic reasoning. This requires formality (i.e., both formal syntax and semantics being operational and/or logical), but formality is not necessarily enough, since the reasoning must also be efficient to be of practical use. This is covered by what we term analyzability (to exploit any mathematical semantics) and executability (to exploit any operational semantics). Different aspects of technical actor interpretation appropriateness are a mean to achieve syntactic, semantic, and pragmatic quality (through formal syntax, mathematical semantics, and operational semantics).
- **Organizational appropriateness** relates the language to standards and other organizational needs within the organizational context of modeling. These are means to support organizational quality.

Whereas knowledge externalizability appropriateness and organizational appropriateness is closely linked to particular organizations and modelers involved, for a more general evaluation, we can use the other four categories.

OVERVIEW OF EVALUATION

The evaluation is structured according to the four areas of language quality previously presented. Before presenting the evaluation, we will position UML in relation to the sets of the quality framework.

- **Domain:** According to OMG (2006a), UML is a language for specifying, visualizing, constructing, and documenting the artifacts of software systems, as well as for business modeling and other non-software systems. In other words, UML is meant to be used in analysis of business and information, requirement specification, and design. UML is meant to support the modeling of (object-oriented) transaction systems, real-time, and safety critical systems. As illustrated in Favre (2003), UML is used and adapted for a number of different specific areas.
- **Language:** We have based the evaluation on UML (version 2.0, (Booch et al., 2005, OMG, 2006a)).

The sets "Knowledge," "Model," and "Interpretation" must be judged from case to case in the practical application of a modeling language and tools. Also when it comes to weighting the different criteria against each other, this must be done in the light of the specific modeling task, such as has been done by (e.g., Krogstie & Arnesen, 2004; Nysetvold & Krogstie, 2006).

Due to the limitation on the length of a paper of this kind and the breadth of the evaluation, we will only have room for presenting some of the major results. See Krogstie (2003) for a more detailed description of using the framework for evaluating UML.

Domain Appropriateness

Looking briefly on the coverage of the seven main modeling-perspectives in information systems modeling (Krogstie et al., 2003), we find:

- UML has a very good support for modeling according to an object-oriented perspective, especially for design.
- The structural perspective is also well supported, although not as well as in languages made specifically for this purpose.
- The behavioral perspective is supported particularly through statecharts.
- The functional (process) perspective is supported on a high level through use case modeling, a language that has been highly criticized for not being well-defined (Hitz & Kappel, 1998). Whereas use-cases are meant for requirements modeling, activity diagrams can be used for simple procedural description by showing control flow and the production of data or objects in a process flow. Changes to the activity diagrams are introduced in UML2.0 to improve the modeling of business processes. The lack of traditional dataflow in activity diagrams has been noted as a problem. Note that another upcoming standard in this area, BPMN (BPMN 2006) has been taken over by OMG, although there are no immediate plans for including BPMN in UML.
- The actor-role perspective is partly covered using the collaboration diagrams. Using roles in sequence diagrams or "swimlanes" in activity diagrams, we also get a role-oriented view, but there is no intuitive way to represent organizational and group-structures and relationships in UML.
- There are fundamental problems with expressing certain constraints in any OO modeling framework (Høydalsvik & Sindre, 1993). Temporal and deontic constraints are hard to express. Whereas these kind of concepts are not included in UML, a new initiative within OMG, SBVR (OMG, 2006b), includes such

things as deontic operators. For the moment, there are no plans for including this in UML. There is no support for modeling of goal-hierarchies (Mylopoulos, Chung, & Tu, 1999).
- The language-action perspective, which is most useful for the analysis of businesses, is not supported.

A meta-model of UML is defined (using UML), and there exist extension mechanisms to make the language more applicable in specific domains, although when creating such profiles, it is not possible to describe the semantics of the extensions in a formal manner.

Most of UML is first useful during design. These parts of the language should not be used in analysis and requirements specification, even in areas where the transition from analysis to design is "seamless." (There is much evidence, especially for business systems, that this transition is far from seamless even when using object-oriented modeling in all domains (Davis, 1995; Høydalsvik et al., 1993). Proper guidelines for avoiding this are not consistently provided, and there is limited support for avoiding using analysis and design concepts in the same model.

There are also mismatches between underlying basis and external representation. In sequence diagrams, for instance a number of concepts are semantically vacant (Morris & Spanoudakis, 2001). Some of these problems are addressed in UML 2.0. We also find examples of concrete constructs in the UML meta-model, with no representation in the notation (e.g., namespace and model).

Participant Language Knowledge Appropriateness

It can be argued that for those being familiar with the main OO-modeling concepts and main OO modeling-languages, the core of UML should not represent a too steep learning curve. Almost all CS and IS-degrees now include courses where UML is lectured and used. On the other hand, we have noted the complexity of the language above. The large number of constructs in UML is partly due to its diverse diagramming techniques (Siau & Cao, 2001). Constructs in use case diagrams are very different from constructs in class diagrams. Class diagrams are also very different from activity diagrams or Statecharts. This diversity causes problems. First, there are more constructs to learn. Second, the knowledge and experience gained in using one diagramming technique cannot easily be transferred to another diagramming technique in UML. The definition of language units and increments within units introduced in UML 2.0 will hopefully help in practical application of the language.

Participant Comprehensibility Appropriateness

UML can be argued to be overly complex with 233 different concepts (in UML 1.4) (Castellani, 1999). A similar number of concepts can be found in UML 2.0. In Siau et al. (2001) a detailed comparison between UML and other modeling approaches are presented. Although UML has more diagramming techniques when compared to object-oriented methods such as OMT, OOAD, and Shlaer/Mellor, each of the diagramming techniques in isolation is no more complex than techniques found in these methods. On the overall method level on the other hand, UML stands out noticeably, being most complex according to most of the metrics. On the other hand, Erickson and Siau (2004) point out that the actual usage of a large number of the concepts within UML is limited.

With so many concepts, it is not surprising that some redundancy and overlap is witnessed.

Examples of lacking symbol differentiation is found, for example, that both classes and objects are shown using rectangles. On the other hand, since the text-style of the object gives an indication of this, this is a minor problem.

UML contains many possibilities of adding (often small) adornments to the models. Such small adornments are often difficult to see and comprehend.

A uniform use of symbols is not adhered to. An example is that different symbols are used for a role if it is external to the system (pin-man) or internal (rectangle).

