At the forth meeting of General Office of State Council Informationalization Leading Group in 2004, the main agenda was information resources development. After the meeting, the General Office of the State Council together with the General Office of the CPC Central Committee issued the document "Some Suggestions on Strengthening the Work of Information Resources Development and Utilization." Until now, this file is still one of the most authoritative guiding policies of Chinese information resources development. It outlined the guidelines, basic principles, and general tasks of information resources development in the country. It also attached great importance to fostering the information resources market and industry.

The concept "Information Resources Development" used in this item refers to collection, processing, organization, and dissemination of document resources, as well as their digitalization and networking. Factual and data resources ought to be included in the concept. However, China's progress in these aspects is relatively slow. In recent years, people started to realize the importance of factual and data resources development. The departments concerned have started to work out a plan for constructing the National Data Center.

MAJOR INITIATIVES IN CHINA'S INFORMATION RESOURCES DEVELOPMENT

Under the guidance of the policies introduced in the last section, the Chinese government initiated several major information resources development projects to change the current situation of inconsistency between information resources development and information network construction, as well as to lessen the discrepancy between information resources available and that required by the public.

CALIS (China Academic Library and Information System)

CALIS is an initiative under China's plan to build 100 key universities in the 21st century (named "211 Project" by the Ministry of Education). It aims at constructing a networked information resources sharing system based on the China Education and Research Network (CERNET) so as to parallel the development of a communication network and an information resources network, and provide university faculty and students as well as professionals in research institutions with easy access to a national information service system that is characterized by abundant information resources, advanced technologies, and a convenient service system.

The service system consists of a CALIS national management center, four CALIS national information centers (covering sciences and social sciences, engineering, agricultural science, and medical science respectively), and seven CALIS regional information centers — in Beijing, Shanghai, Nanjing, Guangzhou, Xi'an, Chengdu, Wuhan, and Changchun. The system will be also linked to major information service systems outside China to form China's Academic Library and Information System. The construction of CALIS will greatly increase the amount of information available to academic libraries and also improve their capability in information services (data from *www.calis.edu.cn*).

Digitalization Projects

The China Digital Library Project was carried out under the coordination of the Ministry of Culture. In July 1997, the National Library of China (then Beijing Library), together with the Shanghai Library and a few other institutions, started the Chinese Pilot Digital Library Project (CPDLP). Later in 1998, the Ministry of Culture formally put forward the proposal of constructing the China Digital Library. A variety of enterprises and organizations — such as China Telecom, the National Library of China, the Chinese Academy of Sciences (CAS), the China Aerospace Industrial Corporation, Peking University, and Tsinghua University — participated in the project.

Together with the second phase of the Chinese National Library construction, the Chinese Digital Library Project was formally initiated at the end of 2004. The investment of the project was about 400 million RMB (US$40 million). It has 27 sub-projects belonging to four categories: the technical support environment construction, information resources construction, service system construction, and standards

construction. The whole project is set for completion before the 2008 Beijing Olympic Games, at which time, the Chinese National Digital Library will become the largest Chinese digital information preservation and service facility in the world (Fu, 2005a).

According to the plan, when the project is completed, the National Digital Library will have the information processing capability of:

- Digitalizing 300,000 paper-based documents per year,
- processing 90,000 bibliographic records per year,
- indexing 6,000 hours of video and audio resources,
- storing 200 million metadata records, and
- providing 100 million pages of full-text online.

It will also provide information resources with ancient Chinese characters, such as the bones-tortoise inscription database and Dun Huang database (Fu, 2005b).

Besides the China Digital Library Project, various other digital library projects were also carried out. The construction of Chinese National Science Digital Library (CSDL) started in late 2001. The project, as part of the Knowledge Innovation Project of the Chinese Academy of Sciences, aims to build a digital information service system that meets the international developing trends of digital libraries and caters to the development of the Chinese Academy of Sciences (Zhang, 2002). It should be able to serve the needs of researchers and professionals in information accessing and knowledge innovation.

The total investment is 140 million RMB (US$17.5 million). Until June 2005, CSDL has provided access to 128 scientific documents databases. It collected 13,000 e-books. CSDL service includes online cooperative cataloging, integrated cross-database searching and browsing, online interlibrary loan, and virtual reference. Two databases, the Science China Database and the subject portal, are only available through CSDL. The scope of the former covers almost 3,000 types of Chinese science and technological journals since 1986. The number of abstracts adds up to 1.2 million, still increasing at a rate of 200,000 per year. The number of citation data is 5 million, with a growth rate of 1.2 million per year (Zhang, 2005).

In China's Taiwan Province, eight digital library initiatives are currently underway, including the construction of a Digital Library and Information Center and the building of the Haoran Digital Library in Jiaotong University. The objects of the initiatives are to promote information exchanges among learning and research institutions in Taiwan, and coordinate their purchase of information resources such as databases from foreign countries. Another object is to promote the research on Chinese culture, especially on Chinese history (Lv, 1999).

There are also digitalization projects other than construction of digital libraries. In January 1999, the Geology Department of the Chinese Academy of Sciences raised to the State Council a proposal on strategies of China's "Digital Globe" development, indicating the importance of building a national Global Information Infrastructure and establishing a digital global spatial information sharing system (*Information Industry Newspaper*, November 22, 1999). In November 1999, the first "Digital Globe" International Conference was held in Beijing, showing that the Chinese government attached great importance to international cooperation in this area (*China Computer World*, December 6, 1999). Currently, the prototype of China's "Digital Globe," called the Digital Earth Prototype System (DEPS CAS1.0), has been built. It has been applied in several domains, such as digital tourism and digital Olympic.

Construction of the China National Science and Technology Library

In June 2000, the China National Science and Technology Library (NSTL, *www.nstl.gov.cn*) was formally established through the cooperation of China's Ministry of Science and Technology, the State Committee of Economics and Trade, the Ministry of Agriculture, the Ministry of Health, and the Chinese Academy of Sciences. As a virtual scientific and technical resource center, it consists of nine library and information institutions such as the Library of the Chinese Academy of Sciences, the National Engineering Library of China, the Library of the Chinese Academy of Agricultural Science, and the Institute of Scientific and Technical Information of China. The center utilizes advanced technologies and methods to collect information from domestic and foreign sources. Moreover, the center serves as a bridge of cooperation between Chinese information resources management professionals and their foreign counterparts (Yuan & Meng, 2001).

Special-Topic Information Resources Development

Government Information Resources Development—China Online Government Project

On January 22, 1999, the China Online Government Project Start-Up Conference was held in Beijing, sponsored by China Telecom and the State Economic and Trade Commission, together with the information sectors of more than 40 ministries. At the conference, the China Online Government Project was started.

According to the "White Paper on China Online Government Project," the project refers to the practice by the

government at all levels to establish formal Web sites to promote Office Automation in government work, offer public services via the Internet, and fulfill the roles of management and service in the fields of society, economy, and social life (*www.gov.cn*).

On January 1, 2006, the Web site *www.gov.cn* was formally launched. It has three versions: simplified Chinese, traditional Chinese, and English. Its main columns include China today, national institutions, rules and laws, and news release network service. It received 40.48 million hits from 337,000 users on its debut day. Through the Web site, the public is better informed and can monitor government operation more actively than before. It is believed that the Web site will make a positive impact on building a transparent, efficient, and clean government (BIAN, 2006).

Patent Information Resources Development

Patent information is an essential part of a country's technical information resources. To meet the users' requirement of searching and utilizing patent information, China Patent InfoNet was established by the Retrieving and Consulting Center under the State Intellectual Property Office in May 1998. In January, 2002, its new version (*www.patent.com.cn*) was published online and started to offer all-around services — such as patent information retrieval, introduction of patent laws and regulations, and guidelines for patent application — to patent users and researchers.

Construction of the National Institute for Information Resources Management

Three national research centers for information resources management have recently been set up in Beijing, Nanjing, and Wuhan to promote research on theories, applications, policies, and technologies in IRM; they are affiliated with the Department of Information Management of Peking University, the Department of Information Management of Nanjing University, and the School of Information Management of Wuhan University.

INITIAL IMPACT OF SOME INITIATIVES

CALIS

Started in November 1998, CALIS completed its first phase of construction by the end of 2001. Currently, the system can provide an online public access catalog, interlibrary loan (ILL), Internet navigation, online cataloging, cooperative literature purchasing, and various other services through digitalization of information resources, networking of information services, and cooperation among participating academic libraries. As a result of the first phase of construction, universities and colleges in China now possess greater information resources than ever before; for example, the variety of foreign periodicals increased by one-third, 95% of Chinese literature and 80% of foreign literature are now available, and more than 100 academic libraries offer 24-hour online information services. In addition, 25 distinctive databases and 194 disciplinary navigation databases are built.

In its second phase of construction starting in 2002, CALIS aimed to further strengthen the document supporting ability of academic libraries. Until now the membership of CALIS totaled up to 700. Thirty academic libraries have been developed into digital library bases, acting as the kernels of information service systems and distributing centers of information resources. Besides, digitalized information resources imported from foreign countries are expected to cover all subject, areas while domestic information resources will be as much as several terabytes (Zhu, 2001). The second phase of CALIS construction was combined with the CADAL project in 2004, adopting a new name CADLIS (Chinese Academic Digital Library & Information System). It has strengthened the construction of the full-text database, whose goal is to offer 30,000 e-journals (including 20,000 international journals), 300,000 theses, and 30,000 education and reference books (Xiao & Chen, 2005).

China Digital Library Project and NSTL Construction

Construction of the China Digital Library and the National Science and Technology Library has been advancing smoothly. In April 1999, China Cultural Information Net started operation as the top level of the China Digital Library. In November 1999 and February 2000 respectively, the Capital Library and China Radio International (CRI) became experimental units of the China Digital Library Project. It should include information resources not only from libraries, but also from the government, even from international channels. The ultimate goal of the project is to build a "Digital China." The National Culture Information Resources Sharing Project has been carried out. All resources have been published through Web pages to allow access for people in rural and remote areas. By digitalizing the information resources maintained in public libraries, museums, and art galleries in China, the project aimed to provide cultural services to people in rural areas. The project investment totals 400 million RMB (US$50 million). Until now, 4,226 local centers and backbone service sites have been established (China Radio International, 2006).

The initiative of building the National Science and Technology Library is near conclusion. Through two years of construction, participating libraries now collect more than 16,000 types of foreign scientific and technical literatures (including periodicals, conference proceedings, technical reports, etc.), as compared to no more than 4,000 types in 1996.

Some 6.5 million bibliographical records were put online by the end of March 2002, and this number is expected to increase at a rate of 2 million per year. The network service system provides 24-hour free secondary literature retrieval service to Internet users. In March 2002 alone, 1.37 million users visited the system, as compared to 150,000 when the system was started in January 2001. More than 60,000 users have received full-text document service.

Now it can provide a variety of services such as bibliography searching, full-text browsing, virtual reference, and Chinese and foreign language preprint acquisition through its network service system. By the end of 2005, 35 million bibliographical records had been put online, which is 20 times as many as in 2000 when it opened. The system responds to more than 10,000 requests for full-text service each month, compared to 60 at the beginning of 2000. In 2005 alone, nearly 28 million searches took place with the system. The principle of NSTL is "unified acquisition, standardized processing, data integration, and resources sharing." The main purpose of establishing NSTL was to satisfy the new science and technology information needs, and revitalize the industry-oriented science and technology information service system during the transition from the planned economy to the market economy in China (Zhang, 2006).

Development of Commercial Information Products

Information resource development in a market-oriented approach achieves great effect. Many database and information service providers (such as ICP, ISP) have come into operation, among which the following enjoy a nationwide reputation: China Academic Journals CD-ROM database, ChinaInfo Group, Chongqing Weipu Information Consulting Corporation Ltd. (*www.vipinfo.com.cn*), Beijing Scholar Sci-Tech Co., Ltd., and China Infobank. The Chinese Journal full-text Database includes about 18 million articles from 7,626 major periodicals published in Mainland China since 1976. The database is available both online and in CD-ROM form.

In a broader context, Internet-based information resources have also undergone rapid development. According to statistics from the "Survey on Information Resources in China," which was released by the China Internet Network Information Center in March 2006 (CNNIC, 2006b), there were 2.6 million registered domain names, 694,000 Web sites, 2.4 billion Web pages, and 295,000 online databases within China.

FUTURE TRENDS

The projects we have introduced above lay a solid foundation for the further development of information resources in China. Recently, the Ministry of Science and Technology started up the Science and Technology Documents Resource and Service Platform. Founding of the National Informationalization Directing Committee also boosted the development and utilization of information resources.

In the "2006-2020 National Informationalization Development Strategy" issued by the General Office of the CPC Central Committee and the General Office of State Council, information resources development was positioned in a significant place. It was listed as one of the national informationalization strategic goals. It was also one of the nine strategic tasks of national informationalization. Network information resources development was one of the six strategic plans of national informationalization (*Tianjin Daily*, May 9, 2006).

According to the "2004-2010 National Science and Technology Fundamental Platform Construction Blueprint," the Science and Technology Documents Sharing Platform is one of the four fundamental platforms. The platform construction includes two projects: one is science and technology document resources construction; the other is documents service ability construction. The platform includes a network service system, an integrated resources navigation system, and an individualized knowledge service system. The investment of the system is estimated at 150 million RMB (US$12.5 million).

Looking into the future, we can feel the long road ahead for China to improve its information resources. Efforts need to be made in a number of areas: first, the digital library projects need to be further expanded; second, the government should continue its support for information resources development projects; and third, the issue of nationwide cooperation across industries needs to be addressed properly as one of the most important problems in information resources development.

CONCLUSION

This article introduces the history and present situation of information resources development in China. Some major information resources development projects at the national level are discussed. Several of the projects have already generated positive impact on the society and laid a solid foundation for the further development of information resources in China.

KEY TERMS

Digital Library (DL): A cultural infrastructure that collects and stores information in electronic format and supports its users in accessing a large collection of information effectively through digital means.

Information Resource: A collection of valuable information generated by human activities. In a broader sense, it also includes related equipment, personnel, and capital.

Information Resources Development: The process of collecting, processing, storing, disseminating, and utilizing information resources according to the need of the society.

Information Resources Management (IRM): Refers to the planning, organization, allocation, and utilization of information and related resources through legal, technological, and other methods to support institutional goals and missions.

Information Service: The activity of providing information products and related services according to users' need. In a broader sense, it refers to providing users with information through any form of product or service.

Informationalization: The process of social advances in which human society transforms from industrial society to information society.

Information Sharing in Innovation Networks

Jennifer Lewis Priestley
Kennesaw State University, USA

Subhashish Samaddar
Georgia State University, USA

BACKGROUND

Innovation networks help members develop new products at a faster rate with lower investment commitments. The R&D consortium named Semiconductor Manufacturing Technology (SEMATECH), with member firms such as Motorola, Texas Instruments, and others, is an example of such a network. In a study of this network, Lim (2000) found that the network members were able to develop an innovative copper-based semiconductor that rivaled a similar product developed by (at the time) an independently operating IBM. The SEMATECH consortium experienced a significantly abbreviated time line and collectively invested significantly less money than did IBM with almost identical results. Lim attributed the innovative success of SEMATECH to the "connectedness" of the firms.

Researchers engaged in studies examining interorganizational alliances generally agree with the findings of Lim and others that innovation network alliances represent a potential solution to mitigate environmental uncertainty, in part through the sharing of information (e.g., Gulati & Gargiulo, 1999). Van de Ven (2005) refers to this strategy for dealing with environmental uncertainty as "Running In Packs." The basic logic is that as a network grows in membership, the amount of information any individual firm can access grows, and the value of membership in that network grows. Consequently, firms engaged in networks typically realize superior economic gains from their increased access to information relative to independent or nonaligned firms (e.g., Carlsson, 2002; Van de Ven, 2005).

Since organizations join networks to mitigate costs and uncertainties, the question of how network characteristics affect (or not) the transfer of information is relevant to both practitioners as well as researchers in knowledge management and/or organizational learning. For instance, some innovation networks are composed of members engaged in similar activities while other networks are composed of members engaged in very different activities. Some networks tolerate more competition among their members than others. Finally, some networks are more centrally governed than others. These differences in how an innovation network is formed and governed raises an important question—Given that firms embedded within organizational networks experience greater exchange of information relative to firms operating outside of a network, how do the different characteristics of these networks impact the movement of that information?

In this chapter, we will first review the two primary factors that have been demonstrated to influence the transfer of information—*absorptive capacity* and *causal ambiguity*. We then review three characteristics of *multi-organizational networks—governance structure, scope of operations*, and *intensity of competition*—with particular attention to the issue of information transfer. We develop six testable propositions regarding how these network characteristics would be expected to affect absorptive capacity and causal ambiguity among networked firms. Finally, we discuss future and emerging trends related to the transfer of information among networked firms.

INFORMATION SHARING

Economic theories such as the *knowledge-based view of the firm,* view information as an asset that will move unencumbered and without cost within and among organizations; although information is recognized as an asset, unlike other assets, its transferability has no associated costs. However, some authors have suggested that this may not be the case (e.g., von Hippel, 1994). In fact, the transfer of information is not necessarily frictionless and has even been described as "sticky"and the organizational implications associated with transfer "stickiness" can reach beyond issues of cost and simple inefficiencies (Szulanski, 1996). Information is increasingly recognized as the engine of economic growth and a source of competitive advantage, and where its transfer is difficult, the implications are more strategic and may threaten a firm's long-term competitiveness, including, new enterprise formation; the exploitation of technological know-how; and the successful development and commercialization of new products and services (Teece, 2001).

Absorptive Capacity

An organization's absorptive capacity has been described as the organization's ability to first recognize and then realize any value from the external information to which it is ex-

posed (Cohen & Levinthal, 1990). Such exposition arguably increases when a firm becomes a member of a network. As a result, if absorptive capacity is low, the transfer of information is less likely to occur. In a networked context, the absorptive capacity of the recipient organization is integral to the success of *information sharing*. The ability to identify new, relevant information and have the processes in place to then bring it internal to the organization quickly becomes a competitive advantage when translated into economic rents. However the paradox of absorptive capacity is that an organization that does not have it may not understand that they need it; organizations with low absorptive capacity will be less likely to value external information (Mosakowski, 1997).

Causal Ambiguity

Unlike absorptive capacity, which is considered to be an enabler of information sharing, the presence of causal ambiguity has been identified as an isolating mechanism of information, impeding its movement within and among organizations (Knott, 2003). The concept of causal ambiguity is centered around the organizational inputs and the causal factors used in combination to generate known outcomes. Organizational inputs can be the raw materials used to manufacture a product, and the causal factors can be viewed as the processes used. When an organization is successful in benefiting from an innovative process but does not know what combination of inputs and process factors generated the final outcome, their knowledge is, at best, causally ambiguous.

Causal ambiguity as an inhibitor of information transfer has been recognized across much of the research in organizational learning. Mosakowski (1997) developed a useful typology through which to examine the effects of causal ambiguity on decision making. Extending the work of Lippman and Rumelt (1982), Mosakowski determined that although increased causal ambiguity has the potential to increase competitive advantage by increasing the difficulties associated with imitation by competitors, increased causal ambiguity has the impact of decreasing information transferability by associating its application.

CHARACTERISTICS OF ORGANIZATIONAL NETWORKS

In this chapter, we approached the examination of networks using two established perspectives. The first, *transaction cost economics*, recognizes that exchange agreements between and among firms must be governed and contingent on the transactions to be organized; some forms of governance are better than others (Williamson, 1973, 1975). Specifically, this includes examination of centralized and decentralized governance. The second perspective, *social network theory*, examines the individual *nodes* and *linkages* within a network to explain how organizations (or individuals) will interact (e.g., Westlund, 1999). Using these well-established perspectives as a basis, we discuss the three primary characteristics of an interorganizational network that would be expected to have particular influence on the transfer of information—governance structure, scope of operations, and intensity of competition.

Governance Structure

Networks of organizations represent an organizing principle residing between pure market-based transactions and complete organizational self-sufficiency (Thorelli, 1986). However, once "within" the network, the question of governance structure remains to be determined. In his work on transaction cost economics, Williamson (1973, 1975) identifies the preferred governance structure for providing authority to address issues related to opportunistic behavior, information impactedness and bounded rationality as centralized or hierarchical. This governance structure would also be expected to have the ability to mandate standardization of operations, language, policies, and so forth. Conversely, a decentralized governance structure is described as one of peer group associations, without subordination, involving collective and usually cooperative activities, but deficient in its ability to address opportunism and free-rider abuses. A decentralized governance structure has been suggested as preferable to facilitate innovation and new knowledge creation, where the former structure has been suggested to better facilitate the transference of existing information (e.g., Adler, 2001; Chen & Edgington, 2005).

Scope

Researchers engaged in social network theory and organizational alliances have stated that the degree to which the members of a multi-organizational network or of a dyadic alliance demonstrate operational homogeneity affects the likelihood of information transfer (e.g., Westlund, 1999). Specifically, operational similarity has been used to explain, in part, when information does or does not transfer between or among alliance partners (e.g., Simonin, 1999). For the purposes of this chapter, we will refer to this network characteristic of member similarity as the *scope of operations*, where a high scope network will have operationally dissimilar members while a low scope network will have operationally similar members.

Intensity of Competition

The concept of linkages among the nodes or members in a network has been identified to have significant impact on

how well information does or does not transfer (e.g., Uzzi & Lancaster, 2003). The linkages that exist among network entities have been described as being either *integrated* or at *arm's length* (Dacin, Ventresca, & Beal, 1999). Integrated linkages are defined as shifting the expectations among the network members away from a behavioral basis of opportunism to a behavioral basis of cooperative behavior, where these expectations then facilitate the transfer of information (Uzzi & Lancaster, 2003). Alternatively, linkages at arm's length are described as creating impersonal, atomistic behavior, characterized by instrumental profit-seeking on an individual member basis (Uzzi & Lancaster, 2003).

Why would an organization voluntarily join a network, where the linkages among the members would be characterized as being at arm's length? Consider the VISA network. Individual banks are fierce competitors, yet collectively benefit from the functionality of the global card acceptance afforded by the VISA network—relationships among the members would be described as impersonal and profit seeking, with linkages created for the purposes of decreased transaction costs. This seemly paradoxical concept of arm's-length linkages among networked entities has been found to be particularly evident in industries characterized by rapid change. Powell, Koput, and Smith-Doerr (1996) found that as the technological sophistication of an industry increases, the intensity and number of competitive alliances also increases.

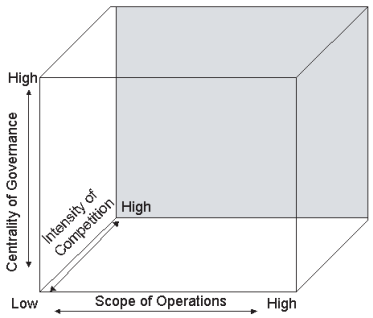
When there is a regime of rapid technological development, research breakthroughs are so broadly distributed that no single firm has all the internal capabilities necessary for success ... Firms thus turn to collaboration to acquire resources and skills they cannot produce internally, when the hazards of cooperation can be held to a tolerable level. (Powell et al., 1996, p. 117)

In this article, we will refer to this characteristic of a network as the *intensity of competition*, where low intensity of competition will equate to integrated linkages and a high intensity of competition will equate to arm's-length linkages.

Using the three characteristics of a network described in this section, different network forms can be examined

Consider Figure 1. Although a conceptually infinite number of networks could be described using the three characteristic continuums represented, consider a typical innovation network that has been formed with the objective of mitigating costs, risks, and environmental uncertainty. Innovation networks are typically characterized by a decentralized governance structure, with limited ability to regulate or punish, comprised of nonsubordinated peers. These networks also typically exhibit a high scope of operations—where member firms may include public companies, universities, nonprofit firms, governmental and quasi-governmental firms.

Figure 1. Characteristics of multi-organizational networks



Finally, innovation networks may exhibit a range of intensity of competition—where otherwise competitive firms agree to collaborate for specific purposes—such as Motorola and Texas Instruments did as members of the R&D consortium SEMATECH, referenced previously.

An assessment of how each characteristic of this network would be expected to affect absorptive capacity (an enabler of information transfer) and causal ambiguity (an isolating mechanism of information transfer) is developed next.

FUTURE TRENDS

Cohen and Levinthal (1990) highlight the importance of possessing certain commonalities to facilitate absorptive capacity and the effective sharing of information among organizations. Cohen and Levinthal and others (e.g., Lane and Lubatkin, 1998) have identified several factors, which contribute to an organization's absorptive capacity. Two of these factors include a commonality of language and a common base knowledge—where common knowledge translates to an intersection, not an overlap of knowledge. A complete overlap of knowledge is inefficient and represents limited opportunity for transfer.

Given that organizations generally join innovation networks for the purposes of gaining access to new information, they would be expected to come to the network with some common or *base* knowledge. This is true because if organizations did not have a base knowledge of the topic in question, transfer would be almost impossible. For example, if a network was developed to research a particular form of cancer, and a strong base knowledge of biochemistry were required, an organization with no previous experience in the area of biochemistry would have a limited ability to absorb or contribute to the exchange of information. In ad-

dition, within the context of this base knowledge, it would be logical to conclude that a common language is used. For example, the Human Genome Project, incorporates government (e.g., U.S. Department of Energy), quasi-government (e.g., National Institutes of Health), private (e.g., Wellcome, IBM), and research (e.g., MIT, Baylor College of Medicine, Washington University) institutions. Each organizational entity approaches the project with some common working knowledge of, for example, genetics, which is then used to develop new knowledge related to gene sequencing, bioinformatics, and other topics. Although these respective organizations may use completely different vernaculars within their respective operating environments, within the context of the Human Genome Project, it would be expected that in the pursuit of new knowledge, the organizations would engage in a common language.

Proposition 1. *Low centrality of governance in the innovation network contributes to high organizational absorptive capacity.*

Proposition 2. *High scope of operations in the innovation network contributes to low organizational absorptive capacity.*

Proposition 3. *Low to medium intensity of competition in the innovation network contributes to high organizational absorptive capacity.*

The innovation network is most common in environments characterized by rapid and turbulent change, where inputs and/or causal factors may not be understood prior to an outcome (Mosakowski, 1997). Scenarios characterized by complexity and ill-structured problems are considered to have high causal ambiguity. This is logical—if a particular process or product has many interdependent components, identifying or isolating the impact of each one on the eventual outcome would be difficult. Simon (1962) suggested that more hierarchical structure helps to mitigate this complexity. However, this structure is generally not present in an innovation network, in part because it has been shown to decrease new knowledge creation and innovation (e.g., Adler, 2001).

Proposition 4. *Low centrality of governance in the innovation network contributes to high organizational causal ambiguity.*

Proposition 5. *High scope of operations in the innovation network contributes to high organizational causal ambiguity.*

Proposition 6. *Low to medium intensity of competition in the innovation network contributes to high organizational causal ambiguity.*

CONCLUSION

In this chapter we examined three characteristics of the innovation network. The developed propositions could indicate that this network would experience problems with information sharing. Initially, this expectation may violate conventional wisdom—we stated earlier that the primary motivation to participate in this network form was access to new information. However, a further consideration of knowledge creation versus established information transfer may explain the (possibly) perceived violation. This network type is not based on the need to transfer an existing information asset within the network, but rather on the need to develop new, unproven knowledge. Therefore, it is not surprising that these characteristics—some competition, low centralization of governance, and high scope of operations—could be expected to restrict the flow of information, but facilitate new knowledge creation.

It is our intention that this chapter will provide researchers in the areas of organizational learning and knowledge management with rich concepts for further examination. From our perspective, a rich opportunity for further examination is embedded in questions regarding how differently organized networks, which reside in different positions within the cube identified in Figure 1, would experience information transfer differently. Would a supply chain network experience absorptive capacity and causal ambiguity differently than would an innovation network? How would a co-op network of members simultaneously competing and collaborating, experience information transfer? Although much research has been done to establish that networks are superior to dyads and dyads are superior to independently operating firms regarding the transfer of and access to information, a large theoretical gap exists regarding how differently organized networks experience information transfer differently.

KEY TERMS

Absorptive Capacity: The ability of a firm to recognize the value of new, external information and assimilate it and apply it to commercial ends.

Causal Ambiguity: The "knowability" (the extent to which something *can* be known) and "knowness" (the extent to which something *is* known) of two sets of elements—(1) the organizational inputs and (2) the causal factors that are used in combination to generate outcomes.

Innovation Network: A structured network of N organizations sharing common goals related to research and/or development of new products/technologies (e.g. The Human Genome Project). This network type is characterized by a decentralized structure, low-medium competition and uncommon scope of operations among members.

Inter-Organizational Network: A community of practice of N organizations, where N is more than two. In this chapter, network types are defined through three primary characteristics—the degree of centralization of authority, competition, and commonality of operations.

Knowledge Management: Knowledge management (KM) is the organization, creation, sharing, and flow of knowledge within and among organizations.

Social Network Theory: A theory, which explains how individuals or organizations will interact based upon the nodes and linkages within the network.

Transaction Cost Economics: A theory most typically associated with Williamson, which explains that firms will organize in a manner to minimize the costs of production, including the costs of transaction and exchange.

Information Society Discourse

Lech W. Zacher
Leon Kozminski Academy of Entrepreneurship and Management, Poland

INTRODUCTION

Information society (IS) has a short history as a form of human organization and social context. However, information (signals, communications, various data, etc.) and use thereof have always been fundamental to people's existence, survival, and development. Some important milestones included the Gutenberg printing press, telephone, radio, TV, computer, and all electronic devices and systems related to ICTs. In fact, the progress of technology, especially of electronics and telecommunications, marked out the directions and potentialities of social change.

Coined as a term in the 1960s, information society is just emerging nowadays mostly in developed countries. As a result of the effect of present technological, economic, and political globalization processes, the whole world is being impacted and transformed by ICTs. IS can be *per se* perceived as the intellectual (scientific) model or ideal type having a set of specific characteristics and assigned interpretations.

Needless to say, in the real world there are only *concrete individual different* information societies. Their difference concerns mostly: geographic, historical, educational, technological, cultural, political, and economic aspects and advancements already achieved in IS development (i.e., its stage, directions, pace, and so on) and their multifaceted impacts on societies, organizations, and individuals. In the social sciences—especially in sociology and political science—there are some indicators enabling measurement of these advancements and their consequences.

The aforementioned societal advancements, initially always pre-informational or not yet informational, are constantly emerging from some "embryos"—often scientific and technological—and are progressing via multidimensional processes of organizational, social, economic, political, cultural innovations, and by their diffusion. In fact, all segments and features of society are heavily affected by them. These impacts are rather difficult to measure and evaluate. Quite often, they are treated generally as ICTs' impact on a society. Certain analytical methods and procedures connected with *technology assessment* or—more comprehensive—*impact assessment* can be applied to this end. Since IS is still emerging, or in other words *in* the *statu nascendi* stage, it is reasonable and necessary to apply a prospective approach to its investigations and evaluations.

Therefore, the future of ISs should be of interest not only to researchers, but also governments, business, and the public—referred to as *civil society* in democratic countries. Increasing use of the word "future" in its plural form, "futures," has been accepted for a long time. In English this form has already functioned for decades, while in other languages "future" is used only in singular. The other reason is that people (and scientists) often perceived the future as non-optional (a rather fatalistic approach). By using the plural form, we emphasize the conviction and hopes that the future will be multi-optional, thus very differentiated for regions, states, societies, communities, and individuals. Therefore, differentiated ISs will not have the same futures. As such, the future of the whole world will be extremely complex. It does not seem probable that there will be one future for all.

Historically, various societies have had divergent take-off points, possibilities, development opportunities, trajectories, as well as performance, behavior, policies, cultural heritage, social capital, and so forth. In spite of some universalistic tendencies in production and consumption patterns, many diverse *gaps* currently exist in political systems, media performance, and so forth. Some time ago, it was fashionable to refer to them as technological, organizational, or managerial, information. There are other forms and names, for example, presently we talk about the digital divide and knowledge gap. Technological developments, their diffusion and transfer all over the world do not make the world equal regarding the stage and impacts of IS progress (understood in the abstract).

The irregular development of economies and societies throughout the world seems to be a historical regularity. The same applies to the present stage of development connected with ICTs. A historical perspective of IS development in particular countries requires grouping such into classes:

- *pioneering countries*—in ICTs production, use and wide diffusion in all sectors of economy and social life;
- *imitators*—taking advantage of technology transfer, FDIs, and global networking, however the diffusion of ICTs may be limited to selected sectors; and
- *lagging behind*—for a variety of reasons, for example, educational, technological, economic, political, cultural, and so forth, such countries may have trouble introducing and effectively utilizing ICTs.

A similar division is possible made within particular countries. The developmental dualism seems to be common in many parts of the world, especially in the less advanced

states. However, some regrouping is occurring. Until recently the only pioneers were the United States, Japan, and Western Europe. Due to the global reach of transnational corporations, FDIs, international trade, and global networking, as well as national strategies and efforts, some countries have become increasingly competitive (e.g., China, India). Moreover, the internationalization of ICT production is rapidly growing. In addition, some countries (including the entire European Union) declare they are building an information society.

Nevertheless, particular ISs will not have the same faces throughout the world despite some strong similarities, universalistic trends, similar strategies and policies of governments and business, and certain parallel human activities. The chaos of developing a diversified and turbulently changing environment may outweigh some, mostly technological, deterministic tendencies. Technological determinism that assumes "one way for all" seems to be merely an intellectual idea or simplistic concept rarely functioning in reality (if so, with some time and space limits).

Summing up: various emerging information societies are highly differentiated and will probably also have differentiated info-futures. Apart from certain similarities and some evident universalization, the growing info-diversity may occur and greatly shape the world's societies. Therefore, even a general abstractive model or pattern of an information society may need reinterpretation based on actual experience. So far, the known prophecies and visions of IS development, elaborated in Japan, the United States, and Western Europe, will probably not match the real course of events, the real potentials, needs, and aspirations of billions of people. All the aforementioned differences were reflected in the IS discourse.

BACKGROUND: INFORMATION SOCIETY - DEFINITIONS AND DISCUSSIONS

ICTs, their multifaceted impacts, the change of sociocultural context, and the global dimensions of all emerging transformations need permanent investigation, analysis, interpretation, and forecasting, required not only for research, theorizing, or education.

All theorists, futurists, and analysts dealing with the IS problem express a conviction that there is some possibility and social ability to steer and control occurring changes and transformations.

For all these reasons, there have been numerous efforts to define problems, recognize and evaluate processes, and predict the possible future course of IS around the world since the 1960s.

Providing one commonly accepted definition of IS seems to be very difficult. There are many terms or qualifications directly or indirectly connected with broadly understood IS. To name several examples: *information society, information rich society, cyber-society, computer society, telematic society, network society, virtual society, e-society,* and the like. These terms underline the role of various characteristics and symbols like, for example, access to information, cyberspace as a new social space, use of computers, telecommunications networking, virtualization, and electronization. All are relevant and in fact complementary. However, various authors tend to support their own interpretation concerning the most important features. The long list includes examples such as Masuda (1981a, 1981b), Negroponte (1996), Dertouzos (1998), Castells (2000, 2004), Wellman (1999), and Virilio (1998). Many authors add such qualifications as *digitalization*, referring to the advances of info-technology (e.g., Tapscott, 1998), and *mediatization*, referring to the overwhelming role of mass media (e.g., Lievrouw & Livingstone, 2002; Downing, 2000).

It is quite difficult to find truly precise definitions in the very extensive literature on this subject. Quite often, there are descriptions, characteristics, and qualifications that are rather general and vague (i.e., not comprehensive). In many cases, though the term "information society" appears in the title and in the text of a book, article, or document, it is not explicitly defined, but used as a kind of label, taking for granted that the content would sufficiently explain all terms.

However, there have been many efforts in the past to describe, analyze, and evaluate ongoing technological, socioeconomic, and cultural changes connected with new ICTs. For example, Bezold and Olson (1986) reviewed first the specific *societal impacts*—past, present, and probable—of the information revolution. Subsequently, they discussed different *whole-system* images of how an information society may evolve. They contrasted images of the civilizational and societal transformations of leading future-oriented thinkers, such as Bell (1973), Toffler (1980, 1990; Toffler & Toffler, 1995), Naisbitt (1982), Harman and Markley (1985), and Masuda (1981a, 1981b), who believed that a new stage of civilization is emerging, with information and ICT playing a pivotal role in the social transformation. However, they differ on such matters as the *key driving forces* for societal change, the *main features,* and the *overall pattern* of change. Bell (1973) announced the emergence of post-industrial society in which the critical driving force for change is the codification of theoretical knowledge generating the exponential growth of science, systematic R&D, and new intellectual technologies. Toffler (1980, 1990; Toffler & Toffler, 1995) developed the theory of a third wave driven by growing socio-economic complexity, diversity, heterogeneity, and connected with demassification of production, media, lifestyles, and so forth. The newly emerging social order demanded higher levels of information flow.

Naisbitt (1982) believed social development rather than technological change leads to information society, although

technology greatly stimulates the transformations. He stressed the changing structure of the economy (rising dominance of the information sector) and the role of information (including new information jobs) as the key strategic resources.

Harman and Markley (1985) noted that current problems require something other than industrial technology and a worldview hailing from the industrial era. They argued that new images of the future and new values were required, along with a shift in the hierarchy of information types (data, information, knowledge) with emphasis on wisdom. In their view, this may lead to a "learning society," but "failure futures" are also possible in spite of information richness.

Masuda (1981a, 1981b) elaborated "The Plan for an Information Society: Japan's National Goal Toward the Year 2000," in which he set out the most radical vision of development based on three stages—automation, knowledge creation, and system innovation—with the computer as a key driving force.

All authors mentioned above appreciated the great transformational role of information and information technologies for social change. All except Bell (1973) envisioned a *multi-optional future*—not necessarily positive and democratic. However, all authors assumed some *possibility and social ability* to steer change by decisions, policies, business behavior, education, citizen participation, and so forth.

Based on the *alternative futures approach,* Bezold and Olson (1986) worked out four scenarios:

- the High-Tech Information Society,
- the Creative Society,
- Things Bog Down, and
- 1984 and Beyond.

The first scenario was similar to Bell's (1973) image, the second to the images forecasted by Toffler (1980, 1990; Toffler & Toffler, 1995), Naisbitt (1982), Harman and Markley (1985), and Masuda (1981a, 1981b) (see Bezold & Olson, 1986). The last two presented a less optimistic future, even with the possibility of authoritarianism.

Bezold and Olson (1986) in their report used the following definition of IS:

A society that reflects the growing importance of information in the shift from manufacturing jobs, in the growth of information purchases, in the importance of information in business and personal life, and in the enhanced level of information built into products. (Bezold & Olson, 1986, p. A-24)

This definition is economically (business) oriented.

A more recent approach was presented within the ESRC Research Program, "Virtual Society?: The Social Science of Electronic Technologies." The program "was set up to research the implications of the continued massive growth in new electronic technologies" (ESRC, 2000, p. 3). It posed two questions: "Are fundamental shifts taking place in how people behave, organize themselves and interact as a result of the new technologies? Are electronic technologies bringing about significant changes in the nature and experience of interpersonal relations, in communications, social control, participation, inclusion and exclusion, social cohesion, trust and identity?" (ESRC, 2000, p. 3).

The answers had to serve the *policy agenda* and contribute to *business success,* to the *quality of life,* and to the *better future of society* (see also Woolgar & Ingram, 2000). The program formulated the rules of virtuality and especially emphasized the role of the local social context—finding expression in the cultural capacity to make the best use of new technologies. It further considered relations between technologies and social theory (Woolgar, 2000).

Interestingly, computer specialists such as Bill Gates (Microsoft), Nicholas Negroponte, and Michael Dertouzos (the latter two from MIT) preferred to use terms such as *information revolution, information age, digital life, world,* and *future.* Their books (Gates, 1996; Negroponte, 1996; Dertouzos, 1998) are the visionary guides to the future. They focused on how ICTs transform human life and the world. As active participants in the creation of the information age, they present deep insights into the technological problem. They do not theorize on society, dealing rather with the lives of individuals. They are optimistic, though they see a dark side of new technologies. For Negroponte (1996), the coming digital future is an "age of optimism" (p. 227).

Mattelart (2001) presents a very broad historical and cross-disciplinary perspective. Instead of using the term IS, he prefers "society of information." The central focus of Mattelart's investigations are information and its history. He is skeptical about the idea of commonly accessible information, pointing out the conflicting interests of governments and societies, even stimulated by the international context (e.g., terrorism) and the continuing role of development (Mattelart, 2001). Interestingly, Mattelart refers to the historical anticipations of the ideas of globalism and world networks, which are very fashionable at the present time.

The apologetic discourse on IS is also criticized by May (2002). In fact, his criticism is directed against the overoptimistic and exaggerated beliefs and convictions concerning the stage, development, span, and transformational potential of the "information age," "new economy," and "information society." He rightly points out that all these new ideas do not necessarily invalidate what we already know about society, the economy, and the world.

There have been many changes we might link to the development of new information and communication technologies (ICTs). However, there is also much about the global information society which is similar to previous modes of

social interaction: economics is still recognizable as modern (or perhaps late) capitalism; despite forecasts of increased 'virtualization', politics, communities and other aspects of social existence remain located in the material world; states continue to play an active and important role in our lives. Thus, there is no need to dispense with our previous 'ideological baggage'. Indeed, the claim that we should is ideological in itself. It represents a dismissed of well-developed arguments regarding the contested and contingent character of capitalism, while also presenting a specific set of contemporary social relations as natural and outside history. (May, 2002, p. 149; see also Schiller, 1999, who used the term "digital capitalism")

Castells (2000, 2004) is a very influential author who argues that the widespread deployment of ICTs produces a networked society in which new communication capacities can be beneficial both for organizations (like companies) and individuals. Further, he finds that electronically mediated networks greatly support development and diffusion of information and knowledge. Physical resources are increasingly substituted for the mobilization and coordination of knowledge and information resulting in information capitalism and the network society. In spite of some controversies and criticism (also by May, 2002), Castells' (2000, 2004) approach seems to be useful. Needless to add that some other researchers made use of the network approach as well (e.g., van Dijk, 2006; Wellman, 1999).

It seems to be quite justified to review the IS problem in the EU documents and publications since the European Union is a historically unprecedented grand socio-political project. IS building is part of that project's agenda. Evidently, this agenda is more policy oriented.

FAST, the early program of the Commission of the European Communities, subtitled "Sub-Program Information Society—Research Activities," focused on "the societal changes towards which Europe and the world are heading, based on the enormously enhanced capabilities in information handling which microelectronics and associated technologies provide" (FAST, 1980, p. 1). The program emphasized computer technology, microelectronics, and automation. Subsequently, innovation, job creation, representation, and sharing of power, impacts on the way of life (transport, communication, work, leisure), along with distribution of risk and benefits, were the subjects of investigations and debate.

The famous Bangemann Report on "Europe and the Global Information Society—Recommendations to the European Council" stated:

The widespread availability of new information tools and services will present fresh opportunities to build a more equal and balanced society and to foster individual accomplishment. The information society has the potential to improve the quality of life of Europe's citizens, the efficiency of our social and economic organization and to reinforce cohesion. (Bangemann Report, 1994, p. 5)

However, the report concentrates not on technology, but on market-driven changes. It considers issues such as protection of intellectual property rights, privacy, electronic protection, legal protection and security, media ownership, competition policy, and financing.

Another EU document, referred to as the "green paper" on "Living and Working in the Information Society: People First," stresses fundamental social problems, for example, work (skills revolution, job insecurity, new forms of work organization), employment (management of the job transformation process, education and training to match the ICT revolution), social cohesion, public policy, new regulatory framework, human resources, empowerment, and integration (Green Paper, 1996). The EU document, subtitled "A European Way for the Information Society," points out:

[ICTs] are rapidly becoming central to economic, cultural and civic life in the industrial countries. Access to ICT will increasingly be essential to full participation and citizenship…Internet access will become a fundamental right…ICT abolishes distance and ignores borders…The information society is necessarily a global society. (A European Way, 2000, p. 5)

Moreover, it proposes a distinctive European Way based on liberty, equality, fraternity, solidarity, and sustainability. It also addresses other issues, including the rights of the individual, lifelong learning, global communication, new culture of government and of public service oriented towards a "network mentality," global governance, and dialogue (A European Way, 2000). This document of the Information Society Forum encourages joint reflection on the future of the information society through global dialogue based on the necessary core values. This approach is not only normative, but to some extent also policy oriented, because it also provides a set of more concrete recommendations.

The global dimension of the information society was discussed in EU documents even earlier (e.g., I&T Magazine, 1995).

F.R. de Bruïne, of the European Commission DG XIII, explains:

Information superhighway, Infobahn, global networked economy, global information infrastructure, global village…these and other popular labels abound. In Europe, the preferred term 'information society' reflects concern with the wider social and organizational changes that will result from the information and communications revolution. This revolution is driving the transformation from a society based

on physical goods to one increasingly based on knowledge and information. (Bruïne, 1995, p. 10)

In the EU, some other terms like "information society based on knowledge" or "e-Europe" have been recently used (see, e.g., the Lisbon Strategy or the E-Europe Web site). These are extensions of previous definitions and concepts, and serve the debates and policies well.

Information society as a social and political project has always been the subject of interest for government, politicians, international organizations, as well as NGOs and various social movements. Examples follow.

During the 1992 U.S. presidential campaign, Al Gore introduced the issue of national (then global) information infrastructure. A special advisory council at the White House was appointed after the election. The Project of National Infrastructure promised many good jobs for highly skilled persons (e.g., for "symbolic analysts"), mass development of telemedicine, stimulation of democracy ("interactive citizen"), and modernization of education. The actual goals, however, were U.S. competitive advantage in world trade, and technology transfer and research.

G7 and G8 meetings have also dealt with the "new world information order" (in 1995 and 2000) and adopted the notion "global information society." Information superhighways were left to private sector initiatives and market forces in accordance with the recommendation of neo-liberal economics (e.g., presented in the form of "new economy"). E-commerce, digital market, global competition, deregulation, piracy, intellectual property rights, and so forth gained more interest than social visions, even in the EU.

The United Nations—via its agency, UNESCO—organized workshops and conferences (e.g., the World Summit on Information Society in 2003 and 2006) in order to debate the conditions for common access to cyberspace, limiting the digital divide, and introducing NGOs to the discourse, The international discourse on global IS is continued both in global competition—technological and economic, piracy protection, rights of intellectual property, standards, telecom deregulation—and also under the banner of e-governance, strengthening democracy, and global civil society.

BETWEEN THE IS DISCOURSE AND THE REAL PROCESSES AND CONTEXTS

The IS discourse will certainly continue. The above presented definitions and concepts are in fact complementary in spite of their diverse orientations (cognitive, ideological, practical). Therefore what really matters for the future are the real processes and the contexts of the emerging information societies. So not to discuss more on the terms and their interpretations, it seems reasonable to adopt the following general definition: *information societies are societies in which info-activities are prevailing,* which implies sufficient infrastructure, education, access, and efficiency. However, the predominance of info-activities may differ substantially. There are societies able to create ICTs and use them effectively on a large scale like the most advanced countries, sometimes referred to as *high-tech societies.* There are also societies that simply participate, via technology transfer, international technological cooperation, adaptation of info-oriented patterns of education, mass culture, consumption, and so forth, in the civilizational mega trend related to the mass production, wide diffusion, and mass application of information. The leading or pioneering countries (societies) have the potential (educational, scientific, financial, managerial), not to mention the proper infrastructure and government policies, to create the new ICTs and exploit them everywhere. Government orders that stimulate ICTs are often in the field of military systems and equipment connected with automated battlefields, military robots, intelligent ammunition, telecommunications systems supporting info-war, and the like. In the beginning of the information revolution (approximately a half a century ago), the governments of technologically leading countries usually supported intensive research in the R+D sector and also the processes of harnessing new technologies into industry—for example, acting in various ways to diminish risk for companies. This support is important nowadays too. It can be implemented in the form of public-private partnership, favorable legal regulations, and policy measures.

Therefore, the supply side of ICTs and their multifaceted uses and impacts were ensured by the R+D sector–public and private: public university labs, labs of big corporations (like Bell, IBM, Microsoft, Philips), small innovative firms (like Intel or, at one time, Apple), high-tech centers (like Silicon Valley or similar centers, e.g., Bangalore in India or science parks in Europe), and entrepreneurial companies that immediately commercialized emerging innovations and placed them in markets locally and globally. Scientists, governments, and businesses created new knowledge and new products and services based on this knowledge, as well as transformational patterns and potentials for change of all leading societies and—by transfer, exchange, impacts—other societies all over the world. Great TNCs play a tremendous role in diffusion of IC technologies, systems, and products through FDIs with new technology and organization, international trade, joint ventures, and so forth, not to mention the influence of their immense marketing and advertisement efforts.

There is of course the demand side of ICTs and their uses. This side is predominantly stimulated through education, national and global media, imitation of consumption patterns of technologically leading countries, import of

technologically advanced goods, as well as advertisement and marketing of novel technologies and products. Here, psychological and cultural (also religious) openness and capacities are also crucial. Readiness to use ICTs, to adapt to them, to modify our own behavior, and finally to be a part of a global network seem to be the *conditio sine qua non* of the information civilization's success and of social change (both in a collective and an individual sense).

To make potential demand truly effective, some technical and financial barriers should be overcome, for example wide access to infrastructure, inexpensive computers and programs, and cheap Internet access are necessary. Countries with inferior education, low technology, inadequate technical infrastructure, and low income levels have serious problems in joining the "ICT world club." Thus, they should be the object of effective assistance and cooperation from international organizations and businesses as well. Only their inclusion in the processes of ICT globalization will allow achievement of global rationality and sustainability, not only of the technological kind.

Information society (IS) is currently the emerging form of human organization. General IS discourse tends to concern an abstract model (i.e., ideal construct) with its characteristics and interpretations. In the real world, there are only concrete individual information societies emerging mostly in advanced countries. They differ significantly from each other, because of the experience and potentials (educational, technological, economic, cultural, etc.) of their achieved stage of IS development, along with the diversity of their effects and impacts. Furthermore, their strategies, policies, and performance thereof also play extensive roles. Finally, the external environment is undoubtedly crucial in the current highly interdependent and networked world.

As result of all these conditions, potentials, strategies and actions, diversity of impacts, and unequal external dependence, the future of the world's information societies will be quite diversified and heterogeneous. The info-futures will be full of gaps, divides, collisions, and conflicts. Therefore, the idea of a uniform global information society, in spite of the globalization of ICTs and their prevailing impacts, also seems rather utopian due to its incompatibility with the existing and predictable diversity of the world.

FUTURE TRENDS

There are at least two emerging trends in IS research. One is the general, global, and civilizational approach, the other is represented by various disciplines and studies in particular areas. It is also possible to separately categorize investigations focusing strongly on technology from non-technological ones, which reflects "two cultures" in the sciences.

Studies of particular areas are more empirical and should form a cognitive base for more general studies. A cross-disciplinary approach should be recommended, because such is the actual nature of the problem.

Moreover, two other (not only) methodological—problems emerge:

1. whether and how much the general and domain studies reflect the actual transformations in real world (also in the cyber-world), and
2. what kind of feedback dominates between general and particular studies.

Of course, a kind of cognitive time-lag is always possible. Additionally, the ever-present propensity toward utopian (or dystopian) thinking can serve ideological, political, or even religious goals. Increasingly complex reality and progressively narrowing empirical investigations are immense challenges for any reasonable generalization. Thus, the problem at hand and its research should be future oriented and open ended. But how does one avoid excessive value judgments, overstatements, absolutist approach, one-sided opinions, unjustified simplifications, and optimistic or pessimistic emotions notoriously present in theories and their criticisms?

It is interesting to consider which approach connected with understanding of man-computer-cyberspace relations will win. For the time being, there are two presumed attitudes. One treats a computer as a machine to be used as other machines in the past; the same refers to the Net, regarded as an additional social space in which human life existence will carry on as usual. The other emphasizes a strong transforming force embedded in computers and networks which can radically change our lives and ourselves. Therefore, the difference is between *using* the Net and *being* (*living*) in the Net. The increasing convergence of media and VR technologies and their massive diffusion will probably act more for the latter option. The problem is, however, the low predictability of the course of events, behavior, and choices of the next generations brought up in the digital culture (i.e., e-generations).

The discourse on IS is rather controversial regarding civilizational, technological, and especially social and cultural issues. Some authors tend to deal mostly with the technology-man relation, others concentrate on social and cultural change; there are many examples of both orientations.

Some works may already be referred to as classics. Their ideas, theories, and empirical analyses are fundamental (additionally, one can find the comprehensive literature reviews in these works). Their general observations and views were influential and often survived. More contrasts and controversies emerge when considering and debating specific problems and issues. Moreover, the time factor is verifying the past intuitions, hypotheses, and criticisms.

Besides general views concerning IS as a result of

civilizational and technological change modified by various cultures, there are several more particular orientations and fields of IS discourse. They present interesting current and future research opportunities. The following exemplification is limited to keywords reflecting their possible profiles:

- *future or futures:* info-futures;
- *globalization:* global information society;
- *capitalism:* information or digital capitalism;
- *LDCs:* pre-information societies, info, late-comers;
- *culture:* cyber-culture, cyber-art;
- *values:* Internet ethics, multiculturalism, cosmopolitanism;
- *knowledge:* network production of knowledge, knowledge society, new episteme, knowledge property;
- *education:* e-learning, connected intelligence;
- *democracy:* teledemocracy, netocracy, democracy.com, info-civil society, e-democracy;
- *governance:* e-government, e-governance;
- *business:* e-business, e-commerce, e-banking;
- *Internet:* cyber-space, telework, net games, VR, crimes, terrorism;
- *communications:* mobile phone, global media, massive surveillance;
- *society, community, individual:* IS/knowledge-based society, telecommunities, virtual societies, netizens, global netizens, multiidentity, networked invidualism, monadization in the Net; and
- *posthuman era:* post-info-society, bio-info-society, posthuman society, e-herd, e-swarm, human-machine aggregates, intelligent mobs, cyborgization.

There are numerous additional research interests (e.g., power, state, war, work, terrorism, environment, feminism) representing areas also radically transformed by ICTs.

Area studies can generate some important warnings as well as some policy-oriented directives and recommendations. They can stimulate thinking, decision making, and multi-optional acting, along with the greatest possible exploitation of multi-criterial rationality, also in the long term.

CONCLUSION

The problem discussed above has three dimensions. The first refers to *real phenomena and processes* driven by or connected with ICTs. They should be observed, identified, recognized, measured, and analyzed. The second concerns their *interpretations and evaluations.* This is more subjective, normative, often biased, ideologized, and controversial. Controversies even concern fundamental problems like continuity vs. discontinuity in development, transformations of forms vs. substance, meaning and importance of ICT implications, and so on. Thus, the ICT discourse tends to be vivid and, ultimately, inconclusive. The third dimension of the problem, the *future*, significantly reinforces this situation. This dimension is inherently burdened with risks and uncertainties connected with the future course of real processes and human behavior, values, and choices. In spite of all these difficulties and limitations, there are efforts to make the ICT discourse policy-oriented and to use it for elaboration of strategies and policies of governments, businesses, and civil societies.

The discussion presented here is extremely broad, complex, and further complicated because it is relatively new and interdisciplinary. Moreover, entities such as information civilization, information economy, and information society have only emerged in recent decades, while also being highly diversified in time and space. As such, it is very difficult and demanding to investigate processes, which are often radical and hardly predictable especially in their long-term effects and impacts.

As a result, theories, recommendations, and conclusions have rather limited validity (cognitive, scientific, intellectual, practical, political). Apart from being to some extent general and perhaps universal, they ought to relate to real particular societies or other human groupings (entities) that can emerge in the future.

Nevertheless, some concrete practical recommendations seem to be possible for governmental and corporate strategies, for example concerning procedures of e-government or e-business strategies. Some may also be useful for people in their various roles—as citizens, netizens, consumers, electorate, and media auditorium. At present, it is not reasonable enough to elaborate recommendations based on past experience for would-be societal forms such as e-herd, e-swarm, intelligent mobs, for possible posthuman creatures. It can only be advised to stimulate the efforts of our imagination and our alternative thinking abilities, which can be instrumental for elaborating multi-optional scenarios of info-futures.

KEY TERMS

Future: An image of what may be, composed of a set of elements in which interactions are shaped largely by a set of driving forces; also called a macroscenario (according to Bezold & Olson, 1986, p. A-23).

Future Scenarios: Comprehensive, internally consistent descriptive images of the future based on assumptions about relevant forces of all kinds (technological, economic, political, social, educational, environmental, etc.) together with their multiple interactions; external conditions and influences should be also considered.

Future Types: Possible (open to all possibilities); plausible (an image of the future based on forecasts that might reasonably occur); preferred (the future desirable and sought after).

Info-Futures: Future alternatives of development of societies, organizations, and institutions related to information (production and applications) and ICTs.