Technical Actor Interpretation Appropriateness

The UML-syntax is rigorously defined and the language is described through a meta-model made in the structural model of UML with accompanying descriptions of the semantics. Using UML to model UML means that some of the definitions are circular, and this leaves UML (formally speaking) undefined. This would be unproblematic if most practitioners already understood the meaning of the core concepts (classes, inheritance, and associations) that are involved. In UML 2.0 a formal (operational) action language have been included to support a wider repertoire of modeling techniques. Only some parts of UML have been provided a formal (operational) semantics. So-called semantic variation points are included in UML 2.0 to clearly indicate where the semantics is not rigorously defined. In any case, the UML meta-model only describe the structural aspects of the language, and not the behavioral aspects.

FUTURE TRENDS

Modeling as a general technique within information systems development has received increasing interest over the last years, and will continue to be of high importance, for example, in connection to the OMG MDA approach and business process support. Due to its strong support, UML is probably the best general modeling language to adopt as a basis for object-oriented development if one is not already using another language with good tool support that one is satisfied with. Most of the accidental problems such as inconsistencies in the language-descriptions found in earlier version of UML seem to be addressed in UML 2.0, but there are still concerns. UML 3.0 is already planned, but it is difficult to judge what this will look like. Judging from the time it has taken to finalize UML 2.0, we expect to have to relate to this for a number of years.

CONCLUSION

UML has been developed and refined over the last 10 years, but there are still some major weaknesses with the approach. Even if it has not been possible to agree on a standard process, outline process guidelines need to be included--even if the best that can be done is to describe a number of alternatives. Particularly problematic is the logical/physical confusion in the UML-definition. As discussed by Davis (1995), there are fundamental differences between the models related to analysis, design, and requirement specification. What our investigation has also illustrated is that although there is a perceived need to extend the expressiveness and formality of the language, the language has several weaknesses regarding comprehensibility appropriateness, and is already looked upon as difficult to comprehend. The distinction between infrastructure and superstructure provided for UML 2.0 tries to address this. Looking at the accepted 1000-plus-page proposal for UML2.0 superstructure alone does not give us much hope that the whole of UML will be particularly much easier to learn and use, as pointed out also in France, Ghosh, Dinh-Trong, and Solberg (2006).

KEY TERMS

Analysis Model: A model developed to learn all aspects of a problem domain to determine the best way to solve a specific set of user needs.

Design Model: A model developed to represent the optimal technical solution of a specified user need (as represented in a requirements model).

Model: An abstraction represented in a modeling language.

Modeling Language: A language (i.e., a set of symbols, and rules for how to combine these symbols) to represent knowledge relevant in (information systems) development.

Requirements Model: A model to represent the external requirement to a system without taking into account how the system looks inside.

UML (Unified Modeling Language): A general-purpose visual modeling language that is used to specify, visualize, construct and document the artifacts of a software system.

Visual Modeling Language: A diagrammatic modeling language (i.e., where the models made in the language are 2-dimensional diagrams).

Evaluating Computer Network Packet Inter-Arrival Distributions

INTRODUCTION

The past decade could be classified as the "decade of connectivity"; in fact, it is commonplace for computers to be connected to an LAN, which in turn is connected to a WAN, which provides an Internet connection. On an application level this connectivity allows access to data that even five years earlier were unavailable to the general population. This growth has not occurred without problems, however. The number of users and the complexity/size of their applications continue to mushroom. Many networks are over-subscribed in terms of bandwidth, especially during peak usage periods. Often network growth was not planned for, and these networks suffer from poor design. Also, the explosive growth has often necessitated that crisis management be employed just to keep basic applications running. Whatever the source of the problem, it is clear that proactive design and management strategies need to be employed to optimize available networking resources (Fortier & Desrochers, 1990). This is especially true in today's world of massive Internet usage (Zhu, Yu, & Doyle, 2001).

BACKGROUND

Obviously, one way to increase network bandwidth is to increase the speed of the links. However, this may not always be practical due to cost or implementation time. Furthermore, this solution needs to be carefully thought out because increasing speed in one part of a network could adversely effect response time in another part of that network. Another solution would be to optimize the currently available bandwidth through programming logic. Quality of service (QOS) and reservation bandwidth (RB) are two popular methods currently being utilized. Implementation of these optimization methods is rarely simple and often requires a high degree of experimentation if they are to be effectively configured (Walker, 2000). This experimentation can have detrimental effects on a live network, often taking away resources from mission critical applications. The client/server model so popular in Internet communication is a prime example of a system that can benefit from an analytical modeling strategy (Postigo-Boix, Garcia-Haro, & Melus-Moreno, 2005).

THE BENEFITS OF SIMULATION

Therefore, the most efficient way to ascertain the potential benefit and derive baseline configuration parameters for these optimization methods is through simulation or mathematical modeling. Simulation can be very effective in planning a network design. For example, what if network link number three was increased to 10Gbs? Would workstations on that link experience an improvement in response time? What would happen to workstations on the other part of the total network? Another approach to ascertain if a given network will exceed its capacity is based on network calculus (Cruz, 1991; Le Boudec, 1998). In this method the characteristics (such as speed, maximum packet size, and peak rate) of the network architecture are analyzed, and performance bounds are defined. The goal then is to devise control/management programs (such as QOS and RB) that will keep the workload within those defined bounds. There are numerous applications of this control/management logic, such as Cruz (1995), Cruz and Tsai (1996), Firoiu, Le Boudec, Towsley, and Zhang (2002), and Vojnovic and Le Boudec (2002). Recent work has focused on integrated service on WANs across service providers (Cruz & Santhanam, 2000). These control/management programs have proved very effective under a variety of circumstances, but are influenced by the packet inter-arrival rate as well. Therefore, if a network designer is contemplating invoking one of these options, simulation could be used to test how the option in question would improve performance on his or her system, provided an adequate method could be found to describe

the distribution within that network. Simulation has been used for many years in network design; however, the time and cost of its use have often been prohibitive. In recent years, new windows-based point and click products such as Comnet III (and its successors Network & Simscript) have eliminated the drudgery and the cost of writing simulations via a command line interface (CACI, 1998). Under Comnet III the appropriate devices are selected, connected together, and their characteristics defined. There is still a limiting factor in this process: the definition of the distribution of the packet inter-arrival rates. The theoretical model often used to describe computer networking is the Poisson. This model may have been adequate for some of the first single tier, single protocol networks. However, it lacks validity in describing the total stream in today's hierarchically complex multi-protocol networks. In the classical Poisson process model (such as M/M/1), when the number of arrivals follows a Poisson probability distribution, then the time between arrivals (inter-arrival time) follows a decaying exponential probability distribution. A number of studies confirm that the actual inter-arrival distribution of packets is not totally exponential as would be expected in the classical model (Guster, Robinson, & Richardson, 1999; Krzenski, 1998; Partridge, 1993; Vandolore, Babic, & Jain, 1999). However, in light of recent changes in networking regarding line speed and number of connected hosts that in effect have tripled in magnitude, the Poisson model is being reevaluated. Specifically, Karagiannis, Molle, and Faloutsos (2004) found that the stream as a whole may not be exactly Poisson, but some of it components might fit quite well. Those cases involved sub-second streams and large multi-second streams.

The inter-arrival distribution selected can have a major impact on the results of the simulation (Guster, Safonov, Hall, & Sundheim, 2003; Guster, Sohn, Robinson, & Safonov, 2003). In a study by Krzenski (1999) that analyzed the simulated performance on a shared Ethernet network, 12 different inter-arrival distributions were tried within the same simulation problem. These included the gamma distribution, which is a generalization of the exponential distribution, allowing for a modal inter-arrival time (the most commonly occurring time between arrivals) to be moved out away from the very short, nearly instantaneous time occurring with the exponential distribution. Another distribution among the 12 was an integer distribution, whereby equal probabilities are assigned to different values that are equally spaced throughout the possible inter-arrival times. Among the 12 distributions, there were vast discrepancies in the results. For example, the number of collision episodes varied from 310 with a gamma distribution to 741 with an integer distribution. These results further support the need to have the correct distribution in simulations designed to provide design and management feedback about computer networks. The frustration of the past work and the need for additional research is best summarized by Partridge (1993, p. 3):

… We still do not understand how data communication traffic behaves. After nearly a quarter of a century of data communication, researchers are still struggling to develop adequate traffic models. Yet daily we make decisions about how to configure networks and configure network devices based on inadequate models of data traffic. There is a serious need for more research work on non-Poisson queuing models.

A number of different strategies have been employed in the development of models used to describe packet inter-arrival rates (Guster, Litvinov, Richardson, & Robinson, 2002). Perhaps the most valid is to record all of the packet arrival times for the time period desired and use that to generate the distribution. The advantage of this strategy is accuracy, but it often requires massive amounts of data to be recorded and processed. To lessen this burden, often a representative sample from the time period is used. However, validating the sample period is often difficult, especially if the file size is not large. Known distributions have been used with limited success (Guster & Robinson, 1994, 2000; Guster, Robinson, & Juckel, 2000). For simple networks, exponential distributions provide some promise; however, they fail to deal with the intricacies of complex multi-protocol networks. Tabular distributions, in which one column describes the interval and a second column describes the probability of a value from that interval occurring, offer a moderate degree of accuracy, but they take time to derive, and their sophistication is related to the number of rows included. Regression and ANOVA have been used in some cases but lack the ability to describe the peaks and valleys associated with packet arrival data. Time series deals with these variations better but still lacks the sophistication needed and requires relatively complex models to even come close (Guster & Robinson, 1993). Packet trains are very effective in describing packet traffic from a single session such as telnet (Vandolore et al., 1999) but lack the complexity to deal with multiple concurrent sessions on the same network. However, the basic idea of breaking the total stream into subparts has been improved using a multilevel traffic approach. Karagiannis, Papagiannaki, and Faloutsos (2005) have been able to devise a classification schema based on the applications that generate them and have been able to classify 80-90% of traffic with more than 95% accuracy.

FUTURE TRENDS

Two non-Poisson queuing models have offered a degree of promise. One method involves viewing the observation interval as containing several independent Poisson processes rather than as a single exponential distribution. In a study by Guster et al. (1999), actual data were analyzed and shown to contain three Poisson processes of differing characteristics. During the first phase activity was increasing. During the

Figure 1. Frequency counts of packet inter-arrival times for Ethernet text data

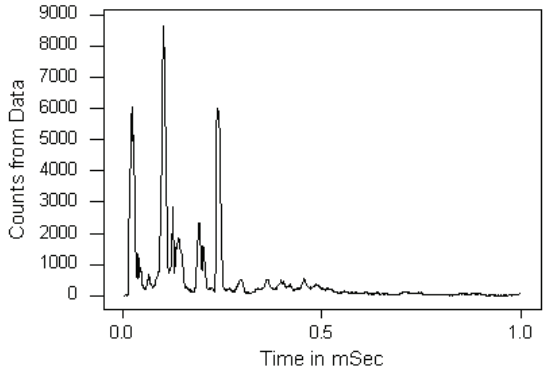

Figure 2. Distribution function for the actual data, the Poisson model, and Markov model