Information Era: An era where information is the main strategic resource upon which individuals, organizations, and societies rely for their growth and development. Also called *information millennium.*

Information Society (IS): A society predominantly dealing with production and applications of information in all spheres of life (i.e., economic, social, political, cultural, etc.). It is also assumed that the mass info-activities are based on sufficient infrastructure, access, education, cultural capacity, efficiency, and so forth. Synonyms and closely related terms include *information-rich society, network (or networked) society, e-society, virtual society, information society based on knowledge* (or *knowledge society*).

IS Determinants of Development: There are many—mostly complex, interrelated, and often fuzzy—conditions, factors, and mechanisms (including historical, geographic, economic, technological, educational, social, cultural, political, psychological, etc.) that determine the character, structure, pace, and effectiveness of IS emergence and its progress. They are connected with certain existing potentials, situations, and external context, as well as with deliberate efforts (like business strategies, government policies, activities of international organizations, people's attitudes, education systems, and media presentations of the advanced patterns of IS development).

IS Diversity: The real world's societies are much diversified in terms of the advancement of IS characteristics and indicators. The most developed create ICTs and use them widely and effectively. Most world societies are merely users and imitators (via technology transfer). There are also many limited to being merely impacted by ICTs (via the global Net, FDIs, international trade, etc.).

IS Futures: The future of particular information societies should be presented and debated as multi-optional, not as universal/uniform—that is, the same for all societies. Such is implied by their diversity, which determines their differentiated progress now and in the future. Therefore, any conclusions and recommendations ought to consider their specificity, especially if they have practically oriented ambitions. It is important to remember that all long-term visions, predictions, and forecasts of IS are uncertain, even if we hardly strive for them.

Information Systems and Small Business

M. Gordon Hunter
University of Lethbridge, Canada

INTRODUCTION

The subject area of the application of information systems to small business is a thoroughly interesting, yet relatively under-researched topic. Small business is an important part of any economy. In the United Kingdom, 25% of the gross domestic product is produced by small business, which employs 65% of the nation's workers (Ballantine et al., 1998). In Canada, 43% of economic output is accounted for by small business, employing 50% of private sector employees (Industry Canada, 1997). Further, governments view the small business sector as that component of the economy that can best contribute to economic growth (Balderson, 2000). Given the importance of this sector of the economy, it is incumbent upon researchers and managers of small business to develop a better understanding of how information systems may contribute to the operation and growth of individual businesses as well as the overall sector.

The objective of this article is to provide an overview of information systems used by small business. Research projects are presented that describe the current situation. Recommendations are then proffered for various stakeholders who should contribute to a more effective use of information systems by small business.

BACKGROUND

There does not seem to be a commonly accepted definition of a small business. Thus, individual researchers have adopted a definition for their specific projects. Some definitions include annual revenue, amount of investment, or number of employees. The definition mostly used is number of employees (Longnecker et al., 1997). The European Parliament (2002) has also adopted number of employees as a definition and has further refined the category. Thus, 0 to 10 employees represent micro businesses, small businesses include 10 to 50 employees, and medium businesses have 50 to 250 employees.

Beyond the size aspect of small business, there are others that differentiate them from large businesses. Stevenson (1999) has determined that from a strategic perspective, managers of small businesses tend to respond to opportunities presented by their environment in a multi-staged approach by committing a minimum of resources. Another differentiating factor is "resource poverty" (Thong et al., 1994). This term refers to the lack of time, finances, and human resources.

Laudon and Laudon (2001) suggest that an information system is "interrelated components working together to collect, process, store, and disseminate information to support decision making, coordination, control, analysis, and visualization in an organization" (Laudon & Laudon, 2001, p. 7). As indicated previously, managers of small businesses emphasize short-term decisions in their allocation of scarce resources. However, most information systems require a long-term plan with a significant one-time initial financial commitment. This conflict may result in inefficient investment in information systems, which in turn may negatively impact the financial situation of the small business.

Recent research has supported the contention that the use of information systems by small business represents a unique approach. For instance, Belich and Dubinsky (1999) and Pollard and Hayne (1998) determined that the issues being faced by small business managers (lack of time, skills, and financial resources) are different than those faced by large business managers. Further, Taylor (1999) investigated the implementation of enterprise software in small businesses and found that neither the businesses themselves, nor the software vendors were fully cognizant of the unique problems (matching system capability to functional requirements) encountered by small business managers. Finally, Hunter et al. (2002) identified two major themes regarding small business use of information systems. These themes are "dependency" and "efficiency". The authors suggest that the adoption of information systems increased the small business' dependency on an internal champion, and a series of external stakeholders, including consultants and suppliers. Hunter et al. (2002) suggest this increased dependency results from the approaches to business (Stevenson, 1999) taken by the manager and the concept of resource poverty (Thong et al., 1994). The efficiency theme suggests that small business managers primarily use information systems as an operational tool to help complete daily activities.

Earlier research (Nickell & Seado, 1986) determined that small business was mainly using information systems for accounting and administrative purposes. Research conducted in the 1990s (Berman, 1997; Canadian Federation of Independent Business, 1999; Fuller, 1996; Lin et al, 1993; Timmons, 1999) noted a growing interest by small business in employing information systems for daily operations. While small business has been more than prepared to exploit

the use of information systems to support daily operations (El Louadi, 1998), there exists little evidence that they are prepared to employ the technology in a strategic manner (Berman, 1997). Bridge and Peel (1999) determined that small businesses employed computers mainly to support daily operations and tended not to use them to support decision-making or long-term planning. Current research suggests this situation has not changed. For instance, Dandridge and Levenburg (2000) found that information systems were being employed for daily operations and there was little use of computerization for competitiveness aspects such as accessing the Internet.

A number of research projects have identified that small businesses have not adopted Internet use because of lack of knowledge and experience (Damsgaard & Lyytinen, 1998; Iacovou et al., 1995; Kuan & Chau, 2001). Another set of contributing factors relates to the lack of personnel and time (Bennett et al., 1999). Even when time and personnel are available, there seems to be reluctance by small businesses to investigate the use of the Internet (Chapman et al., 2000).

Burgess and Trethowan (2002) examined the use of Web sites by small businesses, represented by general practitioners, in Australia. They found that while there was reasonably high use of computers to improve efficiency and lower costs, there was not much use of computers for Web sites. Those who had Web sites mainly employed them to provide basic information and contact details.

FUTURE TRENDS

This section presents a number of recommendations for various stakeholders intent on increasing the use of information systems within the small business sector. These recommendations represent suggestions for the future and reflect a synthesis of available literature, presented in the previous section, in the area in conjunction with, and in the specific context of, previous research (Hunter, 2002; Hunter & Long, 2003;Hunter et al., 2002).

Small Business Manager

To overcome the limitations of being dependent upon others' expertise, managers need to gain an understanding of the capabilities of information systems. While managers do not need to know how to design or develop information systems, they do need to understand how technology might be used as a key resource in adding value to the firm's core business products or services.

Further, the small business manager should establish a relationship with a specific individual regarding a source for advice. The recommendation is for the manager to establish a relationship with someone who is independent of a specific solution and who will be prepared to play a strategic role, taking a long-term perspective. It is incumbent upon the manager to review the relationship to ensure that the recommendations being proffered are appropriately contributing to the long-term success of the firm.

Also, managers should take a proactive approach toward the adoption of information systems. This would involve actively seeking out ways to leverage information systems to create or improve products or services offered to customers. However, the manager should avoid being an early adopter of new hardware and/or software applications.

Consultant

It is important for consultants to recognize that in regard to the nature, timing and acquisition of resources, the small business manager generally aims to minimize the amount of resources used at each stage of the firm's growth. Generally, consultants need to be able to provide opportunities for small businesses to "phase in" information systems in stages. Doing so will accommodate small business practice and form the foundation for a mutually beneficial ongoing relationship.

Vendor

Vendors should make a visible commitment to small business through the establishment of an entity specifically directed at small business. The small business sector is a large and important one; thus target marketing this sector makes good business sense. Also, software vendors must ensure that an application performs the necessary functions for small business. It is incumbent upon the vendor to ensure the hardware or software addresses the appropriate functionality of the small business.

Government

Government can help overcome resource poverty by providing advice and financial incentives to small business. By initiating relationships with small business managers, individuals representing government services can more effectively support these managers by tapping into their informal networks to exchange required information. The role of tax and other financial incentives may be employed to encourage the expanded use of information systems.

CONCLUSION

Information systems have increased the efficiency of daily operations for small business.

Generally, evidence suggests that information systems expenditures are being made in reaction to needs or problems, rather than as a result of a long-term coordinated plan. The suggestions included here should contribute to more effective use of information systems by small business.

KEY TERMS

Dependency: The requirement to rely upon another individual or organization.

Effectiveness: The ability to accomplish a task with fewer errors.

Efficiency: The ability to accomplish a task with few resources.

Information Systems: Interrelated components working together to collect, process, store, and disseminate information to support decision-making, coordination, control, analysis, and visualization in an organization.

Internal Champion: Highly respected individual within the organization who possesses expertise in a specific area, specifically information systems.

Resource Poverty: The lack of time, finances, and human resources.

Sales/Revenue: Receipt of income for the exchange of goods or services.

Small Business: Various categories may be employed to define this term. Some examples are as follows:

Employees:

- Micro business: 0 – 10 employees
- Small business: 10 – 50 employees
- Medium business: 50 – 250 employees

Stakeholder: An independent party who may have the ability to impact another party.

Strategy: A business plan of action.

Information Systems Curriculum Using an Ecological Model

Arthur Tatnall
Victoria University, Australia

Bill Davey
RMIT University, Australia

INTRODUCTION

To those of us involved in research and teaching in information systems (IS), it is clear that curriculum innovation and change is complex, and anything but straightforward. The amount of control that individual IS academics have over the curriculum varies between universities. In some cases there is complete control over curriculum content whereas in others just control over delivery with content determined externally. This article concentrates on the former situation but still has some relevance to the later. All curriculum innovation is complex (Fullan, 1993) due to the involvement of a large number of human actors, but in information systems curriculum change this is particularly so due to the need to consider the part played by such non-human actors (Latour, 1996) as the technology itself.

We will argue that if you want to understand *how* IS curriculum is built, you need to use models and metaphors that relate to how people interact with each other, with the environment, and with non-human artifacts. One such approach is provided by the ecological metaphor described in this article in which we argue that systems of education may be seen as ecosystems containing interacting individuals and groups. The interactions between these will sometimes involve co-operation and sometimes competition, and may be interpreted in terms of these forces along with mechanisms for minimizing energy expenditure. In this article we will examine the application of this metaphor to curriculum change in information systems.

BACKGROUND

Nordvall (1982) identifies several models for curriculum change that he suggests all have relevance, in the higher education context, at the subject, course, and institutional levels. These are:

- Research, development, and dissemination models
- Problem solving models; social interaction models
- Political and conflict models
- Diffusion, linkage, or adaptive development models

Models of change based upon a process of research, development, and dissemination (RDD) are probably the most common way of attempting an explanation of the process of curriculum development (Nordvall, 1982). In models like this, relying on logical and rational decisions, curriculum change depends on the use of convincing arguments based on programs of research. A rational and orderly transition is then posited from research to development to dissemination to adoption (Kaplan, 1991). These could then be considered as "manufacturing models" as they follow a fairly logical and straightforward mechanical approach with one thing leading directly to another and do not allow for or consider other influences such as those due to human interactions. If we were to accept a manufacturing model like this, then we might expect some curriculum outcomes to be consistently apparent across the world:

- As research would have shown that several specific programming languages were much more widely used and better to teach than others, all courses requiring programming would use just these few languages, and there would be no arguments regarding the best language to teach.
- As research would show the advantages of object-oriented methodologies all computing courses would teach only these and ignore other approaches.
- The content of courses around the world would be designed to achieve similar goals and outcomes, and contain similar content.
- Research would show the ideal method of teaching computing concepts and issues and classroom delivery of content would be moving toward this researched ideal. Everyone would then use these ideal delivery methods.

It is easy to illustrate that these predictions are not borne out in fact, as programs of study show wide variance within any given country and around the world. Many different programming languages and development methodologies are used, and a wide variety of techniques is adopted for classroom delivery. Some innovations seem to be accepted world wide, but many are accepted only locally. We will here

provide an alternative model that we believe better explains how IS curriculum is really developed.

Metaphors and Models

Before proceeding, however, we need to caution the reader on the limitations of models and metaphors. The dictionary describes a metaphor as a term "applied to something to which it is not literally applicable, in order to suggest a resemblance" (Macquarie Library, 1981, p. 1096). Metaphors are useful, not in giving a literal interpretation, but in providing viewpoints that allows us to relate to certain aspects of complex systems.

We contend that most curriculum models and metaphors are too simplistic to allow a useful view of a curriculum development as a complex system involving human and non-human interactions. In this regard, ecological model offers two main advantages:

- A way of allowing for the inclusion of complexity
- A new language and set of analytical and descriptive tools from the ecological sciences

AN ECOLOGICAL MODEL OF CURRICULUM CHANGE

In ecology organisms are seen to operate within a competitive environment, which ensures that only the most efficient of them will survive. In order to survive, they behave in ways that optimize the balance between their energy expenditure and the satisfaction they obtain from this effort. These two key principles underlie the discipline of ecology, which is concerned with the relationship of one organism to another and to their common physical environment (Case, 2000; Townsend, Harper, & Begon, 2000). Habitat, ecological niches, and the exploitation of resources in predator-prey interactions, competition, and multi-species communities (Case, 2000) are all important considerations in ecology.

We have argued (Tatnall & Davey, 2002, 2003, 2004) that these ideas correspond to the process of curriculum development in that an educational system may be seen as an ecosystem and that the interactions within this can then be analysed in terms of ecological concepts such as competition, co-operative behavior, and niche-development. Curriculum change can be interpreted in terms of mechanisms for minimizing energy expenditure and decisions that individuals make about whether to cooperate or to compete.

In information systems curriculum development we should thus look at all the factors, both human and artifact, to see which could be expected to compete, and which to cooperate to become part of the surviving outcome. A non-human stakeholder such as a development tool or methodology must cooperate with the environment, compete successfully, or die out. This may mean a new curriculum element becomes incompatible with an old element and so replaces it. Alternatively it may mean that two new design tools can be used together, or that a particular curriculum element is compatible, or perhaps incompatible, with the desires and interests of a particular faculty member.

Ecological metaphors have been used in areas other than biology and IS curriculum change. An ecological framework has been used quite successfully in other areas including mathematics curriculum (Truran, 1997) and a study of the effects of violence on children (Mohr & Tulman, 2000). Ecology as a framework tells us to expect progress of a task through cooperative or competitive behaviors of the animate and inanimate factors in the environment. A factor that cannot compete or cooperate is inevitably discarded.

Ecosystems and Complexity

An ecosystem contains a high degree of complexity due to the large number of creatures and species living in it, as well as the variety of interactions possible between each of these. The "ecosystem" represented by the curriculum in a university information systems department contains (at least) the following "species": lecturers, researchers, students, professional bodies, university administrators, and representatives of the computer industry. The "environment" also contains many inanimate objects relevant to the formation of the curriculum, including computers, programming languages, textbooks, lecture rooms, analysis and design methodologies, networks, laboratories, programming manuals, and so on.

Curriculum development can be seen as attempting to introduce change within an ecosystem. The problem, of course, is the large number of interested parties that must be contended with before change can be implemented. Curriculum development is more complex than resolving the conflicting needs of students, employers, academics, and the academy. There is ongoing conflict between many things such as educational philosophies, pedagogical preferences, perceived resource constraints, and personal issues. To investigate the interrelationships between these entities we will look now at competition, co-operation, niche formation, and energy expenditure.

Competition

Competition in nature can occur both within and between species. In many species the males compete with each other for mates, while different species of fish compete for the best feeding areas. In IS curriculum we see many examples of competition, some of which are useful in determining the "fittest" topics and techniques best suited for survival (Darwin, 1859) in the curriculum, while others involve time-wasting clashes of personality between academics.

One example of competition seen in recent years in many IS departments is in programming between .Net and Java. The advocates of Java will contend that its use in producing Web-based applications and its non-proprietary nature mean that it is the best language to teach. .Net advocates, on the other hand, argue that while this may be so .Net is easier to use, and being backed by Microsoft has a considerable advantage in its use by industry. This, they contend, makes it the best vehicle to introduce students to programming. The result of this competition is, most likely, that one language will survive in the curriculum and the other die out. Similar examples can often be seen in competition between different methodologies and between software products. Most university courses now make use of Microsoft Office rather than Lotus, Word Perfect and the like, as Microsoft has clearly won the competition and become dominant in this area.

Co-Operation

There are many examples of unexpected co-operation between organisms in nature: the oxpecker bird that lives with a rhinoceros, sharks, and suckerfish, barnacles that attach themselves to whales, and dogs and cats living in close proximity with people. It is also possible to think of an organism living in co-operation with its environment: something the native peoples of many countries speak about.

In an educational program such as an IS degree some courses rely on earlier courses, that is, they have prerequisites. This can be seen as a form of co-operation in which each course benefits from the existence of the other. Another similar example is in software and programming languages where, for instance, the use of VB in a computer laboratory requires the presence (and co-operation) of Microsoft Windows. Likewise subject material that relies on the use of a specific textbook could also be seen as an example of co-operation.

Ecological Niches

An ecological niche is a place where a particular species that is well suited to this environment is able to thrive, where other species may not. A curriculum example of this is in the teaching of the PICK operating system by a university in Australia. Some years ago PICK was a serious challenger to UNIX for the "universal operating system" in business, but PICK has now decreased in importance. Despite the fact that no other university in the region now teaches it, and its place being challenged by more recent operating systems, PICK has remained in the curriculum of this university. It has remained largely because an academic involved in its teaching was able to argue convincingly (Tatnall & Davey, 2001) that learning PICK allowed students to take up jobs in the small number of prominent local industries using this system: that it filled an important ecological niche.

Energy Expenditure

It is easy to find examples of minimization of energy expenditure in curriculum development in the use of curriculum templates and the copying of curriculum from other institutions. Perhaps the greatest reduction in energy expenditure can be gained by using, without change, a model curriculum or the curriculum from another university. A related example is seen in choosing curriculum elements so that they fit in with existing university resources.

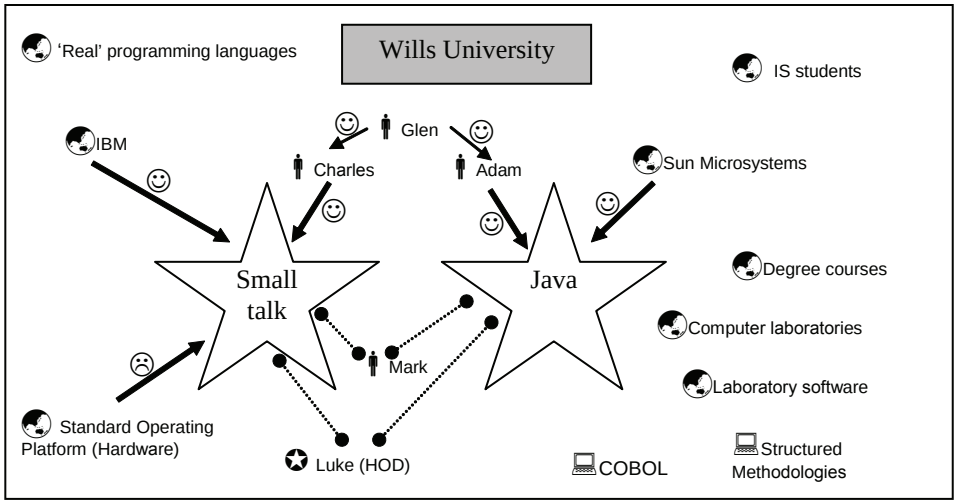
AN EXAMPLE: CHOOSING BETWEEN OBJECT TECHNOLOGIES

This example involves introduction of object-oriented (OO) technology into an undergraduate degree curriculum at Wills University in 2003 (although the case is real, the name of the university is fictitious). The non-human organisms in this case include existing structured methodologies and technologies such as structured analysis and design, and structured programming languages such as COBOL (Tatnall & Davey, 2004). New contenders with some support amongst the humans included an IBM version of Smalltalk and surrounding object-oriented methods in direct opposition to the Java tool set from Sun Microsystems.

In retrospect it can be seen from study of the minutes of meetings and discussion papers that a small group of human "organisms" played significant parts in the ecosystem during the introduction of the technology. These humans included an academic with ultimate responsibility for signing off any change, the existing academics in charge of target subjects, and the co-ordinator of teaching into the degree. The issue of changing technology had been raised several times over a number years, and the University was clearly several years behind in making decisions on this technology. During this period both the head of the department and the controller of the degree had been co-operating to minimize energy expenditure so that the output of the degree was constant (and a zero input for some output can be seen as very efficient). This co-operation between organisms can be seen to explain conservative behavior in organizations, but such a view overlooks the amount of energy required to overcome the desire of other organisms to make change. In this case a predator arrived in the environment in the form of a visiting professor who had been funded by the department to come to Australia to contribute to their research efforts. As an "outsider" the professor could be expected to have little impact as many factors existed in the environment strongly promoting the technology, and these had resulted in no change.

The effect of the visiting professor, however, was marked, and one of the academics involved with the target subjects used the forums provided to mount a campaign for change.

Figure 1. Wills University environmental interactions diagram (Adapted from Tatnall & Davey, 2004)



This co-operation between predators was aimed at the grazing organisms in that the visiting professor was motivated to have *some* effect occur as a result of his funded trip, and the interested academic could establish a reputation by being associated with such a change. At this stage the exact nature of the technology could be seen as irrelevant, as almost none of the relevant decision makers had any knowledge of the technology. As pressure mounted to make change the two other main organisms (academics) arose as interacting entities. Whereas one was championing the IBM Smalltalk technology, the other had been researching Java. In each case the co-operation between the technology and the human stemmed from invested time in gaining knowledge of the technology. A significant problem, however, was that the university's standard hardware operating platform did not contain sufficient memory to run Smalltalk satisfactorily.

Eventually the decision makers were spending so much energy in containing the move to new technologies that a decision was forced upon them. At this stage a coalition of predators achieved dominance in the environment as shown in Figure 1. Faced with this array of predators, the Java technology achieved dominance.

FUTURE TRENDS: APPLICATION OF THE ECOLOGICAL MODEL

No one individual can be identified as the main element in seeking to introduce the object-oriented technologies into the degree course. Let us suppose that an academic with a strong interest in OO had desperately wanted to introduce Java into the curriculum. He or she would have quickly seen the visiting professor as an ally with whom he or she could co-operate and then gone in a search for other allies, and any potential competitors. When it became clear that the main problem was one of energy expenditure—"why change when all is going well?"—he or she could have specifically addressed this by attempting to show how the change was inevitable and how inaction would just result in more energy expenditure at a later time.

CONCLUSION

Researchers investigating curriculum development, or any other field, must use language in framing their research questions. The language used often reflects a general viewpoint of the field being investigated and will always embody some metaphor for the principle components of the field. The metaphor is not useful in *proving* relationships but can be used to convey meaning once relationships are discovered, and an appropriate metaphor can lead the researcher toward or away from useful possible conclusions. Many of the metaphors for curriculum development are simple ones from areas such as the manufacturing-type research, development, and dissemination models described earlier. Any investigation of development processes in rapidly changing areas such as information systems shows that a common factor is complexity. This leads the search for a suitable metaphor to those disciplines that have accommodated complexity. One such area is ecology, and we have shown how ecological principles appear to provide good descriptions of common curriculum development activities. The ease with which the metaphor can be used to describe

Table 1. Application of the ecological model

Step	Ecological model	Example
1.	Examine the environment in which the IT curriculum change occurs.	This might be a university department of information systems or computer science, a departmental sub-unit, or perhaps an entire university faculty.
2.	Look for all relevant entities that might constitute this ecosystem.	Academics, students, university administrators, course advisory committees, local industry representatives, computer networks, programming languages, development methodologies, text books, courses of study, university handbooks, and so on.
3.	Look at all interactions between entities and classify these as co-operative, competitive, or niche forming.	Some interactions may not easily fit a single category.
4.	Look for examples of potential co-operation and for co-operative entities.	One academic course can be seen to co-operate with another by acting as a pre-requisite. Visual Basic requires the co-operation of Microsoft Windows in laboratory computers in order to operate.
5.	Look for examples of potential competition and for competitive entities.	The Java and .Net programming systems can be seen to be in competition with each other. Another example is OO development methodologies and conventional structured methodologies.
6.	Look for potential niche applications	In one particular university the teaching of the PICK operating system and PICK basic constitutes a niche application, as it prepared this institution's students for work in specific local companies.
7.	Look at the level of energy expenditure (both in keeping the current curriculum in place and in introducing change).	How much energy does a reactive head of a department have to expend to prevent change? Alternatively, how much energy does an enthusiastic faculty member have to expend to bring about drastic change? (There are, of course, many other possibilities regarding energy expenditure between these extremes.)

actions within IS curriculum development shows that it can be useful as a set of language elements that might lead the researcher to framing useful questions that do not trivialize the complexity of the field.

IS curriculum development involves a complex process of negotiation between actors, and one that cannot be simply explained by reference to a set process of referring new ideas to a series of university committees. The choices of individual academics, or groups of academics, to adopt or ignore a new concept or technology, and to compete or co-operate, must also be considered. This inevitably involves a negotiation process between many different actors. We have argued that this negotiation process can be analyzed in terms of ecological behavior and have utilized an ecological metaphor to assist in visualizing the curriculum development process.

KEY TERMS

Competition: When two individuals or species are in competition with each other, they are each striving for the same thing. In biological systems it is typically food, space, or some other physical need, but in the model described in this article, it can be any matter relating to IS curriculum. When the thing they are striving for is not in adequate supply for both of them, the result is that both are hampered, or adversely affected, in some manner.

Co-Operation: Occurs when one species works with another in order to achieve an outcome beneficial to one or both. Proto co-operation is the situation in which both benefit by the co-operation, but can survive without it. Mutualism occurs when each benefits and cannot otherwise survive. Commensalism occurs when two species habitually live together; one species being benefited by this arrangement and the other unharmed by it.

Ecological Metaphor: A way of describing a complex situation, such as IS curriculum development, by providing a way of allowing for the inclusion of complexity, and a language and set of analytical and descriptive tools from the ecological sciences.

Ecological Niche: A place where a particular species that is well suited to this environment is able to thrive, where other species may not.

Ecosystem: In the context of this article, the ecosystem represented by the curriculum in a university information systems department contains (at least) the following "species": lecturers, researchers, students, professional bodies, university administrators, and representatives of the computer industry.

Metaphor: A term applied to something to which it is not literally applicable, in order to suggest a resemblance.

Minimization of Energy Expenditure: A principle of ecology in which a species uses the least possible amount of energy to achieve its purpose.

Information Systems Research Relevance

INTRODUCTION

Though there have been extended deliberations for making information systems (IS) research more relevant[1] and useful for IS executives, to our knowledge, there has been no empirical study which examines the *extent of relevance* in the current IS research. In this chapter, we analyze the *topical relevance* of 388 published academic articles in the three top IS journals: *MIS Quarterly (MISQ), Information Systems Research (ISR),* and *Journal of Management Information Systems (JMIS),* for a 5 year period from 2000-2004. We do this by examining their *fit* with the key issues for information technology (IT) executives identified by the latest Society for Information Management (SIM) survey. Based on our results, we make recommendations for making IS research more meaningful for practitioners.

BACKGROUND

The importance of relevance of IS research has been highlighted by a number of scholars. For example, Benbasat and Zmud (1999) quoting from the title of a 1990 Business Week article highlighted that useful research should not be "in the ivory tower, fuzzy, irrelevant and pretentious" (p. 3) rather it should be relevant for practitioners. In a similar vein, there has been a growing debate about crisis in the IS discipline. Scholars have identified various ways of resolving this crisis (Agarwal & Lucas, 2005; Benbasat & Zmud, 2003; Hirschheim & Klein, 2003; Lucas, 1999; Markus, 1999). Some of them have recommended the need for according greater sociopolitical and cognitive legitimacy by addressing the needs of all stakeholders of IS research (Aldrich, 1999). As IS professionals form a major part of the IS discipline stakeholders, an important way in which the IS discipline can address their needs is by making research more useful and relevant for them (Agarwal & Lucas, 2005; Benbasat & Zmud, 2003).

Scholars like Davenport and Markus (1999) and Benbasat and Zmud (1999) view the goal of "research relevance" as critical to the long term survival and success of the field. They suggested that IS researchers can make their studies more relevant by choosing research topics which are considered to be important by practitioners. Three of the four dimensions of relevance identified by Benbasat and Zmud (1999) pertain to the content of articles (interesting, applicable, and current) as shown in Table 1.

IS research has often been criticized for its failure to address the issues relevant for business practitioners (Saunders, 1998; Zmud, 1996a, 1996b). Researchers have been exhorted to incorporate greater relevance in their research, in addition to instilling research rigor, to make it more useful and applicable for practitioners (Benbasat & Zmud, 1999; Davenport & Markus, 1999). However to date, there have been no studies which assess the "extent of relevance" of current IS research. Over half a decade after the deliberations of senior IS researchers on the issue of instilling greater relevance in IS research, it is an opportune time to take stock of the practitioners' concerns in subsequent IS research. In this study, we address this vital issue about relevance in IS research in three ways. First, we investigate how relevant for practitioners is the current IS research? For doing this we analyze the topical relevance of the published IS research, which encompasses the dimensions of articles' content (interesting, applicable, and current). Second, we develop a measure called the journal relevance coefficient (JRC)

Table 1. Dimensions of research relevance (Benbasat & Zmud, 1999)

Category	Dimensions of Relevance	Description
Content	Interesting	Does IS research address the problems or challenges that are of concern to IS professionals?
	Applicable	Does IS research produce the knowledge and offer prescriptions that can be utilized by practitioners?
	Current	Does IS research focus on the current technologies and business issues?
Style	Accessible	Are IS research articles able to be understood (in terms of tone, style, structure, and semantics) by IS professionals?

which is used to assess the relevance of IS journals. Third, we provide specific recommendations for addressing the concerns of IS practitioners.

METHODOLOGY

For seeking an answer to our research question about the relevance of current IS research, we examine the *fit* of the relevant topics identified by the IS professionals, with the topics of research in the top three IS journals namely, *MISQ, ISR, and JMIS* for 5 years (from 2000-2004). We posit that the top three IS journals are a reflection of IS academic research.

The key issues identified in the sixth[2] formal survey by the SIM have been used as current concerns of IS professionals (Table 2) for conducting our analysis in this study (Luftman & McLean, 2004). The sixth formal survey was authorized by the SIM executive board, 9 years after the last formal survey was conducted in 1994 (Brancheau et al., 1996).

We analyzed 388 articles published during last 5 years (2000-2004) in the three top IS journals: 104 in *MISQ*, 111 in *ISR*, and 173 in *JMIS*. Based on the topics and the abstracts of the articles, we identified the dominant concern being addressed in each article. If the content matched with one of the top 20 concerns identified in the latest SIM survey (Luftman & McLean, 2004), it was grouped there, otherwise it was grouped into a 21st category: others. The *others* category indicates that the dominant theme of the article does not address any of the concerns mentioned in the top 20 concerns.

Table 2. IT management concern: Ranking of importance (Luftman & McLean, 2004)

Rank	IT Management Concern
1	IT and business alignment
2	IT strategic planning
3	Security and privacy
4	Attracting, developing, and retaining IT professionals
5	Measuring the value of IT investments
6	Measuring the performance of the IT organization
7	Creating an information infrastructure
8	Complexity reduction
9	Speed and agility
10	IT governance
11	Business process reengineering
12	Introducing rapid business solutions
13	Evolving CIO leadership role
14	IT asset management
15	Managing outsourcing relationships
16	Leveraging the legacy investment
17	Sarbanes-Oxley Act of 2002
18	Globalization
19	Offshore outsourcing impacts on IT careers
20	Societal implications of IT

DATA ANALYSIS AND DISCUSSION

To our knowledge, there are no known measures for analyzing the relevance of academic journals. For this study, to understand the relevance of journals, we followed a two pronged approach. First, we developed a measure called JRC to analyze the aggregate relevance trends of journals across the years. Second, we analyzed the data to understand the trends in terms of topics in IS research.

Journal Relevance Coefficient

The aim of the JRC is to understand the relevance aspect of the published articles in the three journals, in an aggregate way. For calculating JRC, we use the following methodology. First, we assign a weight to each of the 21 issues identified in the IT executive survey (Table 2). For simplicity we assign equal interval weights in the reverse direction of ranks, for example, the top ranked topic *IT and business alignment* is assigned a weight of 21, whereas the last ranked item *others* is assigned a weight of 1. Next, we multiply these weights to the corresponding values (or frequencies of articles). This gives us a rank weighted table across the years for each of the journals. Next we sum up the weighted value for each year for each journal. To calculate the JRC, we divide this value in each year for each journal by the maximum possible value that can be attained (i.e., assuming all the articles in that year address the top concern for IT professionals, a weight of 21). The resulting value gives the JRC for that journal, for that particular year. JRC expresses in a uniform way the extent of relevance being addressed by the journals in a particular year. In notational terms, this can be expressed as follows:

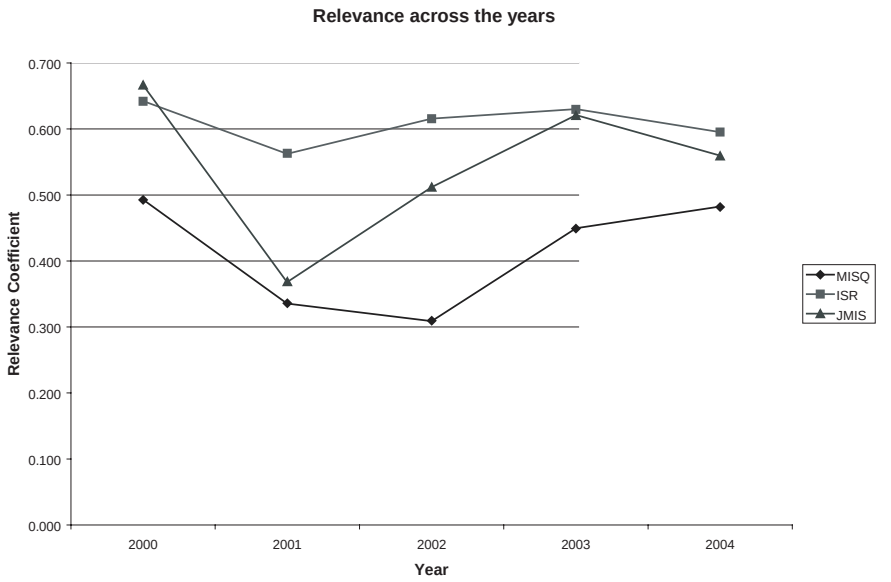
$$(JRC)_{j,y} = \frac{\sum_{i=1}^{n} x_i w_i}{N \sum_{i=1}^{n} x_i}$$

,where $(JRC)_{j,y}$ is the journal relevance coefficient for journal j (MISQ, ISR, or JMIS) for year y (2000-2004), n is the rank of topics identified as relevant for practitioners x_i is the number of articles for the i^{th} rank and w_i is the weight assigned for i^{th} rank article and N is the total number of articles analyzed.

The JRC is a fair indicator of the relevance of published research in the journals and can be used to compare the *relevance* of the IS journals across the years from 2000-2004. Figure 1 shows the movement of relevance coefficients across the years for the three journals in this study: *MISQ*, *ISR*, and *JMIS*.

From the chart in Figure 1, we observe that *ISR* is cur-

Figure 1. Journal relevance coefficients over the years



rently the *most* relevant journal for IS professionals *in terms of topics studied* and *MISQ* is the *least*. The interpretation of these results comes with some caveats (1) the analysis takes into consideration only the "topical relevance," it is possible that the writing style is more practitioner friendly in *MISQ*; (2) *MISQ* also publishes another journal especially for practitioners namely, *MISQ Executive*, where the issues discussed tend to be more relevant for practitioners; and (3) we have assumed that the relevant topics identified in the survey of 2003 do not change remarkably in the period from 2000-2004, but the dynamism of IT may inhibit this stability of relevant topics. Even with these limitations, the point to be observed is that the current trend (2003-2004) for *ISR* and *JMIS* is a falling one in terms of relevance, whereas for *MISQ* it is an increasing trend, which is encouraging for *MISQ*.

Though there is an increasing trend in the relevance of IS articles for the top three journals, the absolute values of the JRC still range between 0.48 and 0.60 for the three journals in the year 2004 as shown in Table 3. This broadly signifies that we are addressing about 60% of the concerns of the IS executives. There is a greater need and scope for addressing the needs of IS practitioners in terms of selection of research topics.

From the detailed account of topical analysis of journals, we observe a perceptible gap in the requirements of the IS executives and the actual research by IS academics. Combined topic-wise academic research published in all the three journals is indicated in Table 4.

We observe that comparatively less research (< 14%) has been done on the top *four* issues identified by the SIM survey (Luftman & McLean, 2004). Hence this study identifies four areas where research should be taken up by academics, namely: (1) IT and business alignment; (2) IT strategic planning; (3) security, and privacy; and (4) attracting, developing, and retaining IT professionals.

Apart from the under-researched areas, we observe that there are some areas which have been the topic for most of the research in the IS field. For example, measuring value of IT investment and measuring the performance of IT organization form about 19% of the total IS research. Similarly IT governance is also an area which has been paid a lot of attention by IS researchers and forms over 13% of the total IS research.

Table 3. Journal relevance coefficient (JRC) across the years for the three journals

	2000	2001	2002	2003	2004	Total
MISQ	0.49	0.34	0.31	0.45	0.48	0.43
ISR	0.64	0.56	0.62	0.63	0.60	0.61
JMIS	0.67	0.37	0.51	0.62	0.56	0.54

RECOMMENDATIONS

Based on this study, we offer a set of recommendations for IS researchers and academics.

Table 4. Aggregate topic wise published research in the three journals (2000-2004)

Rank	Issues	MISQ	ISR	JMIS	Total	Percent
1	IT and business alignment	3	2	1	**6**	**1.55**
2	IT strategic planning	2	3	8	**13**	**3.35**

- **Recommendation #1. Researchers, while choosing research topics should consider not only the theoretical significance of the topics but also their relevance for practitioners:** As highlighted by earlier researchers (Benbasat & Zmud, 1999; Davenport & Markus, 1999), business is an applied field and the needs of the IS executives should be addressed more closely. Our study indicates that only about 48-60% of the concerns of the IS professionals are being addressed by the current research, hence there is a need for instilling greater relevance in IS research.
- **Recommendation #2. Regular surveys to feel the pulse of IT executives should be conducted to provide guidelines for practical research to academics:** For conducting research on topics relevant for IS executives, it is important to know the topics which are interesting, applicable, and current for them. This can be known only if we have regular surveys like the one conducted by SIM in 2003. This particular survey was conducted by SIM after a gap of 9 years (the last one was in 1994). The conduct of surveys should be institutionalized on a regular basis and the results should be proactively propagated to IS academics.
- **Recommendation #3. Professional bodies and conferences should proactively assist in disseminating information and details about conducting relevant research:** Professional bodies like Association of Information Systems (AIS), IS conferences [like International Conference on Information Systems (ICIS), International Federation for Information Systems (IFIP), AMCIS (Americas' Conference on Information Systems) , etc.] can be used as a platform for disseminating information about relevant topics. This will increase the awareness of IS academics about these topics; also the institutional endorsement of these topics will add to the value of doing research on the identified topics by the IS researchers.
- **Recommendation #4. There is a greater need to study the topics of IT and business alignment; IT strategic planning; security and privacy; and attracting, developing, and retaining IT professionals:** Our study indicates that the aforementioned top four key issues for IS executives are highly under researched in terms of published papers in the top three IS journals. There appears to be an imperative need to incorporate these as important topics of research by IS academics.

FUTURE TRENDS

Results from our research reveal that the issue of relevance for IS executives is not being adequately addressed by current IS research. Based on the results, we make recommendations for increasing the relevance of future IS research for practitioners. We also identify four top concerns of the IS professionals, which have not been adequately researched, namely (1) IT and business alignment; (2) IT strategic planning; (3) security, and privacy; and (4) attracting, developing, and retaining IT professionals. Future IS researchers must

focus on these topics to address the requirements of the IS practitioners thereby making research more meaningful for them.

Though in our study we restricted our analysis to the topical relevance, it is equally important to make the article's style amenable for the IS practitioners, which implies that the tone and language should be direct, simple, and easily comprehensible by practitioners (Benbasat & Zmud, 1999). This important aspect of relevance can be analyzed in detail by future research.

CONCLUSION

This article revisits the often debated question about the relevance of current IS research. Though there has been a lot of discussion and deliberation on the issue, to our knowledge, there has been no empirical investigation about the extent of relevance of current IS research. Our empirical study, which investigates the extent of relevance of published research for the last 5 years (2000-2004) in the three top journals in the field of IS: *MISQ, ISR*, and *JMIS* provides a broad overview of the entire discipline and its focus on the requirements of IS practitioners. We develop a measure for estimating the relevance of IS journals (JRC), which can be used by future studies for estimating the extent of relevance exhibited by various journals. A periodical evaluation of the JRC can help us assess if we are adequately addressing the needs of the IS practitioners through our research.

The results in this study indicate that the current level of relevance of top three IS journals is grossly inadequate (the maximum value of JRC is 0.60, for the year 2004). This implies that for ensuring long term survival and growth of the IS discipline, the topics relevant for IS executives have to be studied in a more organized fashion, so that this important stakeholder group understands the value added by research for them.

KEY TERMS

Discipline Stakeholders: Discipline stakeholders are all the logical segments of population who are impacted by and also impact the research in a particular discipline, for example, the stakeholders in IS discipline are IS and non IS academics, students, and industry and business practitioners.

Information Systems (IS) Practitioners: IS practitioners are the professionals involved with planning and implementing IT resources for their organizations which includes chief information officers (CIOs), IT managers, and other professionals with similar job descriptions.

Journal Relevance Coefficient (JRC): JRC is a measure developed in the current study which can be used to ascertain the extent of *topical relevance* addressed to by the journals.

Research Relevance: Research in applied fields like IS has to be responsive to the needs of business and industry to make it useful and practicable for them. There are four dimensions of relevance in research which deal with the content and style of research articles. For an article to be relevant it must not only be interesting, applicable and current to the needs of the practitioners but should also be written in an accessible and simple style.

Research Rigor: There are two dimensions of rigor in research. *Methodological rigor* implies following established methodological procedures and *philosophical rigor* signifies incorporating theoretical basis into research. For a piece of research to be justified as an academic piece it must have substantial rigor on both these dimensions.

SIM Survey: Society for Information Management (SIM) conducts surveys to assess the needs of the IT practitioners and identifies current areas and topics of concern for the IT executives. Last such survey was done in 2003, the findings of which are available in Luftman and McLean (2004).

Topical Relevance: Topical relevance means that the research topic is useful for the practitioners. This implies that the topic is interesting, applicable, and current to the needs of business and industry.

ENDNOTES

1 Useful and applicable in practice.

2 Ball and Harris (1982) conducted the first survey and produced a list of 18 issues. Subsequently, surveys were held to identify the top IT management concerns by Dickson, Leitheiser, Wetherbe, and Nechis (1984), (1984), Brancheau and Wetherbe (1987), Niederman, Brancheau, and Wetherbe (1991), and Brancheau, Janz, and Wetherbe (1996).

Information Technology Business Continuity

Vincenzo Morabito
Bocconi University, Italy

University of Milano, Italy

INTRODUCTION

Continuity could be and should be strategic for the business competitive advantage. Besides natural disaster, from blackout to tsunami, businesses face in daily activities critical challenges in IT management for assuring business continuity; for example, business continuity management results must be strategic, because of the infrastructural, organizational, and information systems changes that are required to assure compliance with regulatory norms (see, e.g., the impact of Basel II norms in financial sector), or must have and maintain a time-to-market advantage (disasters can facilitate competitors in a first mover perspective). Nevertheless, business continuity is at present often synonymous with risk management at the IT level, disaster recovery at the hardware level, or in the best case—at the data management level—with data quality management. These perspectives fail to unveil the strategic value of IT business continuity as a framework assuring alignment of strategy, organization, and systems, allowing a competitive advantage in a dynamic competitive environment. Moreover, even when business continuity, under these perspectives, has become one of the most important issues in IT management, there still appears to be some discrepancy as to the formal definitions of what precisely constitutes a disaster, and there are difficulties in assessing the size of claims in the crises and disaster areas. Taking these issues into account, we propose: (a) an analysis of the different facets of the concept of business continuity, and (b) an integrated framework for strategic management of IT business continuity. To these ends, we move from the finance sector—a sector in which the development of information technology (IT) and information systems (IS) have had a key impact upon competitiveness. Indeed, banking industry IT and IS are considered "production," not "support" technologies. The evolution of IT and IS has challenged the traditional ways of conducting business within the finance sector. These changes have largely represented improvements to business processes and efficiency but are not without their flaws, in as much as business disruption can occur due to IT and IS sources. The greater complexity of new IT and IS operating environments requires that organizations continually reassess how best they may face changes and exploit these later for organizational advantage. As such, IT and IS have supported massive changes in the ways in which business is conducted with consumers at the retail level. Innovations in direct banking would have been unthinkable without appropriate IS, and merger and acquisition (M&A) initiatives represent the ideal domain to show what value can lead strategic management of IT business continuity. Taking these issues into account, we point out the relevance of continuity for maintaining customers, and time-to-market in complex and evolutionary competitive environments. Due the relevance of IT to maintain a value-added continuity, our contribution aims to clarify the concept of IT business continuity, providing a framework, exploiting the different facets that it encompasses, and showing the strategic implications to the field of IS&T.

BACKGROUND

The evolution of IT and IS has challenged the traditional ways of conducting business within the finance sector, as a consequence of new business models emerging, for example, from e-business (Müller, Viering, Ahlemann, & Riempp, 2007; Pennings & Harianto, 1992; Ross, Vitale, & Weill, 2001). These changes have largely represented improvements to business processes and efficiency, introducing new challenges and critical issues as much as business interruptions can occur due to IT and IS sources. The greater complexity of new IT and IS operating environments requires that organizations continually reassess how challenges change and exploit those for organizational competitive advantage. In particular, this article seeks to investigate how companies in the financial sector understand and manage their business continuity problems. In fact, business continuity has become one of the most important issues in the banking industry (Lam, 2002), but its relationship with disaster recovery still causes some discrepancy in providing a formal definition on the one hand of what precisely constitutes a disaster, and on the other hand of what is business continuity beyond disaster recovery. Taking into account the different typologies of disaster that can occur in particular in the financial sector (Lam, 2002; Nemzow, 1997), we can define a disaster as an incident that leads to the formal invocation of contingency/continuity plans or any incident that leads to a loss of

revenue; indeed, we can consider a disaster any accidental, natural, or malicious event that threatens or interrupts normal operations or services, causing the failure of the enterprise. In the area of organizational crises and disasters, the degree to which a company has been affected by one or more of such interruptions is the defining factor.

These preliminary definitions are relevant because as estimated by the Business Continuity Institute (2007), most organizations facing a significant crisis, without either a contingency/recovery or a business continuity plan, fail to maintain market position competitively or even to survive a year further. Moreover, state-of-the-art analyses (Bank of Japan, 2003; Barnes, 2001; Elliott & Swartz, 1999; Lam, 2002; Nemzow, 1997; Zambon, Bolzoni, Etalle, & Salvato, 2007) point out that only a small number of organizations have disaster and recovery plans, and among those, few have been renewed to reflect the changing nature of the organization.

In this article we consider in particular our experience in studying practices of the Italian banking industry, where major differences emerge in preparing and implementing strategies that enhance business process security. Comparing them with state-of-the-art literature, we notice two prevalent approaches. On the one hand, there are disaster recovery (DR) strategies that are internally and hardware focused (Lewis, Watson, & Pickren, 2003); on the other hand, there are strategies that treat the issues of IT and IS security within a wider internal-external, hardware-software framework. The latter deals with IS as an integrating business function rather than as a standalone operation. We consider this second type of strategy as part of what in literature (Barnes, 2001; British Standard Institute, 2006; Cerullo & Cerullo, 2004; Nemzow, 1997) is defined as business continuity planning (BCP). Taking these issues into account, we point out the need for a comprehensive IT business continuity approach because of the relevance of the IT for the business continuity of the organizations in the finance sector, encompassing technological, organizational, and strategic facets of the whole system carrying out the business activities. We define the IT business continuity approach (IT-BCA) as a framework of disciplines, processes, and techniques aiming to provide continuous operation for essential business functions under all circumstances. IT-BCA considers business continuity planning as a core element of business continuity initiatives.

More specifically, business continuity planning can be defined as "a collection of procedures and information [that have been] developed, compiled and maintained [and are] ready to use—in the event of an emergency or disaster"(Elliott & Swartz, 1999). BCP has been addressed by different contributions to the literature, such as Allen's (2001) studies on Cert's Octave method, the activities of the Business Continuity Institute (2007) and of the British Standard Institute (2006) in defining certification standards and practice guidelines, the EDS white paper on Business Continuity Management (Decker, 2004), and the activity of financial institutions such as the study carried out by the Bank of Japan (2003). This last study illustrates the process and activities for successful business continuity planning in three steps:

1. formulating a framework for robust project management,
2. identifying assumptions and conditions for business continuity planning, and
3. introducing action plans.

Considering the first step above, banks should (i) develop basic policy and guidelines for business continuity planning (*basic policy*); (ii) develop a study of firm-wide aspects (*firm-wide control section*); and (iii) implement appropriate progress control (*project management procedures*). In the second step, banks should (i) recognize and identify the potential threats, analyze the frequency of potential threats, and identify the specific risk scenarios (*disaster scenarios*); (ii) focus on continuing prioritized critical operations (*critical operations*); and (iii) target times for the resumption of operations (*recovery time objectives*).

Finally, in the third step where actions plans must be introduced, the banks should (i) study specific measures for business continuity planning (*business continuity measures*); (ii) acquire and maintain backup data (*robust backup data*); (iii) determine the managerial resources and infrastructure availability capacity required (*procurement of managerial resources*); (iv) determine strong time constraints, a contact list, and a means of communication on emergency decisions (*decision-making procedures and communication arrangements*); (v) realize practical operational procedures for each department and level (*practical manual*); and (vi) implement a test/training program (*testing and reviewing*).

IT business continuity, indeed, is not only an IT/IS issue, but involves organizational facets, having a strategic impact on banks' competitive advantage and value.

IT BUSINESS CONTINUITY AS A STRATEGIC PATH TO VALUE

In this section we discuss the IT business continuity approach as a path to value for banks, encompassing three fundamental facets that can be viewed in a systemic way: *technology, people,* and *process.*

Technology refers to the recovery of mission-critical data and applications contained in the Disaster Recovery Plan (DRP). It establishes technical and organizational measures in order to face events or incidents with potentially huge impact that could even lead to the unavailability of data centers. The DRP development defines and ensures IT emergency procedures that intervene and protect the data relevant for

company activities and services (Wang, Yin, Yuan, & Zhou, 2005). DRP is usually considered the only part of the BCP in banking business continuity initiatives.

Further, *people* refers to the recovery of the employees and physical workspace. In particular, BCP teams should be drawn from a variety of company departments, including those from personnel, marketing, and internal consultants. The managers of these teams should possess "general" skill and be partially drawn from business areas besides the ones coming from the IT departments. Nowadays, this is essential to emphasize the role of human assets and value rather than the traditional focus on hardware and software resources that in most cases are probably protected by backup systems. Finally, the term *process* refers to the development of a strategy for the deployment, testing, and maintenance of the plan. All BCPs should be regularly updated and modified in order to take into consideration the latest types of threats, both at physical and technological levels.

Whereas a simple disaster recovery (DR) approach aims to rescue those facilities and services that can be recovered, a BC approach should treat IT and IS security with a wider internal-external, hardware-software framework where all processes are neither in-house nor subcontracted out, but are a mix of the two, integrating business functions' standalone operations. Thus, the BC approach is a dual approach providing a unified perspective on management and technology function. The BC approach as a global approach also considers all existing relationships in total value chain perspective for business, giving value to clients and suppliers and to protect business both in-house and out. The BC approach incorporates the disaster recovery approach but rejects its exclusive focus upon facilities. The BC approach defines the process as business wide, enabling competitive and/or organizational advantages.

The starting point for planning processes that an organization will use as its BCP must include an assessment of the likely impact of different types of 'incidents' on the business. As mentioned above, the adoption of new technologies continues to become more and more integral and critical for the financial activities. In addition, in order to assess the likely impact on the entire organization, banks must consider the effects on their different business areas. To these ends, we introduce a *vulnerability and business impact matrix,* which is a tool that can be used to summarize the inter-linkages between the various information system services, their vulnerability, and the impact on business processes. For the strategic focus of BCP, an understanding of the relationships between value-creating activities is a key determinant of the effectiveness of any process, both at IT and organizational levels. This way, we can define the correct business continuity perimeter by trying to extract the maximum value from the BCP within a context of bounded and limited resources. Indeed, the BCP teams in the organizations focus on how resources were utilized and how they were added to value-creation, rather than merely being "support activities," consuming financial resources with no productivity outcome. Furthermore, the growing relevance of customer-oriented technologies demands that those managing the BCP process are aware of the need to expand the role of unforeseen events and contingencies, not merely looking inward but actually looking out of the IT and back-office operations. Such a dual focus improves the linkages between customer and client which create competitive advantage. Indeed, in cases where client-oriented business fundamentally depends upon information exchange (e.g., the online equity brokerage services provision), it might be argued that there is a *virtual value chain*, which the BCP team protects, providing the 'market-space' for value creation to take place. Finally, another benefit is that vulnerability and business impact can improve the prioritization of particular key areas.

In fact, today's approach to BCP (Cerullo & Cerullo, 2004; Lam, 2002; Nemzow, 1997; Zambon et al., 2007) is focused on process management and business-driven paradigms; nevertheless, when considering large institutions with systemic impact—not only on their own but on clients businesses as well—two key objectives need to be considered when facing a disrupting event. These have been named *recovery point objective* (RPO) and *recovery time objective* (RTO). The former deals with how far in the past you have to go to resume a consistent situation; the latter considers how long it takes to resume a standard or regular situation. The definitions of RPO and RTO can change according to data center organization and how high a level a company wants its own security and continuity to be (Disaster Recovery Journal & DRI, 2007). For instance, a dual site recovery system organization must consider and evaluate three points of view, namely *application's availability, business continuity process*, and *data perspective.*

Focusing on RTO, data are first impacted before the crisis event due to the closest *consistent point* from which to restart. The crisis opening or declaration occurs after the crisis event. We now define a relevant RTO's event indicators:

- the *computing environment restored point* considers the length of time the computing environment needs in order to be restored (i.e., when servers, network, etc. are once again available);
- the *mission critical application restarted point* indicates the critical applications (in rank order) that are working once again;
- the *applications and data restored point* is the point from which all applications and data are restored; but (and it is a big but)
- the *previous environment restored point* is the true end point when the previous environment is fully restored (this later pointing out the all business continuity solutions are properly working).

Taking these issues into account, natural risks are also increasing in scope and frequency, thus extending actual geographical recovery distance, and forcing businesses and institutions to consider a new technological approach. This later must be introduced to undertake synchronous-asynchronous data replication, focusing on intervals and quality. Therefore, more complex analyses on RPO and RTO are required.

However, from a business point of view, when faced with an imminent and unforeseen disaster, the most important issue is how to reduce the restore or restart time, trying to minimize this window to few seconds or less. New technologies, such as the serial ATA (SATA) and the massive arrays inexpensive disk (MAID), seem to make some progress in reducing the time-related problem in disaster recovery and business continuity initiatives.

The *vulnerability and business impact analysis matrix* discussed above considers these issues and treats each selected business in accordance with the value chain and value system. In fact, in addition to assessing the likely disaster impact upon IT departments, organizations should consider disaster impacts over all company departments and their likely effects upon customers. Organizations should avoid the so-called 'Soccer Star Syndrome' (Elliott & Swartz, 1999); drawing an analogy with the football industry, this syndrome recognizes that management attention is often focused on the playing field rather than on the unglamorous, but very necessary, locker room and stadium management support activities. Defenders and goalkeepers, let alone the stadium manager, do not get paid at the same level as the "star" player, yet their functions are just as vital to achieving the overall objectives of the football team. The value chain provides an opportunity to examine the connection between the whole linkages that deliver customer value. The evolution of crisis preparations from the IT-focused disaster recovery solutions towards the business continuity approach reflects a growing understanding that business continuity depends upon the maintenance of all elements that provide organizational efficiency-effectiveness and customer value, whether directly or indirectly.