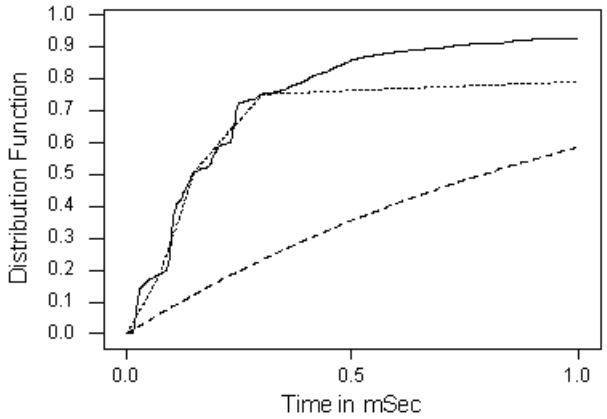

second phase activity was decreasing. The last phase followed a classical Poisson model. For each phase, a power law process model was fit to the data, indicating the nature of the changing traffic intensity (b>1 – increasing intensity, b<1 – decreasing intensity, b=1 – constant intensity). These data were taken over a 24-hour period. The three phases had widely different levels of traffic intensity. In a shorter time frame, for example 10 minutes, one is less likely to see differences in intensity that dramatic. Thus, the power law process model is most appropriate for longer time frames. A second strategy focuses on the influence any given data point has on later data points. In other words, does knowing the magnitude of the packet inter-arrival rate at any point in the time interval make it easier to predict the next inter-arrival time? Historically, there has been a tendency to apply statistical treatments such as regression, ANOVA, or time series analysis to categorize or forecast inter-arrival trends (Frieberger, 1972). These methods have proved to be limited in accuracy in modeling inter-arrival rates and require large, truly representative databases to calculate these values. Therefore, the attractiveness of methodologies such as Markov chains that use a more independent technology is apparent (Robert & Le Boudec, 1996). Specifically, a Markov chain is a tool for modeling how processes behave over time. We classify the process (in this case, the inter-arrival times of packets) into categories called "states." The assumption behind Markov chains is that the probability for what state will be observed next depends only on the previous state. In this context, a process depends only on the most recent inter-arrival time to determine the probability of subsequent inter-arrival times increasing or decreasing (Guster & Robinson, 1994, 2000). To provide the reader with a visual description of packet inter-arrival times from a complex multi-protocol network, a frequency plot is provided in Figure 1. It is the massive peaks and valleys from 0 to about 0.25 milliseconds that make modeling packet inter-arrival times so difficult. There are fairly great discrepancies in the distribution functions of the various distributions. For example, using the actual data from Figure 1, two attempts to model the cumulative distribution of the inter-arrival times are graphed with the actual distribution. Figure 2 depicts the actual data with the solid line, the Poisson model with long dashed line, and the Markov model with the short dashed line. From the data in Figure 2 it is clear that the Markov model fits quite a bit better than the classic Poisson model. To illustrate the effect not having the correct distribution can have on the results of a simulation, a 10-minute sample of packet traffic (packet inter-arrival times) was fed into a database inquiry simulation program. The delay in milliseconds from inquiry to response from that database was recorded. From that sample a tabular distribution was devised and placed into the same simulation and the results recorded. Then the same simulation was run three more times using exponential, lognormal, and normal distributions with the appropriate means and standard deviations derived from the original 10-minute sample. The normal distribution is the classical mound shaped probability distribution used in many statistical applications. The lognormal distribution is the result of exponentiating values from a normal distribution, giving a more realistic, asymmetric distribution for the inter-arrival times. Both the normal and lognormal distributions, like the gamma distribution, have modal values away from the very short, nearly instantaneous time occurring with the exponential distribution. The results are depicted in Figure 3. The tabular distribution was the closest to the actual, but a slight overestimate. All three of the other distributions were overestimates by quite a significant magnitude. From these results it is clear that the validity of any network simulation involving packet traffic is dependent upon using the appropriate distribution. This process can be

Figure 3. Work station average delay observed by varying the packet inter-arrival distribution

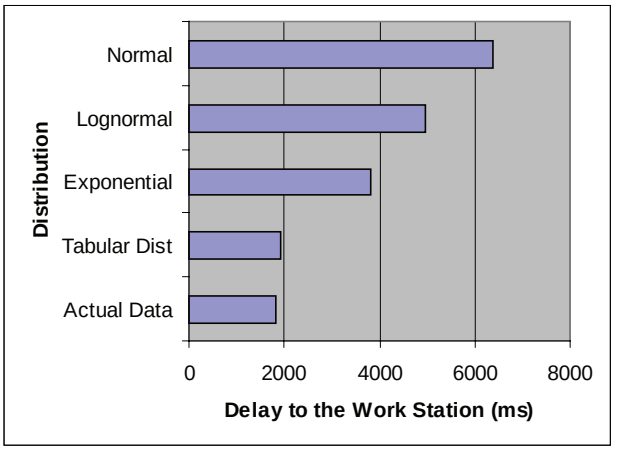

Figure 4. Frequency counts of packet inter-arrival times for Ethernet graphics data

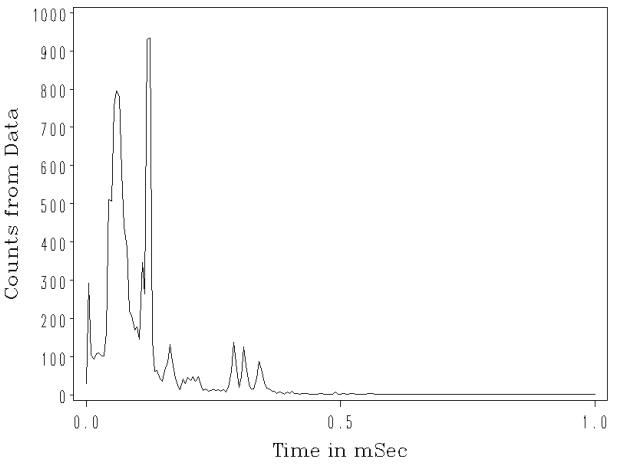

Table 1. Magnitude of initial and steady state values for text-based packets

Data Set	Throughput		Intensity	
	Initial	Steady-State	Initial	Steady-State
8 sessions	3,900	2,340	26	9.1
64 sessions	31,863	26,334	211	73.8
128 sessions	78,328	71,609	452	171.5

Table 2. Magnitude of initial and steady state values for graphics-based packets

Data Set	Throughput		Intensity	
	Initial	Steady-State	Initial	Steady-State
64 session	1458823	2000156	4705	2699
128 session	1751417	3003212	5649	4079

made more sophisticated by classifying the traffic and instead of using a single general distribution employing several specific distributions. For example, Guster, Sundheim, and Safonov (2005) classified traffic as either text- (telnet, ftp, ssh) or graphic- (http, https) based. As would be expected, they found different distributions and packet intensities when the two categories were compared. Figure 4 depicts the distribution of graphical oriented traffic, which can be compared to Figure 1 herein to provide a visual comparison of the two categories. In both cases spikes occur, but not the same number or in the same place. Furthermore, to provide some idea of the difference in intensity, Tables 1 and 2 depict the initial and steady state throughput in bytes for both text- and graphics-based distributions. In Table 1 the results of a workload generated by 64 Web client sessions is displayed. Whereas, in Table 2 the results of a workload generated by 128 Web client sessions is displayed. In the text data there is a very high intensity in the beginning of the session that tapers off after a steady state is reached. This is related to address resolution and forming connections. In the graphic data, it appears there is less "start up" traffic. However, it still takes place but is small in comparison to the massive

screen downloads that follow. A quick examination of the steady state throughput levels reveals that at the same number of client sessions the graphical data is about 70 times greater at the 64 session level and 40 times greater at the 128 session level.

CONCLUSIONS

As the need to make the most of available network bandwidth increases, the importance of having valid simulation techniques available to test optimization methodologies increases. The key to this validity is an inter-arrival distribution that is truly representative of the actual data. This article explored several alternatives in selecting this distribution. First, the actual data obviously offer the best accuracy but are often impractical due to their massive size. Furthermore, selecting a representative sample is often challenging due to widespread variation over time exhibited by most network traffic. Second, the exponential distribution (or any other known distribution), which according to queuing theory should be appropriate, does not fit the data well in a number of studies. Third, the power law process has limited value in relatively short time interval studies. It does, however, offer more promise in data sets involving very large time spans. Fourth, the Markov process has exhibited somewhat promising results. In fact, the visual plots (Figure 2) reveal a much closer fit than the Poisson model. However, Markov models have displayed limitations in the middle time range (.3-5 milliseconds), which make them far from a perfect choice (Guster, Litvinov, et al., 2002). Therefore, much additional work is needed. A simple visual inspection of Figure 1 reveals the complexity of the data and subsequently the difficulty in determining a mathematical model that would truly represent them. The results exhibited by the Markov process are encouraging, and studies that examine more sophisticated Markov related models should be encouraged. Fifth, recent work has shown that breaking the main distribution into several sub-distributions based on the application or service offers promise. For example, the difference in intensity between graphics and text services was illustrated herein in Tables 1 and 2. The importance of obtaining the appropriate distribution for network traffic should not be underestimated. Without it, simulations designed to ascertain network design efficiency, network performance, and the effectiveness of software optimization techniques generate invalid results.

KEY TERMS

Inter-Arrival Distribution: The probability density function that describes likely and unlikely inter-arrival times for packets.

Inter-Arrival Time: The amount of time that elapses after the receipt of a packet until the next packet arrives.

Markov Chain: A model that determines probabilities for the next event, or "state," given the result of the previous event.

M/M/1 Model (Exponential/Exponential with One Server): The queuing model that assumes an exponential distribution for inter-arrival times, an exponential distribution for service times, and a single server.

Packet: A finite stream of bits sent in one block with header and trailer bits to perform routing and management functions.

Packet Intensity: The number of packets transferred per second across a computer network.

Power Law Model: A generalization of the classical Poisson model, allowing for changes in the intensity of the arrivals.

Quality of Service (QOS): A method of marking certain packets for special handling to ensure high reliability or low delay.

Reservation Bandwidth: Reserving a portion of the available bandwidth for a given protocol or application, which ensures its network access will not be adversely affected by massive network traffic generated by other protocols or applications.

Throughput: The number of bytes transferred per second across a computer network.

Evolution of Post-Secondary Distance Education

Iwona Miliszewska
Victoria University, Australia

INTRODUCTION

Distance education is an increasingly common educational alternative, as well as a key contributor to the newly competitive landscape in higher education. Once regarded as an experimental alternative outside mainstream university education, distance education has attained new levels of legitimacy and expansion and has grown into a higher education industry of its own. This article discusses the history and transformation of distance education to create a framework for the sequence of events that have contributed to the distance education movements and shaped modern post-secondary distance education programs.

The article outlines the evolution of post-secondary distance education from its inception to the present: its progression from informal programs offered by individual providers to a well-organised formal educational alternative; its purpose and characteristics; its expansion and internationalisation; and the various forces that have shaped its growth. While noting that technology has its limitations—it can facilitate teaching but not replace it—the article highlights the crucial role that advancements in technology have played in propelling the evolution of distance education, and points to the role of technology in blurring the conceptual divide between distance and traditional education.

BACKGROUND

Although there is no universal consensus on the origin of distance education, most researchers trace its roots to the emergence of correspondence education in the mid-nineteenth century in Europe (Great Britain, France, Germany) and the United States (Matthews, 1999; Peek, 2000; Ponzurick, France, & Logar, 2000). It was the English educator Sir Isaac Pitman who foresaw a need to deliver instruction to a student population that was limitless in comparison to the traditional classroom, and reach out to students in various locations (Matthews, 1999).

In the early years, distance education was dominated by individual entrepreneurs who worked alone; later, organised formal education institutions emerged, such as Sir Isaac Pitman Correspondence Colleges in Britain, and a school in Berlin to teach language by correspondence (Holmberg, 1995; *Simonson, Smaldino, Albright, & Zvacek,* 2000). At the same time, universities in Great Britain, such as Oxford and Cambridge, began to develop extension services. This university extension movement included not only traveling lectures, but also a system of correspondence education (Holmberg, 1995). In the United States, the earliest instance of distance education dates back to 1728 when an advertisement in a Boston newspaper offered weekly shorthand lessons by mail (Gilbert, 2001).

While initially, distance learning was envisioned as:

a way to serve students who lacked access to a complete education, whether due to insufficient resources, geographic isolation, or physical disabilities, it evolved to become a viable way to supplement programs and support innovation, rather than being merely a better-than-nothing alternative to doing without. (Weinstein, 1997, p. 24)

While some scholars identify Pitman as the initiator of correspondence education, other researchers recognise American educator William Rainey Harper as the pioneer of modern post-secondary correspondence teaching (Mood, 1995). Harper helped organise the Chautauqua College of Liberal Arts (New York), the first institution to receive, in 1883, official recognition of correspondence education; from 1883 to 1891, the college was authorised to grant academic degrees to students who successfully completed work through correspondence education and summer workshops.

DISTANCE EDUCATION: EVOLUTIONARY PERSPECTIVE

Growth in Distance Education Programs

The number of distance education programs has increased steadily from the mid-nineteenth century. For nearly 200 years, correspondence education was the primary means of distance education delivery, but in the late 1960s distance education reached a turning point with the introduction of a multimedia approach to its delivery; in addition to print, programs were also delivered through radio, television, audio, and video materials (Matthews, 1999).

In 1969, the Open University was established in the United Kingdom. This institution had a tremendous impact on distance education because it used a multimedia approach to teaching. The British Open University pioneered distance education on a massive international scale and, together with other open universities, helped raise the profile of distance education. For example, in Germany, the FernUnversität in Hagen was founded in 1974 (Matthews, 1999). However, the most dramatic growth of distance education programs has occurred from the 1980s until the present time. Since the mid 1990s, distance education programs have further transitioned into computer-based formats that enable the programs to be delivered fully or in part through the Internet. By the mid 1990s, nearly 25% of the colleges and universities in the United States offered degrees and certificates exclusively through distance education programs; the number grew to almost 58% 5 years later (Matthews, 1999).

In Asia, open and distance education has experienced an unparalleled growth, especially since the early 1990s, as the demand for learning in the region outstripped the capacity of traditional delivery methods by universities. Currently, almost all the countries in Asia have at least an open university. These universities command huge student populations, and of the 11 mega-universities (student enrolment of at least 100,000) worldwide, seven are located in Asia: China, India, Indonesia, South Korea, Thailand, Iran and Turkey (Shive & Jegede, 2001).

In Australia, in the past few decades, postsecondary education has developed an increasingly international orientation as the government encouraged universities to export their courses and import students (Marginson, 2004). Consequently, the export of Australian education now constitutes Australia's third largest services export after tourism and transport, and is judged to be Australia's fastest growing export sector (AVCC, 2005).

Forces Driving Distance Education

One of the major contributors to the dramatic growth of distance education has been technology. Advances in technology, including computer conferencing, interactive media, digital technologies, and the Internet have transformed the world into a borderless educational arena (Frantz & King, 2000). The new technologies significantly increase the reach of distance provision; they enable content to be current; they allow students to interact with instructors and with each other at any time; and, they open up a global market. The technologies not only offer new and better ways of communicating at a distance, but also have the potential to reduce the fixed costs of education (Taylor, 2001).