A final key characteristic of the proposed business continuity approach concerns the primary role of prevention. In the literature, a number of authors have argued that the potential for crises is a "normal" issue for organizations (Greiner, 1989; Pauchant & Mitroff, 1998). Nowadays, crisis avoidance requires a strategic approach and a good understanding of both the organization's operating processes and systems, and the environment where the business operates. To these ends, in the IT business continuity approach, an organization must develop a business continuity planning culture in order to remove the barriers to the development of crisis prevention strategies. In particular, these organizations should recognize that incidents and disasters are more and more triggered by external factors and not only by technical causes, but their effects are largely determined by internal factors that are within the control of their organizations. To face these issues from a BCP-enabled business continuity approach, a *cluster of crises* must be identified and categorized along the axis of internal-external and human/social-technical/economic causes and effects. By adopting a strategic approach, decisions could be made about the extent of exposure in particular product markets or geographical sites. An ongoing change management program could contribute to real commitment from middle managers. Here the focus is not on change management as per se topic, but as a way to the commitment from middle managers who, from our first investigation of the Italian banking sector, emerged as key determinants of the success of the IT-business continuity approach.

Nevertheless, BCP is the core of a business continuity approach, and its success requires the commitment of middle managers. Hence managers need to avoid considering BCP as a costly, administrative inconvenience that diverts time away from primary business activities. As a consequence, strategic business units should own BCP plans, and CEO involvement is a key factor supporting the BCP process. Thus, the recognition that responsibility for the process rests with business managers must be improved and reinforced through a formal appraisal and other reward systems; these initiatives must be integrated by others leveraging peer pressure as relevant to assume responsibility and affect a more receptive culture. Finally, BCP teams need to regard BCP as a process rather than as a specific end point, exploiting business continuity not as a "one facet" event-based recovery activity, but as an organizational change factor, improving IT/IS-oriented innovation and value for the whole business through a risk-aware management culture.

FUTURE TRENDS

Future research should test the IT business continuity approach on strategic activities, such as cross-border M&A initiatives. These analyses are relevant to exploit the whole meaning of the business continuity concept, integrating the still prevailing one based on technological issues in disaster recovery initiatives. Furthermore, future works should investigate alternative measures involving organizational and strategic issues, together with the technological ones. These measures must be introduced to enhance the strategic value of business continuity instruments, such as the above discussed *vulnerability and business impact analysis matrix.*

CONCLUSION

This article argues that to adopt an IT business continuity approach involves a strategic perspective on the different

facets leading to a sustainable competitive advantage. Indeed, IT business continuity is not only a technological issue; it is a proxy for organizational change in terms of culture, structure, and communications. The IT business continuity approach is more and more a driver to generate competitive advantage from efficient and effective flexible information systems, allowing the organization to attract and maintain customers by assuring trust on the capabilities of the organization in facing disaster and a better perceived quality of services in terms of timeliness and currency. Nowadays, referring to organizational change and culture, the IT business continuity approach must be considered a business-wide approach, not an IT-focused one. Supportive measures must be introduced to encourage managers to adhere to the IT business continuity strategic vision. In particular, management as a whole should be committed to the IT business continuity ongoing process. Continuity requires changes of key assumptions and values within the organizational structure and culture, having implications for the role that the IT business continuity approach must play within the strategic management processes of the organization, as well as within the levels of strategic risk that an organization may wish to undertake to secure a sustainable competitive advantage.

KEY TERMS

Business Continuity Planning (BCP): "A collection of procedures and information [that have been] developed, compiled and maintained [and are] ready to use in the event of an emergency or disaster" (Elliott & Swartz, 1999).

Crisis: A critical event, which, if not handled in an appropriate manner, may dramatically impact an organization's profitability, reputation, or ability to operate. Or, an occurrence and/or perception that threatens the operations, staff, shareholder value, stakeholders, brand, reputation, trust, and/or strategic/business goals of an organization (Disaster Recovery Journal & DRI, 2007).

Disaster: An incident that leads to the formal invocation of contingency/continuity plans, or any incident that leads to a loss of revenue; indeed, a disaster is any accidental, natural, or malicious event that threatens or interrupts normal operations or services, causing the failure of the enterprise (Disaster Recovery Journal & DRI, 2007).

Disaster Recovery: The ability of an organization to respond to a disaster or an interruption in services by implementing a disaster recovery plan to stabilize and restore the organization's critical functions (Disaster Recovery Journal & DRI, 2007).

Disaster Recovery Plan (DRP): A plan that establishes technical and organizational measures in order to face events or incidents with potentially huge impact that could even lead to the unavailability of data centers. The DRP development defines and ensures IT emergency procedures that intervene and protect the data relevant for the company activities and services. DRP is usually considered as the only part of the BCP in banking business continuity initiatives.

IT Business Continuity: The ability of an organization to provide service and support for its customers, and maintain its viability before, during, and after a business continuity event (Disaster Recovery Journal & DRI, 2007) through the leverage of IT resources.

IT-Business Continuity Approach: A framework of disciplines, processes, and techniques aiming to provide continuous operation for "essential business functions" under all circumstances.

Recovery Point Objective (RPO): The maximum amount of data loss an organization can sustain during an event (Disaster Recovery Journal & DRI, 2007). RPO deals with how far in the past you have to go to resume a consistent situation.

Recovery Time Objective (RTO): The period of time within which systems, applications, or functions must be recovered after an outage (e.g., one business day). RTOs are often used as the basis for the development of recovery strategies, and as a determinant as to whether or not to implement the recovery strategies during a disaster situation (Disaster Recovery Journal & DRI, 2007). RTO considers how long it takes to resume a standard or regular situation.

INTRODUCTION

Franchising is "a business opportunity by which the owner (producer or distributor) of a service or a trademarked product grants exclusive rights to an individual for the local distribution and/or sale of the service or product, and in return receives a payment or royalty and conformance to quality standards. The individual or business granting the business rights is called the *franchisor*, and the individual or business granted the right to operate in accordance with the chosen method to produce or sell the product or service is called the *franchisee*." (Justis & Judd, 2002)

Information technology (IT) has been widely used in today's businesses. In his best seller, *Business @ the Speed of Thought*, Bill Gates (1999) wrote: "Information Technology and business are becoming inextricably interwoven. I don't think anybody can talk meaningfully about one without talking about the other." Thus, to see how IT is used in franchising, one needs to know how franchising really works. The objective of this paper is to propose an attention-based IT infrastructure that can cultivate the relationship building between the franchisors and their franchisees which will ultimately lead to the success of the franchise organizations.

BACKGROUND

In addition to the popular growth strategy for many businesses, franchising has emerged over the years as a pathway to wealth creation for entrepreneurs (Justis & Vincent, 2001). This article first discusses the operations at both the franchisor headquarters and the franchisee outlets. Second, it reviews the franchisor/franchisee relationship and points out the essential indicators needed to pertain and flourish the good relationship. Third, it shows the inevitability of collaborative learning and innovation, which leads us to the discussion of the working knowledge development among the franchisor and the fellow franchisees. Fourth, we discuss that the proposed attention-based IT infrastructure will enable the knowledge sharing and dissemination between the franchisor and the franchisee; and suggest outsourcing the initial architectural stages of the IT infrastructure to trusted applications service providers.

Understanding the Franchisor

In this section we examine the operational activities at the franchisor headquarters. Figure 1 illustrates the interactions of the franchisor with all four of its entities: business units, prospective franchisees, suppliers, and government; as well as performing relevant activities (represented by rectangles): marketing its products and services, assisting in creating distinguished brand names indispensable in attracting new customers, selling to the franchisees, and handling the diversified financing quandaries.

The franchisor headquarters is required to provide both initial and ongoing support/service to all business units. Business units here include company units, all of the start-up, established and mastered franchisees, and the co-branded units. Among the five different types of business units, the franchisor needs to have intense concentration on supporting the start-up franchisees, since a good start is as efficient as the half way completion of any task. On the other hand, established and mastered franchisees are the ones in need of appealing incentives (e.g., having cobranded units) in order to encourage growth and expansion. Company units are typically used as role models for the franchisees.

To expand the business, the franchisor ought to select and contact the prospective partners (franchisees). The partner selection process is crucial to the success of franchising and requires exceptional attention. Prospective franchisees can be contacted through: (1) leads from marketing channels; (2) referrals, such as satisfied customers; (3) consumers who feel affection to the product/service and would like to be in possession of the business; (4) community and media relationships; (5) public services, like recruiting veterans; and (6) international contacts generated from master franchisees.

Franchise suppliers can be anywhere from products and goods distributors up to business service providers, such as real estate agents, human resources providers, uniform

vendors, marketing and advertising agents, trade show and exposition organizers, accountants, information systems vendors, insurance providers, attorneys, translators, and many others.

Franchisors also need to comply with regulations that govern the sales of the franchises and business transactions in the places where the business located. The overall legal landscape of franchising is complex which includes: (1) federal, state, and international taxes; (2) local, regional, and global laws; (3) insurances, such as workers compensation; (4) possibilities of litigations from government, customers, and franchisees; and (5) supports for international expansion.

As is seen in Figure 1, the franchisor interacts with various business entities and conducts various deeds to fulfil his/her obligations. Moreover, the franchisor goes through a learning process, composed of five stages (Justis & Judd, 2002): (1) beginner—learning how to do it; (2) novice—practicing doing it; (3) advanced—doing it; (4) master—teaching others to do it; and (5) Professional—becoming the best that you can be. Once attaining the advanced stages of development, most preceding struggles have been overcome. However, further convoluted and challenging enquiries will arise as the franchise continues the expansion. This is especially factual once the system reaches the professional stage, where various unpredicted and intricate problems could arise. Bud Hadfield (1995), the founder of Kwik Kopy franchise and the International Center of Entrepreneurial Development, explained it the finest: "The more the company grows, the more it will be tested."

To capture the learning process in Figure 1, a counter-clockwise round arrow is used in each of the five categories. It depicts the increasing intensity of learning in every area of the sub-activities (represented by rectangles) as the franchise struggles to survive and thrive. For example, as the system expands, the real estate sub-activity will become much more complex, since the quandary of territory encroachment becomes more significant and harder to manage.

Understanding the Franchisee

As illustrated in Figure 2, the franchisee sells to customers, perform marketing and advertising activities, handle financial/accounting issues, and manage sales people. Akin to the franchisor, the franchisee outlets (shortened form, franchisee) work together with four entities: customers, franchisor headquarters, suppliers and government. The franchisee customers are divided into five categories and consist of potential, infrequent, frequent, online, and co-branded. Supports from the franchisor headquarter may include demonstrations from field representatives, training and continued education from the management groups, in addition to discussion forums and distance learning.

Suppliers of the franchisee are similar to those of the franchisor. They include both products and goods distributors, business service providers such as real estate agents, human resources providers, uniform vendors, marketing and advertising agents, trade shows and exposition organizers, accountants, information systems vendors, insurance providers, attorneys, translators, and others. The franchisee is regulated by the franchising laws at local, state, and federal level. The regulatory framework contains of: (1) federal, state, and international taxes; (2) local, regional, and global laws; (3)

Figure 1. Understanding how the franchisor works

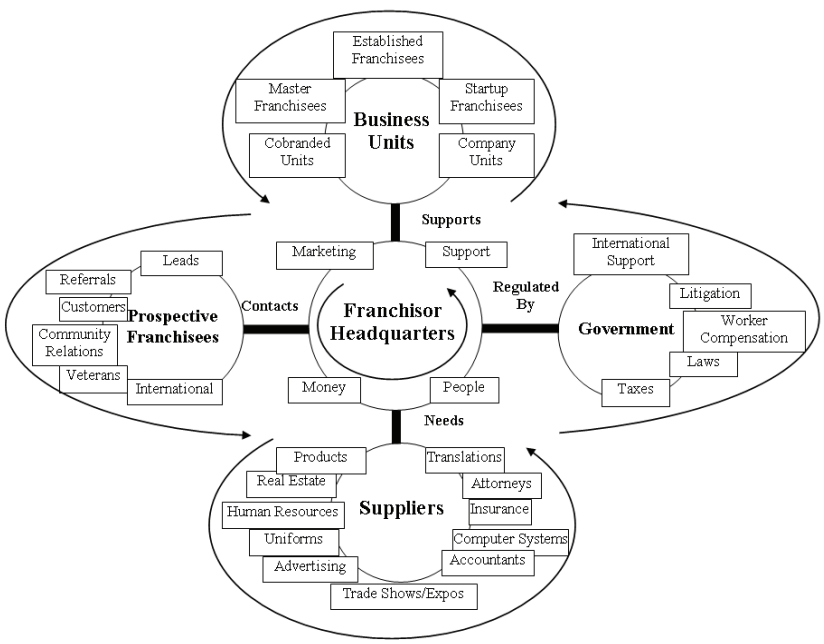

Figure 1. Understanding how the franchisee works

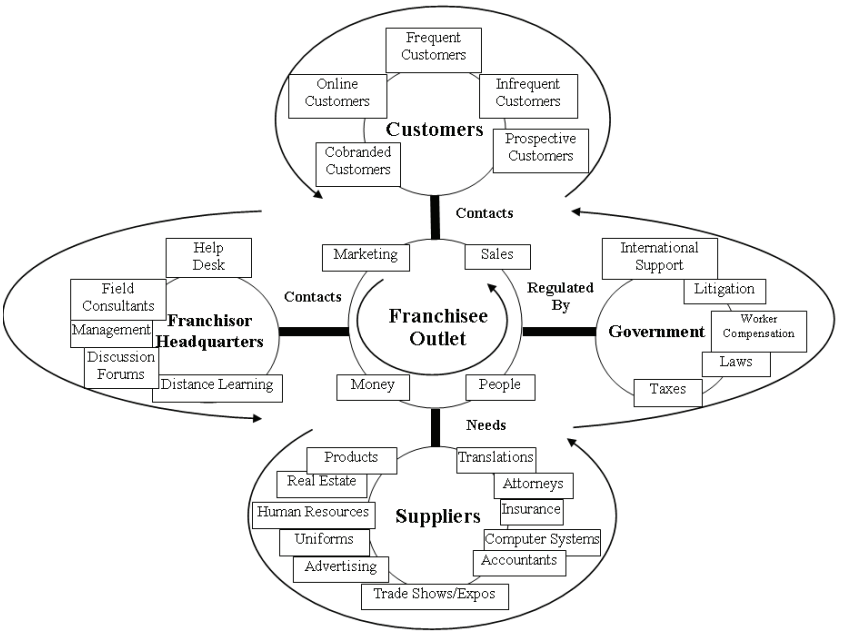


insurances such as workers compensation; (4) possibilities of litigations from government, customers, and franchisees; and (5) support for international expansions.

The franchisee also goes through the above mentioned five stages of learning (i.e., beginner, novice, advanced, master, and professional) represented by a counter-clockwise round arrow used in each of the five categories in Figure 2. Once again, the arrow depicts the increasing intensity of learning as the franchisee continues growing the business and many unforseen problems/issues may rise up to challenge the practices.

Understanding the Franchisor/ Franchisee Relationship

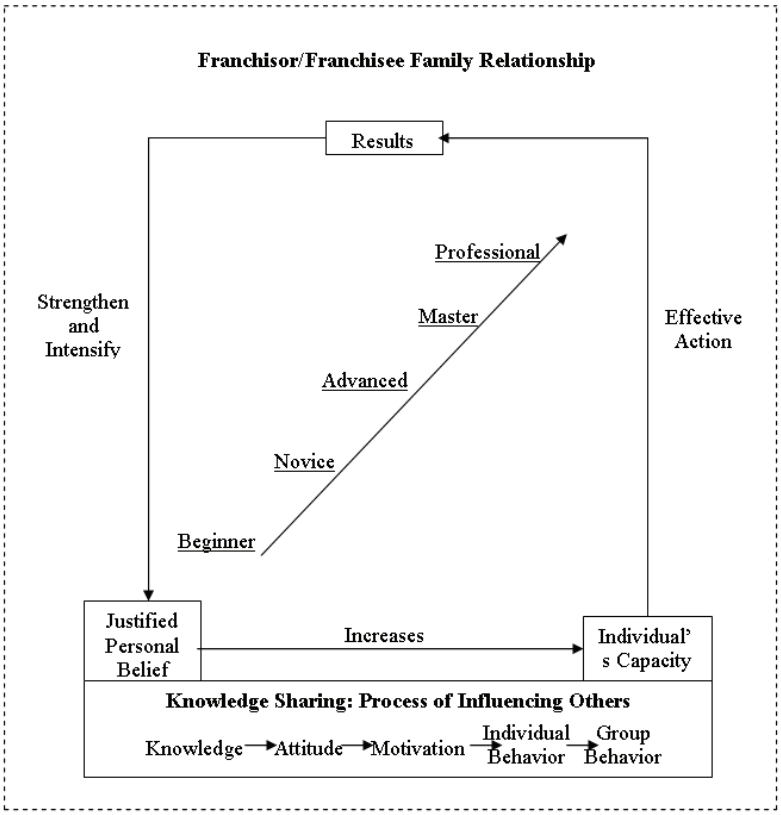
Developing a high-quality "family" relationship between the franchisor and the franchisee is believed to be the most significant factor for the success of a franchise (Justis & Judd, 2002). To understand how the relationship is developed, one needs to know the franchisee life cycle (Schreuder, Krige, & Parker, 2000):

- **The Courting Phase:** Both the franchisee and the franchisor are eager with the relationship. This typically corresponds to the beginner stage of the franchisee.
- **The "We" Phase:** The relationship starts to deteriorate, but the franchisee still values the relationship. This typically corresponds to the novice stage of the franchisee.
- **The "Me" Phase:** The franchisee starts to question the reasons for payments to their franchisors. They may start to think that the success so far is purely of his/her own work. This typically corresponds to the advanced stage of the franchisee.
- **The Rebel Phase:** The franchisee starts to challenge the restrictions being placed upon. This typically corresponds to the master stage of the franchisee. The rebel ones tend to be those who know the system very well and are capable of influencing others to follow them.
- **The Renewal Phase:** The franchisee realizes that the "win-win" solution is to continue teaming up with the franchisor to develop the system. This typically corresponds to the professional stage of the franchisee.

Thus, the major challenge for the franchisor is to turn a rebel franchisee into the renewal one. A viable solution for the franchisor is to provide a learning and innovative environment where the franchisee can continue contributing to the growth of the system. Successful collaborative learning and innovations will provide a strong incentive for the professional franchisees to continue their renewal relationship with the firm, which in turn will have positive impact on maintaining the good relationship with other franchisees and recruiting new ones. On the other hand, constant failures in this stage will intensify the rebel franchisees to dessert the firm, which in some cases lead to the demise of the franchise.

Lying behind the successful collaboration is the working knowledge of the franchise firm. Knowledge is defended

Figure 3. Understanding the franchisor/franchisee family relationship



as "a justified personal belief that increases an individual's capacity to take effective action" (Alavi & Leidner, 1999). Knowledge becomes "working" when the action produces results. When knowledge produces results, the personal confidence strengthens, intensifies, and justifies. The more superior the individual's capacity becomes, the better results are attained. This spiral-up cycle of working knowledge development is very important in the context of franchising. Figure 3 shows that the development process is incrementally developed through the five stages of the spiral-up cycle defined earlier: beginner, novice, advanced, master, and professional.

The foundation of the learning cycle is the capability of sharing and coaching the working knowledge throughout the franchise system. The process of influencing others for knowledge dissemination consists of five steps (Justis & Vincent, 2001): (1) knowledge, the proven abilities to solve problems in the franchise environment; (2) attitude, constructive ways of presenting and sharing the working knowledge; (3) motivation, incentives for learning or teaching the working knowledge; (4) individual behavior, the strengths of the participants to learn and enhance the working knowledge; and (5) group behavior, collaborative ways to create, dissimilate, and manage the hard-earned working knowledge.

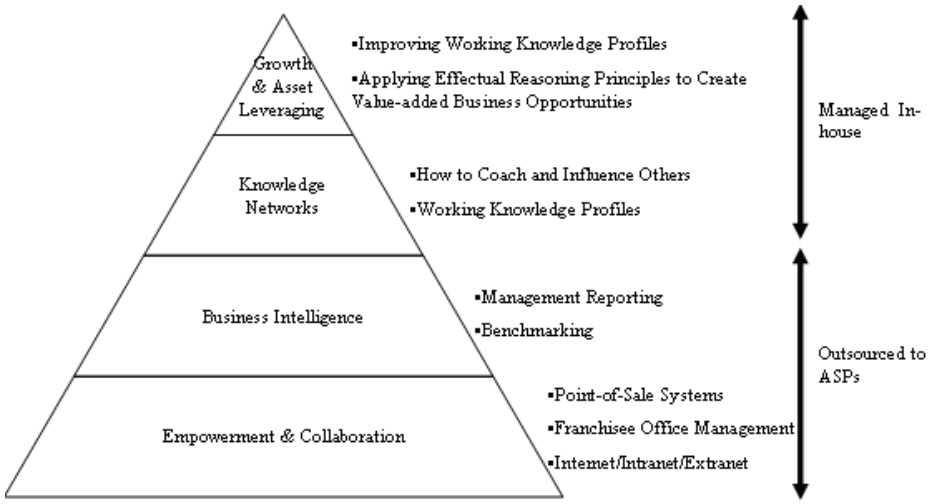
The franchisor/franchisee "family" relationship building in Figure 3 is also surrounded with dashed line, denoting that the relationship is enlarged and expanded without limits as the franchisee incrementally learns the working knowledge through the influencing of the franchisor and the fellow franchisees. By going through the processes of learning and influencing, both the franchisor and the franchisee progressively gain the working knowledge and mange the franchisee life cycle effectively.

FUTURE TRENDS

An Attention-Based IT Infrastructure in Franchising

In an information-rich world, Herbert Simon (Nobel laureate in Economics in 1978) wrote: "a wealth of information creates a poverty of attention" (Simon, 1971). As such, the "proper aim of a management information system is not to bring the manager all the information he needs, but to recognize the manager's environment of information so as to reduce the amount of time he must devote to receiving it" (Simon,

Figure 4. An attention-based IT infrastrucutre in franchising



1971). From the discussions in the last section, it is obvious that an attention-based IT infrastructure in franchising shall be one devoted to enabling the building of a good "family" relationship between the franchisor and the franchisee. In Figure 4, we propose such IT architecture (Chen, Chen, & Wu, 2005, 2006) for franchise organizations to manage the immense information produced by the firms.

The architecture, adapted from Gates' Digital Nervous Systems (1999), consists of the following four layers:

- **Empowerment and Collaboration:** Point-of-sale and office management systems are used to empower the franchisees (Chen, Justis, & Chong, 2002). Internets, Extranets, and Intranets networking the franchisor, the franchisees, customers and suppliers are deployed to improve collaboration (Chen, Chong, & Justis, 2002).
- **Business Intelligence:** Data warehousing and data mining techniques are used to convert volumes of data into reports and benchmarks for management to glean business intelligence (Chen, Justis, & Watson, 2002; Chen, Justis, & Chong, 2004; Chen, Zhang, & Justis, 2005).
- **Knowledge Networks:** Intranet-based systems consisting of the skills of coaching/influencing others (Chen, Seidman, & Justis, 2005) and working knowledge profiles (Chen, Hammerstein, & Justis, 2002) are implemented for knowledge sharing and learning within the franchise business. A distance-learning curriculum (Chen, Chong, & Justis, 2000) of working knowledge modules can also be deployed.
- **Growth and Asset Leveraging:** Value networks (Chen, Justis, & Wu, 2006) are developed with the goal of improving working knowledge profiles and applying effectual reasoning principles (Chen, Yuan, & Dai, 2004) to create value-added business opportunities (Chen, Justis, & Yang, 2004).

To demonstrate how the attention-based IT infrastructure is related to the activities of the franchisor, the franchisee (shown in Figures 1 and 2), and the "family" relationship building (shown in Figure 3), we show in Figure 5 the character of the business process, the information flow in the franchise business, and clarify the rationale behind the necessity of the attention-based IT infrastructure. The foundation of the architecture, adapted from Inmon (1996), consists of four levels: (1) data collected from the empowerment and collaboration activities of the franchisor (Figure 1) and the franchisee (Figure 2); e-business strategy shall be one empowering the franchisor and the franchisees to do their activities (Chen, Chong, & Justis, 2002); (2) reconciled data in the franchise data warehouse (Chen, Justis, & Watson, 2002); (3) derived data residing in data marts based on various franchisee-centered segmentations such as franchise development and support; and (4) business intelligence reports generated from analytical data analysis; for example, management reporting and benchmarking could be produced by online analytical processing (OLAP) periodically which periodically may lead to more proactive analysis of top/low performer attributes using the data mining techniques (Chen, Justis, & Chong, 2004).

The business intelligence reports will help the franchise system to identify key top performers and their success attributes. With their involvement, working knowledge profiles can be developed and dissimilated throughout the knowledge networks of the business using coaching/influencing techniques (Chen, Hammerstein, & Justis, 2002). The top of Figure 5 depicts such a knowledge sharing and

Figure 5. Implementing the attention-based IT infrastructure in franchising

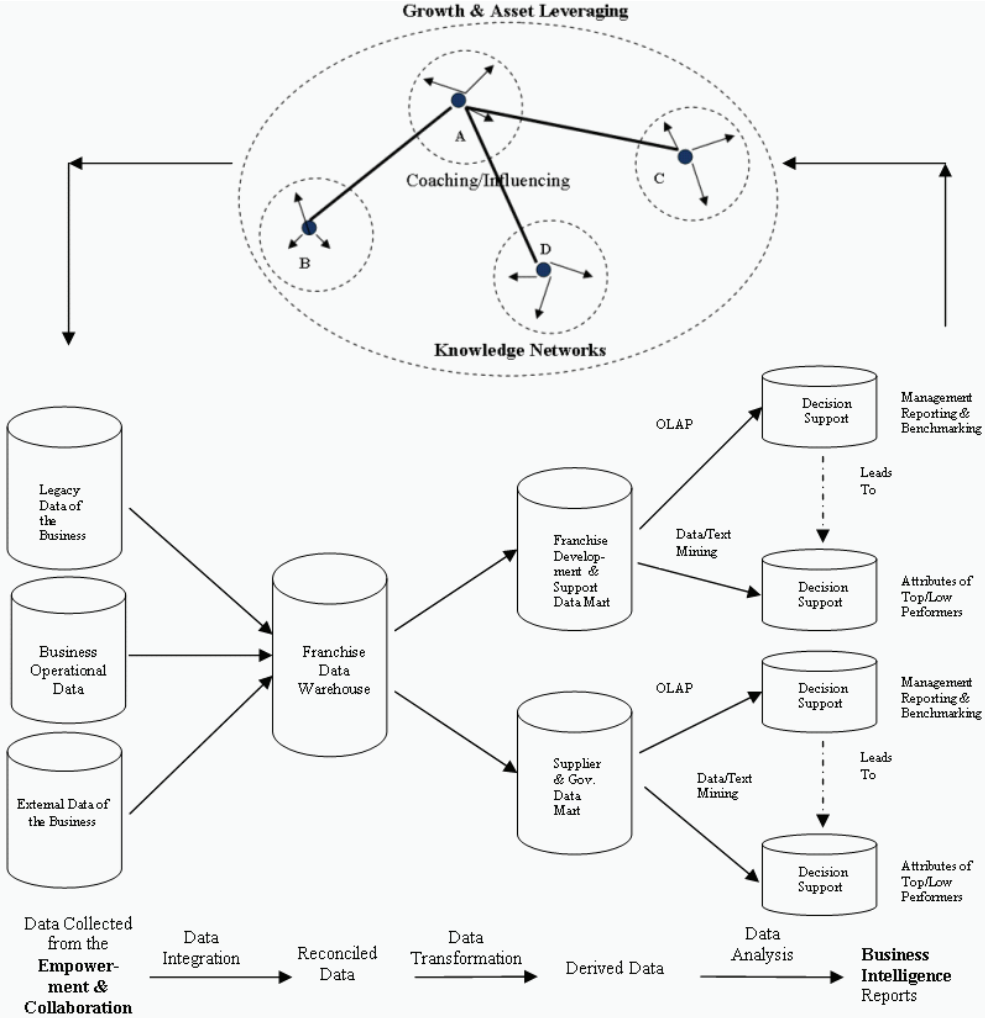


Figure 5. Implementing the Attention-based IT Infrastructure in Franchising

dissemination idea described in Figure 3 in detail. There are four franchisees (A - D) in the figure. Each franchisee (a dot) has his/her personal knowledge network (arrows pointing out of the dot). The knowledge network may include the customers' likes and dislikes, the kind of employees to hire, the competitors' and suppliers' pricing strategies, the social needs in the local community. Each franchisee is surrounded with a circle with dashed lines, meaning there is no limit to the personal knowledge network. Supposing franchisee A is the top performer and is charged and rewarded with coaching/influencing other franchisees to survive and thrive. Thus, clusters (connected dots) of knowledge network are formed and surrounded with a circle with dashed lines, meaning there is no limit for improving and leveraging the assets of the business (Chen, Justis, & Yang, 2004).

Using the attention-based IT architecture as a guide, we recommend franchise organizations to outsource IT in the first two layers to application service providers (ASPs) (Chen, Ford, Justis, & Chong, 2001). The concept of subscribing IT services through ASPs has special appeal in the franchising industry because an ASP can duplicate success for former similar franchises quickly and economically.

CONCLUSION

Franchising has been popular as a growth strategy for small businesses; it is even more so in today's global and e-commerce world (Chen & Wu, 2006). Although IT is quite important in franchising, IT researchers have largely ignored

this arena. One major reason is that few IT researchers are vested in the knowledge of how franchising functions, and without this intimate knowledge it is difficult to implement effective IT systems. Based on years of academic and consulting experiences in franchising and IT, an effective framework of IT in franchising is proposed. At the heart of the framework is to manage working knowledge and use IT to build up the "family" relationship between the franchisor and the franchisee.

KEY TERMS

Attention-Based IT Infrastructure: An IT infrastructure which is able to sort through volumes of data and produce right information at the right time for the right persons to consume.

Franchisee: The individual or business who receives the business rights and pay the royalties for using the rights.

Franchisee Life Cycle: The stages a franchisee goes through in the franchise system: Courting, "We", "Me", Rebel, Renewal.

Franchising: A business opportunity based on granting the business rights and collecting royalties in return.

Franchisor: The individual or business who grants the business rights.

Franchisor/Franchisee Learning Process: The stages of learning, including Beginner, Novice, Advanced, Master, and Professional.

Franchisor/Franchisee Relationship Management: The vital factor for the success of a franchise, including: Knowledge, Attitude, Motivation, Individual Behavior, and Group Behavior.

Information Technology in Survey Research

Jernej Berzelak
University of Ljubljana, Slovenia

Vasja Vehovar
University of Ljubljana, Slovenia

INTRODUCTION

Data collection based on standardized questionnaires represents one of the central tools in many research areas. Early surveys date back to the 18th century (de Leeuw, 2005), while a major breakthrough came in the 1930s with the application of probability samples. By using surveys, today governments monitor conditions in the country, social scientists obtain data on social phenomena and managers direct their business by studying the characteristics of their target customers.

The importance of survey research stimulates ongoing efforts to achieve higher data quality and optimized costs. Early on researchers recognized the potential of technological advances for the achievement of these goals. In the early 1970s telephone surveys started replacing expensive face-to-face interviews. Computer technology developments soon enabled computer-assisted telephone interviewing ("CATI"). The 1980s brought new approaches based on personal computers. Interviewers started to use laptops and respondents sometimes completed questionnaires on their own computers. Another revolution occurred with the Internet in the subsequent decade. The pervasive availability of Internet access, and the growing number of Internet-supported devices, coupled with the advance of interactive Web technologies (like Ajax) are facilitating developments in contemporary survey research.

Internet surveys show the potential to become the leading survey approach in the future. According to the Council of American Survey Research Organizations ("CASRO"), the Internet already represents the primary data collection mode for 39% of research companies in the USA (DeAngelis, 2006). The rate of adoption is slower in academic and official research but it is far from negligible. These technological innovations have, however, created several new methodological challenges.

BACKGROUND

Survey research can be performed using different modes like paper-and-pencil, mail or Internet surveys. Two characteristics of these modes (Groves et al., 2004) highlight the impact of modern technology on survey research: The presence of information technology during data collection and the degree of the interviewer's involvement.

Computer-assisted survey information collection ("CASIC") is a term embracing various modes that rely on computer technology for data collection (Couper & Nicholls, 1998). Computerized questionnaires offer numerous advantages. Answers are entered directly into a computer, which eliminates transcription-related errors. Enhanced possibilities of standardization ensure higher data quality and a lower burden on respondents. For example, answers can be limited to predefined options, irrelevant questions are automatically skipped over, answers can be subjected to real-time control and so forth.

Some computerized modes require an interviewer to be present either physically or remotely (e.g., CATI). In others, respondents complete a questionnaire by themselves. Self-administration offers benefits to respondents and researchers. Respondents can complete a questionnaire at the time and place of their preference and might have an increased sense of privacy. Researchers benefit especially from the absence of interviewers which prevents interviewer-related biases and significantly lowers research costs.

The widespread computer technology allowed both aspects to merge into computerized self-administered questionnaires ("CSAQ"). The trend toward paperless (computerized) and interviewer-less (self-administered) surveying corresponds with the general cost-optimization efforts of the research industry. Table 1 summarizes the most important survey modes based on CSAQ. They rely on electronic networks which make data instantly available to a research organization (Nathan, 2001).

Information technology has introduced new input and output technologies. Questions can be presented not only textually but also as audio or video clips. Answers, on the other hand, can be provided and recorded either manually (e.g., using a keyboard) or automatically with speech recognition. Even more advanced technologies that recognize gestures, writing and touch are establishing new potential for surveying respondents with certain disabilities (Johnston, 2007).

Internet surveys are probably the most revolutionary mode. They were enabled by progress in transmission procedures, standardized Web browsers, e-mail clients and integrated technologies (Lozar Manfreda, 2001). E-mail

Table 1. Common survey modes based on computerized self-administered questionnaires

CSAQ survey mode	
Touch-tone data entry ('TDE')	A telephone survey where respondents answer prerecorded questions by pressing appropriate numerical keys on a handset.
Interactive voice response ('IVR')	A telephone-based approach supported by the computerized voice recognition of answers. Modern systems utilize advanced speech recognition to automatically record complex answers.
Internet surveys	A range of modes based on one or more Internet services (like e-mail or Web). Respondents access and answer a questionnaire using an Internet-enabled device, usually a personal computer.
Virtual interviewer	Largely an evolving mode that can integrate various technologies (Web, speech recognition etc.). A virtual interviewer, usually a video clip of a real person, poses questions to respondents. In the future, completely virtualized characters might be used.

surveys already offered faster and cost-effective data collection (Bachmann, Elfrink, & Vazzana, 1996; Sheehan & Hoy, 1999). However, they were soon replaced by more powerful Web surveys. Interactive Web surveys are based on a continuous interaction between the system and the respondents (Conrad, Couper, & Tourangeau, 2003). The advance of modern Web technologies, like Java, JavaScript and ActiveX, fostered the implementation of feature-rich and flexible Web questionnaires. The Internet has thus become a medium for survey research, enabling different combinations of input and output technologies. Internet surveys currently remain prevailingly based on textual questionnaires. Yet, some visual or audio elements, including multimedia, are already used as enhancements of textual contents.

The implementation of Internet surveys is simplified by dedicated software tools. They provide features of questionnaire design, respondent recruitment, survey administration and data analysis. According to the WebSM portal (2007), in 2007 there were more than 300 of such tools available. They range from simple tools for single-question daily polls to advanced integrated solutions for complex data collection (Berzelak, Lozar Manfreda, & Vehovar, 2006). Especially promising is the development of some open-source solutions that allow a high level of flexibility for deployment according to a researcher's specific needs.

In the subsequent part, we focus on information technology's impact on different steps of the survey process. The emphasis is on Internet surveys which are the most promising approach and integrate several IT-based modes.

THE INTEGRATION OF INFORMATION TECHNOLOGY IN THE SURVEY PROCESS

Questionnaire Design

The appropriate implementation of a survey questionnaire is critical to the quality of obtained data (Dillman, 2007). There are important differences between perceptions of CSAQ and paper questionnaires. Graphical elements of Web survey questionnaires, for example, attract more attention than text (e.g., Tourangeau, Couper, & Galesic, 2005) and navigation with a keyboard and mouse causes a loss of eye-hand centralization (Bowker & Dillman, 2000).

Computerized questionnaires, including those of interactive Web surveys, offer a lot of design flexibility. Questions can be presented using different visual elements like check-boxes, radio buttons, sliders and so forth. Images, video and audio clips can be easily included and without extra cost. While multimedia elements might increase the motivation of respondents, the effects can also be negative or unpredictable (Dillman, 2007; Lozar Manfreda, Batagelj, & Vehovar, 2002). There is also strong evidence that different visual presentations of questions impact the answers provided by respondents (Couper, Tourangeau, & Conrad, 2004; Smyth, Dillman, Christian, & Stern, 2006). The employment of design features should be thus subjected to careful methodological examination.

Technological limitations should also be considered. The extensive use of images and multimedia is likely to exclude respondents with slow Internet connections. Further, questionnaires based on modern Web technologies can cause incompatibilities between technological platforms. The research by Buchanan and Reips (2002), for example, found personality differences between PC and Mac users. Incompatibilities can thus prevent the surveying of specific groups and significantly distort the results.

Web survey questionnaires can be simultaneously deployed on personal computers, mobile phones, handhelds, interactive TV and other Internet-enabled devices. However, some important barriers remain. The screens of mobile devices have low resolution which aggravates the deployment of complex questionnaires. Mobile phones also lack technological standardization (Tjøstheim, Thalberg, Nordlund, & Vestgården, 2005) and usually only offer limited bandwidth. Interactive TV devices (e.g., WebTV) could bring surveying closer to the everyday activities of respondents, but they remain underdeveloped. These technologies, however, might become an important vehicle of future survey research.

Sampling and Recruiting

The basic principles of sampling remain largely the same as in traditional survey modes. Yet technology has aggravated the problem of noncoverage. The employment of IT-based surveys is usually limited to segments of the population that are adequately covered with necessary technology. For example, those without Internet access cannot be reached using Web surveys. As they often significantly differ from those who do have access, the results can be highly distorted. While the coverage of organizations in the USA and the EU is almost complete, it is far lower when it comes to households. Data for 2006 show that Internet access exceeds 70% of the adult population in only a few EU member states and amounts to 73% in the USA (Eurostat, 2006; Madden, 2006). The integration of Web surveys into probability samples thus represents one of the most challenging problems of contemporary research methodology.

Information technology has enabled new approaches to the recruiting of respondents. Random visitors to Web pages are often invited to a survey using intercept sampling, usually implemented with pop-up windows or banners. In addition, invitations can be conveniently distributed by e-mail. Complete and consistent lists of e-mail addresses are, however, rarely available. The exceptions only include specific groups like the employees of an organization.

These problems can be partly overcome by mixed-mode surveys (de Leeuw, 2005). The preselection of respondents for a Web survey can, for example, be made by postal mail. Those without adequate technology are then offered to participate using a traditional mode (e.g., a mail survey). Mixed modes are, however, expensive to realize. In addition, various modes can differently impact answers and cause a mode effect (Dillman, 2007).

Data Collection

The logic of the data collection process is similar in all CSAQ modes. Respondents answer a computerized questionnaire remotely. The data are then transferred through a corresponding network (like the Internet or GSM) and automatically stored in a database.

IT-based data collection allows the recording of paradata, or data about the process of data collection (Couper, 2005). In Web surveys, they can provide information on a respondent's IP address, the duration of surveying, navigation throughout the questionnaire and so forth. This helps to effectively monitor, understand and manage the survey process.

An adequate response rate is necessary to obtain sufficiently reliable and valid data. Recent research shows that Web surveys yield, on average, 11% lower response rates than traditional modes (Lozar Manfreda, Bosnjak, Berzelak, Haas, & Vehovar, 2008). Information technol-

ogy, however, provides new opportunities for improving response rates. Innovative features can help to create user-friendly questionnaires that might heighten the motivation of respondents. Some new forms of incentives (e.g., PayPal) are available as well.

Survey Management

The effective management of a survey project ensures the high quality of obtained data at optimized costs. It is thus important to adequately balance errors and costs. In CSAQ, errors usually arise due to noncoverage and nonresponse problems. Especially Web surveys are often regarded as being an inherently cost-effective alternative. However, this becomes questionable as errors are taken into account (Vehovar, Lozar Manfreda, & Batagelj, 2001).

The survey process should adhere to relevant ethical standards and guidelines. These are well-established in general survey research, but are relatively incomplete for Internet surveys. Some of them (e.g., ESOMAR, 2005; MRA, 2000; MRS, 2006) already address important issues caused by the incorporation of information technology. These include the problems of unsolicited e-mail invitations, privacy and security threats, online informed consent, combining data from different sources, surveying children and minorities and several others. However, in practice it is often difficult to satisfy these principles. The confidence of respondents is also frequently shaken by online frauds and the large number of unsolicited e-mails. Such issues will need to be resolved by future standards and guidelines.

FUTURE TRENDS

The strong impact of information technology has importantly determined the future of survey research. It is likely that further development will be characterized by the integration of technologies, devices, data collection methods and different data sources.

CSAQ modes will be additionally fostered by the growing importance of related fields like e-learning, human-computer interaction, usability studies and online research. The wider availability of Internet access among the general population will help overcome the noncoverage problem. Text-to-speech ("TTS") and speech recognition are likely to further impact the technological foundations of surveying. The integration of these approaches will enable synergetic effects, leading to new important advances. A nearly science-fictional example might be completely virtualized interviewers that would automatically adapt to respondents' specific characteristics.

An important trend involves the distribution of questionnaires among a variety of devices. As smart-phones (like iPhone) are gaining in popularity, more powerful mobile devices might become prevalent. Advances in mobile communications, including the broad growth of 3G and WLAN, will encourage the implementation of mobile computerized self-administered questionnaires ("MCSAQ"). This will greatly overtake the current use of mobile phones, which remains largely restricted to telephone interviewing (Kuusela, Vehovar, & Callegaro, 2006) and very limited SMS surveys (Townsend, 2005). Respondents could then be reached virtually anywhere and anytime, facilitating the continuous measurement of target groups (Couper, 2005).

Future survey research tends to be increasingly based on mixed-mode surveys. Different modes will be employed in different steps, compensating for the weaknesses of individual modes (de Leeuw, 2005; Dillman, 2007). The whole project will be managed through integrated centralized data management. Information technology might also encourage combinations of online quantitative (e.g., Web surveys) and qualitative methods, including online focus groups and in-depth interviews (Lobe, 2006).

Technologically, it is already easy to combine survey data with data about phone calls, TV watching, shopping and so forth. Integrations with the Global Positioning System ("GPS") and Geographic Information Systems ("GIS") provide new opportunities for spatial and location-based research. However, such combinations raise serious ethical and methodological questions. As Couper (2005) states: "The more we can potentially learn about people, the fewer people there may be willing to give us such access into their everyday activities" (p. 493). These challenges will therefore have to be appropriately addressed by professionals and thrown open to public debate.

CONCLUSION

Recent innovations in survey data collection have been greatly influenced by information technologies. Cost-reduction trends continuously demand a move toward interviewer-less and paperless surveying, an area in which technology offers enormous potential. It provides innovative possibilities for questionnaire design, communication with respondents and data collection. These factors can significantly contribute to higher data quality, which is inevitably related to research costs.

Internet surveys are already widespread in the business sector and are being increasingly adopted in academic and official research. The existing limitations, like inadequate Internet coverage, methodological dilemmas and ethical issues, will almost certainly be adequately resolved. This will reduce the barriers for the Internet becoming a central surveying technology, at least in more economically developed countries. Further innovations and integrations will provide fresh opportunities for survey measurement, but will also raise new issues that will require appropriate solutions.

Information technology will definitely underlie the future of survey research. This, of course, does not mean that the demise of traditional survey modes is soon likely. However, they will be increasingly complemented and substituted by new, IT-based survey data collection.

KEY TERMS

Computerized Self-Administered Questionnaires (CSAQ): Survey modes implemented with computerized questionnaires that are completed by respondents themselves (without an interviewer). CSAQ modes include Internet surveys, interactive voice response, touch-tone data entry and others.

Interactive Voice Response (IVR): A telephone survey mode based on prerecorded questions or text-to-speech technology and technology for voice recognition. Answers provided by respondents are automatically recognized and stored in a database. A modern IVR system can incorporate advanced speech recognition, enabling the automatic textual recording of complex answers.

Internet Surveys: computerized self-administered survey modes with questionnaires distributed and answered using one or more Internet services. The prevailing type is Web surveys, which has almost completely replaced e-mail surveys. Internet surveys can be distributed across various devices, including personal computers, mobile devices and interactive TV.

Mixed-Mode Survey: A survey based on a combination of different modes at various stages of a survey project. This helps to overcome the limitations of an individual mode. For example, respondents without Internet access can be offered the opportunity to complete a paper questionnaire instead of a Web one. Modern technology enables the advanced centralized data management of mixed-mode surveys.

Mobile Computerized Self-Administered Questionnaires (MCSAQ): Computerized questionnaires completed by respondents using mobile devices, usually mobile phones. Common examples are the very limited SMS surveys and the more powerful mobile Internet surveys.

Virtual Interviewer: A computerized survey mode in which questions are presented to respondents by a virtual interviewer. This is usually a prerecorded video clip of a real person asking questions. It can be provided via different media, including the Internet. The future development and integration of information technologies may enable completely virtualized characters with an adaptable appearance for different surveying contexts.

Web Survey: An Internet survey mode with questionnaires administered on the World Wide Web. Respondents access and answer the questionnaire using a Web browser. Modern Web technologies enable the client-side execution of advanced questionnaire features, including real-time skips over questions, the control of answers and others. Images and multimedia elements can also be included to enhance the contents of a questionnaire.

Information Technology Outsourcing

Anne C. Rouse
Deakin University, Australia

INTRODUCTION

Organizations have used external vendors to supply information technology (IT) functions since the first commercial implementations. In the sixties, the use of facilities management, contract programmers, and contract project management were common, but during the 70s, many organizations relied increasingly on internal delivery of IT services. The term "outsourcing" arose in the late 80s. Since that time industry has seen a fundamental change in the way information technology (IT) services are organized and delivered, with increasing reliance on external, outsourced providers. Managing outsourced IT service delivery has now become a core competence for organizations

BACKGROUND

According to Willcocks and Lacity (1998, p. 3), outsourcing involves "handing over to a third party [the] management of IS/IT assets, resources and/or activities for required results". There is general consensus that outsourcing involves delegating the responsibility for "how" to produce definable outcomes to an external party, while retaining responsibility for specifying "what" is to be delivered. Instead of controlling the behavior of service staff directly, the purchaser controls performance through a contract or service agreement, which articulates the services required, and the performance criteria.

The rise of the term "outsourcing" occurred when, in the 80s, several large U.S. corporations announced they were handing over control of their IT function to one or more vendors. The most prominent of these was Eastman Kodak. At that time, it was common in the trade literature (and some academic literature) to argue that IT had become a commodity. By outsourcing IT, it was asserted that organizations could more easily concentrate on core business. In the early 90s, announcements like Eastman Kodak's tended to produce a rise in share price, as the market anticipated consequent cost savings or improved organizational performance. Thus, the stock market response was an important outsourcing driver. Another significant driver was the growth of communications technologies, which enabled vendors to provide services remotely.

A less-frequently acknowledged reason for the rise in outsourcing was IBM's entry into the IT services arena, joining Electronic Data Systems (EDS), which had been spun off as a separate IT service vendor from its parent, General Motors. The dwindling profitability of hardware and software sales acted as an impetus, as outsourcing provided a relatively stable and long-term source of income and profits. Thus, in many ways, outsourcing is a vendor-driven phenomenon.

In the fifteen years since IT outsourcing emerged as an academic topic, the phenomenon has grown and adapted, and now embraces a range of variants. These include "business process outsourcing" (BPO), "off shore outsourcing" or "offshoring", and "application service provider" services (ASPs). Gartner (2005) reports that outsourcing is the prime driver for the IT services market, estimated to be around $US600 billion in 2004. While growth in the IT outsourcing market has slowed, the growth in new outsourcing forms (offshoring, and BPO) is reportedly strong, so the topic is likely to remain important in the IS discipline for some time.

THEORETICAL UNDERPINNINGS

There is no generally agreed "theory" of outsourcing but a range of theories drawn from economics, strategy, marketing, and public policy have been used to understand the phenomenon.

Economic Theory

Economic theories tend to view outsourcing as a variation on the "make or buy" decision that organizations must take and to view sourcing decisions as being based on relative costs. Outsourcing is seen to lead to lower cost of delivery under certain circumstances.

The most influential economic theory, and probably the most widely used in outsourcing research, is *transaction cost theory (TCT)* (Williamson & Masten, 1999). This theory predicts when decision makers will choose the *market* to deliver services and when they will choose in-house delivery through the organizational *hierarchy*. These are seen as polar forms of service provision, although a range of hybrid forms are possible.

According to TCT, the relative costs for these two strategies depend on two types of costs: production costs—usually reduced in markets because of competition—and transaction costs; and the costs of finding, contracting with and dealing

with vendors in the market. Transaction costs are difficult to measure and can be so high as to outweigh the outsourcing savings associated with reduced production costs. TCT predicts that several factors will influence whether outsourcing leads to cost savings, including level of uncertainty, frequency of transactions, and extent to which the services are "asset specific", that is, tailored to a specific vendor or purchaser and so not easily deployed elsewhere. Some TCT propositions have been confirmed for IT outsourcing (Aubert, Rivard, & Patry, 2004) though it is also argued that many of the TCT constructs are difficult to operationalize and so the theory is difficult to disprove (Ghoshal & Moran, 2005).

Resource dependency theory, and the *Resource-based view (RBV)* of the firm are two economic theories that underlie the "core competency" argument discussed next. Resource dependency theory argues that organizations will seek to reduce dependency on external providers for key resources and that factors increasing dependency include a small number of potential suppliers, and switching costs. Resource-based theory (Barney, 2002) argues that it is differences (heterogeneity) in resources between firms that allow some to sustain competitive advantage and that outsourcing allows firms to access resources (usually intangible) they do not currently have. They can then devote attention to resources and capabilities they do possess that are likely to lead to greater profitability. These include resources/capabilities that are rare, valuable, difficult to imitate, and not easily substituted—such services should not be outsourced.

Another economic theory with implications for outsourcing is *agency theory* (Laffont & Martimort, 2002). This recognizes that the provider has different motives from the purchaser and that there is often information asymmetry between the two. This theory proposes that the purchaser needs different forms of control for different types of services. Where it is difficult to measure the effort involved in service delivery, agency theory predicts that an outcomes-based, contractual form of control (like that associated with outsourcing) will lead to lower costs.

Strategic Management Theories

Much of the impetus to outsource IT has come from strategic theories related to the idea of *core competency* and the notion that managerial attention is a limited resource. The underlying proposition is that modern organizations cannot concentrate on all business functions and still achieve sustainable advantage so they must focus on those key processes or capabilities where they have unique advantages. Organizations should delegate to external providers as many non-core processes as possible, in the expectation that vendors will, through specialization and economies of scale, be able to provide higher quality services at lower cost.

As a result of this theory, there appears to be general consensus (e.g., Lacity & Willcocks, 2001) that core, or "strategic" IT services, should be kept in-house, while non-core services and commodities should be outsourced. However, this proposition has proved difficult to test as few IT services are commodities, and it is not easy to operationalize "core" services. An assumption underlying the core-competency view is that managing the relationship with a vendor will drain less attention than providing services in-house and that economies of scale and specialization will reduce vendor production costs low enough to outweigh increased transaction costs. These propositions have not been empirically verified.

Marketing Theories

While economic theories concentrate on the relative costs of outsourcing, marketing theories concentrate on the way quality, success, and value are judged by purchasers of outsourced services, and the way relationship elements, like trust, affect these judgments. An important notion that is used in studying outsourcing is that of *service quality* (Parasuraman & Zeithaml, 2002), which predicts long-term satisfaction with a vendor and intention to re-purchase.

There has been increasing attention devoted in the IT outsourcing literature to the effects that the quality of the outsourcing relationship and notions of trust have on outsourcing satisfaction and other success measures (Kern & Willcocks, 2002; Lee, Huynh, Kwok, & Pi, 2003). Theories underlying this research include service quality theory, theories related to trust, and exchange theory. Good overviews of service marketing and relationship theories can be found in White and Schneider (2003).

Public Policy Theories

The public sector is a major user of IT outsourcing, and in some regions (particularly, the UK and Australasia) has pioneered large-scale outsourcing arrangements. In the public policy literature, outsourcing is often couched as part of the "steer rather than row" philosophy (Osborne & Gaebler, 1993). This philosophy, in turn, has been influenced by strategic management theories discussed previously.

OUTSOURCING RESEARCH

A brief check of electronic resources (like ABI Inform) reveals thousands of articles on outsourcing and hundreds of papers labeled "peer reviewed" or "academic". An examination of these, though, will show that most of them are practitioner (or academic) opinion. Much of the IT outsourcing literature is written either directly, or indirectly by staff employed by outsourcing vendors or by specialist outsourcing advisory services.

A detailed review of the mainstream academic literature to 2001 is found in Dibbern, Goles, Hirschheim, and Jayatilaka (2004). This reveals that systematic empirical research into outsourcing has been limited and that much of this has concentrated on the reasons purchasers choose to outsource (or not outsource). The predominant research methodology has been "case studies" but the depth to which case studies are reported, and the extent to which the researchers adopted a critical, theory-testing approach, has varied. There have been few theory-testing studies in the literature and very few studies that have statistically tested propositions related to outsourcing practices.

A widely cited and influential paper was published by Lacity and Willcocks (1998). This summarized 61 sourcing cases the authors had undertaken (of which around half involved outsourcing). The authors compared these cases to explore various outsourcing propositions but recognized that opportunistic cases are often atypical and that their research might not generalize to wider populations. More recent survey research (Lee & Kim, 1999; Rouse & Corbitt, 2003) has not been able to confirm one of their most widely-recognized assertions—that "selective" outsourcing is generally more successful than "total" outsourcing. It is possible that other findings Lacity and Willcocks reported were unique to the cases they studied.

Drawing on either their own outsourcing experience, or on case studies, a number of writers have produced practical guidebooks for managing outsourcing arrangements. The prescriptions supplied in these guides provide rich source material for researchers, though few recommended practices have been confirmed empirically. Instead, much of the empirical research has investigated motivations for IT outsourcing. The most common goals include: to save costs, to concentrate more on core business, to gain access to skills and technologies not provided in-house, and to get better quality service or advice. Outsourcing is often employed to gain greater long-term flexibility by exchanging fixed costs or capital for variable costs. Public sector agencies also seek to outsource to increase accountability. Surprisingly, little evidence exists to confirm that these benefits (other than access to new skills and technologies) are widely obtained from outsourcing.

More recent qualitative research has been concerned with the quality of the outsourcing relationship (e.g., Kern & Blois, 2002; Barthelemy, 2003; Levina & Ross, 2003; Lacity, Feeny, & Willcocks, 2004). Confirmatory research has also investigated the role of relationship elements in outsourcing success (e.g., Lee, 2001). However, confirmatory research is currently held back by the lack of agreement about what the dependent variable should be and how it should be measured. It is not yet clear whether judgments about the relationship are the result of vendor performance, and consequent purchaser satisfaction, or whether a high quality relationship leads to satisfaction.

There is growing interest in the academic literature on the reconciliation of competing goals, and the management of the downsides or risks of outsourcing. Hirschheim and Lacity (2000) warned that in many cases there is a trade off between different goals. So, for example, flexibility often involves higher short-term costs while exchanging capital for variable costs is often more expensive in the long run. A common theme in the literature is that outsourcing tends to bring both benefits and downsides and that even after 15 years of research still involves substantial risks. These may include failure to obtain expected cost savings, reduced business flexibility, loss of control, increased dependence on the provider (even "lock in"), threats to privacy/confidentiality, and intellectual property issues (Aubert et al., 2004).

Key researchers currently conducting empirical research into IT outsourcing are included in Table 1. Excluded from this table are researchers who have reported one-off case studies or studies into the motivations/drivers of outsourcing.

In summary, a review of the literature reveals that, despite a large body of academic literature, the empirical evidence base for making outsourcing decisions is surprisingly thin. The research available to guide decision makers consists mainly of singular case studies, argumentation, and opinion, and there have been few attempts to validate claims.

FUTURE TRENDS

A growing trend in the trade literature has been the reporting of "consultant" surveys claiming IT outsourcing has generally failed to meet expectations, particularly for cost savings. This may be self-serving, though the limited academic data that has been gathered to date tends to confirm it (see Rouse & Corbitt, 2003). It is expected that more researchers will undertake hypothesis testing studies to determine whether the theoretical benefits of outsourcing are widely encountered and what the boundary conditions are.

The growth in new variations of outsourcing (BPO, offshoring, and ASPs) provides additional research focuses, and proponents argue that these may lead to greater economic benefits than IT outsourcing has been able to provide. However, as with IT outsourcing, there has been little systematic research to date, and the little research that has been done has generally involved isolated, often anecdotal case studies.