In addition to advances in technology, there are several other forces driving distance education including: the arrival of the Information Age, changing demographics, changing work and social patterns, declining government funding for further education, and competition in the educational market.

The transition from the Industrial Age to the Information Age has brought about appreciation of intellectual capital, which is now regarded as a valuable commodity. Cunningham et al. (2000) pointed out that the arrival of the Information Age heralded a new conception of knowledge. While previously, knowledge was of importance to an educated elite, and was applicable to a limited range of professions, its present cachet is much broader: it applies to a wide workforce, and it encompasses a variety of skills including "*thinking* skills, teaming capacity, and communication skills" (Cunningham et al., 2000, p. 21). Thus, knowledge workers represent a growing proportion of today's workforce, and the value of intellectual capital drives the demand for continuing education and emphasises a shortened lifespan of knowledge (Cunningham et al., 2000).

The explosion of knowledge, one of the consequences of the Information Age, also promotes distance education. There is a proliferation of new information: "in the past, information doubled every ten years; now it doubles every four years" (Aslanian, 2001, p. 6). It is no longer possible to *know everything*, even about one specialized discipline, so the aim of education must be *learning to learn* (Cunningham et al., 2000). Therefore, education can no longer be regarded as preparation for work, but rather as a lifelong effort to ensure employability rather than employment.

In view of these changing demands on the workforce, employees and employers alike increasingly regard adequate training as a valuable commodity; for employees "the opportunity for training is becoming one of the most desirable benefits any job can offer" (Cetron & Davies, 2005, p. 43); and, employers view "employee training as a good investment" (Cetron & Davies, 2005, p. 49). Thus, some of the changes underpinning the growing demand for lifelong learning "will demand short accelerated programs, well-suited for online delivery, and portfolio credentials" (Howell, Williams, & Lindsay, 2004); this, in turn, will drive the growing demand for distance education.

Changing demographics are also a driving force in distance education (Jones, 2001). High school leavers now represent only one type of tertiary student. Another type, increasingly growing in importance, is composed of adult learners, referred to by Cunningham et al. (2000) as *earner-learners*, who have paid jobs and seek postsecondary qualifications to maintain and enhance their careers. In addition, the importance of lifelong learning has shifted: it can no longer be regarded as a "discretionary personal investment; it has become an essential personal investment as people scramble to bolster their credentials in a volatile global work place" (Jones, 2001, p. 109). Lifelong learners represent a large and rapidly growing student body and demand relevant and accessible continuing professional development programs (Jones, 2001).

Because of the decreasing number of employees, and increasing demands on the ones that remain in the organisation, it has become increasingly difficult for employees to be released for training. This has sparked a trend to have educational programs delivered to companies, especially in global corporations. In Australia, the Coles Myer Institute is an example of a corporate education model. Established in 2003, it is a partnership between Coles Myer and Deakin University. The Institute provides Coles Myer employees, located across the organisation's 2,000 plus sites throughout Australia, with integrated vocational and professional development courses, and pathways to higher education awards (Walker, 2005).

Another factor contributing to the expansion of distance education is the rising cost of living and the tightening labor market: these factors have resulted in an increased number of two-income families. For many, sacrificing one income to return to studies is not an option. In addition, there is an increasing need to balance academic endeavors with work and family commitments. Thus, students with families and in the workforce demand programs that would fit their lifestyles; conventional time- and place-dependent education is not usually suitable. Bates (2000) points out that such students will particularly look for educational programs with *personally relevant content* that could be obtained through small specialized learning units.

Declining funds also drive distance education opportunities. Governments are increasingly reluctant to fund the growing demand for further education, so institutions of higher education are driven toward "for profit" education. They expect that students will be attracted to distance education programs, as they will be willing to pay for the opportunity to study while not being restricted by location or time (Bates, 2000).

Competition is another driving force. The corporate world sees the potential in the educational market and challenges universities by providing alternative programs to meet the rapidly growing demand. Middlehurst (2003) identifies the following categories of commercial provider and provision: corporate universities, private and for-profit providers, media and publishing businesses, and educational services and brokers.

Many corporations, especially large ones such as McDonalds, Ernst & Young, or Lufthansa, are developing corporate universities; at present, there are more than 2000 of such initiatives worldwide (Middlehurst, 2003). New private higher education institutions have also emerged recently on the distance education market as a result of a growing demand for foundation-level higher education (learners in the 18-25 age group), and for continuing and specialist education. These institutions usually provide programs in business, engineering, information technology, and teacher training to the niche market of working adults (Middlehurst, 2003; Ryan, 2002).

In addition, there has been a growth in the activities of commercial companies supporting online infrastructure of universities, including the Provincial Radio and TV Universities in China, or BBC's alliance with the Open University in the UK. Publishing companies, such as Pearson and Thomson Learning, are also involved in supporting educational providers, and developing new initiatives. While universities supply learning, assessment, and accreditation services, the publishers contribute their expertise in marketing, distribution, and content and electronic delivery systems (Middlehurst, 2003).

Finally, there has been huge growth in educational brokers over the recent years (Cunningham et al., 2000). The brokers, of whom Learnerdirect in the UK is an example, mediate between learners, companies and providers. They provide learners with access to study materials through conveniently located learning centers. Corporations are also promoting distance education course design, and course management tools (Middlehurst, 2003). This marketing effort further increases competition and applies additional pressure on the nonprofit university sector to provide distance education opportunities.

Effect of Technology on Distance Education

Over the years, changes in technology generated several significant milestones that affected the distance education market in terms of scale and delivery. Having examined the milestones, Sherron and Boettcher (1997) define four generations of distance education technologies according to five characteristics: (1) media and technologies, (2) communication features, (3) student characteristics and goals, (4) educational philosophy and curriculum design, and (5) infrastructure.

The first generation includes the period between early to mid twentieth century when print, radio, and broadcast television prevailed. Those media involved one-way communication as information was passed from teachers to students; there was no interaction among students, and minimal interaction between students and teachers. In addition, the radio and television broadcasts were time-dependent (Sherron & Boettcher, 1997).

The advent of the VCR and cable television in the early 1960s heralded the beginning of the second generation. The milestone that distinguished the second generation from its predecessor was the removal of time dependency: the broadcast portion of a distance education program was no longer tied to predetermined times (Sherron & Boettcher, 1997). In addition, videocassettes with their stop and rewind options gave learners control over the learning material: lectures could be interrupted and reviewed (Gunawardena & McIsaac, 2005). However, this generation still afforded

little interaction among students and between students and teachers.

The third generation arrived by the mid 1980s together with the personal computer and two-way videoconferencing. Two milestones separated this generation from the previous ones: one, the new technologies made it possible to communicate increasingly complex and large amounts of information to students; and two, they enabled interaction among students, and between students and teachers.

The growth in technological advancements accelerated significantly during the 1990s with the use of computer-mediated learning technologies; for example, two-way interactive video; Web-based asynchronous communication; and online or off-line Internet Web-based instruction (Ponzurick et al., 2000). It was also the beginning of the fourth generation. The fourth generation signified yet another milestone namely, increased interactivity among students, between students and teachers, and between students and content thanks to high-speed networks and more sophisticated software. Consequently, the amount and types of information that can be communicated significantly increased, and the exchange of information took significantly less time (Sherron & Boettcher, 1997).

The rapid dissemination of communication networks, computer-mediated learning technologies, and multimedia technologies in distance education provided the means for the introduction of more effective resources for learning than was previously possible. These technologies facilitated a shift in the relationship between teaching and learning in the distance education context: learning became the focus, rather than teaching; assisting students to become independent learners became the major goal; and the role of a teacher was transformed to that of a mentor and facilitator. This approach teaches learners how to learn, and provides them with the resources to enable them to learn in a manner which is relevant to their own intellectual and social circumstances (Gunawardena & McIsaac, 2005).

The current landscape of distance education includes a wide spectrum of technologies, spanning all generations. Although the technologies of the first generation have been surpassed by several other generations, they continue to play a considerable role in distance education. Radio and television are viable options in developing countries such as India and China where the infrastructure to support more recent technologies has yet to be developed (Middlehurst, 2003). In addition, print "remains a very important support medium for electronically delivered distance education" (Gunawardena & McIsaac, 2005, p. 365). In Thailand (e.g., at the Sukhothai Thammathirat Open University) print materials and audio cassettes are used as core media supplemented by educational radio and television programs, limited computer-assisted instruction, and face-to-face tutorials (Brahmawong, 2001). Even in the more developed Asian countries, for instance at the Korea National Open University, printed textbooks, satellite television, and audiocassettes remain the main teaching medium; videoconferencing systems, and the Internet are supplementary (In-sung, 2001). And, while much is being said about "potential uses of information and communication technologies, the major delivery methods for most distance education programs in Asia still rely heavily on print and the postal system, the "correspondence education" of yesteryear" (Shive & Jegede, 2001, p.11). In developed countries, radio and television are used extensively by institutions, such as the British Open University and FernUniversität in Germany, to deliver programs to a large number of learners (Gunawardena & McIsaac, 2005).

FUTURE TRENDS

The distinction between distance and traditional education will continue to fade due to advancements in interactive multimedia technologies such as automated response systems and interactive multimedia online, which allow for individualised and collaborative learning. These technologies also enable the creation of virtual communities in traditional settings. Consequently, all interactions with teachers, course content, learning activities, assessment, and support services will be delivered online even for campus-based students (Taylor, 2001).

Global connectivity and *networking* will replace *separation* and *distance* as the main characteristics of distance education. Students can increasingly participate in cooperative learning activities through computer networks. Thus, global classrooms may have participants from various countries interacting with each other at a distance (Gunawardena & McIsaac, 2005). Even a decade ago, Hall (1995) suggested that the descriptor *distance learning* was becoming less and less relevant with respect to distance programs and students, and proposed that *connected learning* might be a more accurate descriptor, reflecting the impact that technology has on distance education pedagogy.

Individualization and student-centred learning will increasingly underpin the distance education practice. This will be partly achieved through the provision of specially designed learning resources, with which the students will engage in an interactive manner. Consequently, the teacher's role will increasingly shift from one of a provider of information to one of a mentor and facilitator of learning. Thus, distance education teachers will discover that they need to develop a new set of skills if they are to be effective educators, which has obvious professional development implications.

Although technology is a central part of many distance education programs, it is important to remember that technology is just the method of facilitating connection and conveying content; technology is not the focus of the learning endeavour. According to Weinstein:

… the human touch cannot be delivered remotely. Distance learning technologies are intended to support an integrated program, not replace it. Balancing virtual and real interaction will be one of the key educational challenges as we enter the 21st century… (Weinstein, 1997, p. 25)

In short, any attempt to use technology to significantly reduce human contact within the learning environment would result in significant quality losses.

CONCLUSION

The expansion of distance education is set to continue to be driven by the growing needs of life-long learners, political and economic pressures, advances in technology, and changing conceptions of the nature of education. Distance education is evolving and changing so rapidly that no one can accurately predict its future. However, distance education seems to be moving away from delivering education at a distance, and toward providing a convenient educational alternative to students not even geographically separated from their teachers. The emphasis seems to be shifting away from the very term *distance* that used to define distance education, toward the term *connected* education, an education that connects learners with teachers, and learners with learners.

KEY TERMS

Asynchronous: Communication in which interaction between parties does not take place simultaneously.

Distance Education: The separation of student and learner in space or time, the use of educational media to unite teacher and learner and carry program content, and the provision of two-way communication between teacher, tutor, educational institution and the learner.

Educational Program/Course: A set of units/subjects, that lead to an academic qualification, for example, a degree.

Multimedia: Any document that uses multiple forms of communication, such as text, audio, or video.

Network: A series of points connected by communication channels in different locations.

Online: Active and prepared for operation; also suggests access to a computer network.

Two-Way Communication: A form of transmission in which both parties are involved in transmitting information: common forms include telephone conversations, instant messaging, and computer chatroom communication.

Executive Judgment in E-Business Strategy

Valerie Baker
University of Wollongong, Australia

Tim Coltman
University of Wollongong, Australia

INTRODUCTION

One of the main strategic challenges for organizations today is to effectively manage change and stay competitive in the future. Change appears to be the only constant in contemporary business and is present in every industry and in every country (Brown & Eisenhardt, 1998). Moreover, the key area of importance, current within many organizations, is how to effectively leverage technology within such a complex and dynamic business environment (Sauer & Willcocks, 2003). The alignment or fit approach, which has its roots in contingency theory, has long been promoted as the way to get high returns from technology investment. However, the realization of advantage from the Internet and related e-business technology investment has long been a source of frustration for corporate executives. Impressive performance returns by companies such as Dell Computers, Cisco Systems and General Electric illustrate that returns can be achieved by linking the Internet and related e-business technologies to firm strategy. These companies have shown that successful management of their IT investments can generate returns as much as 40% higher than those of their competitors (Ross & Weill, 2002). Yet, many executives view the Internet and related e-business technologies with intense frustration. They recollect investment in the great speculative bubble of the 1990s and excessive expenditure on year 2000 (Y2K) compliant systems (Keen, 2002). They recall high profile examples of botched enterprise resource planning (ERP) systems that have consistently run over time and budget and report that customer-relationship management (CRM) initiatives were largely a flop (Reinartz & Chugh, 2002). Unfortunately, it is not yet clear how firms should go about capturing the potential that exists in e-business, as few normative frameworks exist to guide practitioner investment.