An emerging topic is how the risks and downsides of IT outsourcing (and later variants like BPO and offshoring) can better be identified and managed (e.g., Bahli & Rivard, 2005; Rouse & Corbitt, 2003b) . There is growing interest in the quality of the vendor-client relationship. With increasing proportions of IT services now outsourced, this is likely to be an area of growing interest in the future.

Table 1. Key IT outsourcing researchers and their research focus

Researcher(s)	Nature of research	Key findings
Ang; Ang and Straub	Large quantitative studies	Outsourcing is related to skills shortage; outsourcing success is predicted by fulfilled obligations; outsourcing adopters tend to concentrate on production cost savings but non-adopters on transaction costs.
Aubert, Rivard and Patry	Quantitative studies, theoretical studies, case studies	Uncertainty is the major deterrent to outsourcing, access to technical skills is the major driver; outsourcing is risky; risk management model proposed.
Barthelemy	Case studies	Outsourcing needs both hard (contractual) and soft management strategies; outsourcing has hidden costs, though some can be mitigated.
Kern; Kern and Willcocks; Willcocks and colleagues	Case studies focusing on vendor-client relationship	A range of practices recommended as likely to lead to success; outsourcing can result in negative outcomes where both vendor and client suffer from over-promising; the vendor-client relationship evolves over time and involves contractual and non contractual elements; post contract management is important to success.
Lacity, Hirschheim	In depth case studies of outsourced and insourced IT services	Outsourcing motives are frequently political; the strategy has substantial risks; outsourcing benefits can often be obtained through in-house delivery; outsourcing usually involves trade-offs.
Lacity, Willcocks, Feeny and colleagues	Case studies; cross case comparisons; small-n surveys, global outsourcing	The search for cost savings is the major driver for outsourcing; "selective outsourcing" is generally successful; a range of practices are recommended as likely to be successful; models of the outsourcing process proposed; key criteria for benchmarking suppliers and determining "knowledge potential" proposed.
Lee, Leet et al., Lee and Kim	Large quantitative studies	Relationship quality and trust predict outsourcing success; outsourcing falls into distinct configurations.
Rouse; Rouse and Corbitt	Large quantitative study, longitudinal case study, focus groups	Outsourcing is riskier than recognized; outsourcing leads to satisfaction, cost savings, in only a minority of organizations; some practices lead to discernible benefits, while others (e.g. "selective outsourcing") do not; selective outsourcing not more successful than total outsourcing.

CONCLUSION

Despite more than 15 years of study, there are large gaps in academic knowledge related to IT outsourcing. The emphasis on case study research, and the scarcity of statistically-reliable studies have resulted in an abundance of conflicting findings and claims, with limited hypothesis-testing research to reconcile these. Consequently, a number of unchallenged recommendations regarding when, what, and how to outsource have arisen. There is a need for researchers to shift emphasis from theory-generation to theory testing so as to discover which plausible recommendations are supported by evidence, and to determine the boundaries for current theory. This in turn requires that attention be paid to the dependent variable(s) associated with outsourcing success and to the various competing expectations and consequent trade-offs that outsourcing involves.

KEY TERMS

Application Service Provider (ASPs): Standardized IT applications (such as enterprise processing, office systems, and e-mail) or software that is hosted by a provider, and accessed over the Internet by purchasers, who are charged on a transaction basis.

Business Process Outsourcing (BPO): The outsourcing of relatively complex IT-supported business functions or processes. In practice, this often also involves "offshoring".

IT Insourcing: This is a term with multiple meanings and so often unclear. It can mean services delivered in-house; services put to tender and then awarded to an in-house team in competition with the market; or services originally outsourced then brought back in house (this latter is sometimes labelled "backsourcing").

IT Outsourcing: The provision, at an agreed price, of specified IT services by an external vendor that is contracted to manage the day-to-day activities (and IS/IT assets and resources) so as to meet agreed performance and quality standards. Outsourcing can involve either the once-off development of a new information system or the ongoing provision of IT services (such as mainframe operations, PC support, software maintenance, etc.) over a specific period.

Off-Shore Outsourcing or "Offshoring": Outsourcing that is provided across national borders. In most cases this involves sourcing services from a low-salary nation like India, China, or parts of the former Soviet Union, where "salary arbitrage" (definition follows) leads to reduced costs.

Salary Arbitrage: Differences in average salary rates between developing nations (such as India, China, various South American countries) and developed nations in Europe, North America, etc.

Transaction Costs: The costs of contracting with a vendor through the marketplace, in contrast to coordinating and managing service provision "in-house" (i.e., through the hierarchy). Key costs include finding, choosing, contracting with, monitoring, and controlling the work of the vendor, as well as coordinating the vendor's activities with others being carried out by the purchaser.

Information Technology Strategy in Knowledge Diffusion Lifecycle

INTRODUCTION

A progressive liberalization and deregulation of international trade, and the rapid development and diffusion of information and communication technology (IT) have fundamentally changed the global competitive dynamic environment (Ernst & Kim, 2002). Growing around these is a new information age economy whose fundamental sources of wealth are knowledge and communication rather than natural resources and physical labor (Kanter, 1994). The simultaneous development of the knowledge economy (Dunning, 2000) and the information technology economy (Varian, Farrell, & Shapiro, 2004) provides both opportunity and challenge for the organizations, and also requires us to develop from a comprehensive perspective by combining knowledge management with the information technology strategy.

In the knowledge economy, the importance of knowledge diffusion dynamics has been increasingly recognized in development economics over the last decade (World Bank, 1999). Knowledge diffusion can be defined as the adaptations and applications of knowledge documented in scientific publications and patents (Crane, 1972). Knowledge diffusion is part of the knowledge management process, realizing the proliferation of knowledge and information among different individuals across time and space (Chen & Hicks, 2004). According to the extent of knowledge diffusion, the knowledge diffusion lifecycle can be divided into four stages, including incubation, nurture, promotion, and popularization (Lang & Yuan, 2004). In this lifecycle, knowledge diffusion refers to promoting the innovation and core competence formation, so how to accelerate the knowledge diffusion has become an important issue for organizations.

The development of information technology establishes a solid base to accelerate knowledge diffusion. IT and related organizational innovations provide effective mechanisms for constructing flexible infrastructures that can link together and coordinate economic transactions at distant locations (Broadbent, Weill, & St. Clair, 1999). In essence, IT fosters the development of leaner, meaner, and more agile production systems that cut across firm boundaries and national borders. The underlying vision is that accelerating knowledge diffusion can speed up the dissemination of information technology. Knowledge diffusion is an essential content of the business strategy (Borghoff & Pareschi, 2003).

However, existing theories of both information technology and knowledge have not specified the information technology strategy in the knowledge diffusion. This article introduces the information technology strategy in knowledge diffusion based on the knowledge cycle theory. The article describes how to advance knowledge diffusion by using the matched information technology strategy in a different knowledge diffusion lifecycle. The article shows how firms innovate and research to imitate knowledge and improve the diffusion of knowledge.

BACKGROUND

The relationship between knowledge and information is essential. Knowledge may be defined as information whose validity has been established through a test of proof and can therefore be distinguished from opinion, speculation, beliefs, or other types of unproven information (Liebeskind, Oliver, Zucker, & Brewer, 1996). This definition of knowledge consists of two primary classifications: information (explicit knowledge) and know-how (tacit knowledge) (Nonaka, 1991). Knowledge in this article refers to explicit knowledge. Information is knowledge that can be transmitted without loss of integrity once the syntactical rules required for deciphering it are known. Thus, knowledge as information implies knowing what something means and that it can be written down (Nonaka, 1994).

Throughout the 1990s and early 2000s, both researchers and practitioners (e.g., Cowan & Jonard, 1999; Morone & Taylor, 2004) have discussed the model of knowledge diffusion within organizations. They develop a model in the framework of graph theory. The aim of their model is to capture effects of incremental innovation and their diffu-

sion over a network of heterogeneous agents. The idea that knowledge diffusion is necessary to an organization's success has become the focal point of strategy and the strategic planning process (Liebeskind et al., 1996). Knowledge has emerged as the most strategically significant resource of the firm (Grant, 1996b).

"Lifecycle" within knowledge management exists because it is evident that organizational knowledge does indeed have a lifecycle. The knowledge is discovered, captured, utilized, and eventually retired rather than killed. Siemieniuch et al. (1999) refer to the knowledge lifecycle starting point—that knowledge is not a unitary thing and it has a lifecycle in a competitive environment. In other words, if a company is to keep competitive, it must address the issues of new knowledge generation, propagation across the organization, and the subsequent knowledge retirement. They indicate that: (1) knowledge will age as the context changes; (2) humans will be intrinsic components in all processes involving the creation, utilization, and retirement of knowledge; and (3) the management of knowledge is a critical, core competence of the organization.

Siemieniuch and Sinclair (2004) also introduced the Cross Sectoral Learning in the Virtual Enterprise (CLEVER) process framework for knowledge lifecycle management (KLM). The model was developed to help organizations in the manufacturing and construction domains to tackle ill-defined knowledge management problems. Focusing on organizational and cultural issues, rather than technological ones, the framework aids the user organization in translating vague KLM problems into a set of specific knowledge management issues.

Sakol (2002) introduces the knowledge lifecycle interplay between the user study and product development phases, and introduces a method, concept, and model for the entire design process. The three proposed solutions are: object-mediated user knowledge elicitation–OMUKE, pattern of user knowledge–PUK, and use process-based product architecture–UPBPA.

OMUKE is a method proposed for capturing user knowledge. The method is built from empirical research of existing methods (convergent perspective approach) and an experimental study with the OMUKE software agents. The method can be effectively used to capture user knowledge and use it to form the product architecture in knowledge lifecycle processes.

According to the extent of knowledge diffusion, the lifecycle of knowledge diffusion will be divided into four stages, including incubation, nurture, promotion, and popularization. The knowledge lifecycle can be represented as the curve in Figure 1. The development of a core IT and communications infrastructure supports knowledge lifecycle management.

INFORMATION TECHNOLOGY STRATEGY

I

Information technology strategy refers to the IT applications used to help the organization gain a competitive advantage, reduce competitive disadvantage, or meet other strategic enterprise objectives (Bergeron, Bateau, & Raymond, 1991). Clearly, this is a critical resource, as discussed earlier. It is therefore vital that a suitable IT infrastructure is in place, with the right applications implemented. There must also be the right information- and knowledge-sharing policies in place. While scholars have explained the knowledge diffusion lifecycle and information technology in knowledge management (Siemieniuch, 1999), combining the information technology strategies with knowledge diffusion will be a potential power to accelerate the knowledge use.

Information Technology Strategy for Knowledge Diffusion

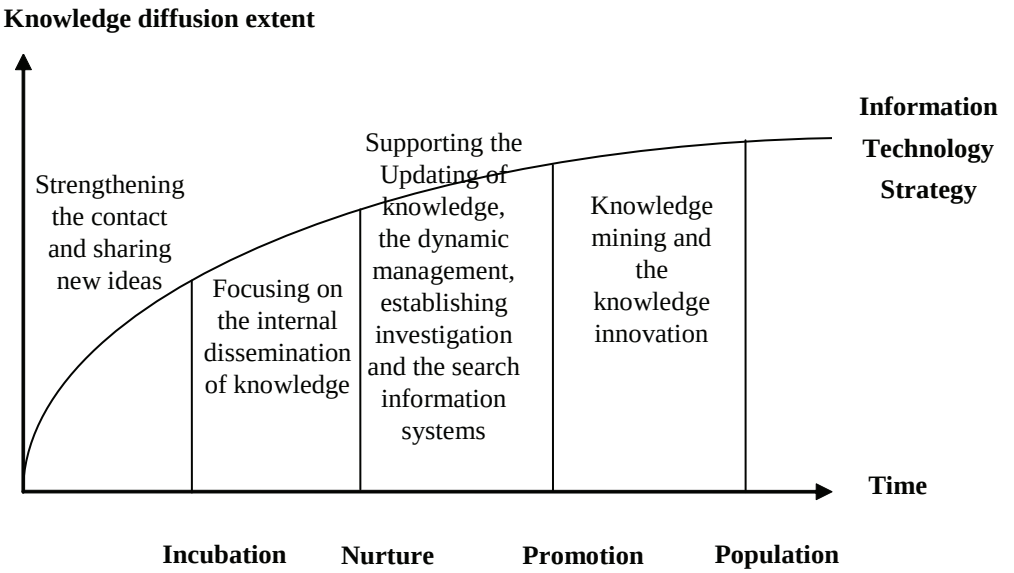
According to the extent of knowledge diffusion, the lifecycle of knowledge diffusion will be divided into four stages, including incubation, nurture, promotion, and popularization. Based on the literature, this article mainly explains how to integrate information technology with knowledge diffusion effectively in the four stages of the knowledge diffusion lifecycle.

The article provides a framework in which the knowledge diffusion lifecycle can be represented from an IT perspective, as Figure 1 shows (Lang & Yuan, 2004). Different IT strategies can be matched with the different sections of knowledge development.

Firstly, in the knowledge incubation stage, the information technology strategy emphasizes the strengthening of the contact and sharing new ideas. The knowledge incubation stage is the process of the generation of knowledge. The knowledge transforms into structural knowledge and was integrated into the knowledge resources of the company.

As stated above, knowledge capture and formalization is a critical process. This knowledge becomes an intellectual asset for the organization, owned by the shareholders in theory. It also becomes a tool for others to use, with a shorter learning time than would otherwise be the case. Perhaps more importantly, it can encapsulate best practice as a standard process for the organization. In this phase, new knowledge is still in a state of non-clarity: knowledge encoding and storage systems do not have much value. So strengthening the contact and the sharing of these new viewpoints and ideas, information systems play a very important role. The Linux system succeeds in providing a platform for exchange for everyone talking about the system, so that the system's various ideas and viewpoints on the platform by in-depth discussions can be further discussed and improved.

Figure 1. Information technology strategy in the knowledge diffusion lifecycle



Current practice for knowledge incubation seems to vary, depending on the circumstances. For problem solving, it has been suggested that discussion-capturing software agents is an appropriate methodology (Conklin, 1996). Software agents for assessing, selecting, and accumulating knowledge have appeared as good tools.

Secondly, in the knowledge nurture stage, the organization tries to gain the interests from the knowledge, so the information technology strategies focus on the internal dissemination of knowledge.

As in the knowledge incubation stage, information technology systems equally focused on the internal knowledge and information dissemination. To achieve this goal, establishing a detailed database is very important. Organizations also need to establish an online area in the existing internal network to exchange ideas and expertise. What is clear form for those companies who are regarded as leaders in this field, to incubate the knowledge is a non-trivial process. The mere provision of access to formal knowledge by wide distribution of books, software agent applications, and so on does not ensure that the knowledge will be understood, absorbed, and utilized. Each of these steps requires a process and maintenance of the process. Two highly regarded texts are those by Eason (1988) on the implementation of change and Humphrey (1989) on capability maturity models of processes, which includes the management of their lifecycles.

To ensure that new knowledge is error free, that includes a context to provide the knowledge with meaning and the conditions under which it can be used. Moreover, creating an organizational environment where accumulation and use of knowledge is in people's best interest. The use of performance assessment and the redesign of jobs are very important. Structuring workgroups is also conducive to innovative performance. This implies the autonomy for workgroups, with a clear target, sufficient resources, and the development of a commitment for the organization's goals. None of these is easy to achieve, but they are essential for motivating the new knowledge and new style of working.

Thirdly, in the knowledge promotion stage, organizations will grab interests by the spreading of knowledge. Therefore, information technology systems must support the updating of knowledge, the dynamic management, the establishment of an effective investigation, and the search information systems. Knowledge database plays an important role in the promotion of a universal stage. Knowledge coding and standardization in the organization enable it to open to the public, and it is easy for competitors to copy. The competitive advantage will come from the extent to which the information is easy to access and the extent of the quality previously made, rather than hide the knowledge.

Finally, in the knowledge popularization stage, the effective utility of the information technology in the knowledge

mining and the knowledge innovation are the most essential strategies. To popularize the knowledge that has already been popularized, it is very important to update the knowledge. Organizations must maintain the dynamic management on the original content of the document, increase new information in accordance with the applicable principles, and make the document files so they no longer change. With the passage of time, there will be a lot of documents on this knowledge published, thus the establishment of an effective investigation and search system in the literacy stage is also essential.

In this stage, an alternative approach is to provide the knowledge within a context, so that potential users can gauge for themselves the usefulness or otherwise of the knowledge (for example, when created and for what purpose, when used and for what purpose, amendments and why, and so on). More than this might be required, for example, many design ideas that are discarded for one reason or another may well contain knowledge about components that are worth keeping for future use. A particular instance of this concerns a revolutionary design in the late 1980s for fuel-injection systems, wherein an obsolete design from another company in the 1930s proved to have within it a key chunk of knowledge that overcame a severe design limitation and enabled the new design to work. In this particular instance, the retrieval from the archives happened because the designer was old enough to have been in the company when the obsolete design was still in use, and an evaluative analysis had been performed on it.

The lifecycle of knowledge diffusion can help enterprises develop each stage of knowledge diffusion and the strategic management of knowledge. From the perspective of the lifecycle, the enterprise managers could understand clearly which stage the enterprises are in. Then, the enterprises could find a balance between the storing of the knowledge and the sharing of knowledge, but they should also realize that in any case the efforts cannot avoid the possibility that the knowledge created is eroded with the passage of time. Finally, enterprises should focus on the characteristics of the knowledge in the different stages of the lifecycle, making good use of information technologies to transform the new ideas into concrete products and services, and acquire more benefits from the current stage of development of their own technology and knowledge management strategy.

FUTURE TRENDS

As stated above, the combination between the knowledge diffusion lifecycle and information technology provides us with an innovative way to implement the matched information technology strategies in the four different stages of the knowledge diffusion lifecycle. The information technology strategy supports the process of knowledge diffusion simultaneously. Especially in the knowledge economy, more organizations will become knowledge based. Knowledge diffusion may become an important process of knowledge management. Combining the information technology strategies with the corporate strategies may enhance competitiveness of enterprises greatly. Thus, the integration of the information technology strategy and the other strategy of the enterprises, such as the research and development strategy, will establish a more effective knowledge management model.

Moreover, more information technologies that have been expressly designed with knowledge management will be available in the future. The design and application of knowledge-oriented information technology provided the focus for the conference on Practical Applications of Knowledge Management held in October 1996 in Basel, Switzerland. Borghoff and Pareschi (1997) selected several contributions related to technologies supporting various types of organizational knowledge during different phases of its lifecycle—for example, a workgroup system, an experimental workflow management system in the process management of knowledge, a full-fledged knowledge engineering approach suitable for building corporate memories, the intelligent filtering system, and so on. Those information technologies were developed for process management, cooperate memories, and information filtering in knowledge management. All of these information technologies provide the guidance for the application of them into the knowledge diffusion process. More specific information technologies should be researched and developed in the future.

CONCLUSION

Based on the knowledge lifecycle theory, this article introduces effective information technology management strategies in the four stages of the knowledge diffusion lifecycle. Fundamentally, knowledge diffusion is part of the knowledge sharing process, realizing the proliferation of knowledge and information among different individuals across time and space. According to the extent of knowledge diffusion, the lifecycle of knowledge will be divided into four stages, including incubation, nurture, promotion, and popularization. Combing with the literature, this article mainly explains how to integrate the information technology with the knowledge diffusion effectively in the four stages of the lifecycle. Firstly, in the knowledge incubator stage, the information technology strategy focuses on strengthening the contact and sharing new ideas. Secondly, in the knowledge development stage, the organization tries to gain the interests from the knowledge, so the information technology strategies focus on the internal dissemination of knowledge. Thirdly, in the knowledge promotion stage, organizations will grab interests by the spreading of knowledge. Therefore, information technology systems must support the updating of knowledge, dynamic management, the establishment of

an effective investigation, and the searching of information systems. Finally, in the knowledge popularization stage, the effective utility of information technology in knowledge mining and knowledge innovation are the most essential strategies.

In conclusion, based on the knowledge diffusion lifecycle, this article makes detailed explanations on the information technology strategy of knowledge diffusion at different stages. This research will enlighten the implementation of an information technology strategy in knowledge diffusion and promote the development of the society in fierce knowledge competition.

KEY TERMS

Information: Knowledge that can be transmitted without loss of integrity once the syntactical rules required for deciphering it are known (Nonaka, 1994).

Information Technology Economy: The economy based on the production, assignment, and application of information technology (Varian et al., 2004).

Information Technology Strategy: The information technology applications used to help the organization gain a competitive advantage, reduce competitive disadvantage, or meet other strategic enterprise objectives (Bergeron et al., 1991).

Knowledge: Information whose validity has been established through a test of proof and can therefore be distinguished from opinion, speculation, beliefs, or other types of unproven information (Liebeskind et al., 1996). This definition of knowledge consists of two primary classifications: information (explicit knowledge) and know-how (tacit knowledge) (Nonaka, 1991). Knowledge in this article refers to explicit knowledge.

Knowledge Diffusion: The adaptations and applications of knowledge documented in scientific publications and patents (Crane, 1972).

Knowledge Diffusion Lifecycle: According to the extent of knowledge diffusion, the knowledge diffusion lifecycle can be divided into four stages, including incubation, nurture, promotion, and popularization (Lang & Yuan, 2004).

Knowledge Economy: The economy based on the production, assignment, and application of knowledge. Knowledge is the key economic asset that drives long-run economic performance (Dunning, 2000).

Knowledge Lifecycle: Knowledge is not a unitary thing, and in a competitive environment it has a lifecycle. There are four different phases of the knowledge lifecycle—socialization, internalization, externalization, and combination (Nonaka & Takeuchi, 1995).

Knowledge Lifecycle Management: The management of the environment that makes knowledge flow through all the different phases of its lifecycle (Borghoff & Pareschi, 1997).

Knowledge Management: The management activities of creating, acquiring, interpreting, retaining, and transferring knowledge to improve performance by purposefully modifying behavior based on new knowledge (Borghoff & Pareschi, 1997).

Inheritance in Programming Languages

Krishnaprasad Thirunarayan
Wright State University, USA

INTRODUCTION

Inheritance is a powerful concept employed in computer science, especially in artificial intelligence (AI), object-oriented programming (OOP), and object-oriented databases (OODB). In the field of AI, inheritance has been primarily used as a concise and effective means of representing and reasoning with common-sense knowledge (Thirunarayan, 1995). In programming languages and databases, inheritance has been used for the purpose of sharing data and methods, and for enabling modularity of software (re)use and maintenance (Lakshmanan & Thirunarayan, 1998). In this chapter, we present various design choices for incorporating inheritance into programming languages from an application programmer's perspective. In contrast with the language of mathematics, which is mature and well-understood, the embodiment of object-oriented concepts and constructs in a concrete programming language is neither fixed nor universally accepted. We exhibit programs with similar syntax in different languages that have very different semantics, and different looking programs that are equivalent. We compare and contrast method inheritance, interaction of type system with method binding, constructs for method redefinition, and their implementation in widely used languages such as C++ (Stroustrup, 1997), Java (Arnold, Gosling, & Holmes, 2005), and C# (Hejlsberg, Wiltamuth, & Golde, 2006), to illustrate subtle issues of interest to programmers. Finally, we discuss multiple inheritance briefly.

BACKGROUND

SIMULA introduced the concepts of *object*, *class*, *inheritance*, and *polymorphism* for describing discrete event simulations (Meyer, 1999). Subsequently, object-oriented programming languages such as Smalltalk, C++, Object Pascal., and so forth used these concepts for general purpose programming (Budd, 2002).

Object/Instance is a run-time structure with state and behavior. Object state is stored in its fields (variables) and behavior as its methods (functions). *Class* is a static description of objects. (In practice, a class itself can appear as a run-time structure manipulated using reflection APIs such as in Java, C#, CLOS, and so forth.) A class defines type of each field and code for each method, which inspects and/or transforms field values. (By field we mean *instance* field, and by method we mean *instance* method. The discussion of static fields and static methods, and access control primitives such as private, protected, and private, are beyond the scope of this chapter.) *Inheritance* is a binary relation between classes (say P and Q) that enables one to define a class (Q) in terms of another class (P) *incrementally,* by adding new fields, adding new methods, or modifying existing methods through overriding. A class Q is a *subclass* of class P if class Q inherits from class P.

```
class P {
      int i;
      int f() { return 2;}
      int f1() { return f() + i;}
      void g() {}
}
class Q extends P {
      int j;
      int f() { return 4;}
      int h() { return i + j;}
}
class Main {
      public static void main(String [] args) {
            Q q = new Q();
            P p = q;
            p.f1();
      }
}
```

Every P-object has an int field i, and methods f(), f1() and g() defined on it. Every Q-object has int fields i and j, and methods f(), f1(), g() and h() defined on it. Q inherits i, f1(), and g() from P, and overrides f() from P.

The variable q of type Q holds a reference to a Q-instance (an object of class Q) created in response to the constructor invocation 'new Q()' (Gosling, Joy, Steele, & Bracha, 2002). The variable p holds a reference to the same Q-instance as variable q (*dynamic aliasing*) through the *polymorphic assignment* 'p = q.' In general., *polymorphism* is the ability of a variable of type T to hold a reference to an instance of class T and its subclasses. The method f1() can be invoked on the variable p because it is of type P and f1() is defined in class P. The method f1() can be successfully invoked on a Q-instance due to method inheritance. *For a subclass to be able to reuse separately compiled method binaries in the ancestor class, the layout of the subclass instances should coincide with the layout of the ancestor instances on com-*

mon fields. The body of f1() invokes f() defined in class Q on a Q-instance referred to by variable p through *dynamic binding.* In other words, it runs the code associated with the object's class Q rather than the variable's type P. *For the method calls compiled into the ancestor's method binaries to be dynamically bound, the index of the method pointers in the ancestor method table and the descendent method table should coincide on the common methods.*

The implementation technique for reusing parent method binaries in a straightforward way works for languages with only single inheritance of classes. A language supports *multiple inheritance* if a class can have multiple parents. The implementation of multiple inheritance that can reuse separately compiled parent method binaries requires sophisticated manipulation of object reference (self/this pointer adjustment) (Stroustrup, 2002, Chapter 15), or hash table based approach (Appel, 2002, Chapter 14), in general.

Object-oriented paradigm and imperative/procedural paradigm can be viewed as two orthogonal ways of organizing heterogeneous data types (data and functions) sharing common behavior. The relative benefits and short comings of the two paradigms can be understood by considering the impact of adding new functionality and new data type. Procedural paradigm incorporates new functions incrementally while it requires major recompilation to accommodate new data types. In contrast, the object-oriented paradigm assimilates new data types smoothly but requires special *Visitor* design pattern to deal with procedure updates. Another significant advantage of object-oriented paradigm is its use of *interface* to decouple clients and servers. Wirth (1988) elucidates type extension that bridges procedural languages such as Pascal to object-oriented languages such as Modula-3 via the intermediate languages such as Modula and Oberon.

COMPARISON OF METHOD INHERITANCE IN C++, JAVA, AND C#

In this section, we discuss subtle issues associated with method inheritance in programming languages using examples from C++, Java and C#.

Single Inheritance and Method Binding in C++ vs Java

Consider a simple class hierarchy consisting of Rectangle, ColoredRectangle, and Square, coded in Java. The state of the instance is formalized in terms of its width and its height, and stored in int fields w and h. The behavior is formalized using perimeter() method which is *defined in* Rectangle, *inherited by* ColoredRectangle, and *redefined/overridden in* Square (let us say for efficiency!).

```
class Rectangle {
    int w, h;
    int perimeter() { return (2*(w+h)); }
}
class ColoredRectangle extends Rectangle {
    int c;
}
class Square extends Rectangle {
    int perimeter() { return (4*w); }
}
class OOPEg {
    public static void main (String[] args) {
        Rectangle [] rs = { new Rectangle(),
            new ColoredRectangle(), new Square()};
        for (int i = 0 ; i < rs.length ; i++ )
            System.out.println( rs[i].perimeter() );
    }
}
```

The array of rectangles is a polymorphic data structure that holds instances that are at least a Rectangle. The for-loop invokes the "correct" perimeter-method on the instance referred to by the polymorphic reference rs[i] through run-time binding of the call rs[i].perimeter() to the method code based on the class of the instance referred to by rs[i] (dynamic type of rs[i]) rather than the declared type of rs[i] (static type of rs[i]).

This code can be minimally massaged into a legal C++ program. (Note that perimeter is explicitly prefixed with keyword *virtual* in C++. #include's have been omitted.)

```
class Rectangle {
    protected int w, h;
    public virtual int perimeter() { return (2*(w+h)); }
}
class ColoredRectangle : public Rectangle {
    private int c;
}
class Square extends Rectangle {
    public int perimeter() { return (4*w); }
}

void main (char* argv, int argc) {
        Rectangle rs [3] = { Rectangle(),
            ColoredRectangle(),  Square()} ;
        for (int i = 0 ; i < RSLEN ; i++ )
            cout << rs[i].perimeter() << endl;
}
```

The main(…)-procedure in C++ resembles the corresponding main()-method in Java syntactically, but they are very different semantically. The array of Rectangle is a homogeneous structure with each element naming a Rectangle instance. The initialization assignments cause the common fields to be copied and the additional subclass instance fields to be ignored (projection). In other words, there is no polymorphism involved. Similarly, the call rs[i].

perimeter is *statically* bound and invokes the code in class Rectangle on a "direct" instance of Rectangle.

The driver code can be modified into another C++ program that is *equivalent* to the Java program given earlier using pointers and dereferencing operator.

```
void main (char* argv, int argc) {
      Rectangle* rs [3] = { new Rectangle(),
            new ColoredRectangle(), new Square()} ;
      for (int i = 0 ; i < RSLEN ; i++ )
            cout << rs[i]->perimeter() << endl;
}
```

The array of Rectangle is a homogeneous structure of polymorphic references with each element holding a reference to a (possibly indirect) Rectangle instance. The initialization assignments cause the array to hold references to three instances : a Rectangle, a ColoredRectangle and a Square. Similarly, the call rs[i]->perimeter is dynamically bound. In other words, for the ColoredRectangle instance, it runs the inherited code from class Rectangle, while for the Square instance, it runs the redefined/overriding code from class Square.

Java uses dynamic binding of methods as the default, while C++ uses static binding of methods as the default. To specify dynamic binding in C++, an explicit keyword *virtual* is necessary in front of the original overridden method definition.

Method Redefinition in Java and C#

C# resembles C++ and differs from Java in that dynamic binding of methods is not the default. To override a method, the overriding method signature must not only match the overridden method's signature, but it must also contain the keyword *override*. It is also possible to support a new subclass method that matches the parent method's signature but is logically distinct from it using the keyword *new*, instead of *override*. The rationale for this design decision is to achieve robustness in the context of code evolution in the face of changes to the parent class methods.

Consider the following C# class definitions.

```
class Parent {…}
class Child : Parent {   public virtual void m(){…} }
```

A subsequent update to the parent class with a new definition of the method m() as shown below goes undetected in Java, while C# throws an error.

```
class Parent {  public virtual void m(){…}  }
```

In C#, the programmer can state that the method m() in the subclass child is related to the method m() in the class parent by changing the former using the keyword *override* or proclaiming their independence using the keyword *new*.

```
class Child : Parent {public virtual override void m(){…}}

class Child : Parent {public virtual new void m(){…}}
```

Method Overriding in C++ and Java

A method defined in a class is guaranteed to be available in all descendant subclasses in Java (signature-based subtyping). A subclass may either inherit the method code from the ancestor or override it. In contrast, this claim does not hold in C++.

The following Java code compiles without any error. Both child and grandchild instances have two methods defined on them: one with signature m(int) and another with signature m(int, boolean).

```
class Parent { void m(int i) {  } }
class Child extends Parent { void m(int i, boolean b) {  } }
class GrandChild extends Child { void m(int i, boolean b)
{  } }
class Overload {
      public static void main(String[] args) {
            Child c = new Child();
            GrandChild gc = new GrandChild();
            c.m(5,true);                  c.m(6));
            gc.m(1,false);                gc.m(2));
}}
```

On the contrary, the following C++ code compiles with two errors. Both child and grandchild instances have only one method defined on them, and its signature is m(int, boolean). The method with signature m(int) is defined only for direct instances of Parent, and is not defined for child and grandchild instances.

```
class Parent {
      public:     void m(int i) {  }
};
class Child : public Parent {
      public:     void m(int i, bool b) {   }
};
class GrandChild : public Child {
      public:     void m(int i, bool b) {   }
};

int main() {
      Child* c = new Child();
      GrandChild* gc = new GrandChild();
      c->method(5,true);      c->method(6);      // ErRoR
      gc->method(1,false);    gc->method(2);     // ErRoR
}
```

The reason for this discrepancy can be traced to the way the method calls are resolved in C++ and Java. In C++, the

method name is searched starting from the class in which the method call appears, up the class hierarchy. The search stops at the first class that contains a definition of the method name m. Subsequently, C++ tries to match the entire signature of the method call m(…) using all the explicitly given overloaded definitions of m(…) in the "matched" class. If a method matching the method call signature is found, the search stops with success. Otherwise, C++ gives a compile-time error. In contrast, Java continues its search all the way to the root of the tree-structured class hierarchy to find a method that matches the method call signature. Effectively, in Java, if a method m(…) is defined in a class, it is also defined on all instances of its descendant subclasses.

INTERACTION OF TYPE SYSTEM WITH METHOD INHERITANCE IN JAVA AND C#

A method call in Java and C# is processed in two steps: The signature of the method to be called is fixed at compile-time, while the method definition to be invoked for a method call is determined at run-time. The static determination of method signature uses type coercion rules.

Consider the following Java class definitions and the driver program illustrating a variety of method calls. There is only one method in class P, while there are two methods in class C. The method f(P) defined in class P has been redefined in class C.

```
class P {
   public void f(P p) {   }
}
class C extends P {
   public void f(P p) {   }
   public void f(C cp) {   }
}

class Calls {
   public static void
      main(String[] args) {
         P pp = new P();   C cc = new C();   P pc = cc;
         pp.f(pp); pp.f(cc); pc.f(pp); pc.f(cc)  cc.f(pp); cc.f(cc);
   }
}
```

To process the call objExp.meth(arg), the compiler determines the static type of objExp, say T, and searches for a definition of meth compatible with the argument arg in the associated class T. The compiler freezes the signature of the method call at this stage. At run-time, the method code is chosen using the frozen signature in the class associated with the run-time object that objExpr evaluates to. For the call pp.f(pp), the frozen signature is f(P) and method run is the one defined in class P. For the call pp.f(cc), the frozen signature remains f(P), because the compiler searches for the definition of f(…) in class P, yielding the unique signature f(P), which is admissible as cc's type C is compatible with class P (coercion). The method run is the one defined in class P because pp refers to a P-instance. For the calls pc.f(pp) and pc.f(cc), the frozen signature remains f(P), but the method run is the one defined in class C because pc refers to a C-instance (dynamic binding). For the calls cc.f(pp) and cc.f(cc), the frozen signature is f(P) and f(C) respectively determined by searching class C, the declared type of cc, for a method signature match. (See Table 1)

Table 1.

Call	Compile-time Signature	Run-time Code
pp.f(pp)	f(P) in P	f(P) in P
pp.f(cc)	f(P) in P	f(P) in P
pc.f(pp)	f(P) in P	f(P) in C
pc.f(cc)	f(P) in P	f(P) in C
cc.f(pp)	f(P) in C	f(P) in C
cc.f(cc)	f(C) in C	f(C) in C

Compilation and Interpretation of C++, Java and C#

C++ programs (*.h and *.cc files) are separately compiled into assembly language to yield object code (*.o files). These are statically or dynamically linked with library routines to obtain the executables (*.exe or a.out files) that are ready to run.

Java compiler translates source programs into machine independent Java byte code. Java 1.0 run-time for a specific platform (hardware/operating system combination) interprets Java byte code by repeatedly converting each instruction into machine code for the platform and then running it. Execution of loops could be improved by factoring out the translation of byte code into machine code and caching it first-time around the loop. This led to Java 1.1 that improves the execution efficiency by *just-in-time* compilation of the entire Java byte code program into platform-specific (native) code before running it. Subsequently, this approach was observed to cause slow start-up because of wasteful dynamic compilation of rarely used byte code segments. The Hotspot virtual machine introduced with Java 2.0 begins as an interpreter, and through profiling determines frequently executed code segments (hotspots). Subsequently, it selectively just-in-time compiles only the "hotspots." This reduces the start-up time and improves the behavior of long-running server programs.

C# sources are compiled into Microsoft intermediate language (MSIL). At run-time, the MSIL code is just-in-

time compiled and executed using Common Language Runtime (CLR).

In relation to object-oriented programming, it is possible to replace dynamically bound calls to the *final* methods (methods that cannot be overridden), or to methods in the terminal classes, by static binding. Hotspot virtual machine goes further in aggressively inlining small method bodies, and statically bound calls. Due to potential dynamic class loading, Hotspot virtual machine can reverse its inlining decisions if newly loaded classes extend the existing class hierarchy.

Another major aspect of modern object-oriented language run-time is the garbage collection. Refer to (Venners, 2000) for lucid details on Java virtual machine in particular and garbage collection in general.

MULTIPLE INHERITANCE

Even though the software engineering benefits of multiple inheritance are abundantly clear, the incorporation of multiple inheritance into concrete programming language is fraught with significant complexity. Essentially, undesirable problems sneak in when accommodating good examples. Thus, there is no consensus among researchers on the semantics of multiple inheritance in the presence of method overriding and potential conflicts due to multiple definitions (Meyer, 1997).

Thirunarayan et al. (2001) reviews the approach taken in C++, Java, and Eiffel, and explores the patterns and the idioms used by the Java designers and programmers to redeem the advantages of multiple inheritance. The chapter also discusses an alternative to multiple inheritance using constructs for type-safe automatic forwarding.

FUTURE TRENDS

The systems programming languages such as SmallTalk, Common LISP, C++, Java, C#, and so forth provide the necessary infrastructure for building large applications, with efficiency of execution as an important goal. With the advent of the Internet and the WWW, there has been a sudden surge of scripting languages such as TCL/TK, PERL, Python, Ruby, Visual Basic, JavaScript, PHP, and so forth that are primarily designed for gluing applications quickly, with programming flexibility as an important goal (Ousterhout, 1998). Several scripting languages support advanced object-oriented programming features including multiple inheritance, prototypes and delegation, run-time addition of members to instances, meta-programming and reflection, and so froth. We expect future programming languages to support features that enhance programmer productivity through code reuse, program reliability through strong typing and exception facility, rich functionality through domain-specific APIs, program efficiency through dynamic optimization, and ease of use through GUI.

CONCLUSION

We selectively reviewed the basics of object-oriented programming language features and illustrated the subtleties associated with the inheritance of instance methods in widely used systems programming languages such as C++, Java and C#. For example, we explained the superiority of Java's signature-based method inheritance over C++'s use of method name-based search, C# rationale of versioning robustness for deviating from Java's instance method inheritance, and clarified Java and C#'s implementation of instance method binding using statically computed method signature and dynamically determined method definition. Overall, C++ comes across as feature-rich with lot of legacy applications, while Java and C# come across as cleaner designs for developing new applications.

In future, we expect the scripting languages popularized by improved hardware resources, and demanded by rapidly evolving, distributed and heterogeneous WWW, to support object-oriented programming features to improve programmer productivity, program reliability, functionality and ease of use.

KEY TERMS

Class: A static description of objects. It defines types for fields and code for methods.

Multiple Inheritance: A language supports multiple inheritance if a class can have multiple parents.

Object: A run-time structure with state and behavior. Object state is stored in its fields (variables) and behavior as its methods (functions).

Static/Dynamic Binding: Binding is the association of method code to a method call. Binding carried out at compile-time is called static binding, while the binding carried out at run-time is called dynamic binding.

Strong/Static/Dynamic Typing: A strongly typed language guarantees that in a program all the operations are applied to operands of compatible type, and any type violation is flagged by the language implementation. A statically typed language makes such guarantees by compile-time analysis of a program. A dynamically typed language makes such guarantees using run-time checks. Modern object-oriented languages such as Java and C# are strongly typed and straddle the two extremes, by checking type constraints statically as much as possible, and generating code for performing additional type constraints at run-time in situations where those checks are data dependent.

Subclass (Inheritance): Inheritance is a binary relation between classes that enables one to define a class in terms of another class incrementally, by adding new fields, adding new methods, or modifying existing methods through overriding. A class Q is a subclass of class P if class Q inherits from class P.

Subtype (Polymorphism): A class Q is a subtype of a class P if an instance of Q can be used where an instance of P is required. A variable is said to be polymorphic if it can hold a reference to objects of different forms. Typically, a variable of type P can hold a reference to an instance of a subclass of class P.

Innovation Generation and Innovation Adoption

Davood Askarany
The University of Auckland, New Zealand

INTRODUCTION

The growing level of global competition is forcing organizations to make dramatic change and improvements in order to compete, prosper, and survive (Kotter, 1996). During the past three decades, the world has witnessed some spectacular changes that have provided a totally new environment for organizations. These changes include technological and administrative innovations that organizations are dealing with in different areas of their operations such as manufacturing process, operation technologies, and information systems (Shields, 1997). It can be argued that the growing level of global competition has lead to the adoption of technological evolution, which may also require the adoption of complementary administrative innovation (e.g., Baines & Langfield-Smith 2003). Given this information, to keep pace with other competitors in the global market, the adoption and the diffusion of latest ideas, techniques, practices, and processes has become a key factor for success in organizations. Therefore, this places a greater emphasis on the innovation generation and innovation adoption in organizations in order to compete, prosper, and survive.

BACKGROUND

According to diffusion theory (Rogers, 2003), we may expect that innovation generation and innovation adoption do not simply emerge and develop full-blown. Some groups of people, some places, or some organizations may have immediate access to the innovation; some may access it later, and some may never access it. As Schumpeter (1934) remarked, an innovation and its diffusion are part of a larger pattern of social, political, and economic activity. Therefore, it is expected that innovation generation and innovation adoption be influenced by a variety of factors.

Mansfield (1961) suggested that innovation adoption is a function of the degree of uncertainty associated with the innovation, the amount of investment required to adopt the innovation, and the extent of economic advantage of the innovation. Other researchers, including Brown (1981) and Robinson and Lakhani (1975), proposed a supply and demand rationale for the explanation of innovation generation and innovation adoption. Obviously, Mansfield's (1961) suggested factors for innovation adoption could be included in such a supply and demand concept. Brown (1981) explained that the market and infrastructure factors provide the supply side of innovation adoption and shape its course. He further emphasized that the central element of a supply framework is the diffusion agency.

Clark (1984) believes that the demand approach in the process of innovation generation and innovation adoption is more diverse and more extensive. It focuses on the adoption of innovations, which are available to everyone. He thinks the supply approach is dealing with cases where the innovation is not universally available due to the fact that the supply is under control. In other words, when every potential adopter of an innovation does not have equal access to an innovation, the supply factor might be considered as an important influencing factor in the diffusion process of that innovation.

The learning perspective has been introduced as another factor affecting the innovation generation and innovation adoption (Sahal, 1981). Expanding the scope of influencing factors, Hagerstrand (1967) proposed an information transfer explanation as another factor influencing the innovation generation and innovation adoption. Other researchers like Sharif and Kabir (1976) considered the diffusion of an innovation as a replacement process and claimed that the dynamics of this replacement process account for the diffusion rate during the diffusion period. However, in some cases, an innovation might be an addition to an employed technique or an ongoing capacity and not a complete replacement.

Surprisingly, continuity of the innovation progress (as an influential factor) is suggested as having a negative impact on the diffusion of an innovation. Brown (1981, p. 158) confirms that "deliberation and slowness in the adoption decision is encouraged by the continuity of the innovation process which results in many improvements during the course of diffusion." Rosenberg (1976) also confirms that there is often a delay in adoption because of the expectation of future improvements in the innovation. He emphasizes that the expectation of continued improvement might lead to a slowing down in the rate of diffusion of an innovation.

Røvik (1996) introduces "fashion" as an influencing factor, which could play an import role in the diffusion process of an innovation. He argues that the process of diffusion of innovation follows selective perception, which adjusts to the social environment and copes with what is in fashion

and what is out of fashion and usually certain innovations are chosen that seem to be more fashionable. According to Røvik (1996), "fashion" is a human-made and dynamic phenomenon that spreads by drawing attention to it. Fashion can present itself in many ways: as ideas, social organizing, specific structures and processes in organizations, and so forth. Røvik refers to fashion as an institutionalized standard for implementing new ideas, change/innovation in order to organize successfully, be up-to-date, and efficient. According to Røvik (1996, p. 159), fashion also refers to the notion that organizations are torn between "signalling a common identity and belonging to a group of organisations" and "the motive of distinguishing themselves from the other organisations and attracting attention." From this perspective, fashionable idea and innovations/changes spread by imitation, but, after a while they will be so common that some organizations may wish to demonstrate their uniqueness by developing new ideas (innovation generation) or implementing new innovations (innovation adoption), which in turn become fashionable, and so the process starts all over again.

Kanter, Barry, and Todd (1992) stress that executive sponsorship, participation, coalition building, and change agents are critical to the success of change initiatives in the process of implementing organizational change. Change agents should identify and involve opinion leaders, decision-makers on resources, functional experts, and other important persons as early as possible in the project-planning phase. They further emphasize the importance of the involvement of the people in successful implementation of changes in organizations. They suggest that all members of the change team and other employees affected by the change must not feel like as if they are just the tools for change or the subject of change; rather they should be given the chance to become actively involved, to contribute their own experiences. Every employee should feel that his/her contribution to the change process in organizations is important and valued. Thus, people will develop a sense of responsibility and ownership regarding the process of changes, which, in turn may serve as a major source of motivation to facilitate the process of such change(s) in organizations.

Most of contextual factors addressed in the diffusion literature are consistent with other theories in relation to innovation/change such as institutional, contingency, cognition, and expectancy theories. For instance, the influence of institution on diffusion of innovation addressed in diffusion literature (Rogers, 2003) supports DiMaggio and Powell's (1991) suggestion that the power of institutions may play an important role in the diffusion process of innovation. DiMaggio and Powell (1991) see the influence of institutions in almost every aspect of human life, from the way people eat to the way they shake hands and engage in conversation. According to DiMaggio and Powell (1991), institutions can be habits and social protocols right through to cultural templates and frames of meaning that define what is expected and what is regarded as "rational" or appropriate in a given situation.

Resistance to change has been mentioned by Brown (1981) as another factor, which might result in lags in the use of innovation or a slow rate of diffusion. He also refers to the development of technical skills among users as another influencing factor, which is expected to facilitate the diffusion of an innovation. Another factor influencing the rate of diffusion of an innovation is said to be profitability. Linstone and Sahal (1976) propose that the more profitable the innovation and the smaller the required investment, the greater the rate of diffusion. Profitability of an innovation can be interpreted as cost saving, relative advantage, or cost effectiveness of that innovation. Competition is said to be another factor influencing the diffusion rate of an innovation. Parker (1974) states that some of the early adoption takes place because certain firms wish to gain an advantage over their competitors. Then later adopters follow the adoption either to remain competitive or to take advantage of the innovation.

Innovation generation or innovation adoption is also expected to be affected by the characteristics of the innovation. Rogers (2003) has identified five aspects of an innovation, which affect its rate of diffusion in a population to whom the innovation is relevant. He argues that the high rate of diffusion of an innovation would be a feature of its "relative advantage" over the current practice, its "compatibility" with other aspects of the culture, its "complexity" of understanding, its "trialability" to experience, and its "observability" to see the results.

Despite Rogers (2003), Goss (1979) and Gotsch (1972) argued that there should be less stress on the role of innovation itself (characteristics of innovation) and more on the spatially variable character of society into which innovation is introduced. They believed that the diffusion rate of an innovation depends less on the nature of innovation than on the type of society existing before the innovation, while Rogers (2003) believes that the level of diffusion of an innovation depends more on its characteristics than any other influencing factors.

Yapa and Mayfield (1976) indicates that the availability and distribution of resources or individual access to the means of production and public goods affect the innovation generation and innovation adoption. Examples of resources in this context would include capital, information, public goods or services such as electricity, transportation, water systems, network communications, and education.

Innovation generation or innovation adoption is expected to be influenced by the size of firms, too. In general, large firms have several advantages over smaller firms in terms of innovation generation and innovation adoption. Brown (1981) argued that one of the advantages of large firms is their greater ability to afford capital, to put up with the costs of innovation, and bear the risk of failure. Larger firms are

also capable of better affording managerial and technical specialists. However, he further confirmed that while this might be true for higher-cost demanding innovations, there is evidence that for lower-cost innovations, size might not be important. Also, it might be argued that diffusion of some kinds of innovations may be much easier in small firms than in large firms, as small firms are expected to have less bureaucratic systems.

With regard to the previous discussion, there are, however, some significant differences in the emphasis on the factors, which are introduced as influential factors on innovation generation and innovation adoption. Some suggested factors tend to give more attention to the characteristics of the innovation itself and of the adopting firms; whereas, some other suggested factors have tended to give relatively more emphasis to the society, economy, and communication or information flow process. According to contingency theory, it is difficult to generalize such preferences; depending on the type of societies and innovations, the importance and the influence of factors responsible for innovation generation and innovation adoption might change. Social concerns in some societies might give added importance to some innovations that might have otherwise not generated of diffused, and reduce the importance of other innovations. Furthermore, an innovation generation or innovation adoption might be associated with a specific social, economic, geographical, and institutional situation within which its generation and its diffusion are more likely.

Given the variation of influencing factors addressed in the literature, Askarany (2005) develops a diffusion model classifying all influencing factors into three main categories—characteristics of innovation, characteristics of adopters, and other social and environmental factors—and divides all innovations into two main groups: innovation generation and innovation adoption.

INNOVATION GENERATION AND INNOVATION ADOPTION MODEL

Rogers (2003, p. 12) defines an innovation as "an idea, practice, or object that is perceived as new by an individual or other unit of adoption." Further, he suggests that if the individual has no perceived knowledge about an idea and sees it as new, it is an innovation. Likewise, Damanpour and Gopalakrishnan (1998, p. 3) define innovation as "the adoption of an idea or behaviour new to the organisation." The common criterion in any definition of innovation is newness. According to Rogers (2003), newness in an innovation might be expressed not only in terms of new knowledge, but also in terms of first persuasion, or a decision to adopt. The second element that needs some clarification is diffusion. Wolfe (1994) explains diffusion of an innovation as a way the new ideas are accepted (or not) by those to whom they are relevant. Rogers (2003) extends this definition to consider diffusion as a process by which an innovation is communicated through certain channels over time among the members of a social system.

A clear understanding of the complexities of the innovation process and of alternative diffusion methods is central to any innovation diffusion study. Depending on the source of innovation, the diffusion of the innovation might follow different stages, so that alternative approaches and perspectives might be applicable under different innovation diffusion processes.

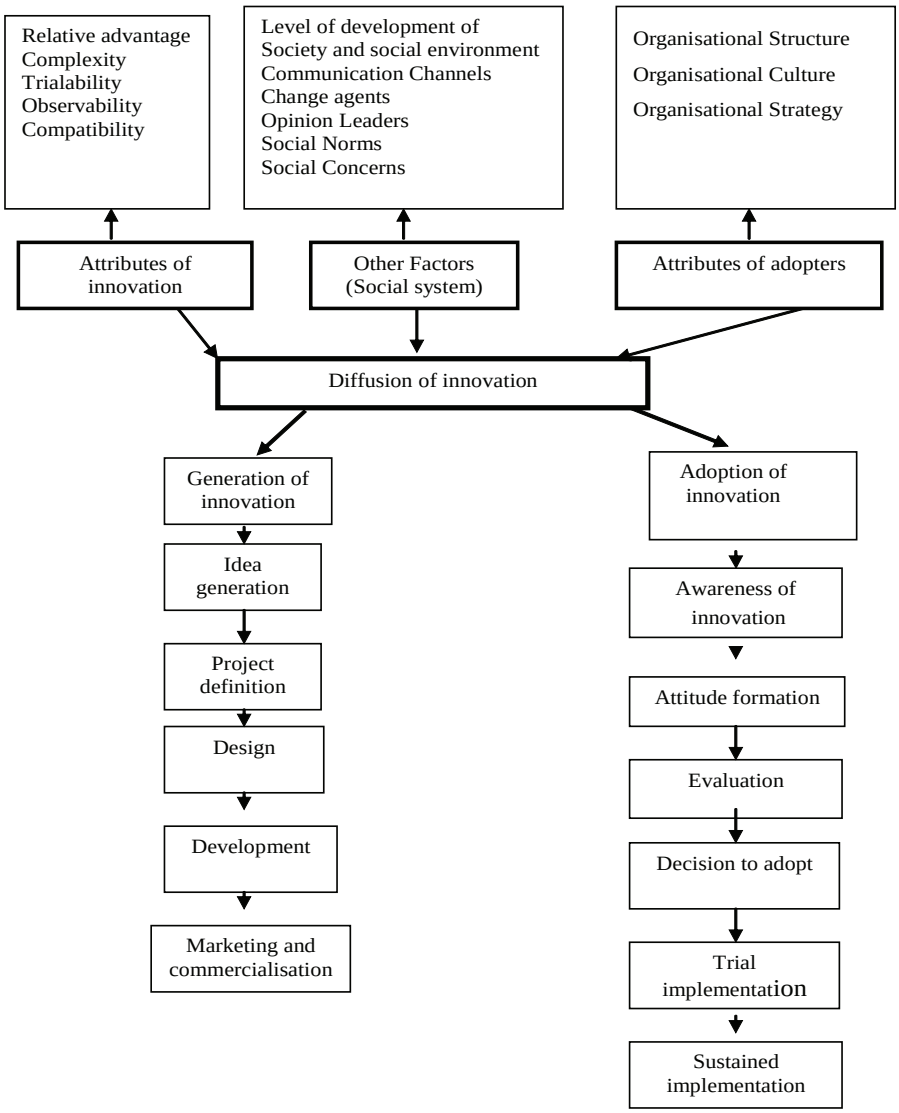
According to Damanpour and Gopalakrishnan (1998), diffusion of innovations in organizations takes place in two ways: generation and adoption. In the case of generation, innovations are generated by organizations for their own use or for export to other organizations. In the case of adoption, innovations are imported into the organization for adoption. The process of adoption of an innovation is a very long and difficult process, especially because many innovations need a long period of time to become widely adopted (Rogers, 2003). Rogers further emphasises that increasing the diffusion rate of an innovation is a common problem for potential adopters of that innovation.

The process of innovation diffusion is different when the innovation is generated by the organization; in this case, the main stages include idea generation, project definition, design, development, and marketing and commercialization (Cooper & Kleinchmidt, 1990). In the case of adoption of an innovation, which has been developed outside the organization, the stages will be awareness of innovation, attitude formation, evaluation, decision to adopt, trial implementation, and sustained implementation (Zaltman, Duncan, & Holbek, 1973). Furthermore, Wolfe (1994, p. 411) added that when innovation is generated in the organization, the stages "tend to be mulled and overlapping," while in the case of adoption the stages "tend to occur in the expected order." Depending on whether the innovation is generated within or adopted by an organization, two alternative general models can be formulated to describe the diffusion process.

Contributing to the diffusion of innovation literature, Rogers (2003) suggests that there are six phases for the diffusion of an innovation: recognition of a problem or need, basic and applied research, development, commercialization, diffusion and adoption, and consequences. Given this explanation, Rogers emphasises that these six phases are somehow arbitrary as they might not always occur in order, and some of them might be skipped in the case of particular innovations. An innovation development consists of all decisions and activities and their impacts, which occur during these phases. These suggested stages for innovation development are largely consistent with the generation approach of Damanpour and Gopalakrishnan (1998).

However, Zahra and Covin (1994) adopt a different perspective suggesting that there are three major sources

Figure 1. A general diffusion model



of innovation: imitative, acquisitive, and incubative. They define these three major sources of innovation as follows. Imitative sources are those innovations that are first introduced by other firms and then copied by organizations. Acquisitive sources also include those innovations that have been developed by other firms but are acquired through purchase, licensing, acquisition, or merger. Finally, incubative sources are those innovations that have been developed in organizations for their own use. This categorization is compatible with the generation and adoption approach of Damanpour and Gopalakrishnan (1998) in that "imitative innovations" and "acquisitive innovations" can be classified as "adopted" innovations and "incubative innovations" as "generated" ones.

From a process point of view, Rogers (2003) divides the innovation process in organizations into two sub-processes: an initiation process and an implementation process. The initiation process itself includes two stages: agenda setting and matching. These two stages involve all activities such as information gathering, conceptualizing, and planning for the adoption of an innovation. The implementation process includes three stages: redefining/restructuring, clarifying, and routinizing. These three stages contain all of the actions, events, and decisions involved in implementing an innovation. This classification is again consistent with the adoption method explained by Damanpour and Gopalakrishnan (1998).