BACKGROUND

One area of scholarly activity where consistent advances have been made regarding the determinants of firm performance is in structural contingency theory. Here, the contingency factor (i.e., environment-structure) has enabled predictions to be made in a relatively unambiguous manner (Donaldson, 1995). Applied to an e-business setting, contingency theory argues that performance increases can be expected whenever information technology is applied in an appropriate and timely way, in harmony with business, environmental and organizational conditions. Consider a typical scenario where an executive wants to make a strategic investment in information systems. They have two choices: (1) a system to support backend operations using ERP technology, and (2) a CRM support system. How do they prioritise between these competing investments? Contingency literature would argue that it depends upon the organization's strategy and decision-making information requirements (Chandler, 1962; Child, 1972; Galbraith & Kazanjian, 1986). Manufacturing excellence strategies associated with companies like Carrefour or Ford Motor Company would get greater value from ERP systems. Customer intimacy strategies at companies like CitiBank or IBM Global Services would benefit most by customer feedback systems.

As simple as this observation may appear, the application of alignment has proven elusive. Despite 20 years of effort and investment in consulting advice, CIOs are still struggling with the same set of alignment problems. A recent survey by CIO Insight (Patterson, 2001) highlights the point that only 34% of organizations considered the link between their IT priorities and their enterprise strategy to be "strong." While these statistics reflect the difficulties of coordinating complex organizations, they provide evidence that most managers are not using the basic tools of alignment that have been developed over several decades of research.

Priem and Cycyota (2000) equate the process of alignment between IT strategies and business goals with executive judgment. The literature regarding judgment theory argues that firm success can be explained by the judgments executives make concerning the current state of the environment and the vision of the organization. In uncertain times, where market pressures and time constraints dominate the business landscape senior manager's perceptions, skill and vision often form the basis on which strategic choices regarding IT investments are made. For example, it takes little more than a browsing of the management section of the local bookstore—blazoned with titles such as Inside the Minds: Leading CEOs—or a visit to the local news agent to pick

up a recent copy of Forbes, Fortune or Business Week to recognize the importance that publishers and managers place on the philosophies and actions of even some of the least successful or most unlikely of management leaders. Perhaps more relevant is that often the appointment of "higher quality CEOs" leads to immediate stock market reactions and greater long term performance. One such example was the reappointment of Steve Jobs as CEO of Apple Computer. Jobs has been widely praised for his skill in judging the commercial potential of convergent Internet technologies and his return to the company was considered instrumental in its reversal of bad fortunes (Stevens, 1997).

The corollary here is that judgment is an essential skill for setting the overall direction of the organization. In turbulent environments, often the context of e-business, quick trade offs need to take place, as the strategic direction of the firm enables it for the future. This being the case management discretion becomes increasingly important, as decisions are made "on the fly" with little information or understanding of the decision problem. Management play a vital role in "trading off" elements of organization control, that is, structure for better adaptation, a view supported by complexity theory (Brown & Eisenhardt, 1998). This theory views strategy as a process which constantly changes, and thus needs a type of structure or execution method that is dynamic and will allow the organization to be ready for the future.

Thus, although judgment appears to be important to organizational success, scholars have largely ignored executive intentions and no empirical link between executive choices and firm outcomes has been established. Instead, strategic outcomes are presumed to be due to strategic choice (Preim & Harrison, 1994). This omission may account in some part, for why practitioners continue to pay little attention to the large amount of published work concerning the antecedents of strategy and performance. This concern provided the motivation for a special issue of the Academy of Management Journal (AMJ, 1998, p.746) that sought greater understanding of the way knowledge is transferred between academics and practitioners. The issue again surfaced in a recent issue of the Academy of Management Executive, providing evidence that practitioners still typically turn to sources of information other than academics or the scientific literature when searching for ways to improve performance (Ford, Duncan et al., 2003).

FUTURE TRENDS

Clearly, we need greater understanding of the conditions which lead executives to make strategic choices if we are to develop research that has an impact on practitioners.

Existing research into the change process and the implementation of e-business related technology is limited because it fails to measure the link between strategic choices and firm outcomes. As we have suggested, the judgments that executives make provides important insight into how IT strategic change or e-business change is approached given different situations and organization contexts.

Peterson (2002) suggests that it is the processing of information and the judgments that are made by top management that leads to critical decisions being made about how firms deal with IT-related strategic change. As the business environment rapidly changes, the variance in possible outcomes ranges from failure to unparalleled success. These differences can largely be explained by the "mythical relationship between technology ecology, human nature, decision cycles, IT and the speed and veracity of their interactions" (Peterson, 2002, p.485). Executives process information about these relationships and form critical strategic judgments regarding the future direction of their organization through its e-business strategy.

Managers face conditions such as dynamic markets, casual ambiguity and path dependence that make it extremely difficult to predict the outcomes of their IT strategic investments. As this illustration suggests, it is imperative that managers have in place strategies to cope with changes as they occur. Faced with external environmental changes (e.g., new rates of Internet adoption, killer mobile commerce applications, etc.), managers need to be able to adjust their strategic choices accordingly "just as water shapes itself according to the ground, an army should manage its victory in accordance with the enemy. Just as water has no constant shape, so in warfare there are no fixed rules and regulations" (Sun Tzu in Hussey, 1996, p.208)

What Sun Tzu highlights is the requirement that strategies be flexible in order to manage strategic change. Mintzberg, Ahlstrand, and Lampel (1998) describe this as an emergent strategy, where rather than pursuing a strategy, an organization makes decisions based on the situation, effectively testing the market as they go.

Thus strategic decisions regarding IT management need to be a mixture of both deliberate and emergent strategies. "Real-world strategies need to mix these in some way: to exercise control while fostering learning" (Mintzberg et al., 1998, p.11). The importance of strategic alignment between the organization and its environment becomes even more critical given recent environmental turbulence and the evolving importance of technology and e-business to competitive advantage.

Executive Judgment and Strategic Alignment

Priem and Cycyota (2000) state that understanding judgments by strategic leaders is essential to determine the role of mental processes in strategy development and how these strategies and processes affect firm performance. They suggest that a number of theoretical platforms commonly found in the strategy literature provide a solid platform from which we