Given the previous classification, Askarany (2005) suggests that the following general diffusion model (Figure 1) can be developed. This diffusion model is highly likely to be applicable to any diffusion study with minor modifications. Under this model, in general, what makes a diffusion research different from other diffusion research is the type or group of influencing factors and the nature of the diffusion process (innovation generation and/or innovation adoption). Therefore, depending on the type of influencing factors and the nature of diffusion process, a more detailed model can be adopted from the suggested general model and modified to tailor a specific diffusion research.

One of the main advantages of the presented model is that it is not only a comprehensive model that distinguishes between innovation generation and innovation adoption/diffusion, but it also is a simplified model that recognizes most of the contextual factors addressed in the literature and classifies them into three main categories: characteristics of innovation, characteristics of adopters, and other social and environmental factors.

Under this model, characteristics of innovations are one of three main categories of influencing factors. Moore and Benbasat (1991) classify characteristics of innovation into eight categories: "voluntariness," "relative advantage," "compatibility," "image," "ease of use," "result demonstrability," "visibility," and "trialability." However, Rogers (2003) after reviewing several thousands of instances of diffusion research, concluded that the main characteristics of innovation can be explained just by five factors: relative advantage, compatibility, complexity, trialability, and observability. Consistent with Rogers, it can be argued that "voluntariness" is more related to attributes of adopters rather than attributes of innovation, and "image" and "visibility" can be explained by the "observability" category. Nevertheless, five categories of characteristics of innovations addressed by Rogers include a variety of influencing factors such as the degree of uncertainty associated with the innovation, the amount of investment required to adopt the innovation, the extent of economic advantage of an innovation, continuity of the innovation progress, overall benefit of an innovation (including economic and non-economic advantages of an innovation), reinventing and dynamics aspects of innovations, profitability, flexibility and capability of modification of an innovation, availability of an innovation and the information about it for potential adopters, and the type of innovation.

Factors related to the adopters of innovations included three categories: organizational strategy, organizational structure, and organizational culture. In other words, most characteristics of organizations can be explained by these three categories. These categories might include factors such as size of organizations, the aggressiveness and innovativeness of their managers, level of information of organizations about the innovation, the learning perspective of organizations, resistance to change, technical skills of the users of an innovation in organizations, competition, and awareness of an innovation as a possible solution or as an available technique for progress.

Factors related to social system include the level of development of a society, communication channels in a society, social concerns, change agents, opinion leaders, and social norms. It might also be possible to include all of the influential factors that could not be related either to the innovation category or to the adopter's category under a social system category.

The previous diffusion model does not give any priority to any influencing groups. However, according to Rogers (2003), the accumulated body of literature on diffusion indicates that much effort has been devoted to studying the innovativeness and determining the characteristics of adopters, while relatively little effort has been spent in investigating how the "properties" of innovations affect their rate of adoption. He suggests that between 51 and 87 percent of variance in the adoption rate of innovations can be explained by the *characteristics of innovations*, suggesting that it is these that have the most significant influence on their diffusion. Highlighting this view, recent studies investigating the impact of other influencing factors (e.g., characteristics of innovators and social systems) on the diffusion of administrative innovations have failed to explain the majority of variances in the diffusion of such advanced techniques (e.g., Chenhall, 2003; Rogers, 2003).

FUTURE TRENDS

Given the speed and the scope of recent technological changes and innovations, it is highly likely that the diffusion of innovation will remain an import subject for future research. An overview of innovation generation and innovation adoption along with the recognition of factors influencing the diffusion of such innovations (presented in this article) is expected to provide valuable guidelines for future diffusion research. Such research is expected to facilitate the innovation generation and innovation adoption, which are seen as key factors for organizations in order to compete, prosper, and survive. Given this, the diffusion model presented in this article could be applicable to studies investigating the innovation generation and innovation adoption of both technological and administrative innovations.

CONCLUSION

The technological and administrative changes and innovations of the last three decades have placed a greater emphasis on facilitating the diffusion of such innovations in organizations in order to provide them with some advantages over

competitors to prosper, compete, and survive. To facilitate the diffusion of innovation in organization and provide a guideline for future diffusion research, the current article explains innovation generation and innovation adoption processes and addresses a variety of contextual factors influencing the diffusion processes of such innovations.

KEY TERMS

Compatibility of Innovation: The degree of consistency of an innovation with the needs, expected values, and the norms of potential adopters and their social systems.

Complexity of Innovation: The degree to which an innovation seems difficult to understand and use.

Diffusion: A process by which an idea, product, practice, behavior, or object is communicated/circulated to those to whom it is relevant.

Innovation: Any idea, product, practice, behavior, or object that is apparent as new.

Observability of Innovation: The degree to which the results of an innovation can be observed or demonstrated.

Relative Advantage of Innovation: The degree to which an innovation seems to be better than the idea, object, practice, or process that it is replacing.

Trialability of Innovation: The degree to which an innovation can be tried on a limited basis before full implementation.

Innovations for Online Collaborative Learning in Mathematics

Rodney Nason
Queensland University of Technology, Australia

Earl Woodruff
OISE - University of Toronto, Canada

INTRODUCTION

The field of computer-supported collaborative learning (CSCL) has been growing in a number of areas and across a number of subjects (Koschmann, 1996; Koschmann, Hall, & Miyake, 2002; Wasson, Baggetun, Hoppe, & Ludvigsen, 2003). One of the most promising pedagogical advances, however, for online collaborative learning that has emerged in recent years is Scardamalia and Bereiter's (1996) notion of knowledge-building communities. Unfortunately, establishing and maintaining knowledge-building communities in CSCL environments such as Knowledge Forum® in the domain of mathematics has been found to be a rather intractable problem (Bereiter, 2002b; Nason, Brett, & Woodruff, 1996). In this chapter, we begin by identifying two major reasons why computer-supported knowledge-building communities in mathematics have been difficult to establish and maintain.

1. The inability of most "textbook" math problems to elicit ongoing discourse and other knowledge-building activity
2. Limitations inherent in most CSCL environments' math representational tools

Therefore, in this chapter, we argue that if mathematics education is to exploit the potentially powerful new ways of learning mathematics being provided by online knowledge-building communities, then the following innovations need to be designed and integrated into CSCL environments:

1. authentic mathematical problems that involve students in the production of mathematical models that can be discussed, critiqued, and improved, and
2. comprehension-modeling tools that (a) enable students to adequately represent mathematical problems and to translate within and across representation modes during problem solving, and (b) facilitate online student-student and teacher-student hypermedia-mediated discourse.

Both of the above innovations are directed at promoting and sustaining mathematical discourse. The requirement that the mathematical problems need to be authentic ensures that the students will have the contextual understanding necessary to promote a discussion about the mathematical models. Comprehension-modeling (Woodruff & Nason, 2003) further promotes the discourse by making student understanding yet an additional object for discussion.

Most textbook math problems do not require multiple cycles of designing, testing, and refining (Lesh & Doerr, in press), and therefore do not elicit the collaboration between people with special abilities that most authentic math problems elicit (Nason & Woodruff, 2004). Another factor that limits the potential of most textbook math problems for eliciting knowledge-building discourse is that the answers generated from textbook math problems do not provide students with much worth discussing (Bereiter, 2002b).

Another factor that has prevented most students from engaging in ongoing discourse and other mathematical knowledge-building activity within CSCL environments is the limitations inherent in their mathematical representational tools (Nason et al., 1996). Most of these tools are unable to carry out the crucial knowledge-building functions of (a) generating multiple representations of mathematical concepts, (b) linking the different representations, and (c) transmitting meaning, sense, and understanding.

Two clear implications can be derived from this review of the previous research. First is that different types of mathematical problems that have more in common with the authentic types of mathematical problems investigated by mathematics practitioners than most existing types of textbook math problems need to be designed and integrated into CSCL environments. Second, a new generation of iconic mathematical representation tools also needs to be designed and integrated into CSCL environments. In order to differentiate these tools from previous iconic math representation tools, we have labeled our new generation of tools as comprehension-modeling tools. Each of these two issues will be discussed in the next two sections of this chapter.

AUTHENTIC MATH PROBLEMS

Credence for the viewpoint that the integration of more authentic types of mathematical problems into CSCL environments may lead to conditions necessary for the establishment and maintenance of knowledge-building activity is provided by the findings from two recent research studies conducted by the coauthors. Although both of these studies were situated within elementary schools, it should be noted that the same math problems used in these research studies could also be used within online CSCL environments to facilitate the development of mathematical subject-matter knowledge in high school students and preservice teacher-education students. Therefore, we believe that the findings from these two studies have much relevance for the establishment and maintenance of math knowledge-building communities not only in elementary schools, but also in secondary school and higher education institutions, too.

In a series of research studies, Nason, Woodruff, and Lesh have been investigating whether having students engage in model-eliciting mathematical problems with collective discourse mediated by Knowledge Forum would achieve authentic, sustained, and progressive online knowledge-building activity. In this section, we focus on two of these research studies.

In the first of the research studies (Nason & Woodruff, 2004), 21 students in a Grade-6 class at a private urban Canadian school for girls were asked to devise an alternative model that could be used for ranking nations' performance at the Olympic games that de-emphasized the mind-set of "gold or nothing." In the second research study (Nason, Woodruff, & Lesh, 2002), 22 students in another Grade-6 class at the same school were asked to build a model that could help rank Canadian cities in terms of quality of life.

In both studies, the students were initially presented with an article setting the scene for the model-eliciting activity and a set of focus questions based on the article. After this 45-minute warm-up activity, the students went through the phases of (a) initial model building (Phase 1, one session of 45 minutes), (b) sharing of initial models (Phase 2, one session of 45 minutes), and (c) iterative online critiquing and revision of models within Knowledge Forum (Phase 3, four sessions of 45 minutes). The sharing of the initial models in Phase 2 was done face to face within the classroom. After the face-to-face sharing of the initial models had been completed, each group attached their math model to a Knowledge Forum note where it could be viewed and evaluated by other participants within the online CSCL community. During the online critiquing and revision of models in Phase 3, Knowledge Forum provided the contexts and scaffolds for intergroup online discourse.

Five important elements of activity consistent with Scardamalia's (2002) principles of knowledge building were observed during the course of these two studies.

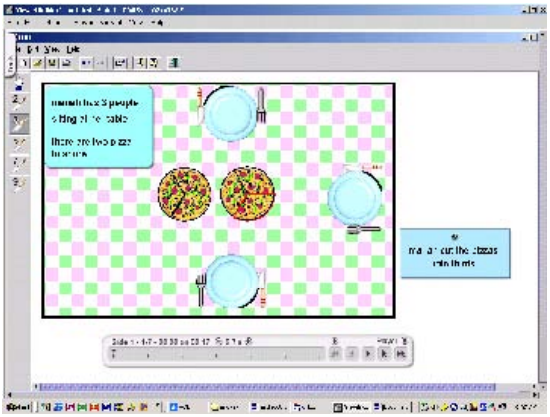
1. Redefinition of the problems, which highlights Scardamalia's principles of improvable ideas and rising above
2. Inventive use of mathematical tools, which highlights Scardamalia's principle of improvable ideas
3. Posing and exploration of conjectures, which highlights Scardamalia's principles of idea diversity and knowledge-building discourse
4. Collective pursuit of the understanding of key mathematical concepts, highlighting Scardamalia's principles of community knowledge and collective responsibility
5. Incremental improvement of mathematical models, which highlights Scardamalia's principle of improvable ideas

Much of the success in establishing and maintaining the online mathematics knowledge-building communities in these two studies can be attributed to the rich context for mathematical knowledge-building discourse provided by the model-eliciting problems. In both problems, students were required to produce a mathematical model for issues that the students found meaningful and relevant. Therefore, they were willing to proceed through multiple cycles of developing, evaluating, and revising their models. This process of proceeding through multiple cycles encouraged much online discourse between the groups in each classroom. The model-eliciting problems also had many different possible solutions. Because of this, there was much heterogeneity in the initial models produced by the groups of students. In order to understand other groups' models and also to explain their own model to other groups, each group had to engage in much iterative online discourse with other groups. During this discourse, they had to ask good questions, propose how other groups' models could be improved, and elaborate on and/or modify their explanations. Finally, the models themselves provided students with artifacts that could be discussed, evaluated, compared, and improved (just like the artifacts built by mathematics practitioners). Unlike the answers produced in most textbook problems that tend to only enable discourse about correctness (or incorrectness), the models produced from the model-eliciting problems were artifacts that could be evaluated and discussed in terms of not only correct usage of mathematical concepts and processes, but also in terms of subjective, nonmathematical factors.

COMPREHENSION MODELING

Evidence to support the notion that the inclusion within a CSCL learning environment of comprehension-modeling tools can do much to facilitate knowledge-building discourse

Figure 1. Screen shot of the problem students are attempting to solve



has been provided by research during the development of CHiLE (constructivist hypermedia interactive learning environment; Charles & Nason, 2000). CHiLE situates the learning of fractions in the context of a restaurant in which the children play the role of a waiter and are asked to partition and share out equal objects such as pizza and apple pies to customers sitting at the restaurant table (see Figure 1). The number of customers sitting at the table and the number of objects to be partitioned and shared can be varied. CHiLE provides the children with five different slicers (a knife-like tool) that enable objects to be cut in halves, thirds, fifths, sevenths, and ninths. With these slicers, the children can also create other fractions such as quarters (by halving the halves) and sixths (by halving the thirds).

CHiLE enables children to generate multiple representations of fraction problems and provides the iconic tools for facilitating synchronous hypermedia-mediated, knowledge-building, child-child and teacher-child discourse. CHiLE, however, has an added facility that enables teachers and children to also engage in online asynchronous knowledge-building discourse. With CHiLE, children are able to make an animated sequence of slides with accompanying text that not only enables them to communicate the solution to a fraction problem, but also the process (or model) that was used to generate the solution. CHiLE thus uses hypermedia as a way to animate and promote mathematical discourse: The strategy (or model) is reified on the screen via the iconic representation, the animation shows the "story," and everything is recorded, thus promoting reflection and revisitation. This is illustrated below in a series of figures (see Figures 1 to 4) generated by two 8-year-old children who had been asked to share one pizza fairly between three people.

Nason and Woodruff (2004) have found that online knowledge-building discourse facilitated by CHiLE operates on two different levels. First, the discourse can occur at the global level and focus on the overall strategy (or model). For example, another group of students, when given the same problem as in Figure 1, decided to slice the pizza into sixths and give two sixths to each person. After looking at one another's models, the two groups of students engaged in robust online debate about which was the "better" strategy (and solution). During this debate, they were able to identify similarities and differences between the strategies, but more importantly, build conceptual links between thirds and sixths. Second, the discourse can occur at the language level. For example, there can be discourse about the best language to insert in a sequence of slides. This discourse often provides the contexts for the introduction of formal mathematical language as a more precise way of communicating meaning within mathematical contexts than natural language.

The hypermedia facilities provided by CHiLE enabled children to engage in online knowledge-building discourse synchronously and asynchronously via iconic, natural language, and/or mathematical language representations.

Figure 2. Early screen shot of students' initial steps toward a solution

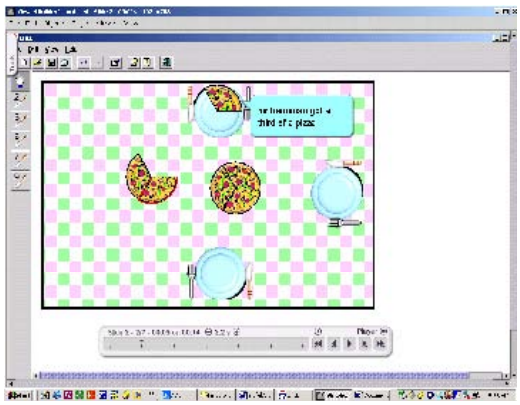


Figure 3. Screen shot midway toward a solution

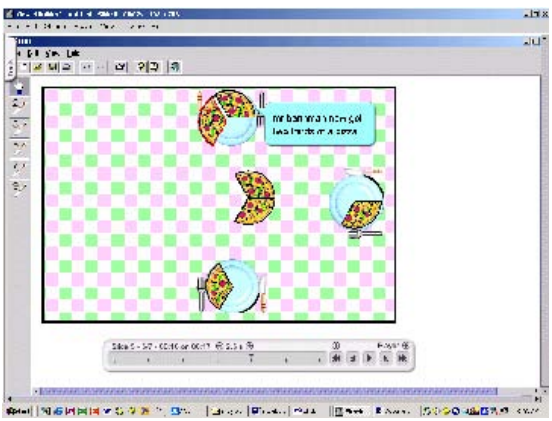

Figure 4. Screen shot of students' proposed solution

CHiLE thus provided one of the most important dynamics that Scardamalia (2002) identified as being a technical determinant of knowledge building and knowledge advancement within online CSCL environments.

CHiLE also provided two other dynamics that Scardamalia indicated were technological determinants of knowledge building and knowledge advancement. First, there is her notion that computer technology should include facilities for bringing together different ideas in such a way that productive use can be made of diversity. The iconic tools provided by CHiLE met this criterion by enabling children to readily

1. generate diverse solutions and solution processes to the same mathematics problem, and
2. communicate both synchronously and asynchronously via the iconic models, natural and mathematical language, and mathematical symbols their diverse solutions and solution processes to others within the online learning community.

Scardamalia also indicated that the computer technology also should provide children with the opportunity and the means to make revisions. Without this, she claimed that children will not be able to work continuously to improve the quality, coherence, and the utility of their ideas. One of the major qualities of CHiLE is the ease with which children can revisit and revise the sequences of slides and their accompanying text. The comprehension-modeling tools provided by CHiLE thus promoted idea diversity, improvable ideas, and knowledge-building discourse, three of the sociological and technological determinants of knowledge building identified in Scardamalia (2002).

FUTURE TRENDS

The research in progress reported in the previous two sections indicates that the inclusion of model-eliciting problems and of comprehension-modeling tools (such as CHiLE) into online collaborative learning environments both have the potential to facilitate the establishment and maintenance of online collaborative mathematics knowledge-building communities in schools and higher education institutes.

However, two important issues still need to be addressed before this potential can be realized. First, the set of principles for informing the design of model-eliciting problems developed by Lesh and Doerr (2003) need to be modified to take cognizance of the differences between online collaborative and traditional classroom environments. Second, the theoretical framework informing the design of comprehension-modeling tools needs to be modified to include not just ideas from research into external mathematical representations that were used to inform the design of CHiLE (e.g., Kaput, 1992; Olive, 2000), but also ideas from research conducted in other areas such as online collaboration (e.g., Klopfer & Woodruff, 2002), cognitive science, and multimedia learning (e.g., Mayer, 2001; Sweller, 1999). Both these issues are the foci of a series of design experiments (Bereiter, 2002a) currently being conducted by Nason and Woodruff.

CONCLUSION

In this chapter, we identified two major reasons why mathematics educators have had limited success in establishing and maintaining online knowledge-building communities.

1. The inability of most textbook math problems to elicit ongoing discourse and other knowledge-building activity
2. Limitations inherent in most CSCL environments' math representational tools

We then proposed how these two problems could be overcome, namely, by the inclusion of mathematical problems that children can analyze and describe through a mathematical model (such as the steps necessary to divide two pizzas among three people) and comprehension-modeling tools (that allow observers to later see how the students have solved the problem) within CSCL environments.

We have targeted our discussion within one CSCL groupware product called Knowledge Forum, but we believe the same principles will apply to any online computer-supported collaborative learning system. To that end, we argued that the development of model-eliciting problems suitable for use in online CSCL environments and of comprehension-modeling

tools is being restricted by the lack of adequate theoretical frameworks to inform the research and development of these two types of artifacts. Therefore, we have proposed that the development of adequate theoretical frameworks to inform the design of these two types of artifacts should be a major research priority in this field.

KEY TERMS

Comprehension-Modeling Tools: Math representation tools that enable users to (a) generate multiple representations of mathematical concepts and processes, (b) dynamically link the different representations, (c) communicate the mathematical ideas they have constructed, and (d) make movie-like sequences of animation slides that enable others to replay the process used to generate the solution.

Computer-Supported Collaborative Learning: collaborative learning mediated by computers.

CSCL: Acronym for computer-supported collaborative learning.

Knowledge Building: Production and improvement of knowledge objects that can be discussed, tested, compared, hypothetically modified, and so forth, and not simply the completion of school tasks.

Knowledge Forum ®: A single, communal multimedia database designed to facilitate computer-supported collaborative learning.

Mathematical Representations: concrete, pictorial, and symbolic models used to represent mathematical ideas.

Model-Eliciting Problems: Mathematical problems that involve producing models for constructing, describing, explaining, manipulating, predicting, and controlling complex systems (Lesh & Doerr, 2003).

Problem Solving: Situation involving an initial state, a goal (or solution) state, and a blockage between the initial and goal states that requires the construction of new knowledge to proceed from the initial to the goal state.

Innovative Thinking in Software Development

Aybüke Aurum
University of New South Wales, Australia

INTRODUCTION

As we enter the third millennium, organizations have to cope with accelerating rates of change in technology and increased levels of competition on a global scale more than ever before. In order to stay competitive within this changing business environment, organizations are forced to constantly pursue new strategies to differentiate themselves from their competition, such as offering a stream of new products and services (Satzinger et al., 1999). Furthermore, there is growing recognition that an organization's capability to deal with change, improve services and quality, cut costs, develop new products, and compete in a global market will depend upon the level of creative and innovative thinking of its workforce (Covey, 1989). In short, in order to remain competitive in an era of increasing uncertainty and market globalization, organizations must constantly be creative and innovative with their products and services.

Software has been widely considered as central to all sophisticated innovations. In the age of the Internet the challenge is to identify and evaluate new ideas, processes and applications. In many of the fastest growing industries, including computer, entertainment, communications, advertising, logistics and finance, software has been the end product itself, or the highest value component in the end product. In other cases, software has been used to support value creation and innovation processes. The growing importance of software-based innovations suggests the need to improve the creative skills of IT professionals. This need, in turn, requires an appropriate response from the IT education and training sector. Moreover, IT education and training should better nurture students' creativity, so that they can be successful in their future roles as innovative professionals and business people. It is particularly important that IT students be given an opportunity to develop and apply creative and innovative skills to software processes and products.

Given the crucial importance of creativity and innovativeness for success in a knowledge economy, the main purpose of this article is to explore concepts about creativity and how they relate to software development by providing empirical research examples in IT education.

CONCEPT OF CREATIVITY

The literature offers diverse conceptual definitions of creativity. Glass (2001) argues that creativity is hard to define, hard to judge and hard to quantize. Kappel and Rubenstein (1999) reason that this is due to fact that creativity is used to describe a variety of things; that is, supporting the creativity process, the creative person or the creative product present different requirements for the definition of the creativity. Tomas (1999), for example, defines creativity in terms of an original idea. Shalley and Perry-Smith (2001) point out that it is not enough to only be original; also, appropriateness is vital in order to distinguish creative ideas from surreal ideas that may be unique, but have unlawful or highly unrealistic implications.

Central to creativity is the ability to generate ideas. Some psychologists and philosophers have argued that idea formation can be explained by way of association (Mednick & Mednick, 1964). This theory suggests that association occurs when two stimuli take place together (contiguity), when two stimuli are similar to each other (similarity), or when two stimuli are different from each other (contrast). Associations may be stimulated by environmental factors, by previous associations, or may be mediated by ideas related to other associates. Therefore, it is possible to have many combinations and permutations. Associations can vary in strength, depending on how often associated ideas occur together or separately.

Lateral thinking is an aid to creativity when one needs to have diverse ideas. It is a function of knowledge and imagination that may bring out discovery, innovation, imagination, and exploration. Lateral thinking consists of seeking as many alternative options as possible to the extent of one's adventurousness. In other words, it is a mental activity involving making connections between knowledge and ideas that were previously unrelated. The basis of lateral thinking is that since many problems require a different perspective to be solved successfully, individuals should suspend their judgment about what is relevant to a course of action.

CREATIVITY TECHNIQUES

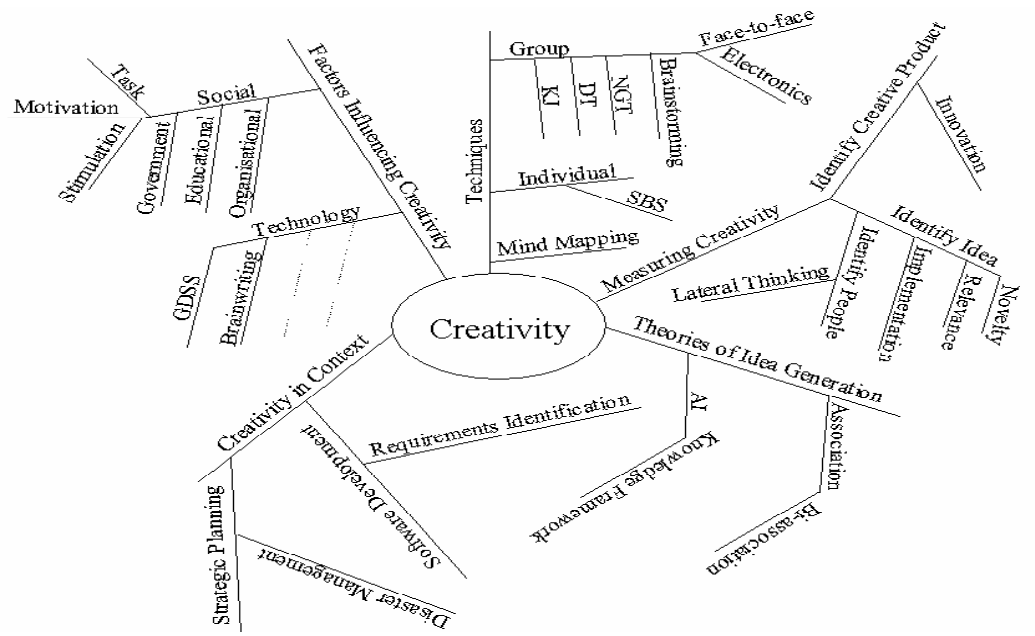
Consistent with the view that creative thinking can be learnt by appropriate stimulation and instruction, a variety of formal techniques have been developed to assist the production of novel ideas including brainstorming, mind mapping or solo brainstorming. Brainstorming and similar idea generation techniques aim to increase the production of novel ideas. The objective is to promote creativity by appropriately managing interaction within group as well as enhancing the creative environment. The procedures involved in the following examples are not difficult and may involve "lateral thinking," where ideas are stimulated by members of the group.

Brainstorming is an idea generation technique that was conceptualized by Walt Disney in the late 1920s and then expanded by Alex Osborn (1957). The objective of brainstorming is to encourage associations. The basic assumption is that it is possible for an individual(s) to generate many ideas, provided that he or she is exposed to stimuli and has experience, knowledge, and the personal flexibility to develop various permutations and combinations, and the capacity to make correct selections. This method initially emphasizes the quantity of ideas generated, leaving the assessment of quality to a later stage. Brainstorming sessions can be conducted electronically or verbally. In electronic brainstorming systems (EBS), group members share their knowledge and ideas by sending their ideas to each other, and by viewing the ideas of other members. Ideas generated from a brainstorming session can be recorded and stored in electronic files, making them easily accessible for printing or later reference (Nunamaker et al., 1991).

Another free association technique is mind mapping. This method begins with writing down a main idea in the centre of the page, and then working outward in all directions, producing a growing and organized structure composed of key words and key images, as illustrated in Figure 1. Mind mapping therefore relies on association (and clustering) of concepts/issues. The association process underling construction of the mind map actually facilitates making connections between concepts, and hence tends to generate new ideas and associations that have not been thought of before.

An example of an individual creativity technique is solo brainstorming (SBS), originally proposed by Aurum (1997). This technique is especially suited to environments where sentential analysis is appropriate, or information sources are document-based (e.g., reports, abstracts). SBS requires the individuals to adhere to a formal protocol, where a series of documents are examined and then edited. The ultimate aim in an SBS session is to determine a sufficient set of issues. As applications of the SBS protocol have been computer-based, all issues are automatically available in electronic form for further analysis. The SBS protocol touches upon an important research issue in the area of knowledge management: whether an increase in an individual's level of domain knowledge will necessarily increase their capacity to be creative within that domain. Central to the SBS protocol is the encouragement

Figure 1. Mind mapping (Aurum & Gardiner, 2003)



of participants to use their cognitive abilities by asking them to make "lateral comments".

CREATIVITY IN SOFTWARE DEVELOPMENT

Software engineering is another domain in which creativity plays an important role. The value of creativity is also well recognised in the field of system requirements determination. Robertson (2001) addresses requirements determination as "requirements discovery," which suggests that many users may not even be aware of their true requirements (e.g., unconscious requirements) without application of techniques for reflection and creativity.

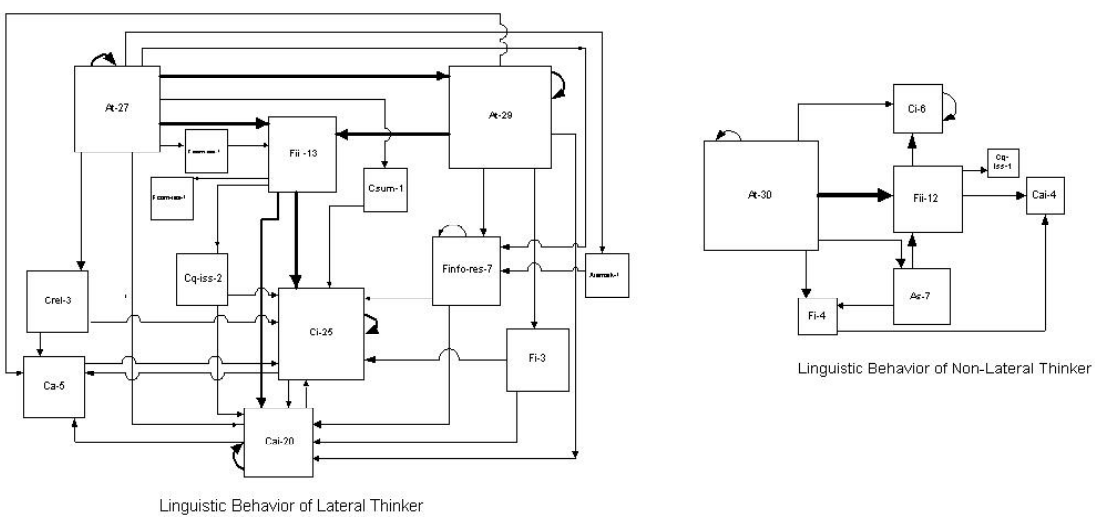
In an experiment focusing upon requirements elicitation, Aurum and Martin (1999) applied the SBS protocol to determine whether application of the protocol would deliver a richer set of requirement statements and insights. An experiment was conducted in which participants were told to adopt the role of a systems analyst retained by a fictitious organization, The Cultural Heritage Authority (CHA), to write requirements specification for their main information systems. The types of documents used as input (external information) to this study included fictitious interviews with users and abstracts from published articles addressing either heritage or marketing issues. Participants' task was to generate ideas and identify issues to be included in CHA's software requirements specification (SRS).

The objective of the research was to investigate whether the application of the SBS protocol had indeed led to a richer level of requirement specifications. The following two research questions are investigated (a) whether application of the protocol would result in identification of more relevant, workable, and original requirements issues, (b) to measure the lateral thinking by examining the linguistic behavior of participants.

The main findings of this study indicated that an SBS-based learning tool had a positive effect on participants' creative performances in development of SRS. This outcome was evident in the originality aspect of task performance, but not relevance and workability. Users were found to generate significantly more original ideas as the result of their interaction with the tool, while maintaining similar levels of relevance and workability (Aurum et al., 2003).

Aurum (1997) suggests that the level of "laterality" for any thought for a given problem can only be assessed with respect to the thoughts generated by others for the same problem. Aurum also found that documents generated from SBS session exhibited some unique characteristics. From linguistic analysis, it was possible to identify those users who were able to think laterally in the SBS session. Furthermore, lateral thinkers displayed a more complex linguistic pattern than non-lateral thinkers, as illustrated in Figure 2. Participants who generated many ideas and identified many issues were

Figure 2. Linguistic behavior of SBS participants



also found to be the lateral thinkers. The findings showed that lateral thinkers wrote many "issue loaded" or "idea loaded" sentences, whereas non-lateral thinkers produced fewer ideas. However, the distinction between these two groups was not clear-cut, but rather a continuum.

The results of this study indicate that the SBS is a promising method for stimulating creative thinking and idea generation in a software development task. Essentially, the brainstorming session helped students uncover ideas without being constrained, stimulate their own thinking by external influences, and capture their thoughts.

These findings also have some important implications for software development and IT education. They demonstrate that creativity can be improved, leading to higher quality software designs. The findings also suggest that the type of tool tested here may be a useful teaching tool in a variety of IT courses involving creative thinking and problem solving. Furthermore, the tool is likely to be most valuable in situations where the problem is unstructured, goals indistinct, and where the outcome of an action cannot always be clearly identified. The tool is a relatively generic one, since it uses a technique that can be applied to a variety of scenarios and can help people process relevant documents whilst identifying issues. These documents act like a 'trigger to stimulate domain-specific ideas from users.

CONCLUSION

Many organizations have come to realize that the creativity of their management and employees is an important source for competitive advantage. However, arguably more can be done within these organizations to promote a creative culture – for example, more organizations should seek to reward management and employees for creative (or divergent) displays, and make creativity supporting technologies more readily available to them.

A number of techniques have been developed to facilitate creativity, with many techniques based upon some form of brainstorming. One theme common to some of the more recent studies on creativity is the importance of a rich source of stimuli to support the creative process, whether the stimuli are: documents, as in Aurum and Martin (1999); group memory, as in Satzinger et al. (1999); or models, as in Shalley and Perry-Smith (2001). Other forms of stimuli include: text, audio, graphics, simulations, video, and so forth (Kletke et al., 2001). Indeed, the effectiveness of the brainstorming technique relies on participants being stimulated by the ideas contributed by others. The potential to cascade ideas is referred to as synergy (Dennis & Valacich, 1993) – that is, the ability of an idea from one participant to trigger in another participant a new idea that would otherwise not have been produced. Another technique is formalizing the creative process through some protocol that can be an effective strategy in terms of supporting the level of intrinsic motivation and mental effort required by participants undertaking a creativity task (Aurum 1999; Paulus & Yang, 2000). Application of a formal protocol is usually at the heart of a creativity technique, and ensures a more systematic and thorough approach to information analysis, which is essential for many creativity tasks.

KEY TERMS

Creativity: There are many views about the definition of creativity. In the context of discovery, creativity is the ability to generate or recognize ideas, alternatives that might be useful solving problems. There are several aspects of creativity, including creative product or value, creative person/people, creative environment, creative symbols and creative process.

Electronic Brainstorming Systems (EBS): A computer-based system that facilitates brainstorming between group members.

Information System (IS): A system that uses IT to capture, transmit, store, retrieve, manipulate or display data for business processes in an organization.

Information Technology (IT): Computer hardware and software, as well as the peripheral devices closely associated with computer-based systems that facilitate data processing tasks, such as capturing, transmitting, storing, retrieving, manipulating or displaying data. IT includes matters concerned with design, development, and implementation of information systems and applications.

Internet: A worldwide network of computer networks that use the TCP/IP network protocols to facilitate data transmission. It provides access to a vast amount of information resources including multimedia (movies, sound, and images), software, text documents, news articles, electronic journal, travel information and so forth. It also provides an environment for buying and selling products and services over a network.

Knowledge Economy: Economic growth is driven by the accumulation of knowledge, which is the basic form of capital. A knowledge driven economy is one in which the generation and exploitation of knowledge plays the predominant part in the creation of wealth.

Knowledge Management (KM): The collection of processes that manage the creation, dissemination, and utilization of knowledge for learning, problem solving, and decision-making. KM often encompasses identifying intellectual assets within organizations. The management of knowledge is regarded as a main source of competitive advantage for organizations. KM brings together three organizational resources: people, process and technologies, and enables the organization to use and share information more effectively

Software Requirements Specification: A document that contains all requirements, for example functional and non-functional requirements and project issues, of the system as agreed upon by customers and software developers.

Institutional Isomorphism and New Technologies

Francesco Amoretti
University of Salerno, Italy

Fortunato Musella
University of Naples Federico II, Italy

INTRODUCTION

Technological factor is mainly underestimated in the literature on institutions and organizations. Although organizational studies and information technology are disciplines dedicated respectively to studying socio-political and technical aspects of organizing, cross-fertilization among such fields has remained quite limited. Only rarely the variable of technology has been interpreted as a crucial element for explaining institutional uniformity. From a more general point of view, changing technical factors have been considered "relatively unimportant sources of organizational change in a mature organizational field" (Yang, 2003, p. 433).

Only after the spread of the information and communication technologies (ICTs), a good number of studies has started to consider the relationships among information technology and organizational structure (Guthrie, 1999). Neo-institutional analysis on the use of information technology was mostly directed at showing how the embeddedness of organizational actors "in cognitive, cultural, social, and institutional structures influences the design, perceptions, and uses of the Internet and related [information technology]" (Fountain, 2001, p. 88). Therefore, it can been argued that most of the literature on this field concerns the way in which technology represents a social construct, because it shows that any technological application is strongly influenced by social aspects, such as cognitive frames, political culture, local traditions and so forth.

Yet, a few contributions have been dedicated until now to investigate how institutions change through the introduction of new technologies. Although technological innovation is said to be the source of variation in a given institutional context, as "new technology offers new possibilities for solving problems [and] new practices arise when innovative organizations take advantage of its novel benefits" (Leblebici, 1991, p. 335), little attention is focused on technological variables. Despite such disregard, in the following article some examples of the strategic use of information and communication technologies will be included, with specific reference to pressures exerted by ICTs for producing "institutional isomorphism."

BACKGROUND

Institutional isomorphism represents a central issue in the neo-institutional approach. Such concepts refer to the way organizations in a population are forced to "resemble" other organizations that "face the same set of environmental conditions." (DiMaggio & Powell, 1983, p. 66). It deals in part with the organizational process of homogenization.

The main contributions on institutional isomorphism can be divided in two different fields of research, only rarely put together. The first one can be identified with the analysis of organization, which looks to pressures leading to conformity among organizational actors. The second one has found new areas of application after the process of globalization: it is the study of policy transfers, which aims at underlining the policy convergence in different political contexts. Both the approaches show many similarities in the discourse on institutional change and can be also associated for the lack of consideration for technological variables. How the adoption of a new technology may influence and being influenced by pre-existing institutional setting has represented a crucial and underestimated issue. Yet, after the spread of ICTs, the relevance of the strategic use of technology for producing institutional effects is becoming more evident.

The analysis of organizational isomorphism refers to a notable source of inspiration. In *The Protestant Ethic and the Spirit of Capitalism*, Max Weber (1905/1958) introduced the imagery of the iron cage to catch the process of bureaucratic homogenization in which the humanity was imprisoned. Organizations were deemed to a destiny of increased rationalization that would make them more similar to each other in structure, culture and outputs. The same image of imprisonment was used—and revised—by DiMaggio and Powell (1983) in their note studies on the mechanisms of institutional isomorphic change. As a constraining pressure which forces one unit in a population to resemble other units that face the same sets of environmental conditions, the concept of isomorphism aims at explaining why there is homogeneity of forms and practices in a given organizational field.

Three type of isomorphism can be identified. Coercive forces occur when an actor influences other actor's behaviour through formal and informal instruments. Generally, in this circumstance an organism legally imposes rules that are to be followed by a specific set of organizations. The most classical and remarkable example is represented by the state in its capacity of acting as a normative power which defines standards and rules of action. Mimetic isomorphism does not derive from a coercive authority, mainly responding to the search for efficiency and the need of institutional legitimacy. It can be argued that an organization that builds a reputation for excellence will attract other organizations trying to imitate its practices. Finally, the third source, the normative one, for producing isomorphism is constituted by the relevant trend of *professionalization*, interpreted as a "collective struggle of members of an occupation to define the conditions and methods of their works, to control 'the production of producers'" (DiMaggio & Powell, 1983, p. 152).

The processes by which isomorphism mechanisms intervene show a mix of different institutional logics. Action is driven by the principle of rationality as well as by rules of appropriate or exemplary behaviour. According to March and Olsen (1995) social actors follow prescriptions of what is socially defined as normal, true, right or good, without, or in spite of, calculation of consequences and expected utility. Isomorphism derives from institutional arrangements that link roles/identities, accounts of situations, resources and prescriptive rules and practices. Internalized principles and prescriptions have to be balanced by the calculated expected utility and constrains that a specific institutional frame determines.

The category of institutional isomorphism has been usually applied to the analysis of organizational uniformity in specific organizational fields, which are, in the words of March and Olsen, recognised areas of institutional life. Other contributions have tried to enlarge their perspective. With the increase of interdependence due to globalization, the idea of isomorphism has been used to underline a growing phenomenon of policy convergence from one political setting to another. Dolowitz and Marsh note that a significant body of literature in political science and in international studies refers to terms as lesson-drawing, policy convergence, policy diffusion and policy transfer in order to indicate "the process by which knowledge about policies, administrative arrangements, institutions and ideas in one political system (past or present) is used in the development of policies, administrative arrangements, institutions and ideas in another political system" (Dolowitz & Marsh, 2000, p. 5). The reasons why the policy transfer occurs run, in a simplified and heuristic model, from voluntary adoption—a rational response starting from the "dissatisfaction with the status quo"—to direct imposition. In addition to this, what is transferred is also variable, and Rose (1993, p. 30) set at the one extreme "direct coping" which regards full "lesson-drawing" of a programme or a policy from one jurisdiction to another, and, at the other extreme "inspiration," with reference to mimetic mechanisms. Although many factors influence the process of institutional adaptation, a crucial point in the literature on isomorphism is that the institutional arena contains a number of exogenous pressures that influence the structure and behaviour of organizations, based on socio-cultural norms or interdependency (Dacin, 1997; Tucker, 1983).

It can be confirmed that both classical studies on organizational isomorphism and analyses on policy transfer underestimate the role of technological variables. Although, as La Porte et al. (2002) put it, "growing homogeneity among modern organizations emerges as a function of unprecedented amounts of newly available information about other organizations in the environment" (p. 435), the role of information and communication technologies remains quite implicit.

The reasons behind such a scarce attention to the potentials of technology in terms of creating institutional uniformity probably rests on a fundamental distinction between institutional and technical sources of organizational practices: technology is said to be the source of variation while institutions are considered responsible for conformity and of predictability of behaviour (Meyer & Rowan, 1977, in Leblebici et al., 1991). Yet it is difficult to defend this statement after the spread of new technologies, when the definition of a computer-based infrastructure was used to establish a true code able to regulate the various actors' behaviour.

For instance, Jane Fountain, by showing how the intensive use of new technologies is embedded in an institutional context with its social, cultural and legal features, observes the collision between traditional practices and traditions with technological innovation. In her contribution *Building the Virtual State: Information Technology and Institutional Change* (2001) she focuses on the role of digital policies, and in particular of e-government, in offering new incentives and constrains to change governments. According to Fountain, it is to be assumed that within a government agency there is a dominant homogenous culture, and the strategic use of new technologies can constitute an instrument for constructing such discourse (Yang, 2003). If her main finding is that institutions are the most important factors in explaining how information technology is being adopted and used in government, at the same time it can be argued that new technologies themselves are a relevant element for the shaping of institutions.

Also, Lawrence Lessig (1999) considers the effects of the introduction of new technologies in influencing institutional settings. What he calls "the code," the complex system of software and hardware instructions defining the Internet rules, seems to show a constitutive potential. Indeed, the idea of the code tends to consider the effects of new technologies not only for creating convergence in the public administrations'

behavior, but also for a more incisive cultural homogenization. A computer code may regulate conducts more than a legal corpus does, as it intervenes at a deeper level, the level of ideas and their diffusion (Lessig, 2001).

THE SEARCH FOR UNIFORMITY: THE CASE OF EUROPEAN UNION

The European Union can be considered one of the most relevant examples of the strategic use of new technologies for institution building (Baptista, 2005; Overeem, Witters, & Peristeras, 2007).

An important body of literature has already put attention on the process of institutional isomorphism developed in Europe. The homogenization pressures in the Old Continent seem to produce "a process of (a) construction, (b) diffusion and (c) institutionalization of formal and informal rules, procedures, policy paradigms, styles, ways of doing things and shared beliefs and norms which are first defined and consolidated in the making of EU decisions and then incorporated in the logic of domestic discourses, identities, political structures and public policies" (Radaelli, 1997, p. 4). Such phenomenon has justified the introduction of categories such as that of "Europeanization" in regard to the transformation of structures and practices of MS's institutions, as activated by the process of European integration. Even if this process is producing different influences in the different contexts, there is no doubt that the various member states' administrations are currently undergoing a transformation stage where they share some common directions (Börzel & Risse, 1999; Heritier, 2001; Riekmann, Puntsher, & Latzer, 2006). For instance, according to Siedentopf and Speer (2003), in Europe an evolving process of increasing convergence between national administrative legal orders and administrative practices of member States is realizing "Convergence is influenced by several driving forces, such as economic pressures from individuals and firms, regular and continuous contacts between public officials of member States, and finally and especially, the jurisprudence of the European Court of Justice" (p. 13).

Literature on institutional isomorphism in Europe seems to underestimate technological variables. Yet digital policies held a central role for the EU development due to its meaningful potential for transformation. It has to be also underlined the priority of the strategic use of new technology for economic purposes. Despite of a poor definition for a comprehensive project, the heavy use of new technologies and the development of a supra-national computer-based architecture have become, indeed, much valued tools aiming at EU major targets, particularly in the area of economic development. For example, the recent *i2010 E-government Action Plan* (European Commission, 2006a) clearly states that those countries with a higher e-government development degree are also at the top level in the main economy indicators: "This strong link between national competitiveness, innovation strength and the quality of public administrations means that in the global economy a better government is a competitive must" (ibidem, p. 3). There are in fact several evidences supporting the positive impact of new technologies, in both the short and long term, on innovation and growth within the public sector. The crucial point here is that digital policies create not only more opportunity of economic development, but also more integrity and standardization in the European administration. Securing competition in the European market required the definition of an integrated service system able to overcome EU's fragmentation and differences, in regard to both the increasing number of MSs and local governments' accountability following the introduction of the subsidiarity principle. With the EU undergoing an expansion process, thus becoming more and more diversified, it was necessary to implement effective public services systems covering the entire European territory and ensuring the full mobility of citizen and goods (p. 3).

Through new ICTs standardization in organisations, infrastructure, administrative procedures, and also in semantic codes, legislation is encouraged in order to produce interaction and integration between European public administrations. If establishing behaviour standards could be considered an important part of the current process of globalization, in different areas, from environmental issues to financial matters (Cassese, 2006), now the computer code seems in charge of deciding the norms to be applied at a global level to cooperation, harmonization and standardization procedures.

A recent report presented by the European Commission to the European Parliament (European Commission, 2006b) also focuses on interoperability as the main goal of the administrative structure. The modernization of public administration is thus finalized to the establishment of a common market and an effective interaction between citizens and companies: "The single market relies on modern and efficient public administrations which facilitate the mobility and seamless interaction of citizens and businesses" (European Commission, 2006b, p. 2). The same approach applies to administrative structures integration in various government levels. The document states that "to be affordable and effective, implementation of the infrastructure required for the delivery of pan-European eGovernment services will have to be guided by an overall conceptual architecture, based on standards" (European Commission, 2006b, p. 9). Therefore, interoperability goal is described as intertwined with the strengthening of economic competition and the overcoming of any obstacle to the establishment of a common market (European Commission, 2006a). Defined as "the key enabler for the delivery of e-government services across national and organizational boundaries," such interoperability systems are regarded as the right tools to ensure the mobility of businesses and individuals, a larger interaction among the

stake-holders, and an effective administrative cooperation (European Commission, 2006b).

Such interoperability can only be actualized by intervening on three different elements, respectively related to the organizational, technical, and semantic dimensions:

- Organizational interoperability is about being able to identify those players and organizational processes involved in the delivery of a specific e-government service and achieving agreement among them on how to structure their interactions, that is, defining their "business interfaces."
- Technical interoperability is about knitting together IT systems and software, defining and using open interfaces, standards and protocols in order to build reliable, effective and efficient information systems.
- Semantic interoperability is about ensuring that the meaning of the information exchanged is not lost in the process, that it is retained and understood by the people, applications and institutions involved (European Commission, 2006b, p. 6).

Finally, the realization of interoperable systems leads to a "one-stop government:" a single point of access to electronic services and information offered by different public authorities. Online one-stop government requires that all public authorities will be interconnected and that the customer (citizen, private enterprise or other public administration) will be able to access public services via a single point, even if these services are provided by different public authorities or private service providers.

The definition of a technological architecture constitutes the premise for further developing of the European Union. If the lack of a cultural integration is among the main causes of the delay of the European experiment—of which a clear example is represented by the failure of the process of treaty ratification—ICTs face the challenge to keep together organizations at different levels of government and to offer sharing cognitive tools for the citizen-user as well. Therefore, the strategic use of new technology can be easily interpreted as a process of institutional building.

FUTURE TRENDS

Due to its more defined characteristics, ICTs policies are doubtless one of the most effective tools for establishing common institutional standards.

The existence of a wider process leading toward increased convergence between national administrative practices can be questioned (Harlow, 2005). In an era in which globalization and international homogenization of regulatory regimes are gradually undermining national institutional distinctions, public officials are increasingly inclined to borrow policy solutions and adopt organizational structures experimented in other countries. Moreover, the need—and imperative—of cooperation in a global market has led to the adoption of standardization procedures in the administrative process (La Porte et al., 2002). Although it remains uncertain that pressures are strong enough to create a uniform model of public administration, ICTs will become a crucial lever toward a greater integration within administrative agencies by providing standards to public actors' behaviour. So, while digital architecture encourages the creation of new networks and executive layers, it seems also to introduce new forms of homogenization of political and administrative action. An example could be taken from the modalities of creation of public Web sites, as governments move toward standardization among various agency portals (West, 2007). By allowing easy Web orientation, the standardization of online environments may increase administrative interoperability.

This discourse can be also enlarged from administrations to other socio-political actors. For instance, parties, interest groups and social movements' organizational features and policy impacts will converge after the impact of the Internet (Chadwick, 2007). Briefly, we can formulate the hypothesis that new technologies encourage organizational hybridity, by noting that a process of transplantation and adaptation of digital networks repertoires previously considered typical of social movements is occurring. At the same time, due to this process, new forms of organization are emerging. By providing more tools of political action, the Internet probably will lead to a convergence in contemporary political mobilization.

CONCLUSION

New technologies are a relevant and underestimated instrument for producing institutional convergence. The concept of institutional isomorphism, as it emerges from the literature on institutional studies, has to be rearticulated in order to consider the role of technological tools, starting from the assumption that ICTs may in several ways conduct to standardization within and between institutions. Indeed, especially supranational governments are betting on their transformative potential for creating integration and interoperability between different levels of government.

Is the homogenization a specific European product or a further puzzle piece of the broader globalization process? The idea of knitting together the world's economies into a single unit seems to suggest the necessity for nation states to adopt a shared administrative model. In addition to this, studies on what it is happening in other nonwestern countries seem to support the thesis of uniformity. For instance, if the European Union tries to reach a difficult equilibrium between the aspiration of administrative decentralization and the need for uniformity, e-government initiatives have

been recently interpreted in China as "vehicles intended to support economic development through an increasingly transparent and decentralized administration while at the same time providing the central government the information and ability to efficiently monitor" (Ma, Chung, & Thorson, 2005, p. 20). Further research may be dedicated to evaluate differences and similarities of various geopolitical areas. Anyway, the strategic use of new technology can begin to be intended as one of the most important variables of institutional isomorphism.

KEY TERMS

Code: The digital architecture which regulates the cyberspace, the complex system of software and hardware instructions defining Internet rules

E-Government: The application of new information and communication technology for the restructuring of public administration and the renewal of the relationship between public institutions and citizen-users

European Administrative Convergence: The process for which administrations become more similar and close to a common European model

ICTs: Acronym for information and communications technologies. It is a general term that describes any technology that helps to produce, manipulate, store, communicate, or disseminate information

Interoperability: Ability of ICT systems and business processes to exchange data and enable the sharing of information and knowledge

Isomorphism: A constraining process that forces one unit in a population to resemble other units facing the same set of environmental conditions. It stimulates an evolutionary path from diversity to homogeneity, as the result of imitation among organizations or independent development under similar constraints

Organizational Hybridity: (a) a process of hybridization based on the selective transplantation and adaptation of digital network repertoires previously considered typical of social movements (b) the emerging of new organizational forms that exist only in hybrid form and that could not function in the ways that they do without the Internet and the complex spatial and temporal interactions it facilitates.

Standardization: The process of creating uniformity through established standards

Instructional Support for Distance Education

Bernhard Ertl
Universität der Bundeswehr München, Germany

INTRODUCTION

During the late '90s, distance education and e-learning were believed to be able to solve almost every problem associated with the further qualification of employees in organizations. Distance education was credited with saving costs for companies, by reducing time and expenses for traveling and with flexible time management. Consequently, many companies started programs for distance education. However, after this initial euphoria, several organizations experienced problems with their programs (e.g., Haben, 2002). The costs for distance education courses exploded, employees refused the new style of learning, and the general question arose as to the effectiveness of distance education (see, e.g., Bernard et al., 2004). Looking at the range of distance education courses at this time, one could see that they used a broad variety of technologies to deliver learning contents to the learners, for example, videos, Web pages, dedicate software for learning, Weblogs, wikis, collaboration tools, videoconferencing, chat, and discussion boards. However, in contrast to the variety of technologies available, the instructional design of these courses was elementary and traditional (see Ertl, Winkler, & Mandl, 2007). Many courses offered recorded classroom lectures and streamed them to participants, or they just presented texts or slides in the style of a book. Such courses experienced a lack in acceptance and thus several efforts of distance education failed because the instructional design of these courses was not able to take advantage of the innovative technologies.

BACKGROUND

To take advantage of the emerging technologies, a new philosophy of learning and teaching is necessary. Moderate constructivist approaches focus on several activities of learners that are necessary for the successful implementation of distance education courses. They build on learners' active knowledge construction and postulate that learning requires learners' active participation. This is in contrast to traditional approaches, which set learners in a receptive role. According to constructivist approaches, learning is mediated by learners' individual prior knowledge, their motivation, and other individual learning prerequisites. Reinmann-Rothmeier and Mandl (2001) describe several key-elements for construction of knowledge according to this philosophy (see also Ertl, Winkler, & Mandl, 2007). They state that a learning process is:

- **Active**, because only active involvement enables learning.
- **Self-directed** and learners have to take active control and responsibility for their learning activities.
- **Constructivist**, which means that learners have to embed new knowledge in their existing knowledge structures.
- **Social** and knowledge acquisition requires a social context.
- **Situated** because knowledge acquisition happens in a specific context and is linked to this context.
- **Emotional**; the emotional component is particularly important for the motivation of the learners.

Besides these constructivist aspects, learning environments require a certain amount of instruction (Ertl et al., 2007; Kirschner, Sweller, & Clark, 2006; Reinmann-Rothmeier & Mandl, 2001). Consequently, learning environments need to find a balance between construction and instruction. This balance can be realized by the design of problem-oriented learning environments (see Mandl, Gräsel, & Fischer, 1998) and case-based learning scenarios (Kolodner et al., 2003). Such learning environments can benefit from new technologies; they can provide tools for supporting the active construction of knowledge (Roschelle & Teasley, 1995), provide an authentic situational context by the display of video cases (CTGV, 1997), enable the social context for spatially-divided learners (Mandl, Ertl, & Kopp, 2006), and motivate learners by the provision of gimmicks and animations (Mayer, Hegarty, & Mayer, 2005). However, none of these benefits are caused by the technology itself—they are introduced by the instructional design of the learning environment including the use of the new technologies.

This chapter focuses on two particular aspects how the instructional design can apply new technologies for the improvement of learning environments: on collaboration-specific methods structuring learners' collaboration, and on content-specific methods that are supporting learners' active construction of knowledge.

COLLABORATION-SPECIFIC METHODS

Methods for facilitating learners' collaboration may be associated with several tools, particularly software products that aim at enabling collaborative work or at supporting particular collaborative tasks (e.g., collaborative drawing or text editing). These tools can support collaboration between learning partners, yet the fact remains that collaborative skills often do not come naturally to the individual learner and must therefore be acquired (see Salomon & Globerson, 1989). Instructional approaches focusing on the improvement of collaboration often refer to methods such as *scripted cooperation* (O'Donnell & King, 1999). Such scripts sequence learners' work on the task. Furthermore, they may provide roles for the learners and encourage them to apply beneficial strategies for solving a task.

As an example, the MURDER-script (Dansereau et al., 1979; O'Donnell & Dansereau, 1992) is comprised of several different aspects, and will therefore demonstrate the potential elements of scripts and their combination. This script relates to a collaboration process in which learners work collaboratively on text comprehension. It divides the collaborative learning process into six phases that focus on individual as well as on collaborative activities. The first phase relates to learners personal motivation for the task ahead (*M*ood). The second phase focuses on individual text comprehension (*U*nderstand). In the third phase, one partner repeats contents of the text from his memory (*R*epeat) while the other partners try to find difficulties and give feedback (4th phase; *D*etect). In the following, learners reflect and elaborate about the content to link the learning material with their prior knowledge (5th phase; *E*laborate). Finally, they check their work against the original text material (*R*eview, 6th phase). Learners may repeat these six phases for several text paragraphs and for each cycle, a different learning partner takes the role to repeat the text contents.

Technologies can integrate such scripts into collaborative learning environments. They may structure the collaboration process or the proceeding in the work on the task. Baker and Lund (1997), for example, report a script, which specifically directed the collaboration process. Their learning environment provided a shared graphics editor for working on a collaborative product and the instructional design added several *speech act buttons* to this editor. Each time a learner had made changes to the collaborative product, the learning environment required both partners to agree on these changes before continuing. They were required to demonstrate this by pressing the respective speech act buttons. The intention of this mechanism was that both learning partners increased their grounding (Dillenbourg & Traum, 2006) and their collaborative commitment to the joint product (Baker & Lund, 1997).

Ertl, Reiserer, and Mandl (2005) showed a different example for scripting in distance education using a videoconferencing scenario. The aim of this script was to facilitate learners during the task of collaborative teaching. This script structured the collaborative proceeding on the task, the roles of the learners, and the application of beneficial strategies regarding the collaborative negotiation. Therefore, the script assigned two different roles to the learners, the role of a teacher, and the role of a learner. Furthermore, it divided the collaboration process into four different phases. Learners worked with a shared application in this scenario, and this application offered learners a space for written externalizations. Furthermore, the application was pre-structured with instructional elements that guided learners according to the script. In the first phase, the participant in the teacher role explained the text material while the partner in the learner role asked comprehension questions. In the second phase, the learner rehearsed the concepts acquired and fixed important aspects in the shared application. The teacher supported the partner and clarified misinterpretations. In the third phase, both partners reflected individually, and in the fourth phase, they discussed the learning material. In this phase, the learner also noted important aspects in the shared application. After these four phases, learners switched their roles and continued with another text.

Results of the study showed that the learning environment with the script was able to facilitate learners' negotiation with theoretical concepts during collaboration. With respect to the individuals' learning outcomes, the script particularly facilitated learners in the learner role. They acquired more knowledge during collaboration than learners without a script (see Ertl, Reiserer, & Mandl, 2005). Other studies also report beneficial effects of scripts in distance education courses. These were related to the learning processes (Baker & Lund,

Table 1. Taxonomy of support methods with different goals

Goal of support	Collaboration-specific methods	Content-specific methods
Improving collaborative processes	Scripts	
Understanding impact factors		Simulations
Understanding structures		Templates
Understanding relations		Conceptualization tools

1997; Weinberger, Ertl, Fischer & Mandl, 2005) as well as to the individuals' outcomes (Rummel & Spada, 2005). Scripts may improve general processes of collaboration (Baker & Lund, 1997), lead to a more homogeneous work on the task (see Weinberger, 2003) and to the acquisition of beneficial collaboration strategies (Rummel & Spada, 2005).

CONTENT-SPECIFIC METHODS

Content-specific methods rely on particular affordances of the course's content domain. They may provide domain categories or ontologies for the learners (see, e.g., Ertl, Fischer, & Mandl, 2006), facilitate the visualization of conceptual relations (see Fischer, Bruhn, Gräsel & Mandl, 2002), or provide simulations or visualizations which help learners to understand particular mechanisms (see Roschelle & Teasley, 1995). Content-specific methods aim for support at a conceptual level and try to facilitate learners' understanding of particular conceptual aspects, relations, or mechanisms of the content domain (see Table 1).

Content-specific methods often rely on a particular representation of important content structures. Zhang and Norman (1994) postulate that this representation of content has an influence on learners' ability to deal with the content. If a method changes the representation of the content then it might be that learners perceive this content in a different manner. This may facilitate as well as impede learning—depending on the match between the representation and the learners' cognitive structure (see Zhang & Norman, 1994). This means that the content structure remains the same (it is isomorph) but the way in which it is presented changes. A rather simple example for this mechanism would be to provide a diagrammatic representation instead of a textual description (see, e.g., Larkin & Simon, 1987). The representation can make important task characteristics salient and function as a representational guide for the learners (see Suthers & Hundhausen, 2003). There is a broad variety of methods and tools for this kind of facilitation (see Löhner & van Joolingen, 2001). They offer different amounts of facilitation to the learners, and they vary with respect to the degrees of freedom the learners have when working with them.

In distance education, one has to distinguish between tools, which enable content-specific facilitation, and the instructional design, which applies the tools to a particular context and provides the facilitation. Powerful tools may offer many possibilities and much freedom to the learners. However, this may be too complex for the learners, who may not have the cognitive ability to apply it correctly and thereby suffer from cognitive overload (see Sweller, van Merrienboer, & Paas, 1998). Consequently, it may be too complex for beneficial activities (see Dobson, 1999) and negate the potential facilitation effect. The instructional design of a distance education course should therefore consider the skills and the prior knowledge of the learners (see Mandl, Ertl, & Kopp, 2006; Shapiro, 2004) and aim for a balance between learners' experiences and the demands of the tools.

In the following, we will describe briefly different forms of content-specific support:

- Tools for simulations (see Roschelle & Teasley, 1995) allow learners to *simulate* scientific processes. The instructional design of these tools is such that the learner can simulate a process according to various parameters. The particular tools for simulations are modeled specifically for this one purpose and might also include visualizations or animations of these processes. Learners can modify the parameters of the simulation and observe the results of this change in the simulation. Thus, simulations aim at understanding the influence of particular factors on a whole (simulated) system.
- Templates are different from simulations in that they *pre-structure* a content domain (see Brooks & Dansereau, 1983; Ertl, Fischer, & Mandl, 2006; Suthers & Hundhausen, 2003). In this case, the tool provides the features to create templates, and the instructional design specifies the contents of these templates. It provides categories that are particularly important for content-specific negotiation and often uses tables for their representation. These tables provide empty spaces for the learners which help them to focus on the important categories. However, learners cannot change the structure of the tables and model new relations. Consequently, templates aim at internalizing the structure of a content area.
- Conceptualization tools allow the visualization of connections between different concepts within a subject matter. They enable learners to illustrate connections between concepts and theories by creating a mind map or a similar diagram. The tool provides the concepts and various types of connecting lines that are then sorted and put together to demonstrate the connections. Learners may thereby create their own representation, but the process is supported by the pre-existing elements used (see Fischer et al., 2002; Suthers & Hundhausen, 2003). Consequently, conceptualization tools are intended to facilitate a deeper understanding of the relationships within a particular content area.

Ertl, Reiserer, and Mandl (2005) present an example for a content-specific method in a distance education course in the style of a template. This template aimed at facilitating learners' learning of text material. It focused learners on important aspects of theories, particularly on the categories of theory concepts, evidence, and personal elaborations with respect to consequences and learners' individual opinion. They used a shared application for providing the template to the learners. The instructional design provided a table

with four cells headed by the respective category names. Furthermore, it anchored the rather broad categories by different prompts in each table cell.

Results of the study show that this template provided several benefits for the learners. They reached a higher score in the category of evidence, and they provided more personal elaborations (see Ertl, Reiserer, & Mandl, 2005). Thus, the template was able to direct the learning process not only to the memorization of facts, but also on the personal contextualization of these facts. Moreover, several other studies have shown beneficial effects of content-specific methods in the context of distance education (see Ertl et al., 2006; Fischer et al., 2002; Roschelle & Teasley, 1995; Suthers & Hundhausen, 2003). Roschelle and Teasley (1995) report beneficial effects of simulations for transactive discourse and knowledge co-construction. Ertl et al. (2006) present a template, which provided benefits for learners' collaborative learning process as well as for their individual knowledge acquisition. Suthers and Hundhausen (2003) reported that a template had facilitated the learners to draw relations between theoretical concepts and evidence. Furthermore, Fischer, Bruhn, Gräsel, and Mandl (2000) found that conceptualization tools homogenized collaborative learning processes.

FUTURE TRENDS

Studies which compared learning environments with a sound instructional design and traditional courses report an increased quality of education, a more active role of the learners, and more motivated learners if they were working in the well-designed learning environment (see, e.g., Hiltz, 1997; Lehtinen, 2003). In contrast, studies which just compared different technologies were hardly able to find any beneficial effects of the technologies for learning (e.g., Clark, 1994; Salomon, 1984; Schweizer, Pächter, & Weidenmann, 2001; Storck & Sproull, 1995). This means that distance education courses can provide "powerful learning environments". However, this power comes from the collaborative setting and from their instructional design rather than from technology. The future of e-learning will evoke some kind of consolidation in the field. Distance education courses will be more and more subject to evaluation. This will disclose how far a particular course or technology can provide benefits for the learners.

CONCLUSION

This chapter dealt with instructional support for distance education courses. This is of particular importance for distance education because many distance education courses have a fairly simple instructional design. They provide either lectures without any opportunity for learners' individual knowledge construction or merely offer resources without any guidance for the learners. Courses for distance education should use well balanced aspects of construction and instruction to provide benefits for the learners. The instructional design of courses may be featured by several methods which apply information technology. Collaboration-specific methods structure collaboration tools to optimize collaborative learning processes. Content-specific methods use tools to facilitate learners' collaborative knowledge construction on a conceptual level. Both can enhance the instructional design and the outcomes of distance education courses.

KEY TERMS

Collaboration: Tightly working together with a strong commitment of collaboration partners.

Collaborative Knowledge Construction: Learners' joint activities to acquire or create new knowledge.

Content Scheme: Tabular representation of domain-specific structure to facilitate learners.

Instructional Design: The didactical rationale for a learning scenario which includes instructional elements as well as the application of tools.

Knowledge Construction: Learners' work with their knowledge in a way that they link their new knowledge to their existing knowledge base in stead of memorizing facts.

Learning Environment: Learners' context in distance education courses that is comprised of instructional, social, and technical aspects.

Powerful Learning Environment: A learning environment which includes instructional elements that evoke learners' active construction of knowledge.

Script: Specification of learning processes which contains procedural aspects, the assignment of roles, and the evocation of beneficial cognitive activities.

Integrating Domain Analysis into Formal Specifications

Laura Felice
Universidad Nacional del Centro de la Pcia. de Buenos Aires, Argentina

Daniel Riesco
Universidad Nacional de San Luis, Argentina

INTRODUCTION

Reusability is widely suggested as a key to improve software development productivity. It has been further argued that reuse at domain level can significantly increase reuse at later stages of development. The development of a particular system that exploits previously accumulated domain knowledge can be the source for new insights about the domain that adds to or refines. The classification of similar problems grouped by domains is the key to find reusable solutions that belong to similar problems. This work deals with the integration of a reusability model into a formal method in order to enhance the benefits of reusability at the domain and design levels. Working with formal methods, software reuse problems such as the detection of inconsistencies in component integration can be revealed in early stages of development.

The rigorous approach to industrial software engineering (RAISE) (George et al., 1995) formal method was originally designed to be applied at different levels of abstraction as well as stages of software development. It includes several definition styles of specifications such as model-based or property-based, applicative or imperative, sequential or concurrent. However, it is not easy to identify reusable specifications, due to the fact that objects identified from this method tend not to be reusable in other applications as they are defined without a proper domain perspective. Even though RAISE supports object-orientation, the major approaches to object identification (keyword analysis, structured analysis, scenario-based analysis) can not provide support for reusability and adaptability of applications without analyzing the commonality and variability among a family of applications in a domain (Lee, Kang, Chae, & Choi, 2000).

To address this problem, there have been methods for reuse whose development has been based on the notion of "domain orientation" (Barstow, 1985; Prieto-Diaz, 1987), which emphasizes a group of closely related applications in a domain rather than a single application. The exploitation of commonality across related software systems is a fundamental technical requirement to achieve successful software reuse. Software product lines (PL) (Kang, Kim, Lee, & Kim, 2003) present a solid approach in large scale reuse. Due to the PL's inherit complexity, many PL methods use the notion of "features" to support domain modeling (e.g., FODA) (Kang et al., 1990), FORM (Kang, Kim, Lee, & Kim, 1998), FeatuRSEB (Griss, Allen, & d´Alessandro, 1998). These methods identify common abstractions across the applications of a domain in order to engineer reusable domain components. Feature modeling mainly focuses on identifying commonalities and variabilities among products of a PL, and organizing them in terms of structural relationships (e.g., aggregation and generalization) and configuration dependencies (e.g., required and excluded).

This work is related to the introduction of a feature-oriented reuse method to the RAISE components specifications and to give a solution to "bridge" the gap between the domain analysis and the specifications in RAISE (Riesco, Felice, Debnath, & Montejano, 2005). In particular, FORM method (feature-oriented reuse method) is introduced in order to gradually improve the reuse of RSL (George et al., 2002) components specifications, incorporating the effectiveness of software reusability as an integral part of the software specification process, considering the following:

- To create a plan of reuse as part of the project plan
- To add steps to look for and evaluate reusable component candidates to use in the project
- To add guidelines to create a future component for reuse
- To evaluate the benefits and costs associated with the practice of reuse in the project
- To finally identify created components of the project which have the potential for reuse in the future

BACKGROUND

PL engineering is an emerging software engineering paradigm, which guides organizations toward the development of products from core assets rather than the development of products one by one from scratch. Two major activities of PL are core asset development (i.e., product line engineering) and product development (i.e., product engineering) using the core assets. The paradigm of developing core assets for application development has been called domain engineer-

ing (DE), in which emphasis is given to the identification and development of reusable assets from an application "domain" perspective (Lee, Kwanwoo, Kang, & Lee, 2002). The purpose of domain engineering is to develop domain artifacts that may be used and reused in development applications for a given domain. DE consists of activities for gathering and representing information on systems that share a common set of capabilities and data. In usual approaches to software reuse, the product of such domain engineering might include only the reusable components and their parametric representations applicable to that domain.

DE, the key to systematic software reuse, has two phases: domain analysis (DA) and domain implementation.

DA is the process of discovering and recording the commonalities and variabilities in a set of software systems, while domain implementation is the use of the information from DA to create reusable assets and new systems within a domain (Frakes, 1994).

The view of DA follows the line of thought pioneered in Neighbors' DRACO system (Neighbors, 1980), where the importance of DA in reusability was pointed out. This is summarized as "to identify objects and operations for a class of similar systems."

DA is a process that affects the maintainability, usability, and reusability of a system and includes:

- Domain definition
- Domain analysis
- The development of a domain architecture
- The construction of components (specifications, design, documentation)

In the field of software engineering, DA is seen as a prerequisite for successful reuse not only by the researchers in the reuse community but also by the methodologists who have introduced component-based development methods (D'Souza & Wills, 1999; Gamma, Helm, Johnsson, & Wlissides, 1995; Jacobson, Booch, & Rumbaugh, 1999). A review of some domain analysis methods is presented in Kang (1990) and an extensive domain analysis bibliography can be found in Hess et. al. (1990).

The result of the analysis, usually known as the domain model, is retrieved for reuse in future developments or similar systems and also, for maintainability of legacy systems.

In a reuse strategy, DA must be maintained over many systems, and the repository should contain domain models that form the basis of subsequent development activities.

DA is essential to formalize reuse. However, it is missing from most software development methods. Reuse engineering extends information engineering by adding the new stage "domain analysis" to provide a place in the life cycle where the most valuable reusable components for the domains of the enterprise can be identified and a library containing these components can be created. At this stage of the software development, working with formal methods (or formal specification languages, specifically) implies to provide a means of unambiguously stating the requirements of a system, or of a system component. In this way, formally specified system components that meet the requirements of components of the new system can be easily identified. Thus, components that have been formally specified and sufficiently well documented can be identified, reused, and combined to form components of the new system.

Nevertheless, the main problem is that the requirements may not be clear. Specially, when the requirements are written in a natural language the result is likely to be ambiguous. The aim of the initial specification is to capture the requirements in a precise way applying a reusability model.

In particular, there are two main activities in the RAISE method: writing an initial specification, and developing it towards something that can be implemented in a programming language (George et al., 2002). Writing the initial specification is the most critical task in software development. If it is wrong (i.e., if it fails to meet the requirements) the following work will be largely wasted. It is well known that mistakes made in the life cycle are considerably more expensive to fix than those made later. So, the introduction of a DA method is a crucial task considering the possibility of reusing the specifications in the future.

Examples of more relevant DA methods include FODA, FORM, and FeatuRSEB. They support the notion of feature-oriented. This is a concept based on the emphasis this method places on finding the features or functionalities usually expected in applications for a given domain. The FORM engineering processes are illustrated in Figure 1.

THE FORM METHOD

FORM product line engineering consists of two major processes: asset development and product development, as it can be seen in Figure 1. Asset development consists of analyzing a product line (domain analysis, feature modeling) and developing architectures and reusable components based on analysis results. Product development includes analyzing requirements, selecting features, selecting and adopting an architecture, and adapting components and generating code for the product.

This method has been applied to several industry application domains including elevator control systems, electronic bulletin board systems yard automation systems and PBX, to create product line software engineering environments and software packages (Kang et al., 2003).

CONCEPTS

Feature-Oriented

The use of "features" is motivated by the fact that users and developers often speak of product characteristics in terms of "features the product has and/or delivers." In a DA, primary inputs are documents of applications (users manual, design documents, etc.). The volume of the documents to be analyzed tends to be enormous in a domain of any reasonable size. The experience has shown that the DA can be performed efficiently by instead analyzing the domain language. That is, services provided, and techniques used in applications are abstracted as "features," and they are used by domain experts to communicate their ideas, needs, and problems. Feature models have been used to support different engineering techniques, re-engineering legacy systems (Kang, Kim, Lee, & Kim, 2005), and other purposes (Czarnecki, & Antkiewicz, 2005). An informal definition of feature is stated as essential characteristics of applications in a domain. Also, rigorous conceptual foundations for feature modeling have been introduced (Asikainen, Mannisto, Soininen, 2006).

Summarizing, features may serve as a means of:

- Modeling large domains
- Managing the variability
- Future planning
- Communication between system stakeholders
- Guiding the PL development

To create coherent models, feature analysis involves tasks for identifying, classifying, and organizing product features as models.

Feature Classification

As potential features are identified, they are classified according to the types of information they represent. For example, users are concerned with functions provided by the systems (i.e., service features), analysts and designers are concerned with domain technologies, and developers are concerned about implementation techniques.

Thus, four categories are distinguished: those about application capabilities, operating environments, domain technologies, and implementation techniques.

A feature model should cover all four categories of features for a domain. To make it possible, FORM uses the following constructs:

- A feature diagram, a graphical AND/OR hierarchy of features, capturing the logical relationships (composition/generalization) among features. Three types of relationships are represented in this diagram: "composed-of," "generalization/specialization," and "implemented-by." Also, features may be "mandatory" (unless specified otherwise), "optional" (denoted with a circle), or "alternative" (denoted with an arc) (see the example in Figure 2).
- Composition rules that supplement the feature diagram with mutual dependency and mutual exclusion relationships.

Depending on the domain, it is possible that AND/OR diagram tends to become complex.

A feature model with AND-nodes at an upper level and OR-nodes at a lower level indicates a high level of reuse opportunity. Alternatives (i.e., OR-nodes) at the upper level

Figure 1. FORM engineering processes

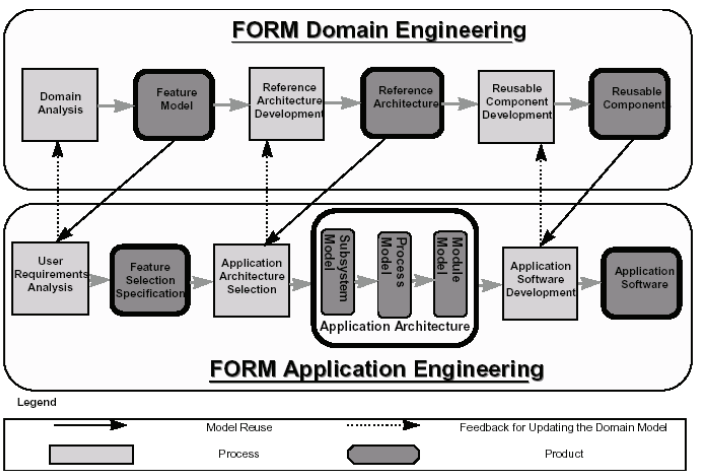

Figure 2. Feature Model of Agriculture system domain

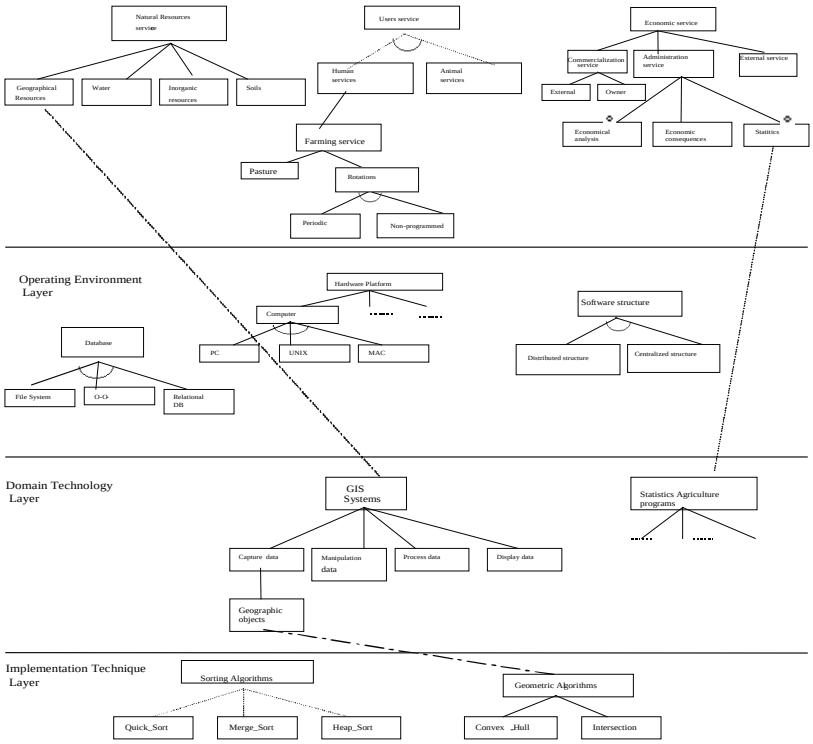

Relationship

Composed of

Generalization/ Specialization

Implemented by

usually mean that applications in the domain do not share much commonalities in terms of services and functions provided by them. This indicates that the domain might not have much reuse opportunity at the application level, although there might still be opportunities for reuse at low-level generic components such as math libraries and abstract data types. Alternatives (OR-nodes) at a lower level indicate different ways of implementing certain components and, with an appropriate application of information hiding and encapsulation techniques, reusable components can be developed.

Features are largely classified into functional and non-functional features. Functional features include services and operations that are needed to provide services. Figure 2 shows the feature model of agriculture system domain (Riesco et al., 2005).

Features are considered following the four level feature hierarchy since the hierarchy reflects step-wise refinement in the reference architecture. These concepts are strongly connected with the style of development in RAISE, where the separate and step-wise are the basis to build a solid specification of an infrastructure.

Figure 2 shows some features (represented as tree nodes) exhibited in the Agriculture system domain. A capability feature characterizes a distinct service, operation, function or performance that a given domain may possess. For instance, “natural resources service,” “users service,” and “economic service” are features that characterize the functional aspects of the agriculture systems. It is assumed that natural resources are geographical resources, water, inorganic resources and soils.

On the other hand, users may be animal or human services. Humans have motivations related to the services that farming groups can do. With respect to economic service, it includes people and other services linked to a different domain. The agriculture system is an information system whose objective is the model, which will help deciders to identify problems with the management and the access to resources for several purposes. Thus, an operating environment feature represents attributes of environment in which this system is operated. In this case, this is not a crucial objective; the hardware platform will be related to the equipment (e.g. “PC”), operating system, database systems,

and software structures. Domain technology feature is more specific to a given domain. For instance, GIS systems are closely related with geographical features and the way to capture process and display data. It works with geographic objects linked directly with geometric algorithms allocated to Implementation technology feature that are more generic and may be used in another domain.

The domain model products should represent the relevant information about the objects and the functionality of a family of a similar system in a domain. The validation of the model is obtained by reproducing known applications through the selection of specific features and building a prototype system.

RAISE SPECIFICATION ARCHITECTURE

To be able to incorporate the idea of reusability in different forms of development, it is necessary to take into consideration many activities that have to be applied to the RAISE method. It provides guidelines to hierarchically structure a specification, aiming the encouragement of separate development and step-wise development.

A development in RAISE begins with an abstract specification and gradually evolves to concrete implementations. Figure 3 shows these phases. RAISE proposes to structure modules hierarchically in order to get a particular component over by reference only to it and its suppliers, to limit the effects of changes of a module to it and its clients, and to limit the properties of a module to it and its suppliers.

It is an object-oriented method and covers a large portion of systems development phases. Nevertheless, in these phases, DA is absent before the first specifications. Our work is focused on the incorporation of DA upon the idea of specifying and designing a family of systems to produce qualitative applications in a domain, promoting early reuse and reducing development costs.

This architecture is the basis to start applying the steps of the RAISE method. Also, in Riesco, Felice, Debnath, & Montejano, 2004) concepts and assumptions of component reuse were analyzed based on the class generality assessment and relations among classes.

Our aim is to concentrate on an earlier analysis according to the "features" for a domain and then, to improve the specifications development by building a feature model.

The Architectural Model

FORM gives a set of guidelines that can be used to derive domain products from the feature model. Each feature somehow constrains the selection of the final reference model considering differences in types of features following the four level hierarchy (Figure 4).

Following, it is discussed how the feature model serves as a guideline to identify RSL reusable modules. In the example illustrated in Figure 3, model service features such as natural resources service, users service, and economic service play different user roles for the purpose of the agriculture systems. Thus, they can be mapped respectively into natural resources, users and economic RSL modules, each of which performs a set of operations with its specific role. Once a feature is mapped into a module, the sub-features of the feature such us geographical resources, water, inorganic resources, and soils can be modules that are part of natural resources following the same type of relationships in the feature model (e.g., generalization, aggregation).

Besides, operations can be mapped as internal functions to provide services, and they are a collection of types and values without type of interest.

On the other hand, non-functional features include end-user visible application characteristics that cannot be identified in terms of services or operations like quality attribute, cost, etc, so, they can not be mapped into any RSL constructions.

With respect to the model operating environment features, the RSL specifications are independent from the operating environment. These features can be mapped into the subsidiary RSL modules, which are less important from the point of view of development.

Figure 3. Phases of the RAISE method

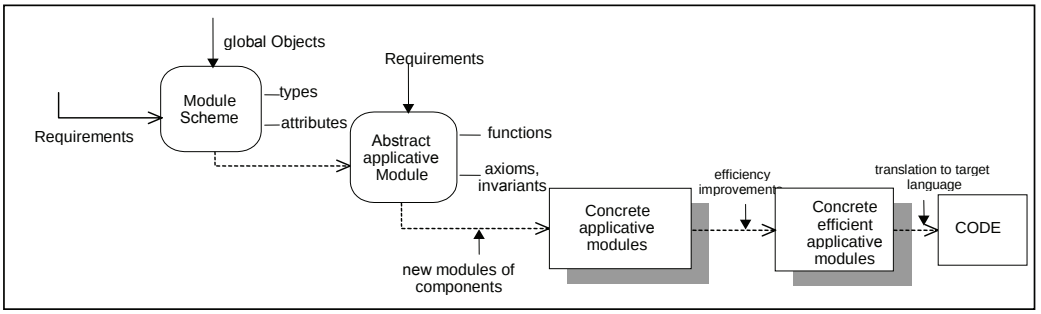

Figure 4. Mapping from feature categories to RSL specification

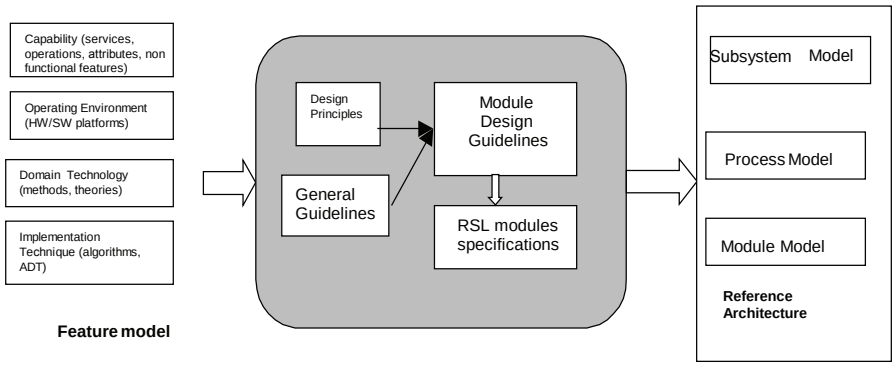

Model domain technology features such as GIS systems will be considered by the RSL system modules and they will be expected to be finally implemented as software modules. In object-oriented terms, they will form the objects of the software system.

Modules derived from implementation technique features are generally used to implement or to derive concrete applicative specifications derived from capability or domain technology features. Both sorting algorithms and geometric algorithms would be part of a module called "algorithms." This module will be defined as a generic module (i.e., a module we expect to instantiate more than once with different parameter), being the sub-features (QuickSort, Merge_Sort, Intersection) the possible instantiations.

Each RSL module derived would be later refined and completed with the definition of functions. In Mauco, Riesco, and George (2001) some heuristics to derive functions in a RSL specification are defined.

Once the RSL modules are derived from the feature model, they need to be organized into a model in order to represent how they are related to each other and what the contexts for their use are.

To finally get the reference architecture model it is necessary to make a sequence of refinements: subsystem architecture, process architecture and the module architecture.

CONCLUSION

Domain analysis is seen as a prerequisite in successful reuse not only by the researches but also by the methodologists who have introduced component-based development methods. FORM is one of the promising methods for the identification of the desired system functionalities. The contribution of this work consists of the integration of this methodology into a formal method. It is a useful tool that allows to work with the identification of commonalties and variabilities among related applications creating a feature model of a specific domain. More precisely, a feature model has been developed for the Agriculture system being the basis to the specifications of the RAISE reusable component.

The use of formal methods in system development can help to overcome inconsistencies, and should aid the promotion of software reuse in early stages of software development.

KEY TERMS

Domain Analysis: DA is a process that affects the maintainability, usability, and reusability of a system and includes:

- Domain definition
- Domain analysis
- The development of a domain architecture
- The construction of components (specifications, design, documentation)

Domain Engineering: DE consists of activities for gathering and representing information on systems that share a common set of capabilities and data. In usual approaches to software reuse, the product of such domain engineering might include only the reusable components and their parametric representations applicable to that domain. DE, the key to systematic software reuse, has two phases: domain analysis (DA) and domain implementation.

Feature:

- Is anything users or client programs might want to control about a concept?
- Is a coherent and identifiable bundle of system functionality that helps characterize the system from the user perspective?
- Is a prominent or distinctive user-visible aspect, quality, or characteristic of a software system or systems?

Feature Modeling: The process where it is documented only functional features but also implementation features, various optimizations, alternative implementation techniques, and so on.

RAISE Method: RAISE is a formal method. It is an acronym for “rigorous approach to industrial software

engineering" It provides facilities for the industrial use of formal methods in the development of software systems. RAISE consists of the RAISE specification language (RSL), which is a powerful specification and design language and a comprehensive development method.

Software Product Line: A software product line is a set of software-intensive systems that share a common, managed set of features satisfying the specific needs of a particular market segment or mission and that are developed from a common set of core assets in a prescribed way.

Integrating Enterprise Systems

Mark I. Hwang
Central Michigan University, USA

INTRODUCTION

In the last two decades many organizations installed enterprise resource planning (ERP) systems as a means to integrate their back-office operations. The need for integration, however, actually amplified with the advent of ERP. In addition to integrating ERP with legacy systems, consolidating multiple copies of ERP running in different business units posed major challenges. Moreover, recent strategic initiatives such as customer relationships management (CRM), supply chain management (SCM), business to consumer (B2C), and business to business (B2B) all require a free flow of information between ERP and other enterprise systems to be successful. It is, therefore, more critical than ever to plan for and implement integration projects involving ERP properly. Hwang (2005) describes the need for integrating enterprise systems in detail. He also discusses several success factors cited in practitioner journals. Since then a handful of empirical studies have been published in the scholarly literature. This article provides a review of those studies with a special focus on the success factors. A consolidated list of success factors is developed for practitioners. Promising research directions are discussed.

BACKGROUND

While researchers have examined integration issues for some time, it was not until the early 2000s that empirical studies involving ERP began to appear in the literature. Table 1 summarizes the characteristics of the five empirical studies reviewed, and Table 2 summarizes the critical success factors (CSF) discussed. Alshawi, Themistocleous, and Almadani (2004) investigated the feasibility of minimizing ERP customization through integrating two ERP packages. They found that an enterprise application integration (EAI) tool was useful in integrating SAP R/3 with an Oracle H/R module at a telecommunication company. Sharif, Irani, and Love (2005) studied the integration project of a global industrial company involving ERP and legacy systems. The integration effort was deemed unsuccessful based on a post hoc evaluation model that they developed. Lam (2005) proposed a CSF model for EAI projects. He termed this the BOTP model, after the categories into which the success factors fall: business, organization, technology, and project. A case study involving a large financial services provider integrating its consumer banking systems revealed three broad groups of success factors: top management support, integration strategy, and project planning and execution. Mendoza, Perez, and Griman (2006) developed a set of 20 CSFs and tested them in two case studies, one in a B2B and the other in an ERP setting. Many but not all of the success factors were present in the two companies. Finally, Stefanou and Revanoglou (2006) examined a successful ERP implementation at a hospital.

Alshawi et al. (2004) and Stefanou and Revanoglou (2006) did not discuss their findings in the context of some type of success models. The three studies that did classified various CSFs by their types (e.g., organization vs. technology) or the type of integration involved (e.g., intra- vs. inter-organization). One group of variables discussed by Sharif et al. (2005), for instance, deals with ERP II tailorability, the ability to integrate ERP with customers via CRM and B2C and with business partners via SCM. Building on the maturity model of Schmidt (2000), Mendoza et al. (2006) developed their list of CSFs based on different levels of integration, from level one point-to-point integration to level

Table 1. Study characteristics

Study	Case Study	CSF Model
Alshawi et al. (2004)	Integrating two ERP systems	No
Sharif et al. (2004)	Integrating ERP with legacy systems	Yes
Lam (2005)	Integrating ERP with legacy systems	Yes
Mendoza et al. (2006)	Integrating ERP with legacy systems; B2B integration	Yes
Stefanou and Revanoglou (2006)	Integrating ERP with legacy systems	No

Table 2. Critical success factors in the literature

Study-	Business	Organization	Technology	Project
Sharif et al. (2004)	1. optimization of business models 2. acceptability of success	1. effect of influencers	**1. vertical specialization** **2. horizontal specialization** **3. extended ERP functionality**	1. scope of technical effort involved
Lam (2005)	1. strong business case 2. overall integration strategy **3. process interoperability with business partners**	1. top management support 2. business process change and overcoming resistance to change 3. good organizational and cultural fit	1. handling legacy systems 2. technology planning 3. common data standards 4. use of right tools 5. use of mature technology	1. realistic project plans and schedule 2. client involvement, communication, consultation, and training 3. required skills and expertise on-board, vendor competence 4. monitoring and feedback 5. proper migration approach 6. adequate testing plans
Mendoza et al. (2006)	1. careful strategy of implementation	**1. valuable support by senior management** **2. change determined and justified at a productivity level** 3. effective organizational change management **4. appropriate strategy of security** 5. known organizational structure	1. standard data model documentation, unification, and updating 2. appropriate configuration of communication software 3. helpful technical support 4. complete technological infrastructure	**1. effective outgoing and incoming communication** **2. adequate management of project scope** 3. appropriate outsourcing management 4. high expertise project team 5. low impact of IS on the organization 6. effective internal and external training plan 7. relevant user involvement 8. valuable project management 9. effective project leadership 10. significant administrative support for the project consultant

four external integration. Lam (2005) does not distinguish internal from external integration projects but acknowledges that some factors such as "process interoperability with business partners" are more important in inter-organization settings than in intra-organization settings.

Table 2 organizes the CSFs into four groups of Lam (2005): business, organization, technology, and project. This is a general classification scheme into which any success factor can be classified. At the same time, it makes sense to differentiate factors that are oriented toward more external integration or ERP II tailorability (Sharif et al., 2005) than internal integration. Those external-oriented factors are boldfaced in Table 2. It is, however, important to note that the internal/external dimension should be treated as a continuum rather than a dichotomy because some factors apply to both intra- and inter-organizational settings (Mendoza et al., 2006)

CRITICAL SUCCESS FACTORS

As can be seen in Table 2, the success factors discussed by different researchers share a number of commonalities. A consolidated list of success factors is presented in Table 3, with factors that are either common across different studies or fit closely with the theme of each category. As shown in Table 3, for instance, the theme of the business factors category is to define the value and strategy of integration. The list in Table 3 is concise and presented in an easy-to-use format for practitioners. It can be expanded or modified as more studies appear in the literature in the future. The next paragraphs discuss all the factors listed in Table 2.

Factors dealing with business aspects are related to the value and strategy of integration. In today's business environment it is critical to demonstrate the return on investment (ROI) of any major endeavors, especially for expensive and complicated integration projects (Lam, 2005). It is also important to develop an integration strategy (Lam, 2005; Mendoza et al., 2006) at the outset including key performance indicators (Mendoza et al., 2006). Sherif et al. (2004) similarly discuss the need for defining the success for integration projects. They also suggest "optimization of business models" as a success factors, because organizations with flexible and adaptive business models are likely to value integration efforts. Finally, Lam (2005) describes "process interoperability with business partners," a factor admittedly more important to external than internal integration projects.

Organizational factors deal with the acceptance of the mission by all the constituencies. Top management support

Table 3. Critical success factors for practitioners

Business Factors: Define the value and strategy of integration • Strong business case; clear key performance indicators • Adequate integration strategy • Proper business models/processes
Organization Factors: Secure acceptance of mission by constituencies • Strong top management support • Strong support/commitment from all levels • Good culture/organizational fit • Proper change management
Technology Factors: Mull over the technical aspects of projects • Good extensibility of ERP software • Appropriate technology planning • Complete technological infrastructure • Standard data model • Good use of right tools
Project Factors: Deal with the management and execution of projects • Proper definition of scope and schedule • Strong user involvement • Adequate skills and expertise • Strong project leadership • Appropriate project plan including testing, training, and conversion procedures

consistently ranks high among success factors for major information systems projects including integration (Lam, 2005; Mendoza et al., 2006). Sharif et al. (2005) discuss the effect of all influencers, including stakeholders both inside and outside of the organization. It is conceivable that commitment from not only the senior level but also every level of the organization is required. Mendoza et al. (2006), for instance, recommend that the implementation team study the organization structure and determine its support for the integration process. The full cooperation from all personnel is more attainable if the integration project fits well with the culture and organizational environment (Lam, 2005; Stefanou & Revanoglou, 2006). Similarly, effective change management is a precondition for organizational acceptance (Lam, 2005; Mendoza et al., 2006; Stefanou & Revanoglou, 2006). Mendoza et al. (2006) further identify appropriate security strategy as a success factor for external integration projects due to the need for safeguarding data and applications that span organizational boundaries.

Technology factors deal with the technical aspects of integration efforts. Sharif et al. (2005) focus on the attributes of ERP packages including vertical specialization, horizontal specialization, and extended functionality. These are all factors affecting how well an ERP package integrates with external systems. Vertical specialization pertains to integration within an industry, whereas horizontal specialization is related to integration with other best-of-breed solutions to create an end-to-end e-business offering. Extended functionality affects how easy it is to integrate an ERP package via componentization or modularization. Mendoza et al. (2006) describe the importance of having a complete technological infrastructure, including an internal network, operating systems, and software tools. They also discuss the need for proper communications software, which applies to point-to-point integrations primarily, and a standard data model to ensure consistent data and secure transactions in structural integrations. Another technology factor is helpful technical support provided by software vendors. Lam (2005) similarly suggests common data standards and the ability to integrate with legacy systems. He also discusses the use of right tools and mature technology, which was echoed by other researchers (e.g., Alshawi et al., 2004; *Themistocleous, 2004)*. All of these require proper technology planning.

Project factors are related to the management and execution of integration projects. An important factor emphasized by all researchers is the proper definition of scope. User involvement is another oft-cited success factor for IS projects and is recommended by both Lam (2005) and Mendoza et al. (2006). Having the requisite skills and expertise, which may come from a team of employees, consultants, and vendors working together, is another common success factor (Lam, 2005, Mendoza et al., 2006). Mendoza et al. (2006) also include effective project leadership, appropriate outsourcing management, and significant support to consultants as additional human capital factors. The project plan should include a proper migration approach (Lam, 2005) and other traditional project management variables such as testing (Lam, 2005), training, and conversion procedures to ensure low impact on the business process (Mendoza et al., 2006). Lastly, effective outgoing and incoming communication is needed to properly determine requirements and needs for external integration projects (Mendoza et al., 2006).

FUTURE TRENDS

Table 2 presents a summary of the critical success factors discussed in the academic literature. One technology factor that is receiving a lot of attention in the practitioner literature is service-oriented architecture (SOA). In a recent survey of IT executives, more than half have invested or are considering implementing SOA to integrate their applications (CIO research reports, 2006). The majority of those respondents also agree that SOA tools and protocols are still evolving. SOA has received major endorsement from key software development tools vendors including IBM, Oracle, and BEA Systems (Morejon, 2005). The potential benefits of SOA include software reuse, low cost of integration, business agility, and risk reduction (Lager, 2006). Similar to many emerging technologies, no universally accepted definition for SOA exists. One view is that it is a paradigm for developing loosely coupled software components or services that

encourages software reuse, integration, and interoperability (He, 2003; Kobielus, 2005). SOA can be implemented under various platform and middleware environments, including Web services (Khanna, 2005; Kobielus, 2005). It is likely that both SOA and Web services will play an important role in integrating enterprise systems in the near future.

The three empirical studies provided support for several but not all of the success factors. Other researchers are encouraged to test these factors in additional case studies or cross-section surveys. Another promising research stream is to further consolidate and refine the critical success factors list. One approach is to combine the most promising factors from the three empirical studies. Another approach is to compare and augment the list with factors found in the practitioner literature. Several factors discussed by Hwang (2005), for instance, robust infrastructure and human capital, have similar counterparts in Table 3. Incorporating practitioners' definitions of these variables into the operationalization of factors in future study will increase the relevance of the research, as will inclusion of new factors such as prioritization of projects. Another useful research area is the dependent variable, the integration success. Sharif et al. (2005) suggest that success be explored from strategic, tactical, and operational aspects. Mendoza et al. (2006) similarly discuss the importance of defining the key performance indicators. Without an agreed-upon definition of success, it will not be meaningful to assess the effect of success factors. Finally, the specific effect of individual factors on success is significant. Some factors are likely more important than others, but which ones? To what degree are they more important and under what circumstances? These are all critical research questions.

CONCLUSIONS

Systems integration is an ongoing issue in the use of information technology by businesses. The introduction of ERP is a step in the right direction toward integration, but it also brings new challenges to the creation of a truly integrated enterprise. Integrating enterprise systems can be expensive and risky; at the same time the financial savings can be substantial (Lam, 2005; Puschmann & Alt, 2004). Many factors come into play in determining if an integration project will be successful. More research is warranted, but the factors that are highlighted in this article should help organizations increase their odds of success.

KEY TERMS

Critical Success Factors: Those things that must go right in order for an organization to achieve its mission.

Enterprise Application Integration: Comprehensive middleware software suits that allow connection to an array of applications including enterprise resource planning, customer relationship management, and to various databases.

Enterprise Resource Planning: Configurable enterprise software that integrates business processes across functions.

Enterprise Systems: Information systems that allow companies to integrate information across operations on an enterprise-wide basis.

Service-Oriented Architecture: A paradigm for developing loosely coupled software components or services, which encourages software reuse, integration, and interoperability.

Systems Integration: The process of tying together two or more computer systems for sharing data and functionality.

Web Services: Technologies that allow easy integration of applications over the Internet or Internet protocol-based networks.

Integrating Natural Language Requirements Models with MDA

María Carmen Leonardi
Universidad Nacional del Centro de la Pcia. de Buenos Aires, Argentina

María Virginia Mauco
Universidad Nacional del Centro de la Pcia. de Buenos Aires, Argentina

INTRODUCTION

The model driven architecture (MDA) is a framework for software development defined by the OMG (Object Management Group, 2006). The MDA initiative shifts the focus of software development from writing code to building models, separating the specification of functionality from the specification of the specific implementation of that functionality (Miller & Mukerji, 2003). Key to MDA is the importance of models and transformations between them in the software development process.

The first model of MDA is the computation independent model (CIM), which describes the business model independently of the software system to be implemented. The CIM is described with a vocabulary that is familiar to stakeholders. As it captures the domain without reference to a particular system implementation or technology, the CIM would remain the same even if the system were implemented mechanically, rather than in computer software (Meservy & Fenstermacher, 2005). CIM reduces the gap between stakeholders and software engineers (Miller et al., 2003).

Recently, some proposals related to business modeling and MDA have appeared, for example, the use of activity diagrams (Mersevy et al., 2005), BPMN (White, 2004), or goal-oriented strategies (Birol, 2006). Several authors agree in the importance of using the "language of the business experts" (Francis, 2006) during the first stages of development, enhancing communication between the domain experts domain and software engineers. From the requirements engineering area, we have been working with natural language requirements models to describe the universe of discourse (Leite, Hadad, Doorn, & Kaplan, 2000). But, to fit in MDA framework, we have to map them into object-oriented models, defining a CIM that will be the basis for a MDA software development. To do this, we have proposed a transformation strategy and developed its associated tool, CIMTool, thus allowing the integration of the natural language models into the MDA framework. In this article, which is an integration of Leonardi (2003), Leonardi (2005), Leonardi and Mauco (2004), and Leonardi, Mauco, and Leoni (2005), we present the overall strategy defining OCL based transformation rules to derive a CIM from the language extended lexicon (LEL) and the scenario model (Leite et al., 2000).

BACKGROUND

MDA is an approach that makes modeling the primary focus of the software development (Miller et al., 2003). It is based on modeling different aspects and levels of abstraction of a system, and exploiting interrelationships between these models. The MDA starts with the idea of separating the specification of the operation of the system from the details of its implementations. In MDA, all artifacts such as requirements specification, architecture descriptions, design descriptions, and code are regarded as models. One of the key features of this framework is the notion of automatic transformations that are used to modify one model in order to obtain another one. MDA defines how models expressed in one language can be transformed into models in other languages. The MDA standard proposes UML as the specification language, and is divided into the following main steps:

- Construct a model describing the business system: Computation independent model (CIM)
- Construct a model with a high level of abstraction: Platform independent model (PIM)
- Transform the PIM into one or more platform specific models (PSMs)
- Transform the PSMs to code

There are some works that propose UML extensions to represent business models (Johnston, 2006; Vasconcelos et al., 2001). These extensions, though not conceived in MDA context, allow the construction of UML models that can be considered as CIMs as they model the business knowledge without considering any software system. However, stakeholders think in terms of processes, goals, resources, actors, among others rather than objects. Object orientation is an abstraction not easily understandable by stakeholders because objects encapsulate data and behavior in the same level (Jackson, 1995). Then, the introduction of techniques

and models closer to stakeholders' way of thinking would be really useful.

During the early stages of development, when the interaction with the stakeholders is crucial, the use of natural language oriented requirements models seems necessary in order to enhance communication. Everyone can read natural language, so it is still used to define the requirements documents (Sommerville, 2005). However, natural language can be ambiguous, surprisingly opaque, and is often misunderstood. This kind of requirements models has to be reinterpreted by software engineers into a more formal design on the way to a complete implementation. In particular, in MDA context it is necessary to transform them to UML models representing the CIM. We can mention some strategies that, though not developed in MDA context, derive UML models from different business models. For example, Díaz, Pastor, Moreno, and Matteo (2004) obtain sequence diagrams from use cases and in Alencar, Pedroza, Castro, Silva, and Ramos (2006), a strategy is proposed to derive class diagrams starting from i* model. In order to improve CIM construction, we describe in the next section a transformation process to automatically derive a class diagram representing a CIM, starting from two natural language requirements models.

A STRATEGY TO DERIVE A CIM FROM REQUIREMENTS MODELS

In this section, we describe the transformation strategy to map the natural language models into a CIM. The section is organized in three subsections: one to present the requirements models, the other presents the derivation strategy, and finally CIMTool, the tool implementing the strategy.

Natural Language-Oriented Requirements Models

The models presented in this section are well known, used, and accepted by the requirements engineering community (Leite et al., 2000). The models are: language extended lexicon model and scenario model.

- **Language extended lexicon:** The language extended lexicon (LEL) is a structure that allows the representation of significant terms of the Universe of Discourse. The purpose of the lexicon is to help to understand the vocabulary and its semantics. It unifies the language allowing communication with the stakeholder. LEL is composed by a set of symbols with the following structure: symbol name: word or phrase and set of synonyms, notions defining the denotation of the symbol and behavioral responses describing the symbol connotation. In the description of the symbols, two rules must be followed simultaneously: the "closure principle" that encourages the use of LEL symbols in other LEL symbols, and the "minimum vocabulary principle" where the use of symbols external to the application language is minimized. LEL terms define objects, subjects, verbal phrase, and states. Figure 1 shows the heuristics to define each type of symbol.
- **Scenario model:** A scenario describes situations of universe of discourse. A scenario uses natural language as its basic representation and it is connected to LEL. Figure 2 describes the components. In Leite et al. (2000) the scenario construction process is described.

Figure 1. Heuristics to represent LEL terms

Subject	**Notions:** Who the subject is.
	Behavioral responses: Register actions executed by the subject.
Object	**Notions:** Define the object and identify relationship with other objects.
	Behavioral responses: Describe the actions that may be applied to this object.
Verb	**Notions:** Describe who executes the action, when it happens, and procedures involved in it.
	Behavioral responses: Describe the constraints on the happening of an action, which are the actions triggered in the environment and new situations that appear as consequence.
State	**Notions:** What it means and the actions, which triggered the state.
	Behavioral responses: Describe situations and actions related to it.

Figure 2. Components of scenario

Title: identifies a sce nario.
Goal: describes the purpose of the scenario.
Context: defines g eographical and te mporal l ocations and preconditi ons.
Resources: identif y passive entities with which actors wor k.
Actors: detail entities actively involved in the scenari o
Episodes: each episode represents an action pe rformed by actors using resources.

The Derivation Strategy

Once the natural language requirements models are defined and validated with the stakeholders, they have to be manipulated in order to be mapped to class diagram representing the structural aspects of a CIM. We propose a rules-based strategy to do this that fit in MDA framework. We illustrate the application of the strategy with examples taken from a milk production system (Mauco, 2004).

As we shown in Figure 3, the process takes as the source model a LEL and a scenario model from a concrete case study and produces a class diagram described following UML 1.5 syntax (Unified Modeling Language specification V.1.5, 2003).

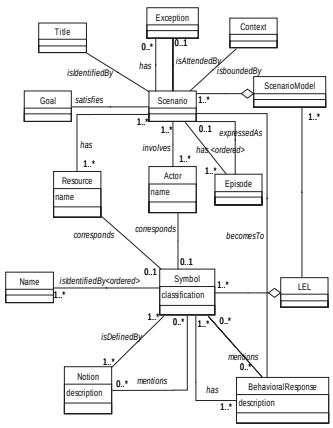
The steps described next organize the application of the transformation rules:

- **Identification of classes:** Taking as input LEL symbols classified as subjects and objects, transformation rules named TRC1 and TRC2 propose the definition of one class for each symbol. TRC2 also defines the methods for the classes coming from object LEL symbols.
- **Identification of methods:** Considering behavioral responses of subject LEL symbols, transformation rule named TRM1 defines the methods for the classes coming from subject LEL symbols (obtained after applying TRC1). Then, transformation rule TRM2 completes the corresponding parameters.
- **Identification of relationships:** The object diagram is completed with the definition of inheritance, aggregation and association relationships through transformation rule TRR by analyzing notions of LEL symbols defined as classes.

The Transformation Rules

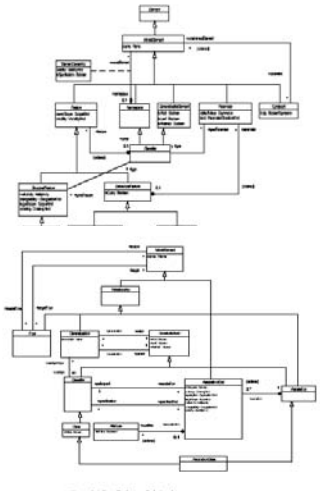
This section describes the transformation rules that allow the derivation of CIM from the requirement models. The transformation language we use is based on the transformation language proposed in Kleppe, Warmer, and Bast (2003), which is an OCL extension. Each transformation rule specification contains a name, the signature, a brief natural language description, and the OCL specification. Parameters may be any of the components of Figure 3, that

Figure 3. The source and the target models of the derivation process



UML class diagram of LEL and Scenario

Transformation rules



Backbone and Relationships Core Packages from UML V.1.5 Metamodel

is, any component of the Requirements Models or any of the components of the target model, referenced in each transformation rule as RM and UML respectively. The parameter TP represents a language dictionary with the language used in the construction of the requirements models (an English dictionary in this case).

TRC1_Transformation SubjectToClass (RM, UML, TP)

DESCRIPTION: Each subject LEL symbol becomes a UML class. The attributes are defined as follows: for each notion that does not contain a LEL symbol, the transformation identifies nouns and defines them as attributes.

Figure 4 shows a subject LEL symbol defining a Dairy Farmer and the class obtained by applying the transformation rule TRC1.

TRC2_ Transformation ObjectToClass (RM, UML, TP)

DESCRIPTION: Each object LEL symbol becomes a UML class. The attributes are defined as follows: for each notion that does not contain a LEL symbol, the transformation identifies nouns and defines them as attributes. Methods are defined adding SET and GET prefixes for each attribute.

Figure 5 shows the notion of the object LEL symbol Plot and the class defined by applying the transformation rule TRC2 to it.

TRM1_TransformationSubjectBehavioral ResponsesToMethods(RM,UML,TP)

DESCRIPTION: Each behavioral response of a subject LEL symbol modeled as a class by TRC1 becomes a method.

```

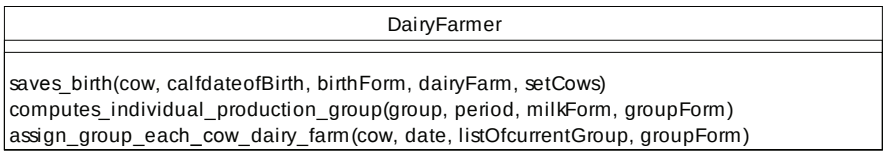
Figure 7. Defining parameters to methods of Dairy Farmer class



already defined (parameter listOfCurrentGroup, Figure 7, corresponds to a set of group).

TRR_Transformation LELRelationshipsToClassRelationships(RM,UML,TP)

DESCRIPTION: This transformation applies to subject as well as object LEL symbols. Notions of a LEL symbol, called L1, modeled as a class are analyzed in order to detect other LEL symbols also defined as classes. For each LEL symbol detected, named L2, the definition of an association relationship between the corresponding classes is considered, taking into account the kind of verbs involved in the descriptions (Juristo, Moreno, & López, 2000):

- **Inheritance relationships:** L1 and L2 have the same classification (object or subject). Besides, L1 appears in one of the notions of L2. The involved notions of L1 and L2 contain, in a complementary way, two kinds of verbs : bottom-up verbs (is a, is a type of, is a class

Box 5. TRR OCL specification

                C.name = S1.isIdentifiedBy(first)
TARGET CONDITION
let
cadidateInheritanceNotions: Set=
        S1.isDefinedBy → select (D1.BottonUpVerbsIncludes(n.description))
CandidateAggregationNotions: Set=
        S1.isDefinedBy → select(D1.Component_Composition.Includes(n.description))
CandidateAssociationNotions: Set=
        S1.isDefinedBy → excludes(cadidateInheritanceNotions union candidateAggregationNotions)
in
cadidateInheritanceNotions → forAll (n.mentions → exists (s: Symbol / s.classification = S1.classification and
Class.allInstances → exists (c1 / c1.name = s.name) and s.isDefinedBy → exists(n1/ n1.mentions-> includes(S1) and
D1.TopdownVerbsIncludes (n1.description)))
        implies  G.oclIsTypeOf(Generalization) and G.child = c1 and G.parent = C
        and c1.generalization = G and C.especialization = G) (*)
candidateAggregationNotions → forAll (and n.mentions → exists (s: Symbol / s.classification = S1.classification and
  (Class.allInstances → exists (c1 / c1.name = s.name)) and s.isDefinedBy → exists (n:notion / D1.
  Content_Composition_VerbIncludes (n.description) and n.mentions → includes (S1)))
        implies A.oclIsTypeOf (Association) and A.connection → at(1).participant = C
        and A.connection → at (1).aggregation = aggregate and  A.connection →
          at(2). participant= c1 and A.connection → at (2).aggregation=none)
candidateAssociationNotions → forAll( n.mentions → exists(s: Symbol/ class.AllInstances → exists(c/c.name=s.name))
          implies A.oclIsTypeOf(Association) and A.connection → at(1).participant= C
          and A.connection → at (2).participant= c1)
```

(*) To simplify the OCL expression we have omitted the expression to define c1 in the right side of each implies expression.

of) or top-down verbs (is, may be, may be classified as, classifies as).

- **Aggregation relationships:** in the notions of the LEL symbol considered as container, verbs of the type "component_composition_verb" must appear "to consist / to contain / to include / to form, to compose, to divide" (these three last in passive voice[1]). In the notions of the "component" symbol, verbs of the type content_composition_verb must appear "it is part, it belongs, it is a component, it is included," among others. As it is not possible to automatically distinguish between an aggregation or a composition relationship, the transformation rule defines the relationship as an aggregation.
- **Association relationships:** any relationship between LEL symbols that does not represent a relationship of the previous types, represents an association. The general verb that appears in the notion is taken as the name of the association.

We illustrate this transformation rule in next subsection.

CIMTool

CIMTool implements the derivation strategy allowing the integration of natural language requirements models with MDA framework (Figure 8).

CIMTool was developed with ´Oracle JDeveloper 10g´ in ´Java 2 Runtime Environment Standard Edition v1.4.2´. As we can see in Figure 9, CIMTool has the following input and output files:

- **XRD file:** An input file with the LEL and scenarios models for a given case study following an XRD specification. The XRD specification is a specialization of XML that integrates the LEL and Scenarios models (Leonardi et al, 2005).
- **XML dictionary file:** Is an input file with a dictionary of the language used to describe the requirements models.
- **XMI file:** An output file with a XMI specification of the diagram class representing the CIM. The file has the XMIv1.2 (OMG XML Metadata Interchange) format; therefore it is possible to integrate the output of CIMTool with other CASE tools, for example, Poseidon

Applying the transformation rule TRM1 to the LEL symbol shown in Figure 4, the methods described in Figure 6 are obtained.

TRM2_Transformation SubjectInformationToMethodParameter (RM, UML)

DESCRIPTION: Each behavioral response of a subject LEL symbol originates a scenario (Leite et al., 2000). The rule models actors and resources of each scenario as parameters of the method obtained by TRM1 from the behavioral response that originated the scenario. The actor referring to the subject LEL symbol in consideration is excluded.

For example, for each method previously defined by TRM1 (Figure 6), parameters are identified considering the scenarios involved (Mauco, 2004). As parameters come from resources and actors, they are modeled as classes when the corresponding resource and actor is a subject or object LEL symbol (TRC1 and TRC2); for example, parameters cow and groupForm in the method assign_group_each_cow_dairy_farm (Figure 7). When the resource or the actor does not belong to the LEL, two things may happen. It may be a word that does not need a LEL entry because it belongs to the minimum vocabulary or it may represent a set. In the first case, it is modeled with a primitive class or type (parameter date, Figure 7), and in the second one no new classes are needed because the parameter is a set of a class

Community Edition v2.6 (Poseidon, Gentleware) and Enterprise Architect v4.0 (Enterprise Architect, Sparx Systems).

- **Log file:** an output file with information of the process.

Figure 10 shows a portion of the XRD input file with a partial description of LEL symbols corresponding to Cow, Dairy Cow, Heifer, and Calf. By applying TRR rule, CIMTool produces an XMI based inheritance relationship. Figure 11 shows the inheritance relationship visualized by Enterprise Architect v4.0.

It is important to remark that the output XMI file representing the CIM must be analyzed by software engineers who will adjust the results obtained after the application of the transformation rules.

FUTURE TRENDS

In order to complete the transformation process, we must define transformation rules for the business rule model based on the manual heuristics proposed in Leonardi (2003). We must also define transformation rules to include the dynamic aspects of the business models. As the strategy deals with natural language oriented models, it would be necessary to incorporate linguistic approaches to achieve a better processing of the information (Diaz et al., 2004; Juristo et al., 2000).

Traceability plays a crucial role. In an MDA specification, CIM requirements should be traceable to the PIM and PSM constructs that implement them and vice versa (Miller et al., 2003). The transformation process we have proposed allows the trace between the source and the target. However, we want to enhance this mechanism by defining another complementary and independent model to capture and represent the relationships created by the application of the transformation rules, as the one proposed in Leonardi (2003).

The success of MDA depends on the definition of transformation languages and tools that make a significant impact on full forward engineering processes. MDA is still evolving and many products claim to be complaint with it. The new results will impact both the process and the tool presented in this article, therefore, they will be adapted to incorporate these results.

CONCLUSION

We present a strategy and its corresponding tool to derive a CIM starting from natural language oriented requirements models. The application of the transformation rules by CIMTool provides a systematic and consistent way of defining a CIM in MDA framework. Though a manual derivation (Leonardi, 2003), generally produces a better and more accurate model definition, transformation rules are a starting point to deal with the great amount of requirements information. In addition, we also take advantage of all the time and effort the definition of requirements and business models consumes, thus reducing the gap between requirements and other development models.

Though the requirements models presented in this article have a precise structure, the use of natural language allows the same semantics to be usually expressed with many different natural language sentences. CIMTool takes always the same decision about certain modeling issues, loosing, in some cases, the real meaning of the essential concept. As a consequence, this strategy unavoidably needs software engineer's participation in order to adjust the CIM obtained after the application of the transformation rules.

Natural language oriented models are widely used in requirements modeling due to their well-known advantages (Francis, 2006; Leite et al., 2000). This kind of requirements models have to be reinterpreted by software engineers into a more formal design on the way to a complete implementation. Therefore, a semiautomatic transformation to map their knowledge into conceptual object models would be really useful. Our proposal is a first step into this direction, aligning with the MDA framework.

KEY TERMS

Business Model: An abstraction of how a business works. It provides a simplified view of the business structure that will act as the basis for communication or innovations and define the information systems requirements that are necessary to support the business.

CIM: MDA computation independent model that describes the business model of the organization. This model is independent of how the system is implemented.

MDA: An approach to IT system specification that separates the specification of functionality from the specification of the implementation of that functionality on a specific technology platform.

Requirements Engineering: It comprehends all the activities involved in eliciting, modeling, documenting, and maintaining a set of requirements for a computer-based system. The term "engineering" implies that systematic and repeatable techniques should be used to ensure that system requirements are consistent, complete, and relevant.

Stakeholder: People or organizations who will be affected by the system and who have a direct or indirect influence on the system requirements. They include end-users of the system, managers and others involved in the organizational processes.

Universe of Discourse: The overall context in which the software will be developed and operated.

ENDNOTE

[1] We decided to eliminate the verbs to have and to posses as indicators of aggregation relationships since, from our experience, they are commonly used by stakeholders to describe properties of concepts.

Integration of MES and ERP

Vladimír Modrák
Technical University of Košice, Slovakia

INTRODUCTION

In the present manufacturing paradigm, manufacturing execution systems (MESs) play a significant role in effective manufacturing management. Offered software solutions simultaneously close the gap between Enterprise Resource Planning (ERP) systems and production equipment control or SCADA (Supervisory Control and Data Acquisition) applications. Current ERP systems usually contain modules for material management, accounting, human resource management and all other functions that support business operations. In the past years, the role of ERP has been extended to cross-organizational coordination. Nowadays, as optimization of production activities is increasingly topical, a cooperation of ERP and MES becomes a serious concern of manufacturing managers.

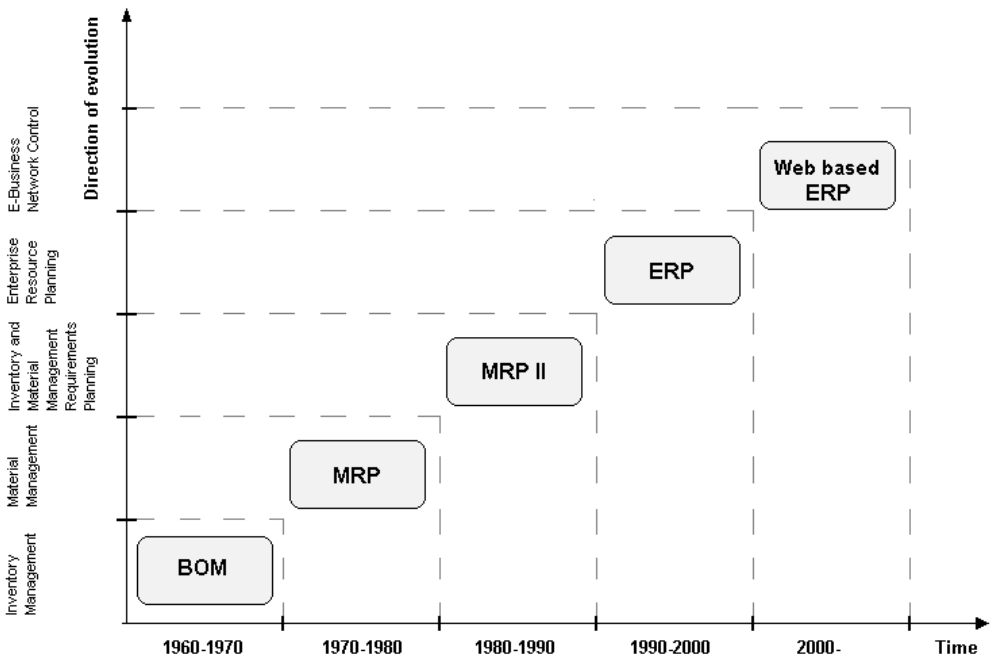
BACKGROUND OF ERP AND MES EVOLUTION

From a historical perspective, the infiltration of information technology into manufacturing technology was conditioned by the development and advancement of host mainframe computing in the 1950s and 1960s. It gave manufacturers the ability to capture, manipulate, and share information and automate calculation and analysis in order to support design of increasingly complex and capable products. Simultaneously, in the framework of manufacturing management, an inventory control took on great importance and most of the software in the 1960s was developed for this purpose. Typically, inventory control was handled by a tool called BOM (bill of materials) processors, which were used as a means to represent process plans. The focus shifted in the 1970s to Material Requirement Planning (MRP) as the complexity of manufacturing operations increased. This managerial instrument enabled financial managers both to view and control their business processes much more closely. The tools to automate business processes were enhanced by adding further functionalities to meet the increased requirements. Subsequently, in the 1980s the term Manufacturing Resources Planning (MRP II) became popular. An MRP II presented extension of MRP functions to achieve integration of all aspects of the planning and control of the personnel, materials and machines (Kimble & McLoughlin, 1995). Following, solutions that are marked by acronym ERP were performed in the early 1990s. An ERP system can be defined as an integrated information processing system supporting various business processes such as finance, distribution, human resources and manufacturing (Choi & Kim, 2002). The newest version ERP II has been much publicized by the Gartner group (Mohamed & Fadlalla, 2005). Fundamentally, ERP II signals a shift in traditional ERP applications from focusing on internal data gathering and management process information to partners, vendors and customers externally via the Web (Farver, 2002). The overall view on evolution of ERP system is shown in Figure 1. Initially, this concept attained a huge popularity among manufacturers, but as the scope of managed systems increased, the ERP system was not suitable for controlling activities on the shop floor level. For this purpose, a new tool of manufacturing management called Manufacturing Executive System was evolved and utilized during the 1990s. There is more interpretation of MES depending on different manufacturing conditions, but the common characteristic to all is that an MES aims to provide an interface between an ERP system and shop floor controllers by supporting various "execution" activities such as scheduling, order release, quality control, and data acquisition (MESA #6, 1997). In a context of the MES development and deployment, it is important to point out that Manufacturing Execution Systems were originally designed to provide first-line supervision management with a visibility tool to manage work orders and workstation assignments. Consecutively, MES expanded into the indispensable link between the full range of enterprise stakeholders and the real-time events occurring in production and logistics processes across the extended value chain (McClellan, 2004).

INTEGRATION OF ERP AND MES

Manufacturing execution systems besides their typical functions were developed and used also as the interface between ERP and process control, because it was generally recognized that ERP systems weren't scalable. The seamless connections often required skilled coding to connect to ERP and process control systems (Siemens Energy & Automation, Inc., 2006). Today, the availability of Web-based XML communications successfully bridges the gaps between MESs and ERP systems. Built on XML, the B2MML (business-to-manufacturing markup language) standard specifies accepted definitions and data formats for informa-

Figure 1. The evolution of ERP systems

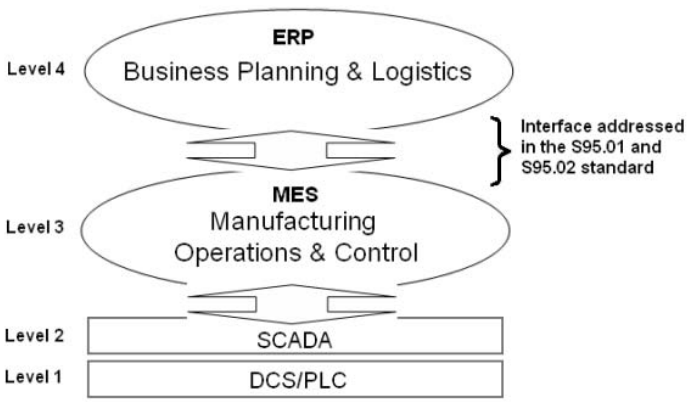


tion exchange between systems, and facilitates information flow and updates between ERP and manufacturing execution systems. It also instigated redefinition of the role of the MES. The ISA SP-95 model (see Figure 2) breaks down business to plant floor operations into four levels.

Levels 1 and 2 include process control zone. The MES layer consists of manufacturing management, dispatching production, detailed production scheduling, reliability assurance, and so forth. A point of debate about MES functionalities is connected with more aspects like different types of manufacturing and others (Modrák, 2005). Level 4 corresponds to the business planning and logistics.

The goal of ISA-95 standard was to reduce the risk, cost and errors associated with implementing interface between ERP and MES. The ISA-95 "Enterprise - Control System Integration" is a multipart series of ANSI/ISA standards that define the activity models and interfaces between manufacturing functions and other enterprise functions. Parts 1 (Models and Terminology), parts 2 (Objects Attributes) and part 5 (Business to Manufacturing Transactions) define the exchange of production data between business and plant systems. B2MML provides a schema implementation of the ANSI/ISA-95 and represents an independent technology implementation of this standard. B2MML has been developed

Figure 2. Position of MES in the hierarchy of IT systems



by The World Batch Forum (WBF) and adopted by players such as SAP and Wonderware. Coupled together, B2MML and ISA-95 permit designers to define the data mapping using a standardized, common terminology and models that can be carried over to the B2MML XML vocabulary (Zurawski, 2007).

The mentioned standards, and other ISA standards, significantly facilitate the implementation of integrated manufacturing systems. It is aimed to integrate ERP systems with control systems like DCS and SCADA. To support batch control level optimization, the standard S88.01 (ANSI/ISA, 1995) has been developed. It provides standard models and terminology for the design and operation of batch control systems. At the control level the key attribute is integration of all process information into one place. For this purpose, both programmable logic controllers and SCADA software are ordinarily used.

An important function of MES is to provide feedback to ERP with the aim to adjust their scheduling data and algorithms in a more realistic manner. In this connection, it is necessary to take in consideration certain aspects of incompatibility. Originally, ERP systems have been developed more for financial managers than manufacturing managers. Moreover, the data flow frequency in ERP system is lower then at the MES level. Accordingly, it would not make sense to feed a quantity of output data available at shop floor level into the ERP system and a reversal. An effort to do so often involved large amounts of manual data entry. Therefore, one important role of manufacturing management optimization by MES may be seen in the reduction of manual data entry on the boundaries of information system layers. Basically, it's relevant in this case when enterprise information and control systems are designing as one complex. Then, expected reductions of manual activities may be compromised by integration of system levels.

Supplementary integration between MES and ERP is seldom uncomplicated. One manner to get around presumable complications is by execution of whole business process modeling. The sense of business process modeling of whole enterprise is to make new organizations of work more feasible than in the past. That is why business process modeling and improvement becomes a key issue of successful implementation of any ERP or MES strategy.

FUTURE TRENDS

As it is observed, production planning activities have become more complex and therefore need to be in principle optimized. Manufacturing Execution Systems, which are positioned between the Enterprise Resource Planning and control systems levels, have significant potential to be effectively used to optimize business processes on the shop floor. Besides that fact, MES are being viewed as critical in getting the most value out of existing investments in automation. Speaking about MES's role, a frequent interest of manufacturers concerns a balanced scale of MES functionalities. As mentioned earlier, it depends on more factors. For instance, when an existing ERP system contains factory floor control functionality, then the functionality model of MES has only supplement character. The scope of functionality is influenced also by changes in using automated identification (AID) technologies, which can have positive impact on the plant floor optimization. To this category of progressive AID technologies that have the potential to change the future in manufacturing, undoubtedly belongs Radio-Frequency Identification (RFID). Mass use of this technology can bring significant rationalizations in the manufacturing automation in the future. This tendency indirectly confirms such IT players as Oracle, SAP, Microsoft and IBM, which are all accelerating efforts to meet the RFID challenge (Rockwell Automation, 2004). The rules concerning manufacturing execution such as control, scheduling, routing, tracking, and monitoring must all be modified to collect as well as respond to new RFID-information. It is predicted that RFID will complement existing MES efforts in genealogy tracking. In this connection, according to Rockwell Automation, RFID could be used in varying scales, either locally or across the entire facility to provide visibility into incoming raw materials, work in process, production sequencing, packaging, palletizing, and warehousing operations as well as in the supply chain management.

CONCLUSION

In reality, the majority of enterprise information and control systems on different levels are developed and operated on incompatible technologies and based on heterogeneous architectures. On the other hand, today's ample standardized communication tools achieve the successful integration of MES and ERP. From "Siemens Energy & Automation, Inc.' view point of view" an integrated system will show real returns: from the ability to monitor—in real time—key performance indicators on productivity, quality, yields, and throughput; to managing inventory locations and raw materials; through remediation processes to isolate and or rework nonconforming products." One of expected directions of MES and ERP integration is synthesis of MES and ERP systems. It is hopefully in the future to be able to simplify implementation issues of information system integration.

KEY TERMS

Distributed Control System (DCS): A supervisory control system typically controls and monitors set points to subcontrollers distributed geographically throughout a factory (Falco, Stouffer, Wavering, & Proctor, 2004).

Enterprise Resources Planning: Configurable enterprise software that integrates business process across functions (Hwang, 2005).

Manufacturing Execution System: A collection of hardware/software components that enables the management to control production activities from order launch to finished goods. While maintaining current and accurate data, a MES guides, initiates, responds to and reports on plant activities as they occur. MES provides mission-critical information about production activities to decision support processes across the shop floor level of manufacturing management (Barkmeyer, Denno, Feng, Jones, & Wallace, 1999).

Manufacturing Resources Planning II: Extends MRP by addressing all resources, in addition to inventory. MRPII links material requirements planning with capacity requirements planning, avoiding over- and under-shop loading typical with MRP (Bradley, 2005).

Programmable Logic Controller (PLC): A small industrial computer used in factories originally designed to replace relay logic of a process control system and has evolved into a controller having the functionality of a process controller (Falco et al., 2004).

Scalability: Understood as the ability to incorporate into the existing system additional resources or meet diverse quality requirements.

Supervisory Control and Data Acquisition System (SCADA): It is a part of the control system, but focused on the supervisory level. As such, it is a purely software package that is positioned on top of hardware to which it is interfaced, in general via programmable logic controllers (PLCs) or other commercial hardware modules (Daneels & Salter,1999).

Integrative Document and Content Management Solutions

Len Asprey
Practical Information Management Solutions Pty Ltd., Australia

Michael Middleton
Queensland University of Technology, Australia

INTRODUCTION

Developments in office automation, which provided multiple end-user authoring applications at the computer desktop, heralded a rapid growth in the production of digital documents and introduced the requirement to manage capture and organization of digital documents, including images. The process of capturing digital documents in managed repositories included metadata to support access and retrieval subsequent to document production (D'Alleyrand, 1989; Ricks, Swafford & Gow, 1992).

The imperatives of documentary support for workflow in enterprises, along with widespread adoption of Web-oriented software on intranets and the Internet World Wide Web (WWW), has given rise to systems that manage the creation, access, routing, and storage of documents, in a more seamless manner for Web presentation. These content management systems are progressively employing document management features such as metadata creation, version control, and renditions (Megill & Schantz, 1999; Wiggins, 2000), along with features for management of content production such as authoring and authorization for internal distribution and publishing (Addey et al., 2002; Boiko, 2002; Hackos, 2002; Nakano, 2002).

If business applications are designed taking into account document and Web content management as integral constructs of enterprise information architecture, then the context of these solutions may be an integrative document and content management (IDCM) model (Asprey & Middleton, 2003). As the name implies, the IDCM model aspires to combine the features of a document management system with the functionality of Web content management. An integrative business and technology framework manages designated documents and their content throughout the continuum of their existence and supports record-keeping requirements.

The IDCM model supports system capabilities for managing digital and physical documents, e-mail, engineering and technical drawings, document images, multimedia, and Web content. These systems may be deployed individually to address a specific requirement. However, due to the volume and varied formats of important documents held in digital format, these systems are often deployed collectively based on a strategic IDCM approach for better managing information assets. An organizational approach to IDCM supports enterprise knowledge strategies by providing the capability to capture, search, and retrieve documented information.

SCOPE

IDCM depends upon effective integration of organizational systems that together are used for managing both digital and physical document types. The scope of this management is across all stages of document lifecycles. It includes provision for distribution of the document content over intranets and the Internet.

Features of enabling IDCM technologies are described in the following section. The technologies may be differentiated into those with core capabilities and supporting technologies.

Core capabilities are: document management; e-mail management; drawing management; document imaging; Web content management; enterprise report management; and workflow. Supporting technologies include: Web services; database management systems; digital signatures; portals; universal interfaces; and network management.

Significant issues that need to be addressed with respect to IDCM solutions include the provision of seamless functionality that may be employed across different capabilities so that currency, integrity, and authority are managed effectively. These in turn must be complemented by user interfaces that provide stylistic consistency and that are augmented by metadata that enhances retrieval capabilities through the supporting technologies.

The following section itemizes the types of features that are required.

SYSTEM FEATURES: CORE TECHNOLOGIES

Document Management

An encompassing approach to document management sees documents within a framework that supports integrity, security, authority, and audit, and that are being managed so that effective descriptions of them are used to support access, presentation, and disposal (Bielawski & Boyle, 1997; Wilkinson et al., 1998). In this context document management applications implement management controls over digital and physical documents. The general capabilities of a document management application are:

- *Document production and capture*—interface with common office productivity software.
- *Classification*—support business classification schemes (e.g., folder structures, document properties).
- *Metadata*—capture of properties that describe document.
- *Check-in/checkout*—maintain document integrity during editing.
- *Version control*—increment versions of document to support integrity.
- *Complex relationships*—manage links and embedded content within digital documents.
- *Security*—implement user/group access permission rights over documents.
- *Document lifecycles*—manage the transition of document states through pre-defined lifecycles.
- *Integrated workflow* to automate review and approvals; controlled distribution of documents.
- *Search and information retrieval*—search metadata or text within documents, or both.
- *Viewing*—view documents in native application or using integrated viewer.

These should be associated with recordkeeping features such as disposal scheduling and archiving.

E-MAIL MANAGEMENT

The growth in e-mail has brought a high demand for solutions that allow enterprises to manage e-mails that have value to the business. The IDCM model offers two types of capabilities:

- *Direct capture*—These applications are often referred to as e-mail archiving applications.
- *End-user capture*—These capabilities are typically offered as a module within document management systems.

Direct capture or archiving facilities intercept incoming and outgoing e-mail. They operate by taking a copy of incoming and outgoing messages that are managed by the e-mail messaging system, and use customized business rules to extract e-mail that may not have a business context. Unwanted e-mail such as spam, or that received from news lists or information bulletins, can be eliminated.

These systems may feature auto-categorization based on metadata such as that contained in e-mail message headers, and possibly also within attachments. Categorization can also occur using the content and context of e-mail by applying techniques such as learning by example from previously processed e-mail. These types of solutions might be valuable for capturing statistical information differentiated by the types of requests made by customers. For example, statistics can aid call centers to monitor turnaround timeframes for responding to e-mail requests, or undertake trend analysis.

Search options include the capabilities to search messages and text attachments. Depending on the capabilities of the system, searches might be invoked from an e-mail client, desktop client application, or Web browser.

Some systems are able to apply rules defined in disposal authorities so that e-mails are purged from the system within a legal framework. In some cases, different retention schedules can be applied to specific categories of e-mail.

End-user capture facilities are adopted by some enterprises to save relevant sent and received e-mails that evidence business transactions into an e-mail management repository, such as a document management system, leaving it up to the user to identify e-mails that need to be saved according to organizational guidelines.

The document management system would need then to integrate effectively with the existing enterprise e-mail client software. This capability would enable end-users to save e-mails and/or attachments to the managed repository, automatically derive metadata from the header of e-mail messages, add custom metadata, and store the e-mail and attachment/s (where appropriate) as a digital record.

DRAWING MANAGEMENT

Many systems for registering or managing drawings have been developed independently of more generic approaches to document management. They may include information systems that enable users to register or index physical drawings in a database, along with generation of transmittals for issue of new documents, and management of the distribution of revisions to drawings and technical documents.

A drawing management system may be differentiated from a registry system in that the software implements automated management controls over the digital drawing objects maintained within a vault-like repository. This capability evolved to support the capture and management of drawings created by Computer Aided Design (CAD) packages. Functionality should include base capabilities such as:

- Integration with CAD tools for capturing electronic drawings.
- Automated features for drawing revision control and revision numbering.
- Management of electronic and hardcopy drawings, technical specifications, and manuals.
- Management of parent-child relationships between multiple drawings.
- Registration and tracking of physical copies of controlled drawings.
- Management of incoming and outgoing transmittals.
- Electronic document review and authorization using integrated workflow.
- Provision of viewing, red line, markup, and annotation functions.
- Maintenance of history logs and audit trails.

Extended capabilities may include automation of drawing numbering, synchronization of digital and physical drawing objects, synchronization of title block and metadata registration and updates, and management of drawing status during engineering change lifecycle transitions.

Drawing management capabilities may be provided by a dedicated drawing management system; as unified functionality within a document management system; as an inbuilt module of an Enterprise Resource Planning (ERP) system, maintenance management system, or similar; or an integral component of a document management application.

DOCUMENT IMAGING

Imaging systems have evolved from the principles of film-based imaging and may now be characterized in two groups for document imaging, these being (a) film-based imaging (micrographics) and (b) digital imaging systems.

In film-based imaging, micrographics technology is used to capture images of physical documents on microfilm, so that the images may subsequently be viewed using a reader, and printed if required. In digital imaging, images of physical documents are captured in a digital file format, with subsequent viewing or printing from the image format.

Digital imaging systems may be differentiated as desktop (ad hoc scanning), workgroup (shared tools in network), or production (high volume, diverse type). IDCM normally implies a workgroup or production environment. Capabilities offered include image manipulation functions such as:

- Capture of hardcopy documents into digital format.
- Capability for scanning and conversion of different sizes, sides (duplex scanning), physical orientation, and physical structure of documents.
- Managing multi-page images as a single entity (e.g., multi-page TIF file).
- Images may be saved to specified file formats. For example, a document might be saved in PDF or JPG for publishing on a Web server, or as a multi-page TIF for viewing/transmission.
- Support for a range of resolution, contrast, threshold, and size settings to meet the diverse requirements of document capture.
- Capture of color and/or grayscale images to suit forms processing and other applications (e.g., colored contour maps).
- Despeckling/deskewing and border removal.
- Multi-level registration capabilities, including batch-, folder-, envelope-, and document-level indexing.

Imaging systems are often integrated with recognition systems to facilitate capture and retrieval. These include technologies for automatically capturing data encoded in barcodes, integration with optical character recognition (OCR and ICR) technologies to enable text information to be extracted from scanned images, and integration with optical mark recognition (OMR).

WEB CONTENT MANAGEMENT

IDCM has the capability to provide a managed environment for the processes associated with publishing Web content. It has been said that a content management system is a concept rather than a product (Browning & Lowndes, 2001). This adds weight to analysis of it within the context of an IDCM model, where documents and their content may be considered more broadly than in terms of Web presentation. Document creation, management, and utilization can thus be undertaken with reference to business requirements and workflow of business processes.

Typically, functionality is characterized in terms of content creation, presentation, and management (Arnold, 2003; Robertson, 2003). Increasingly this functionality is seen to be employed within a unified content strategy for an enterprise (Rockley, Kostur & Manning, 2003).

Content creation functionality includes separation of presentation and content, utilization of elements of documents such as illustrations in different contexts, and continuation of associations between pages after restructuring. Metadata

support should also be available, and markup should be transparent to the content creator.

Presentation elements include multiple formats for distribution of internal material such as manuals and business forms over intranets, and for external material such as marketing information and application forms. Other features expected are template availability through style sheets, integration of multiple formats as compound documents, provision of alternative renditions, and personalization of display according to user profiles.

Management features include version control and integrity maintenance among multiple users, and associated security procedures and audit trails. Managed interfaces to other subsystems should provide for dynamic provision of content to pages so that current data can be presented in validated form within compound documents. There should also be utilization of workflow for accommodating distributed users, content review, and approval processes.

These capabilities are shared at least in part with other IDCM systems' functionality. The IDCM environment has the capability to manage Web content within a continuum that includes initial document creation processes, potentially in a distributed environment, through to managed archiving of content.

ENTERPRISE REPORT MANAGEMENT (COLD)

As digital media have been developed, businesses with high volumes of management information reporting have made increasing use of Enterprise Report Management (ERM). These capabilities enable organizations to capture reports from business application databases and store them in a managed repository, to reduce printing, improve information accessibility, and maintain records.

Technologies that provide support for ERM include output reports in a range of formats. Examples of these include text-based digital format (e.g., XML) that is stored and searched via a document management application, and image format such as TIF or JPG that can be captured and accessed via a document management or imaging application. Reports may be captured on optical disk, using a capability known as Computer Output Laser Disk (COLD), which stores digital reports and enables data to be represented with graphical overlays to facilitate interactive communications.

General ERM capabilities are defined as follows:

- Capture of digital report objects to managed repository (document management, imaging, or COLD application).
- Utilization of indexing capabilities for capturing metadata relevant to the report.
- Support for inquiry and retrieval of metadata or report contents (where applicable).
- Management of database growth to support performance.
- Support for repository that can include different data objects.
- Support for document integrity.
- Control of processes through workflow.
- Provision of extraction and use of parts of reports.
- Support for high-volume printing.
- Management of security—user authentication, group and user levels.

WORKFLOW

Workflow management systems are designed to automate and implement controls over a diverse range of business processes, from the initiation of a process through to execution of all tasks, and process closure. The need for transparent interfaces between the workflow management system and IDCM is vital to maintain the integrity of documents or Web content files during their transition through a workflow process.

There are a number of technology options for enterprises that are seeking a workflow management capability. The most suitable workflow engine will depend on the nature and complexity of the requirement and the functionality supported by the workflow technology options. Options for workflow within the context of IDCM are:

- *Messaging/collaboration systems/workflow:* IDCM should support ad hoc and cooperative review and production of documents and reports, and it may be desirable to support integration with electronic forms for recordkeeping purposes.
- *Embedded workflow:* This capability is offered in systems such as document and Web content applications, or in application suites such as ERP systems. The host application provides inbuilt workflow for facilitating document-centric or process-centric modules.
- *Autonomous workflow:* These types are functional without any additional application software, with the exception of database and message queuing. When used in the context of IDCM, the functionality may support automation of document or Web content review and approval processes.

IDCM ARCHITECTURE

The IDCM system model should feature scalable, flexible, and extensible applications that integrate with the enterprise information architecture, enabling the system to grow with

the organization and facilitate knowledge sharing. Some architectural scenarios include:

- Scalability, flexibility, extensibility.
- Intuitive interface, preferably Web based, to facilitate usability, software upgrades, and support.
- Integrate with heterogeneous operating environments (where required).
- Implement three-tier (or "n-tier") client server architecture to facilitate Web client functionality and usability.
- Support distributed computing environment (databases, document/Web content repositories, replication services).
- Support mobile workers—access from remote sites, limited bandwidth.
- Integration with enterprise backup/recovery and business continuity regimes.

REASONS FOR UTILIZING IDCM SOLUTIONS

The business justification for implementing IDCM solutions ranges widely with respect to policy, compliance, and economics. For example, policy initiatives may include support for customer service initiatives, knowledge management (Laugero & Globe 2002), or risk reduction in relation to brand damage. Compliance with legislative requirements may include administrative requirements that support privacy and freedom of information legislation. Economic justification may include support for timely delivery of product to market, reduction in operational costs, continuous process improvement initiatives, and profit maximization strategies.

CRITICAL ISSUES OF DOCUMENT AND CONTENT TECHNOLOGIES

There are critical issues that must be managed, and it is imperative that organizations undertake risk analysis in order to identify risks and develop strategies to mitigate them. Table 1 summarizes some of the critical issues.

CONCLUSION

The IDCM model supports a business value proposition that aligns enabling systems and technology with an enterprise's strategic, tactical, and operational planning imperatives. The IDCM system architecture provides a range of enabling applications and technologies that support end-to-end business process improvement initiatives and provide a key foundation for knowledge management strategies.

Table 1. A summary of critical issues of IDCM technologies

Business Issues	Technology Issues
Executive management lacks resolve Lack of executive management engagement, both at the start and during the project, may impair outcomes.	**Inadequate infrastructure** Client, server, and network architecture needs to be adequate to optimize performance.
Inadequate planning Poor definition of scope and inadequate product and project lifecycle management may impair outcomes.	**Incorrect technology application** Inadequate business definition and failure to examine solution options results in implementation of inappropriate technology solution.
Inadequate specifications Lack of analysis and determination of requirements leads to project complications and inhibits extensibility of applications across enterprise.	**Integrity of metadata** Metadata can be abused in non-validated fields, which may create significant retrievability issues.
Mandated use may cause rejection Document management is often mandated, without appropriate consultation and analysis.	**Security** IDCM solutions contain vital documents and content files, and security should reflect importance.
Lack of process integration Mandated use is often accompanied by failure to integrate capabilities with existing processes, often meaning duplication of effort.	**System incompatibilities** Lack of proven integration capabilities may impact delivery document/content management enabled end-to-end business solutions.

KEY TERMS

Content Management: Implementation of a managed repository for digital assets such as documents, fragments of documents, images, and multimedia that are published to intranet and Internet WWW sites.

Document Capture: Registration of an object into a document, image, or content repository.

Document Imaging: Scanning and conversion of hard-copy documents to either analogue (film) or digital image format.

Document Management: Implements repository management controls over digital documents via integration with standard desktop authoring tools (word processing, spreadsheets, and other tools) and document library functionality. Registers and tracks physical documents.

Drawing Management System: Implements repository management controls over digital drawings by integration with CAD authoring tools and using document library functionality. Registers and tracks physical drawings.

E-Mail Management: Implements management controls over e-mail and attachments. These controls may be implemented by direct capture (e-mail archiving software) or invoked by the end-user in a document management application.

Recognition Technologies: Technologies such as barcode recognition, optical character recognition (OCR), intelligent character recognition (ICR), and optical mark recognition (OMR) that facilitate document registration and retrieval.

Workflow Software: Tools that deal with the automation of business processes in a managed environment.

Intellectual Property Protection on Multimedia Digital Library

Hideyasu Sasaki
Ritsumeikan University, Japan

INTRODUCTION

The principal concern of this article is to provide researchers and practitioners in information science and technology with legal references on the concepts, issues, trends, and frameworks of intellectual property protection regarding *multimedia digital library* in engineering manner.

Digital library is the global information infrastructure in the networked society (Borgman, 2003). A digital library, as an information system, consists of digital contents in databases and retrieval mechanisms. The right protection of digital library is a critical issue in the digital library community that demands frameworks for recouping their investment in database design and system implementation. Intellectual property law gives incentive to advance appropriate investment in database design and implementation with two types of intellectual property protection: copyright and patent (Jakes & Yoches, 1989; Junghans & Levy, 2006).

Multimedia digital contents take a variety of forms including text, images, photos, and video streams, which often commingle in multimedia digital libraries. Nevertheless, present legal studies are not satisfactory as the source of technical interpretation of the intellectual properties regarding multimedia digital libraries. The intellectual property protection of the multimedia digital libraries demands clear and concise frameworks.

BACKGROUND

In this section, we discuss two main issues on the intellectual property protection regarding multimedia digital libraries. The first issue is the copyright protection of databases to which the multimedia digital contents are stored in multimedia digital libraries. The second issue is the patent protection of the retrieval mechanisms of multimedia digital libraries.

Copyright on Multimedia Digital Libraries

U.S. Copyright Act (2005) defines that a compilation or assembling of individual contents, that is, preexisting materials or data, is a copyrightable entity as an original work of authorship. Gorman and Ginsburg (2002) and Nimmer, Marcus, Myers, and Nimmer (2006) state that a compilation is copyrightable as far as it is an "original work of authorship that is fixed in tangible form."

Multimedia digital libraries consist of multimedia digital contents which are indexed and stored in databases for appropriate retrieval operations and the retrieval mechanisms which are optimized and applied to object domains of those databases. A database of a multimedia digital library is copyrightable in the form of a component of *contents-plus-indexes* while static indexes or metadata are fixed to multimedia digital contents in a tangible medium of repository, that is, database. Static indexes or metadata represent a certain kind of categorization of the entire content of each database in a multimedia digital library (see Figure 1).

The originality on the categorization makes each database copyrightable as is different from the mere collection of its individual contents. What kind of categorization should be *original* to constitute a copyrightable compilation on the database in a multimedia digital library? The court of *American Dental Ass'n vs. Delta Dental Plan Ass'n* (1997) determined that minimal creativity in compilation sufficed this requirement of originality on databases. Any standard or framework on the requirement is not clear in the technical or engineering meanings. A uniform framework on the categorization regarding indexes or metadata of databases in multimedia digital libraries must be formulated in engineering manner.

The European Union has legislated and executed a scheme for protecting a database including its content per se, known as the sui generis right of database protection (Aplin, 2005; Reinbothe, 1999; Samuelson, 1996). That European scheme shares the same issue on the originality regarding the categorization of multimedia digital contents in databases of multimedia digital libraries.

Patent on Multimedia Digital Libraries

U.S. Patent Act (2005) defines that a data-processing process or method is patentable subject matter in the form of a computer-related invention, that is, a computer program. The computer program is patentable as far as the "specific machine … produce(s) a useful, concrete, and tangible result … for transforming … " physical data ("*physical transformation*") (*In re* Alappat, 1994).

The computer-related inventions often combine means for data processing, some of which are prior disclosed inventions. A retrieval mechanism in a multimedia digital library consists of a number of *processes*, that is, methods or means for data processing in the form of combination of computer programs. A set of programs focuses on image processing, while another set of programs operates text mining, for example.

Meanwhile, the processes in a retrieval mechanism of a multimedia digital library comprise means or components for parameter setting which is adjusted to retrieve specific kinds of multimedia digital contents, for example, images in certain domains. The problem is that which process is to realize technical advancement (nonobviousness) on its combination of the prior arts and is to be specific/enable on its parameter setting. These two issues are emerging problems in the advent of multimedia digital libraries. Uniform frameworks on the novel combination and the specific parameter setting must be formulated in engineering manner, respectively.

FRAMEWORKS FOR RIGHT PROTECTION

In this section, we outline the frameworks for intellectual property protection regarding multimedia digital library: copyrightable database and patentable retrieval mechanism.

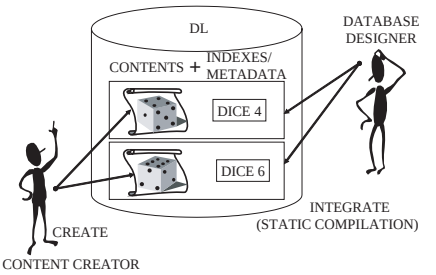
Multimedia Digital Library as Copyrightable Database

Our framework for copyrighting the databases of multimedia digital libraries determines which type of database should be copyrightable in the form of a component of contents-plus-indexes (Sasaki & Kiyoki, 2003, 2004, 2005b). The collection of static indexes and individual contents forms a component of contents-plus-indexes. That component identifies the entire content of each database, as is a static and copyrightable compilation. Copyrightable compilation is to be of sufficient creativity, that is, originality in the form of a component of contents-plus-indexes.

The set of conditions on the original categorization regarding indexes or metadata is formulated as follows (Sasaki & Kiyoki, 2004, 2005b). A categorization regarding indexes or metadata is original only when:

1. the type of indexes or metadata accepts discretionary selection in the domain of a problem database; otherwise, and
2. the type of taxonomy regarding indexes or metadata accepts discretionary selection in the domain of a problem database.

Figure 1. Copyrightable digital library as contents-plus-indexes



A typical case of nonoriginal categorization is a photo film album database which has indexes of consecutive numbers. That case does not accept any discretion in the selection of the type of indexes or metadata, or the type of taxonomy. The photo film album database uses its respective film numbers as indexes for its retrieval operations. The taxonomy of the indexes is only based on the consecutive numbering without any discretion in its selection of the type of indexes or taxonomy regarding a database in a multimedia digital library.

Meanwhile, the discretionary selection of the type of indexes or metadata, or taxonomy constitutes copyrightable compilation of minimal creativity, that is, originality on the categorization regarding indexes or metadata. A typical case of discretionary selection of the type of indexes or metadata is the Web document encyclopedia as a multimedia digital library. Suppose that a database restores pictures of starfish which are manually and numerically numbered by day/hour-chronicle interval that is based on their significant life stages from birth to death. That database is to be an original work of authorship as a copyrightable compilation in the form of a component of contents-plus-indexes. That database of discretionary type of numbering or indexing is an original, that is, copyrightable database in a multimedia digital library.

Multimedia Digital Library as Patentable Mechanism

Our framework for patenting the retrieval mechanisms of multimedia digital libraries determines which type of retrieval mechanism should be patentable in the form of a component of novel combination of prior disclosed processes and/or a component of specific parameter setting (Sasaki & Kiyoki, 2002a, 2002b, 2005a, 2005b). The frameworks focus on the

following three requirements for patentability: *patentable subject matter* (entrance to patent protection), *nonobviousness* (technical advancement) and *enablement* (specification) (Merges & Duffy, 2002).

The requirement for nonobviousness on the combination of the processes for data processing as the retrieval mechanism in a multimedia digital library is listed as follows (Sasaki & Kiyoki, 2005a):

1. The processes for performing a retrieval mechanism must comprise the combination of prior disclosed means to perform a certain mechanism which is not predicated from any combination of the prior arts and
2. the processes for performing a retrieval mechanism must realize quantitative and/or qualitative advancement.

Otherwise, the discussed processes are obvious so that they are not patentable as the processes for performing a retrieval mechanism.

First, a combination of prior disclosed means should not be "suggested" from any disclosed means "with the reasonable expectation of success" (*In re* Dow Chemical Co., 1988). Second, its asserted function on the discussed mechanism must be superior to the conventional functions which are realized in the prior disclosed or patented means in the field of the retrieval mechanism of multimedia digital libraries. On the latter issue, several solutions for performance evaluation are proposed and applicable. Another general strategy is restriction of the scope of problem claims into a certain narrow field to which no prior arts have been applied. This claiming strategy is known as the local optimization of application scope.

A component for parameter setting realizes thresholding operations in the form of a computer program with a set of ranges of parametric values. In retrieval mechanisms, parametric values determine, as thresholds, which candidate image is similar to an exemplary requested image by computation of similarity of visual features (Deb, 2004; Rui, Huang, & Chang, 1999; Smeulders, Worring, Santini, Gupta, & Jain, 2000; Yoshitaka & Ichikawa, 1999). That parameter setting component is to be a computer-related invention in the form of computer program as far as that parameter setting is sufficiently specified to enable a claimed invention or retrieval mechanism (U.S. Patent and Trademark Office, 1996a)

The requirement for enablement on the parameter setting component of the retrieval mechanism in a multimedia digital library is listed as follows (Sasaki & Kiyoki, 2005a):

1(a). The descriptions of the processes for performing a retrieval mechanism must specify the formulas for parameter setting.

1(b). Otherwise, the disclosed invention of the processes should have its co-pending application that describes the formulas in detail.

2(a). the processes must perform a new mechanism by a combination of the prior disclosed means; otherwise,

2(b). the processes should have improved formulas for parameter setting which is based on the prior disclosed means for performing a retrieval mechanism and should also give examples of parametric values on parameter setting in descriptions.

For 2(b), the processes must specify the means for parameter setting by "giving a specific example of preparing an" application to enable those skilled in the arts to implement their best mode of the processes without undue experiment (*Autogiro Co. of America vs. United States,* 1967; *Unique Concepts, Inc. v. Brown,* 1991). U.S. Patent and Trademark Office (1996a, 1996b) suggested that the processes comprising the means, that is, the components for parameter setting must disclose at least one of the following examples of parametric values on parameter setting:

1. working or prophetic examples of initial values or weights on parameter setting; or
2. working examples of the ranges of parametric values on parameter setting.

The "working examples" are parametric values that are confirmed to work at an actual laboratory or as prototype testing results. The "prophetic examples" are given without actual work by one skilled in the art.

The retrieval mechanisms of multimedia digital libraries are patentable in the form of components of novel combinations of prior disclosed processes and/or components of specific parameter settings while they are to satisfy the aforementioned conditions.

FUTURE TRENDS

In the field of visual information retrieval, the digital library community faces a variety of problems. Especially, two problems demand urgent solutions for the future progress of digital library: (1) a framework for protecting a database as a whole and (2) a scheme for protecting parameter settings in the form of trade secret.

Databases contain multimedia information including images and videos. Portable information devices allow people to easily access a large amount of downloadable multimedia files stored in distributed databases around the world. Network technology for efficient data transactions often triggers unauthorized misappropriation of those multimedia files that are important intellectual assets. Even the sui generis right of database protection discussed in Europe

is not to protect any database as a whole in the present legal system. It is necessary to prepare a framework for protecting entire databases including their contents. That framework should determine how and which type of database is to be protected as a whole.

Another emerging problem is discussed on the parameter settings of retrieval mechanisms. Patent application on the parameter setting components demands applicants as developers to make public the detailed know-how on the best range of parametric values in practice. The discovery of those parametric values needs considerable pecuniary investment in research and development. That kind of knowledge should be kept covered in the form of trade secret but not be open in public via patent application. The digital library community demands a scheme that determines which parameter setting component should be patentable or kept secret regarding multimedia digital libraries. It is necessary to prepare a scheme that determines how and which part of parameter setting components should take the form of trade secret.

CONCLUSION

In this article, we have discussed issues on intellectual property protection regarding multimedia digital libraries which consist of indexed multimedia digital contents in databases and retrieval mechanisms. We have presented the frameworks for copyrighting the database of multimedia digital library in the form of a component of contents-plus-indexes, and for patenting the retrieval mechanism of multimedia digital library in the form of a combination of processes and/or a component of parameter settings. We have also pointed out an emerging problem on the trade secret of parameter settings.

KEY TERMS

Combination of Processes: Combination of processes is a patentable computer program or programs as a number of "processes," that is, methods or means for data processing, some of which are prior disclosed inventions.

Contents-Plus-Indexes: Contents-plus-indexes is a component that comprises static indexes or metadata fixed in a database of multimedia digital library.

Copyrightable Database: Copyrightable database is a compilation of individual contents, that is, preexisting data of originality, as fixed in tangible form.

Digital Library: Digital library is a system as an infrastructure for global information, which consists of digital contents in databases and retrieval mechanisms.

Multimedia Digital Contents: Multimedia digital contents are data entities which are stored in multimedia digital libraries in a variety of forms of text, images, photos, or video streams, which often commingle therein.

Multimedia Digital Library: Multimedia digital library consists of multimedia digital contents which are indexed and stored in databases for appropriate retrieval operations and the retrieval mechanisms which are optimized and applied to object domains of those databases.

Parameter Setting: Parameter setting is a patentable computer program or programs which realize thresholding operations with a set of ranges of parametric values.

Patentable Computer Program: Patentable computer program is a computer-related invention in the form of a data-processing process or method to produce a useful, concrete, and tangible result for transforming physical data.

Sui Generis Right of Database Protection: Sui generis right of database protection means a kind of right of database protection which the European Union has legislated as a scheme for protecting databases including contents per se.

Trade Secret on Parameter Setting: Trade secret on parameter setting is a legal framework to keep secret the range of parametric values in practice rather than just patenting parameter setting components.

Intelligent Information Systems

John Fulcher
University of Wollongong, Australia

INTRODUCTION (INFORMATION SYSTEM TYPES & FUNCTIONS)

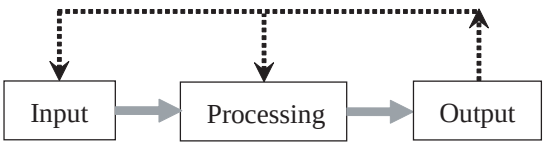
Information Systems (IS), not surprisingly, process information (data + meaning) on behalf of and for the benefit of human users. Information Systems comprise the basic building blocks shown in Figure 1, and as such can be likened to the familiar Von Neumann computer architecture model that has dominated computing since the mid 20th Century. In practice, IS encompass not just computer system hardware (including networking) and software (including DataBases), but also the *people* within an organization (Stair & Reynolds, 1999).

Information Systems are ubiquitous in today's world–the so-called "Digital Age"–and are tailor-made to suit the needs of many different industries. The following are some representative application domains:

- Management Information Systems (MIS)
- Business IS
- Transaction processing systems (& by extension, eCommerce)
- Marketing/Sales/Inventory IS (especially via the Internet)
- Postal/courier/transport/fleet/logistics IS
- Geographical Information System (GIS)/Global Positioning Satellite (GPS) systems
- Health/Medical/Nursing IS

The roles performed by IS have changed over the past few decades. More specifically, whereas IS focussed on data processing during the 1950s and 1960s, management reporting in the 1960s and 1970s, decision support during the 1970s and 1980s, strategies and end user support during the 1980s and 1990s, these days (the early years of the 21st Century) they focus more on global Internetworking (O'Brien, 1997). Accordingly, we nowadays find extensive use of IS in e-business, decision support, and business integration (Malaga, 2005). Let us take a closer look at one of these–Decision Support Systems. A DSS consists of (i) a (Graphical) User Interface, (ii) a Model Management System, and (iii) a Data Management System (comprising not only Data/Knowledge Bases but also Data Warehouses, as well as perhaps incorporating some Data Mining functionality). The DSS GUI typically displays output by way of text, graphs, charts and the like, enabling users to visualize recommendations/advice produced by the DSS. The Model Management System enables users to conduct simulations, perform sensitivity analysis, explore "what-if" scenarios (in a more extensive manner than what we are familiar with in spreadsheets), and so forth.

Figure 1. Generic information system



BACKGROUND

Whenever we encounter "intelligence" in relation to IS, it is usually in the context of (i) the decision making process itself, (ii) intelligent organizations, (iii) software agents, or (iv) the incorporation of Artificial Intelligence (AI) techniques.

For instance, Filos (2006) characterizes a "smart/intelligent" organization as being networked in the following three dimensions: (a) Information & Communications Technology (ICT), (b) organizational, and (c) *knowledge* (it is interesting to note the link here between (c) and the discussion which follows in this article). Furthermore, in the "Digital Age," the latter necessarily incorporates uncertainty and unpredictability. In this regard, Kelly and Allison (1999) demonstrate how the following concepts from Complexity Theory can be applied to improve business:

1. Nonlinear dynamics
2. Open systems
3. Feedback loops
4. Fractal structures
5. Evolutionary theory
6. Group self-organization

Filos (2006) further observes that rather than attempt to control their environments, organizations in the Digital Age will *adapt* to them (lest if they don't, they run the risk of stifling creativity, imagination, and innovation). Again, this notion of "adaptability" will resurface in our impending discussion of "intelligence."

According to Simon and Newell (1961), the human decision-making process comprises three phases, namely: (i) "intelligence," (ii) design, and (iii) choice. The use of the term "intelligence" here has a different meaning from that used in this article. More specifically, it is used by Simon and Newell in the sense of backgrounding a specific topic, as one performs in undertaking a literature review prior to commencing a new research project; in other words, to learn what has gone before (in order to "stand on the shoulders of giants," to paraphrase Einstein), and to avoid "re-inventing the wheel."

"Intelligence" can take yet another meaning within the context of IS, more specifically in relation to system security. Intelligence gathering is a prime concern of the latter, with various IS developed to support these endeavours. There are inherent dangers in such systems however, as flagged by the American Civil Liberties Union (http://www.aclu.org) in relation to the use of biometrics generally, and more especially to the 2008 RFID legislation; stated simply, whereas RFID is capable of providing audit trails, their indiscriminate use *could* encroach on ones privacy). The interests of "Big Brother" (i.e., Government) need to be balanced against citizens' rights in this regard, especially because identity theft has become such a major concern since the turn of the century. Space does not allow us to pursue these issues further, as this really warrants another article (book?) entirely.

INTELLIGENT INFORMATION SYSTEMS

Before we proceed further with our discussion of Intelligent IS, we need to define what *we* mean by the term "intelligence." We can regard "information" as being data + meaning. By extension, we can characterize "knowledge" as information + experience. Defining "intelligence," however, is a rather more challenging task. In the AI world, intelligence is generally viewed as encompassing:

- Awareness of (knowledge about and the ability to interact with) the surrounding environment, and
- An ability to learn from experience and adapt accordingly.

The first of these criteria presupposes an efficient method of encoding, storing and retrieving knowledge. Several different methods exist for doing so, including if…then (or fuzzy) production rules, frames (schema), semantic networks, propositional/predicate logic, or Artificial Neural Networks. The second criteria raises the issue of "learning" from experience, incorporating such knowledge into a "Knowledge Base" (KB), and consulting this knowledge (wisdom?) when encountering new situations and circumstances, whether consciously or unconsciously (i.e., relying not just on reasoning but also on intuition). It also implies some pattern recognition ability, in order to extrapolate from known situations, to apply heuristics (rules-of-thumb), and to build upon existing knowledge.

The claim that IBM's Deep Blue is intelligent because it defeated a human (World) Chess Champion is somewhat missing the point. The ability of the former to look a long way ahead with sequences of next moves–up to 100 billion–is indicative of little more than a brute force approach, after all (i.e., *un*intelligent).

In this article, we will restrict our focus to natural/biological systems that appear to exhibit "intelligence" (irregardless of our specific definition of the latter term). Our premise is that by mimicking (or alternatively taking inspiration from) nature, we stand to develop systems which *naturally* exhibit intelligence." Table 1 compares and contrasts the attributes of such biologically-inspired ("soft computing") approaches with that of logic and reasoning–the underpinning of conventional (algorithmic-based) computing.

REPRESENTATIVE INTELLIGENT SYSTEMS

After briefly describing the underlying principles of each approach, we proceed to cite representative examples where researchers have applied "intelligent" techniques to solve real-world problems. We restrict ourselves to six biologically

Table 1. Classical vs. soft computing

Classical computing	Soft computing
2-valued (Boolean/crisp) logic	many-valued (Fuzzy) logic
precise	approximate
deterministic	stochastic (i.e., incorporates some randomness/unpredictability)
exact/precise data	ambiguous/approximate/inconsistent data
sequential processing	parallel processing

inspired soft computing methods here, these being Artificial Neural Networks, Genetic Algorithms, swarms, DNA immune- and membrane-based computing. We basically don't consider Fuzzy Systems, reasoning systems or rule-based Expert Systems as such. However, we *do* mention such systems in the context of combinations/hybrids of such soft computing techniques, which has become the province of the field of Computational Intelligence–CI–in recent times (Fulcher & Jain, 2008).

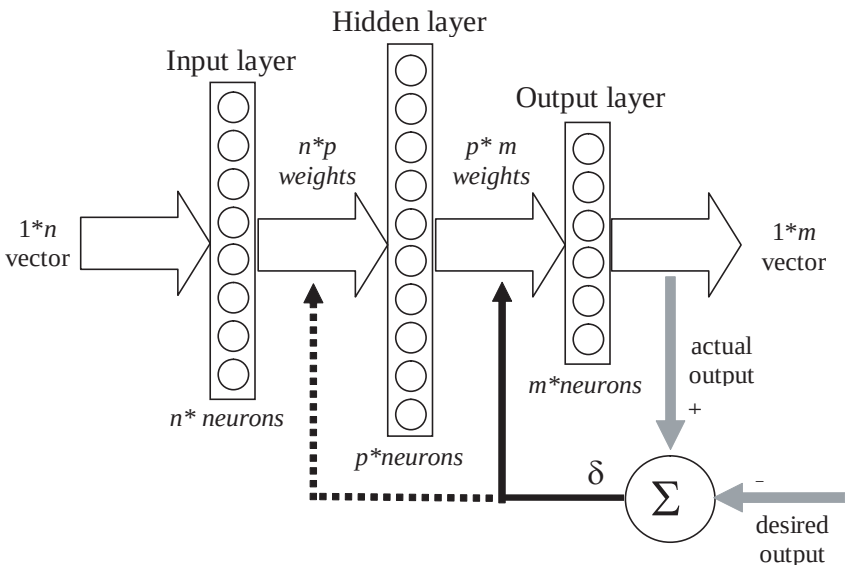
Artificial Neural Networks (ANNs)

Artificial Neural Networks (ANNs) are simplistic models of biological neural networks (brains), typically comprising dozens (but not billions) of neurons and hundreds (not tens of billions) of synapses (connections between neurons). The output (axon) of a biological neuron "fires" (produces a pulse train signal output) whenever the weighted sum of the signals from the inputs (synapses) exceeds some preset threshold. Now excitation (inhibition) of individual neurons is essentially an electrochemical process, involving different concentrations of potassium and sodium ions within and outside of the cell body; moreover, this is inherently an analog (linear) process. In the simplified neuron model commonly used in ANNs, neuron "firing" corresponds to a simple output level shift (0→1; 1→0). One characteristic of biological networks is their localized behaviour; in other words, certain areas of the brain are responsible for processing information incoming from our senses (although substantial preprocessing often takes place in the cerebral cortex prior to arriving in the brain proper), or for producing the necessary outputs (motor movement, speech, and so forth). Some ANN models reflect this localized behaviour, while others employ a more uniform, holistic architecture.

Another characteristic of biological brains is their massively parallel (analog) processing capability, such that despite the relative slow processing capability of individual neurons (milliseconds), their collective processing power far exceeds that of the fastest supercomputers, at least for some tasks. Realization of parallel, analog, neural network hardware in practice is by way of (sequential) digital computer software simulation. The ANN models in common usage are very much simplified versions of the biological networks from which they derive their inspiration. The most popular ANN model (Wong, Lai, & Lam, 2000) is the Multilayer Perceptron (MLP) of Figure 2.

ANNs are not programmed in the traditional algorithmic sense, but rather learn by example, at least in the *supervised* kind. Accordingly, supervised networks require numerous input-output training data pairs in order to learn the underlying "intelligence" of the system under study. Once trained, an ANN is capable of correctly recognizing input patterns not previously met during the training process; in other words, it exhibits generalization ability. Note that such a training process is an inherently data-driven, bottom-up approach (in contrast to conventional model-driven, top-down, algorithmic approaches). Furthermore, the training process can be quite time consuming; however, once trained, an ANN can respond almost instantaneously to new inputs.

Figure 2. A (fully-connected) 3-layer MLP/BP



The Multilayer Perceptron (MLP) of Figure 2 is a fully connected, 3-layer, supervised, feedforward ANN, comprising input, hidden, and output layers, each of which contain *n*, *p* and *m* neurons, respectively. By "feedforward," we mean that connections (weights) only exist in a forward direction, that is, from one of the *n* neurons in the Input Layer to one of the *p* neurons in the Hidden Layer (or from one of the *p* neurons in the Hidden Layer to one of the *m* neurons in the Output Layer). By contrast, no such restrictions apply in brains. The MLP employs the so-called BackPropagation learning rule, which simply stated says that upon presentation of an input-output training exemplar pair, the *actual* output produced by the network is compared with the *desired* output. During each successive training iteration, the weights are adjusted in proportion to this error (Δ or difference) signal: firstly, to adjust the weights connecting the Hidden Layer to the Output Layer, then those between the Input Layer and the Hidden Layer. In this manner, the error signal "propagates" backward from the ANN output to its input, adjusting its weights in the process; hence its name (BP).

Presentation of all input-output training pairs (exemplars)–one "epoch"–will see the weights change in many different (and incompatible/conflicting) directions. In practice *many* epochs will be necessary in order for the network to converge to an acceptable solution (which corresponds to the network having learned *all* I/O pattern associations).

It has been proven mathematically that the BP algorithm will *eventually* converge to an acceptable solution, although this might not be within a convenient timeframe from a user's perspective! In practice, training of ANNs can take several hours, perhaps even overnight, even on top-of-the-range computers. Training ceases when the error (difference) signal falls below a certain level (say 0.1%), or alternatively after a certain predetermined number of training epochs.

Common practice is to divide the available training data in two, then use one half for training and the other half to test (verify) the network once trained. Now in practice such labelled I/O training data (exemplars) may not always be available, and hence some people prefer to use *un*supervised neural networks. One has to exercise caution with the latter, however, because the resulting classes/clusters the network produces are often suspect. We restrict our current discussion here to supervised ANNs, and indeed to only *one* type (MLP/BP).

There is also the issue of how many I-O training exemplar pairs constitute a "minimum-yet-sufficient" set: too few will not lead to network convergence, whereas too many could result in "overtraining" (akin to "overfitting" in mathematical function approximation/curve fitting).

ANNs are especially good at pattern recognition or pattern classification, irrespective of what the pattern actually represents. This means that in practice we need to be able to encode the pattern of interest (be this vision, speech, time series, or whatever) into an appropriate form. Indeed, preprocessing is often the most challenging aspect of applying ANNs to real-world problems. Typical preprocessing tasks include the handling of missing, incomplete or noisy data, and most especially dimensionality reduction (because from what we have already seen, ANN training times are quite long; in fact, they increase exponentially as a function of the number of network weights; accordingly, any reduction in the dimensionality of the training data will have a dramatic effect on network convergence times).

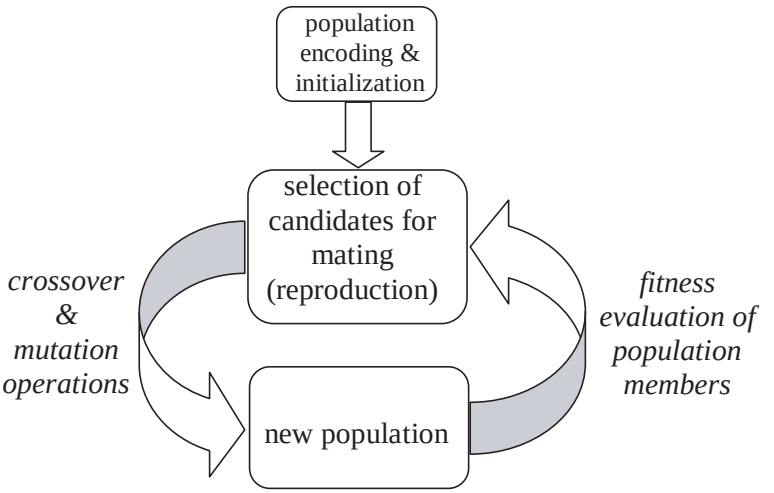
Verma & Panchal (2006) used ANNs (supervised MLP/BP) in a standard pattern classification task, that of discriminating between malignant (cancerous) and benign pap smears. Fyfe (2008) applied an unsupervised ANN–the self-organizing map–to data clustering and visualization. Likewise, Yin (2008) showed how the SOM–and variants thereof–could also be applied to vector quantization, image segmentation, density modeling, gene expression analysis, and text mining. More sophisticated (Higher-Order, supervised) ANN models have been used for both satellite weather prediction (Zhang & Fulcher, 2004) and financial time series prediction (Fulcher, Zhang & Xu, 2006). Zeleznikow (2004) combined ANNs and rule-based reasoning in the development of an Intelligent Legal Decision Support System. By contrast, Fu, Li, Wang, Ong, and Turner (2008) combined ANNs and multi-agents in order to predict network traffic over media grids.

Evolutionary Algorithms

As is the case with ANNs, evolutionary methods take their inspiration from Nature, in this case Darwinism and "survival-of-the-fittest." Although there are other variants–most notably evolutionary programming and genetic programming–we will restrict our discussion here to that of Genetic Algorithms (GAs). We assume the simplified evolutionary model of Figure 3.

Prior to evolving a solution to the problem of interest, we must first be able to encode potential (candidate) solutions into (fixed-length) genetic string form. As with ANNs, in practice this preprocessing stage can often prove the most difficult part of the exercise. Commencing with random bit strings, we first select two "parent" strings from the available population on the basis of an objective (cost or fitness) function, and proceed to "mate" them. As in biological evolution, a "child" will inherit half of its genetic code (attributes, characteristics) from either parent. The aim is that over time stronger members will "evolve" more appropriate solutions to the problem at hand, while at the same time maintaining sufficient diversity among the population as a whole to ensure healthy future generations. As in nature, a certain degree of randomness (mutation) needs to be injected into this process, in order to prevent "inbreeding" and proceeding too far down evolutionary "blind alleys" (dead ends).

Figure 3. The steps in evolution



Not surprisingly, evolution of an acceptable solution can take a very long time, typically even longer than is the case with ANN training.

Mumford (2008) showed how GAs could be applied to set partitioning problems (such as graph colouring, bin packing and timetabling). Ishibuchi, Nojima and Kowajima (2008) evolved Fuzzy Classifiers using evolutionary techniques. Beale and Pryke (2006) combined GAs with interactive 3D dynamic visualization techniques in the realization of their Haiku Knowledge Discovery system. Tran, Abraham and Jain (2006) combined ANNs, EAs and Fuzzy inference methods in the development of intelligent Decision Support Systems (DSS).

Swarm Intelligence

The inspiration for this approach stems from the collective behaviour of bee/ant colonies, bird flocks, animal herds, and other social insects/animals. What we are attempting to exploit using such techniques is a system in which the whole is greater than the sum of the parts, in the sense that whereas individual members are relatively unintelligent, the collective behaviour of the colony/flock/herd exhibits "intelligent" behaviour.

Swarms differ from GAs in that there is no direct influence from one generation to the next; the focus is rather on how *present*-generation members affect the behaviour of others; "peer pressure" in a sense. Such influence is indirect, and often takes the form of general, "broadcast" messages, rather than "peer-to-peer" communication, as it were. A good example of this is the depositing of chemical (pheromone) trails which mark the path from a hive to a food source, say.

Apart from such reliance on indirect rather than direct communication between population members, a couple of other constraints apply to swarms, these being:

- *Intra*generational learning only (i.e., no *inter*generational learning), and
- Individual swarm members are assumed to have identical form, function, and status, and hence are interchangeable.

Actually there are several variants of swarms in common usage, including Swarm Intelligence (SI) (Bonabeau, Dorigo, & Theraulaz, 1999), Particle Swarm Optimization (PSO) (Kennedy & Eberhardt, 1995), Ant Colony Optimization (ACO) (Dorigo, Maniezzo, & Colorni, 1996), and Autonomous Nanotechnology Swarms (ANTS), the latter having been proposed by NASA for future space exploration projects (Hinchey, Sterritt, & Rouff, 2007).

Hendtlass (2004) applied both Ant Colony and Particle Swarm Optimization (PSO) to the Travelling Salesman Problem (TSP). His ACO algorithm can be paraphrased as follows:

- Initialise pheromone levels on each path segment and randomly distribute *N* ants among *C* cities;
- **Repeat**
  - Repeat

    - Each ant decides which city to move to next (provided it does not *re*visit a city)
  - **Until** it returns to its starting city
- Each ant calculates the length of this most recent tour and updates information about the shortest tour found to date;
- The pheromone levels on each path segment are updated (refreshed);
- All ants having completed a predefined maximum number of tours "die off" & are replaced by new ants at randomly selected cities;
- **Until** termination condition met (e.g., shortest path < predefined threshold, or maximum number of tours made).

Khosla, Kumar and Aggrawal (2006) combined PSO and the Taguchi Method to derive optimal Fuzzy Models of a Ni-Cd battery charger. Sharkey and Sharkey (2006) combined swarms and software agents in their work with collective/swarm robotics.

DNA, Immune-Based, and Membrane-based Computing

The three approaches considered so far, while being inspired by nature, are realized in practice by way of software simulations on (silicon-based) digital computers. With the emerging field of DNA computing, we turn our attention to carbon-based computing, or so-called "wetware," a "computer-in-a-test tube," as it were. Classical algorithms are employed, rather than the data-driven approaches characteristic of ANNs, GAs and swarms.

The potential we are attempting to exploit using such an approach is the massive parallelism which results from the *simultaneous* reactions of large numbers of DNA molecules within a single test tube, despite the computation times of individual reactions being quite slow (a similar phenomenon to that previously encountered in relation to biological neural networks; in other words, fast overall behaviour results from the relatively *slow* computations that take place within individual neurons).

Not surprisingly, one of the biggest challenges with DNA computing–just as with Quantum Computing, as it happens–is Input/Output. More specifically, how does one first encode the problem of interest into DNA strand form? Next, having done so, how does one decode the result of the chemical reaction(s) into an intelligible form (and moreover, one that relates back to the problem at hand)?

Watada (2008) demonstrated how DNA computing can be applied to scheduling problems, in particular synchronizing the movements of multiple elevators in a multistorey (high-rise) building.

Immune-based computing (IBC) utilizes "antibodies" to discriminate between "self" (good cells) and "nonself" (bad/cancerous cells) and to affect self-repair. Ishida (2008) applied IBC to the so-called "stable marriage problem," and further showed how IBC could be extended to a general problem solver (the latter, by way of interest, was one of the traditional goals of AI).

The allied field of membrane-based computing is inspired by the so-called "reaction rules" between objects located within the compartments defined by a membrane structure. Not only are objects able to react with each other, they also on occasion pass through the membrane; also, the membrane itself can change shape, divide, dissolve or alter its permeability. Membranes are thus in a constant state of (nondeterministic) transition. Sequences of such transitions are the mechanism whereby we are able to realize parallel computations (Paun, 2002).

FUTURE TRENDS

Now, while much stands to be gained by employing the (largely biology-inspired) "intelligent" techniques discussed above, currently many advances emanate from *combinations* (hybrids) of these, perhaps also incorporating statistical or Machine Learning methods more commonly encountered in Data Mining. Indeed, such hybrid approaches have become a growing concern within the discipline of Computational Intelligence, as previously mentioned (Fulcher & Jain, 2008).

A few representative examples have been mentioned. Considerable activity is currently underway in the research community in developing such hybrid systems, which no doubt will set the research agenda for the foreseeable future. Duch (2007) even suggests that Computational Intelligence *might* be capable of realizing a truly "intelligent" machine where AI has failed to do so during the past 50 years.

CONCLUSION

In this article, we have focussed our attention on Intelligent IS, emphasizing the incorporation of principles imitated from/inspired by nature, in attempts to realize more efficient and better performing systems. The primary areas in nature which have served as inspiration to date include (i) Artificial Neural Networks (biological brains), (ii) Evolutionary Algorithms (Darwin's theories of evolution and survival-of-the-fittest), (iii) swarms (i.e., ants, bees, and flocks of birds), and (iv) DNA, immune-based and membrane-based computing. Several different examples of IS which have employed such biologically-inspired approaches (and most especially *hybrid* techniques) were briefly described. It is the contention of the present author that there is yet more to be gained by adopting such approaches, and no doubt we

will witness the development of many more Intelligent IS in the years (decades) to come.

KEY TERMS

Artificial Intelligence (AI): The field of study devoted to building machines which exhibit "intelligence," as commonly understood in relation to humans.

Artificial Neural Networks (ANNs): Simplified models of the human brain (biological neural network) which are particularly adept at pattern recognition or classification.

Backpropagation (BP) Algorithm: Used to train Multilayer Perceptrons (supervised, feedforward neural networks); BP adjusts the weights connecting neurons in the various layers according to the error (or difference) between actual and desired outputs generated in response to presentation of input-output training pattern pairs (exemplars).

Computational Intelligence (CI): Incorporates ANN, Fuzzy and Evolutionary approaches, and more especially *hybrids* of these (some authors extend this definition to include intelligent agents, stochastic reasoning and other techniques).

DNA Computing: The implementation of classical computing algorithms by way of chemical reactions within a test tube (so called "wet computing").

Evolutionary Algorithms (EAs): An iterative procedure which involve the "mating" of suitable parents from a population of solutions to a problem of interest, in the hope that more suitable "offspring" (i.e., solutions) will evolve over time.

Expert (or Knowledge-Based) System (ES/KBS): Comprise a (Graphical) User Interface, an Inference Engine and a Knowledge Base. The GUI accepts user queries (inputs), and presents the results to these queries (outputs) in a comprehensible manner, usually together with some justification (rules) or confidence level.

Immune-Based Computing: Uses "antigens" to discriminate between "self" and "nonself," and to affect self-repair within a system.

I**ntelligence:** Difficult to define *exactly*, but incorporates awareness of (and ability to interact with and adapt to) ones environment, as well as an ability to learn from experience (thereby increasing our knowledge).

Intelligent System: Used in this article primarily to mean (a) biologically-inspired "soft computing" techniques which can be incorporated into an information system (IS) in order to improve performance, and secondarily (b) in the sense of intelligence gathering, in order to render an IS more secure.

Soft Computing: An older term for Computational Intelligence (see above).

Swarm Intelligence (SI): Refers to a class of algorithms inspired by the collective behaviour of insect swarms, ant colonies, the flocking behaviour of some bird species, or the herding behaviour of some mammals, such that the behaviour of the whole can be considered as exhibiting a rudimentary form of "intelligence."

INTRODUCTION

Agent-based systems are one of the most important and exciting areas of research and development that emerged in information technology (IT) in the past two decades. In a nutshell, an agent is a computer program that is capable of performing a flexible, autonomous action in typically dynamic and unpredictable domains (Luck, McBurney, Shehory, & Willmott, 2005). Agents emerged as a response of the IT research community to the new data-processing requirements that traditional computing models and paradigms were increasingly incapable to deal with (e.g., the huge and ever-increasing quantities of available data). Many IT researchers believe that agents represent one of the most important software paradigms that have emerged since the object orientation.

From the historic point of view, the agent-oriented research and development (R&D) originates from different disciplines. Undoubtedly, the main contribution to the field of autonomous agents came from artificial intelligence (AI). Ultimately, AI is all about building intelligent artifacts and if these artifacts sense and act in some environment, then they can be considered agents (Russell & Norvig, 1995). Also, object-oriented programming (Booch, 2004), concurrent object-based systems (Agha, Wegner, & Yonezawa, 1993), and human-computer interaction (Maes, 1994) are fields that constantly drive forward the agent R&D in the last few decades.

In addition, the concept of an agent has become important in a diverse range of sub-disciplines of IT, including software engineering, computer networks, mobile systems, control systems, decision support, information retrieval and management, electronic commerce, and many others. Agents are being used in an increasingly wide variety of applications—ranging from comparatively small systems such as personalized email filters to large, complex, mission critical systems such as air-traffic control.

BACKGROUND

Even though there is no universal consensus over some key definitions in the field, it is intuitively clear what an "agent" is. One of the most widely used definitions states that "*an agent is a computer system, situated in some environment, that is capable of flexible autonomous action in order to meet its design objectives"* (Jennings, Sycara, & Wooldridge, 1998, p. 8).

There are three key concepts in this definition: *situatedness*, *autonomy*, and *flexibility*. *Situatedness* means that an agent receives sensory input from its environment and that it can perform actions which change the environment in some way. *Autonomy* is seen as the ability of an agent to act without the direct intervention of humans and that it has control over its own actions and internal state. In addition, the autonomy implies the capability of learning from experience. By *flexibility*, we mean the agent's ability to perceive its environment and respond to changes in a timely fashion; it should be able to exhibit opportunistic, goal-directed behaviour and take the initiative whenever appropriate. Also, an agent should be able to interact with other agents and humans, thus to be *social*. Some authors emphasize

the importance of the concept of *rationality*, which will be discussed in the next section.

Moreover, agent technologies can be considered from three perspectives (Luck, McBurney, Shehory, & Willmott, 2005):

- As a *design metaphor*, agents offer designers a way of structuring an application around autonomous, communicative elements;
- As a *source of technologies*, agent-based computing spans a range of specific techniques aimed at supporting interactions among entities in dynamic and open environments; and
- As a *simulation tool*, multi-agent systems offer robust models for representing complex and dynamic real-world environments, such as economies, societies and bio-systems.

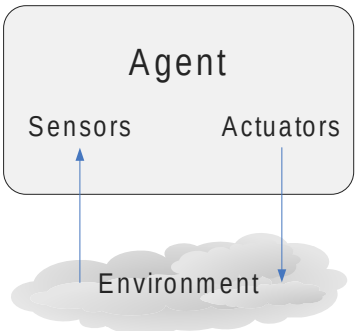
INTELLIGENT SOFTWARE AGENTS

Agents and Environments

Agents can be viewed as software entities that perceive their *environment* through *sensors* and act upon that environment through *actuators* (Russell & Norvig, 1995). There is an obvious analogy with a human agent who has ears, eyes, and other organs as sensors, and arms, legs, and other organs as actuators.

When we refer to an agent's perceptual inputs, we refer to the *agent's percepts.* An agent typically collects its percepts during the time, so its action in any moment generally depends on the whole sequence of percepts up to that moment. If we could generate a decision tree for every possible percept sequence of an agent, we could completely define the agent's behavior. Strictly speaking, we would say that we have defined the *agent function* that maps any sequence of percepts to the concrete action. The program that defines the agent function is called the *agent program*. These two concepts are different; the agent function is a formal description of the agent's behavior. The agent program is a concrete implementation of that formalism.

Figure 1. Agent and environment



As Russell and Norvig (1995) stipulate, one of the most desirable properties of an agent is its *rationality.* We say that an agent is rational if it always does the action that will cause the agent to be the most successful.

The rationality of an agent depends on:

- The performance measure that defines what is a good action and what is a bad action;
- The agent's knowledge about the environment;
- The agent's available actions;
- The agent's percept history.

One of the most cited definitions of a rational agent is:

for each possible percept sequence, a rational agent should select an action that is expected to maximize its performance measure, given the evidence provided by the percept sequence and whatever built-in knowledge the agent has. (Russell & Norvig, 1995, p. 36)

The main challenge in the field of intelligent software agents is to develop an agent program that implements the desired functionalities. Since it is a computer program, we need to have some computing device with appropriate sensors and actuators on which the agent program will run. We call this *agent architecture*. So an agent is essentially made of two components: the agent architecture and the agent program.

The Types of Agents

When we deal with the structure of an agent, we consider various implementation models for agent development. There are several basic types of agents with respect to their structure (Russell & Norvig, 1995).

The simplest kind of agents are the *simple reflex agents*. Such an agent only reacts to its current percept, totally ignoring its percept history. When a new percept is received, a rule that maps that percept to an action is fired. Such rules are known as *condition-action rules*.

Model-based reflex agents are more powerful agents, because they maintain some sort of internal state of the environment that depends on the percept history. For maintaining this sort of information, an agent must have two types of knowledge: (1) how the environment evolves, and (2) how its actions affect the environment.

Goal-based agents have some sort of goal information that describes desirable states of the world. Such an agent's decision making process is fundamentally different, because when a goal-based agent is considering performing an action it is asking itself "would this action make me happy?" along

with the standard "what this action will have as a result?".

Utility-based agents use a utility function that maps each state to a number that represents the degree of happiness. They are able to perform rationally even in the situations when there are conflicting goals, as well as when there are several goals that can be achieved, but none with certainty.

Learning agents do not have a priori knowledge of the environment, but *learn* about it. This is advantageous because these agents can operate in unknown environments and to a certain degree facilitates the job of developers because they do not need to specify their whole knowledge base.

Multi-Agent Systems and Environments

With an agent-oriented view of the world, it soon becomes clear that a single agent is insufficient. Most real-world problems require or involve multiple agents: to represent the decentralized nature of the problem, multiple perspectives, or competing interests.

Systems composed of multiple autonomous components (agents) are considered *multi-agent systems* (MAS), and historically belong to *distributed artificial intelligence* (Bond & Gasser, 1998). MAS can be defined as a loosely coupled network of problem solvers that work together to solve problems that are beyond the individual capabilities or knowledge of each problem solver (Durfee & Lesser, 1989). In an MAS, each agent has incomplete information or capabilities for solving the problem and thus has a limited viewpoint. There is no global system control, the data is decentralized, and the computation is asynchronous.

In addition to MAS, there is also the concept of a *multi-agent environment*, which can be seen as an environment that includes more than one agent. Thus, it can be cooperative, or competitive, or a combined one.

In an MAS and a multi-agent environment, the individual agents need to interact with one another (socialization) either to achieve their individual objectives, or to manage the dependencies that ensue from being situated in a common environment. These interactions range from simple semantic interoperation (exchanging comprehensible communications), through client-server interactions (the ability to request that a particular action is performed), to rich social interactions (the ability to cooperate, coordinate, and negotiate about a course of action).

Agent communication is achieved by exchanging messages represented by mutually understandable syntax and containing mutually understandable semantics. In order to find a common ground for communication, an *agent communication language* (*ACL*) should be used to provide mechanisms for agents to negotiate, query, and inform each other. The most important such languages today are *KQML* (Knowledge Query and Manipulation Language) (ARPA Knowledge Sharing Initiative, 1993) and *FIPA ACL* (FIPA, 1997) proposed by FIPA (IEEE Foundation for Intelligent Physical Agents, http://www.fipa.org/).

Because of the obstacles stemming from heterogeneous nature of agents involved in communication (e.g., finding one another), there is a need for *middle-agents*, which facilitate cooperation among agents and connect service providers with service requesters in the agent world. These agents are useful in various roles, such as *matchmakers* or *yellow page agents* that collect and process service offers ("advertisements"), *blackboard* agents that collect requests, and *brokers* that process both (Sycara, Decker, & Williamson, 1997).

Usability Aspects

The obvious advantage of agents is the clarity that the sole definition brings with regards to the representation of functionality. When an end user is presented with certain software as an agent (for example, an agent for filtering spam email), its functionalities are naturally obvious and the user experiences the system as a personal assistant that will work for him without much need for supervision.

Concerning the agents that communicate directly with end-users, the concept of agents shifts the paradigm of user interaction from simple user computer manipulation to assigning tasks to the computer. Within this scenario, the user assigns the tasks and acquires perception about an agent as an anthropomorphic software entity.

Controversies and Pitfalls of Agent Development

It is not uncommon that some users, not having enough knowledge about intelligent agents express concern (even fear) about their usage. They tend to confuse them with software daemons that send spam email messages, or with software viruses that can damage their systems.

Others perceive danger in the amount of independency that agents possess. Lead by skepticism, they are likely to discard the concept of autonomous software agents in favor of software that allows complete control over every operation it executes. This point of view goes along with arguments that giving too much decision making autonomy to a software entity would lead to dependency on such an entity's "will". Dangers arising from such autonomy are subject of various science fiction works (e.g., 2001: A Space Odyssey).

In the field of software engineering, agents are also criticized. The critiques are primarily concerned with traps in which a developer may fall when developing agents. Those pitfalls include applying agent technology in areas where other software engineering concepts are more suitable, the inappropriate use of other AI techniques, the inadequate number of agents in an agent-system, and so forth (Wooldridge & Jennings, 1998).

APPLICATIONS

Intelligent software agents are a suitable software engineering concept in a wide variety of application domains. Their autonomy qualifies them for successful application in the fields such as: traffic and transportation control, computer networks and telecommunication control, healthcare, and so forth.

Process control software systems require an entity that can supervise a process (e.g., production process) and react when needed. Reactive and responsive, agents perfectly fit the needs of such a task. Example domains in this field include: production process control, climate monitoring, spacecraft control, and monitoring nuclear power plants.

An important application domain is information gathering, where agents are used to search trough heterogeneous information sources (e.g., World Wide Web) and acquire relevant information for their users. One of the most common domains is Web browsing and search, where agents are used to adapt the content (e.g., search results) to the users' preferences and offer relevant help in browsing.

Agent cooperation opens possibilities for applying multi-agent systems to solving constraint satisfaction problems. Auction negotiation model, as a form of communication, enables a group of agents to find good solutions by achieving agreement and making mutual compromises in case of conflicting goals. Such an approach is applicable to trading systems, where agents act on behalf of buyers and sellers. Financial markets, as well as meeting scheduling, travel arrangement composing, and fault diagnosing also represent prominent fields for agent application.

Intelligent tutoring systems often include pedagogical agents, which represent software entities constructed to present the learning content in a user-friendly fashion and monitor the user's progress through the learning process. These agents are responsible for guiding the user and suggesting additional learning topics related to the user's needs (Devedzic, 2006).

Mobility Agents for People with Cognitive Disabilities

Mobility agents is an agent-based architecture that helps a person with cognitive disabilities to travel using public transportation. Agents are used to represent transportation participants (buses and travelers) and to enable notification of bus approaching and arrival. Information is passed to the traveler using a rich multimedia interface, via a handheld device. Customizable user profiles determine the most appropriate modality of interaction (voice, text, and pictures) based on the user's abilities (Repenning & Sullivan, 2003).

This architecture actually imposes a personal agent to guide users with cognitive disabilities and take care that abstract goals as "go home" are translated into concrete directions. To achieve this, an agent needs to collect information about user-specific locations and must be able to suggest the right bus for the particular user's current location and destination.

BluScreen

BluScreen is an intelligent public display, developed at the University of Southampton, in order to adapt the selection of adverts for display to the present audience detected by Bluetooth technology. Customization of content is achieved using history information of past users' exposure to certain sets of adverts, in order to predict which advert is likely to gain the highest attention.

The system is implemented as a multi-agent auction-based mechanism. Each agent represents a stakeholder wishing to advertise, and it is provided with a bidding strategy that utilizes heuristics to predict future advert exposure, based on the expected audience composition. These agents compete in an auction to gain advertising space, ensuring that the most suitable advertising content is selected (Payne, David, Jennings, & Sharifi, 2006).

BluScreen employs the concept of agents' socialization to achieve context aware, intelligent behavior of the system as a whole, relying on particular agents' autonomy to act on behalf of stakeholders and maximize their satisfaction.

Talaria

Talaria System (The autonomous lookup and report internet agent system), named after the Greek Messenger God Hermes's winged sandals, is a multi-agent system, developed for academic purposes at the University of Belgrade, Serbia, School of Business Administration (http://goodoldai.org.yu/talaria/). It was built as a solution to the common problem of gathering information from diverse Web sites that do not provide RSS feeds for news tracking. The system was implemented using the JADE modeling framework (http://jade.tilab.com/).

Talaria integrates information gathering and filtering in the context of supporting a user to manage her/his Web interests. The system provides each user with a personal agent, which periodically monitors the Web sites that the user expressed interest in. The agent informs its user about relevant changes, filtered by assumed user preferences and default relevance factors. Human-agent communication is implemented via email, so that a user can converse with her/his agent in natural language, whereas the agent heuristically interprets concrete instructions from the mail text (e.g., "change site list" or "kill yourself").

Human-like interaction, autonomy-related aspects of this system, and acting on behalf of the user emphasize the usability advantages of this agent-based software.

FUTURE TRENDS

The development of agent technologies is taking place within a context of broader visions and trends in IT, which are about to drive forward the whole field of intelligent agents. We especially emphasize *the semantic Web, Web services, ambient intelligence* and *peer-to-peer computing*.

The semantic Web is the vision of the future Web based on the idea that the data on the Web can be defined and linked in such a way that it can be used by machines for the automatic processing and integration (Berners-Lee, Hendler, & Lassila, 2001). The key to achieving this is by augmenting Web pages with descriptions of their content in such a way that it is possible for machines to reason automatically about that content. The semantic Web offers a solid ground for further development of the agent technologies as well as successful deployment of a variety of agent-based applications. Actually, we share the opinion that the semantic Web itself will be a form of intelligent infrastructure for agents, allowing them to "understand" the meaning of the data on the Web.

The other important drivers of agent development are the *Web services* and *service-oriented computing*, which are likely to become the dominant base technology in the foreseeable future. The Web service technology provides standard means for establishing interoperability between heterogeneous software applications that run on a variety of different platforms. Accordingly, this technology is almost ideal for use in supporting agent interactions in a multi-agent system. Moreover, an agent-oriented view of Web services is gaining an increasing attention, since agent-based systems are naturally seen as "provider and consumer" Web services environments (Booth et al., 2004).

The concept of *ambient intelligence*, being a vision that describes a shift away from PCs to a variety of devices which are unobtrusively embedded in our environment and which are accessed via intelligent interfaces, with no doubt require agent-like technologies in order to achieve autonomy, distribution, adaptation, and responsiveness (Booth et al., 2004). *Peer-to-peer (P2P) computing*, presenting networked applications in which every node is in some sense equivalent to all others, tends to become more complex in the future. Auction mechanism design, agent negotiation techniques, increasingly advanced approaches to trust and reputation, and the application of social norms, rules and structures—presents some of the agent technologies that are about to become relevant in the context of P2P computing (Booth et al., 2004).

Almost each of today's compelling IT visions and trends such as the abovementioned, but also grid computing, complex systems, and many more, will require agent technologies (or something similar to them), before being fully implemented. Agent technologies are upstream of these visions and mission-critical to them. However, to be able to support these visions, the agent-based computing needs further development and strengthening. Some considerable challenges have remained in the agent-based world, among which we emphasize the lack of sophisticated software tools, techniques and methodologies that would support the specification, development, integration and management of agent systems.

CONCLUSION

Research and development in the field of intelligent agents and multi-agent systems is rapidly expanding. It can be viewed as a melting pot of different ideas originating from diverse areas such as artificial intelligence, object-oriented systems, software engineering, distributed computing, economics, and so forth. At its core is the concept of autonomous agents interacting with one another for their individual and/or collective benefit.

A number of significant advances have been made over the past two decades in design and implementation of individual autonomous agents, and in the way in which they interact with one another. These concepts and technologies are now finding their way into commercial products and real-world software solutions. Future IT visions share the common need for agent technologies and prove that agent technologies will continue to be of vital importance.

KEY TERMS

Actuators: Software component and part of the agent used as a mean of performing actions in the agent environment.

Agent Communication Language (ACL): Language used by agents in exchange of messages, defining common syntax for cooperation between heterogeneous agents.

Agent Percepts: Every information that an agent receives through its sensors, about the state of the environment or any part of the environment.

Intelligent Software Agent: An encapsulated computer system that is situated in some environment and that is capable of flexible, autonomous action in that environment in order to meet its design objectives (Wooldridge & Jennings, 1995).

Middle-Agents: Agents that facilitate cooperation among other agents and typically connect service providers with service requesters.

Multi-Agent System (MAS): A software system composed of several agents that interact in order to find solutions of complex problems.

Sensors: Software component and part of the agent used as a mean of acquiring information about current state of the agent environment (i.e., agent percepts).

Intelligent Agents and Their Applications

INTRODUCTION

An agent, in the traditional use of the word, is a person that acts on behalf of another person or group of persons. In information technology, the term *agent* is broadly used to describe software that carries out a special range of tasks on behalf of either a human user or other pieces of software. Such a concept is not new in computing. Similar things have been said about subroutines, reusable objects, components, and Web services. So what makes agents more than just another computer technology buzzword and research fashion?

BACKGROUND

The idea of intelligent agents in computing goes back several decades. Foner (1993, p. 1) dates the first research on software agents to the late 1950s and early 1960s. However, with the breakthrough of the Internet, intelligent agents have become more intensively researched since the early 1990s. In spite of this long heritage, the uptake of these ideas in practice has been patchy, although the perceived situation may be partly clouded by commercial secrecy considerations. Even today, the many different notions of the term *software agent* suggest that the computing profession has not yet reached a generally accepted understanding of exactly what an agent is.

DEFINITIONS AND CLASSIFICATIONS

According to Jennings, Sycara, and Wooldridge (1998, p. 8), "An agent is a computer system, situated in some environment that is capable of flexible autonomous action in order to meet its design objectives." Thus, the determining characteristics of an software agent are:

- **Reactivity:** An agent has profound knowledge of its environment and has the ability to interact directly with it. It can receive input from the outside and can perform reactions with external effects.
- **Autonomy:** An agent is in charge of its own internal status and actions. It can perform independently without the explicit interference of any user or other agents.
- **Proactivity:** An agent has the ability to interpret even minor changes in its environment and can take the initiative to act upon them. It can communicate and interact with entities and can delegate tasks to other agents.
- **Intelligence:** An agent's degree of intelligence is determined by its capability to apply methods of AI in order optimize its action (Meier, 2006, pp. 20-320).

The research literature discusses many different types of agents, carrying out all sorts of functions with what can be termed primary and secondary characteristics. Primary characteristics include autonomy, cooperation, and learning, while secondary characteristics include aspects like multi-functionality, goodwill, or trustworthiness.

A typology of software agents was proposed by Nwana (1996, pp. 7-38):

- **Collaborative agents** feature a high degree of cooperation and autonomy. They are determined by the idea of distributed artificial intelligence and by the concept of task sharing, cooperation, and negotiation between agents.
- **Interface agents** focus on the characteristics of learning and autonomy. By collaborating with the user and by sharing knowledge with other agents, they learn a user's behavior and are trained to take the initiative to act appropriately.
- **Mobile agents** are not static but have the ability to travel. This entails non-functional benefits such as freeing local resources, showing more flexibility, and enabling an asynchronous work scenario.
- **Information or Internet agents** emphasize managing enormous amounts of information. Their main task is to know where to search for information, how to retrieve it, and how to aggregate it.
- **Reactive agents** show a stimulus-response manner as opposed to acting deliberatively. Since they are

based in the physical world and only react to present changes, their behavior is not predetermined.
- **Hybrid agents** comprise more than one agent philosophy and benefit from the combination of different architectures.

Wooldridge and Jennings (1995, pp. 24-30) offer a two-way classification, based on contrasting approaches to building agents. They distinguish the following representative architectures:

- **Deliberative agent architecture:** This classical agent architecture consists of one definite, symbolic world model with all decisions being made on the basis of logical reasoning. Challenges of this approach are the translation of the real world into an accurate model and the establishment of an efficient reasoning.
- **Reactive agent architecture:** In contrast to the deliberative agent architecture, this alternative approach is lacking an explicit and symbolic model of the world as well as extensive reasoning.

Wooldridge and Jennings (1995) also allow for hybrid agent architectures that are built as a hierarchy of deliberative and reactive agent architecture layers.

DISCUSSION

Four aspects are of particular interest when trying to understand how agents work and could be successfully employed in applications and environments: agent knowledge, agent applications, agent standards, and multi-agent systems.

Agent Knowledge

To operate autonomously, any software agent must build up a collection of knowledge, typically data and rules that enable it to serve the principal it is acting for. According to Maes (1994, pp. 2f), an agent's knowledge base should be built up gradually by learning from users and other agents. The key issues are competence and trust. To be competent, the agent must have a knowledge base that is comprehensive and flexible enough to adapt to the user's profile. For an agent to be trusted, a human user must feel comfortable when accepting help from the agent or when delegating tasks to it. Generally, an agent can only learn from its user and other agents if their actions show an iterative pattern. Maes (1994) suggests four different ways of training an agent to build up competence: observation and imitation of the user's habits, user feedback, training by example, and training by other agents.

However, Nwana and Ndumu (1999, p. 10) have criticized Maes' approach, claiming that an agent would not only need to know all peculiarities of the deployed operating system, but also must understand all tasks its user is engaged in. Furthermore, the agent would need to be capable of gathering the user's intent at any time, thus continuously modeling its user. Nwana and Ndumu (1999) identify four main competences for an agent: domain knowledge about the application, a model of its user, strategies for assistance, and a catalog of typical problems that users face in the environment.

Agent Applications

Software agents can be employed in many fields of information technology. One role for agents is to act as an assistant or helper to an individual user who is working with a complex computer system or physical equipment. Examples are:

- **Information agents** (Davies, Weeks, & Revett, 1996, pp. 105-108) that help a human researcher in finding the most relevant material — for example by additionally taking browsing information into consideration (Sharon, Lieberman, & Selker, 2002).
- **Decision support agents** that help a user assess alternative courses of action; functions include filtering and summarization of data, optimizing algorithms, heuristics, and so forth.
- **E-mail agents** (Maes, 1994, p. 5f), which filter spam, allocate incoming mail to folders, and work out addresses to which outgoing mail should be sent.
- **Buying and selling agents**, which assist a user in finding good deals in Internet marketplaces, or *bidding agents* (Morris, Ree, & Maes, 2000), which assist participants in auctions (He, Jennings, & Prügel-Bennett, 2006). These agents have characteristics of information agents as well as of decision support agents.

A second group of applications is where the agent acts as a coordinator of activities, or "virtual manager." Any workflow management system could qualify for this category. Other examples include meeting scheduling agents (Kozierok & Maes, 1993, p. 5), and dynamic scheduling agents that are able to reallocate resources to meet the goals of a business process (Lander, Corkill, & Rubinstein, 1999, p. 1ff). Delegation agents are another example in this category, although they could also be regarded as individual support.

A third group of applications is where the agent continually monitors data and rules in an organization, and on that organization's behalf alerts or sends messages to human recipients. Examples are advertising agents, notification agents, recommendation agents, and selling agents. Such agents are at work when you receive an e-mail from an Internet bookstore about a book that might interest you.

Other agents act as a third party between two humans or pieces of software that need to cooperate. Examples include brokering agents, negotiation agents, mediation

agents, and ontology agents (Helal, Wang, & Jagatheesan, 2001; Pivk & Gams, 2000). An area of application is an electronic marketplace. For example, He, Jennings, and Leung (2003) discussed agent-mediated e-commerce, and Loutchko and Teuteberg (2005) suggested an agent-based electronic marketplace.

Many humans, computer systems, and even other agents depend on one particular specialized task, which is a common agent or subagent, especially useful in an era of information overload. This is a categorization agent (Segal & Kephart, 2000, pp. 2f). Such an agent has the task of applying, and where necessary building up, a classification structure for incoming data. This structure may be particular to an individual (e.g., for e-mail filtering and filing) or it may be for an organizational unit.

Agent Standards

Intelligent agents are intended to function in heterogeneous system environments. To interact smoothly and efficiently in such environments, standardization is essential.

Although agent technology is relatively immature and many researchers still have their own definition of agents, professional bodies have been developing standards for agents since the late 1990s.

These organizations include (Dickinson, 1997):

- ARPA knowledge sharing effort (KSE)
- Agent Society
- OMG Mobile Agent System Interoperability Facility (MASIF)
- The Foundation for Intelligent Physical Agents (FIPA)

The FIPA and MASIF standards are regarded as of special importance for intelligent agents. While the FIPA standard has its origins in the intelligent agent community and has been influenced by the KQML (Knowledge Query and Manipulation Language), MASIF deals primarily with agent mobility.

The FIPA 2000 standard (*www.fipa.org*) specification deals with mobility and tries to integrate MASIF (Milojicic et al., 1998, pp. 50-67). Therefore this specification bridges the gap between the intelligent and mobile agent communities. FIPA's specification is divided into five main categories: applications, abstract architecture, agent communication, agent management, and agent message transport.

Multi-Agent Systems

Much of the recent literature on agents envisages a system with a community of agents that cooperate in some way to achieve an overall set of goals. According to Jennings et al. (1998, pp. 9, 17f), "Multi-agent systems are ideally suited to representing problems that have multiple problem-solving methods, multiple perspectives and/or multiple problem solving entities." Since each agent has a restricted view of any problem and only limited information, multi-agent systems feature a flexible and advanced infrastructure to solve issues beyond individual capabilities. Thus, the system can benefit from every agent's expert knowledge. Other characteristics of multi-agent systems are decentralized data, asynchronous computation, and the lack of a central control system.

A major challenge of multi-agent systems is clearly the means of coordination between agents. Nwana, Lee, and Jennings (1997, pp. 33-55) have identified the following key components in such coordination: foreseeable structures of agent interaction, defined agent behavior and social structures, flexibility and dynamics, and the knowledge and reasoning to utilize the above.

Possible coordination techniques are:

- **Organizational structuring:** The agents' roles, responsibilities, and their communication chains and paths of authority are defined beforehand.
- **Contracting:** All tasks and resources distributed among agents are controlled by a contract net protocol.
- **Multi-agent planning approach:** Agents decide on a detailed and interlaced plan of all activities and goals aimed at. Multi-agent planning can be centralized with one agent reviewing all individual plans and coordinating them into a single — or a distributed — multi-agent plan.

When agents are interacting in a multi-agent system, they may have to negotiate in order to fulfill their interests. Nwana et al. (1997) suggest two different negotiation theories:

- In the **Game Theory-based negotiation** approach, each agent holds a utility matrix that lists how much a certain interaction or goal is worth. During the negotiation process, which is defined by a negotiation protocol, the parties exchange bids and counteroffers following their strategies.
- In the **Plan-based Negotiation Theory**, each agent schedules its actions individually before all plans are coordinated. This is similar to the multi-agent planning coordination approach, but any agent can play the role of central coordinator.

For recent progress on negotiating agents, the reader is referred to Luo, Jennings, and Shadbolt (2006) or Fatima, Wooldridge, and Jennings (2006).

FUTURE TRENDS

We believe the area of support for human users in the carrying out of highly heterogeneous workloads represents a

promising area for the development of agent applications (see e.g. Padgham & Winikoff, 2004, for a practical guide to developing intelligent agent systems). The current support for users who work with a mixture of word processing, e-mail, spreadsheets, databases, digital libraries, and Web search tools is very primitive. The user has to do most of the work in correlating the different sources, and current tools are poor at learning the user's commonly repeated work patterns. The authors of this article feel that agents are the most promising technology to redress this shortcoming, and we have worked on architecture for linking agents with tools such as Groupware and Workflow.

CONCLUSION

In spite of a considerable amount of research, the killer application for intelligent agents is still somewhat elusive. The IT industry still has not reached a consensus about the use of agents now and in the future. Nwana and Ndumu (1999, p. 14) are even more critical, claiming that "not much discernible progress has been made post 1994." The main reason might be that intelligent agent theory integrates some of the most challenging concepts in science, including artificial intelligence (AI), data mining, or contract theory. Agent technology can be considered another new demanding application of these concepts and will succeed or fail depending on any progress in these areas. The take-up of agent technology is therefore likely to suffer the same ups and downs that AI has experienced in recent decades. In the longer term, however, there is a large area of opportunity for agents supporting human users of computer systems which has yet to be fully developed.

KEY TERMS

Artificial Intelligence: Computer systems that feature automated human-intelligent, rational behavior and employ knowledge representation and reasoning methods.

Business Process: A process at the business layer of an organization. Since the 1990s, the focus of any business reengineering project and one of the central inputs for IT design. Also called *workflow.*

Categorization: The process of deducing, from the content of an artifact, the potentially multiple ways in which the artifact can be classified for the purpose of later retrieval from a database, library, collection, or physical storage system.

Contract Theory: Theory dealing with aspects of negotiation and contracting between two or more parties.

Data Mining: Integrating statistics, database technology, pattern recognition, and machine learning to generate additional value and strategic advantages.

Game Theory: Mathematical theory of rational behavior for situations involving conflicts of interest.

Workflow: The automation of a business process, in whole or part, during which documents, information, or tasks are passed from one participant to another for action, according to a set of procedural rules. Also called *business process.*

Intelligent Software Agents in E-Commerce

INTRODUCTION

Agent technology is one of the most widely discussed topics in information systems and computer science literature. New software products are being introduced each day. A growing number of computer information professionals recognize that there are definite issues surrounding intelligent agent terminology. These must be resolved if agent technology is to continue to develop and establish.

Current research on intelligent agent software technology can be categorized as two main areas: technological and social. In the excitement of emergent technology, people often forget to scrutinize how new technology may impact their lives. The social dimension of technological progress is the driving force and most central concern of technology. Technology is not created for its own sake as a technological imperative. This article critiques the current state of software intelligent agents by examining technological issues and the social implications of intelligent agent software technology.

TECHNOLOGICAL ISSUES

An attempt to arrive at a generally accepted definition is the first hurdle. In order for this term to have any effectiveness, there must first be a universal definition that can be agreed upon and used consistently. Unfortunately, there is none. Many proposals for defining an "intelligent agent" have been put forth, but none has received wide acceptance. Some of these proposals are the following:

- "An agent is anything that can be viewed as perceiving its environment through sensors and acting upon that environment through effectors." Russell and Norvig (1995)
- "Let us define an agent as a persistent software entity dedicated to a specific purpose. 'Persistent' distinguishes agents from subroutines; agents have their own ideas about how to accomplish tasks, their own agendas. 'Special purpose' distinguishes them from other entire multifunction applications; agents are typically much smaller."
- "An autonomous agent is a system situated within and a part of an environment that senses that environment and acts on it, over time, in pursuit of its own agenda and so as to effect what it senses in the future." Franklin and Graesser (1996)

While these terms attempt to describe characteristics of intelligent agents, no comprehensive and generic description for these agents has gained wide recognition as the definitive description of a software agent. A consensus definition has not yet been achieved. As Franklin and Graesser (1996) indicate, most of the definitions proposed are derived from conceptualizations peculiar to the subjective views of the individuals. It is important to note that it is this intuitive aspect of an "intelligent agent" which makes it difficult to establish a broadly accepted formal definition. Ironically, it facilitates marketing of intelligent agent software technology.

A second reason for a lack of a consensus definition is that much of the agent research is proprietary. Companies that make investments to sponsor such research do not wish to reveal their competitive edge nor give away the value of their work. Standardization of new technology is difficult. Uncertainty will continue until the companies and individuals with the proprietary information recognize that sharing knowledge benefits everyone.

A third reason for the difficulty for the lack of a generally approved definition of an intelligent software agent, and probably the most important reason of the three outlined in this article, is that intelligent agent software does not seem to be qualitatively different from other software. "Is it an agent, or just a program?" Franklin and Graesser (1996) ask and observe, correctly, that all software agents are programs. The authors also state that not all programs are agents. The implication is that some programs are, in fact, agents. If an "intelligent agent" were just an added complex program, the term "intelligent agent" would simply mean that a software program was simply extended, made more composite

and possibly more useful than other typical programs. An intelligent agent differs from a procedural program in two ways. First, it is an agent and broadly speaking, it is defined as someone or something that acts. To be able to act, the entity must have a purpose or a goal. A computer program can only perform a prescribed set of instructions. An intelligent software agent has the same capability and is similar to a computer program in this respect.

Computer programs act utilizing a relatively low level of logic. These programs cannot act autonomously. For any entity to act with autonomy there must be concomitant independence and freedom. Procedural computer programs do not have volition, because whatever is written into the program is executed. The key factor is logic bound and a closed program. The term "react" is an inherent limitation of closed computer programs. An agent, in the true sense of the word, initiates action. The several reasons illustrate why some time is required for an acceptable definition of software agent. This process is likely to be somewhat similar to the emergence of the distinction between artificial intelligence, expert systems and decision support systems, which became clear gradually with more widespread usage of this distinctive software.

We do not demean the effort that has been invested into these products. Systems that are based on the detection of patterns in conjunction with explicit user commands and preferences are based on straightforward computational mathematics and logic. Technical challenges exist in the areas of security, connectivity, storage, peer group collaboration, network-based services, user interface, stability and standards (Bantz et al., 2003). Park and Park (2003) propose an agent-based system for merchandise management and verify its application in a duty-free shop, which performs evaluating and selecting merchandise and predicting seasons and building purchase schedules autonomously in place of human merchandise managers under a business-to-business (B2B) electronic commerce (EC) environment. In order to facilitate the agent's intelligent behavior, several analysis tools such as data envelopment analysis (DEA), genetic algorithm (GA), linear regression and rule induction algorithm are incorporated into the system.

E-mail and filters reject messages that do not comply to the user's defined preferences. Help engines and data warehousing tools search for built-in patterns. Patterns are pre-built into the engines, which are limited by the closed logic bounds specified by the designs. News and searching tools have a great potential, albeit they pose a concern. The dilemma is if many users have news searching intelligent agent tools constantly searching for information on the Internet, the Internet may possibly be clogged up by too many of these searching tools. Imagine if one of these intelligent agents had a built-in error (bug) that caused the program to continuously spawn even more agents to search the Internet. Moreover, some intelligent agents searching the Internet for information could get lost and not return with the requested information. Thus, one can see the latent technical threat in employing such ill-designed intelligent agents. These "lost" agents may create severe bottlenecks on the Internet.

Although intelligence means people thinking, it may be possible to replicate the same set of behaviors using computation. This idea was discussed by Turing in the 1940s. In 1950 he proposed a test, now called the Turing Test (TT), for computational intelligence. In the test, a human judgment must be made concerning whether a set of observed behaviors is sufficiently similar to human behaviors that the same word - intelligent - can justifiably be used. Feigenbaum (2003) discuss the challenges for computational intelligence, including: 1. an alternative to TT that tests the facet of quality (the complexity, the depth) of reasoning, 2. building a large knowledge base by reading text, thus reducing knowledge engineering effort, and 3. distilling from the WWW a huge knowledge base, thus reducing the cost of knowledge engineering.

Olin et al. (2001) suggest that although tools in the shape of distributed artificial intelligence will be available and be particularly applicable to the complexities of decision-making in the typical global enterprise, a number of issues will arise in the next few years as intelligent agents become the mainstream enablers of "real-time" enterprise process, such as the need to ensure continuity in the transition phase by careful integration of intelligent agent systems in to a legacy systems.

Van Den Heuvel and Maamar (2003) propose a framework for contract-based support to establish virtual collaboration using loosely coupled and heterogeneous intelligent Web services (IWS) in which contracts encapsulate the control information for IWSs engaged in e-business transactions. Since IWS technology is still in its infancy, several important issues must be addressed before agentified Web services can be successfully deployed at e-marketplaces, such as the integration of IWSs with wrapped legacy systems, the semantic integration of Web services, and the integration of Web services into e-commerce transactions (Van Den Heuvel & Maamar, 2003).

While search engines have become the major decision support tools for the Internet, there is a growing disparity between the image of the World Wide Web stored in search engine repositories and the actual dynamic, distributed nature of Web data. The traditional static methods in which search and retrieval are disjoint seem limited. Menczer (2003) proposes using an adaptive population of intelligent agents mining the Web online at query time and presents a public Web intelligence tool called MySpiders, a threaded multi-agent system designed for information discovery and augmenting search engines with adaptive populations of intelligent search agents for significant competitive advantage. Weippl et al. (2003) describe the manifold security threats that occur in mobile agent systems. For instance, when masquerading, an

agent claims the identity of another agent and tries to gain unauthorized access to resources. A possible solution to this security flaw is signing agent code with digital signatures such as those provided by the Java cryptographic extension (JCE 1.2.1). Mobile agents could launch denial of service attacks since too many agents could flood the Java runtime environment. Another relevant issue that needs to be addressed in the future is database intelligent agents' independence of the Java agent platform used for transport agents. Due to the lack of support offered by major Java agent platforms, the unconfined employment of standardized interfaces is not yet possible. Finally the issue of multiple, heterogeneous data warehouse islands that need to be made interoperable is being investigated by using intelligent agents to realize the federation. For instance, Xu et al. (2003) propose a two-layer approach for the formal modeling of logical agent mobility (LAM) using predicate/transition (PrT) nets in which a mobile agent system is viewed as a set of agent spaces and agents could migrate from one space to another.

SOCIAL IMPLICATIONS

The social implications, as with any new technology, include both positive and negative aspects. We are aware that the current literature debate and research on intelligent agent software technology deals in moderation with the topic of the social and ethical implications. Technologies are human artifacts, developed, presumably, for the benefit of humankind and the improvement of the quality of life. New technologies must, however, be tested to determine if the product meets these. Most important is to check if the new technology is significantly different from the existing ones.

One of the major benefits from using intelligent agents is the potential for liberating humans from the tedious task of searching for information on the Internet. The intelligent agent can aid in the search by filtering information that has little or no value. Unfortunately, intelligent agents also have the potential for damage. First, with excessive reliance on intelligent agents, humans can risk an excessive loss of choice. According to Lanier (1999), confining to an artificial world created by a programmer(s) can limit human potential for innovation. Another objection Lanier raises is that human beings degrade themselves by using intelligent agents. When individuals begin to think of computers anthropomorphically, as actually possessing intelligence and autonomy, people will tend to relate to computers as if they were human. The opposite is true too. This is a serious dilemma that must be avoided. An additional technical problem that Lanier (1999) raises is that info-consumers see the world through agents' eyes. The point is that if intelligent agents are used to find useful information, the agents themselves may be manipulated.

FUTURE TRENDS

The technological, social, and ethical issues notwithstanding, the new business environment is characterized not only by a rapid pace of change but also the dynamically discontinuous nature of such change. The issues such as lack of standardization in mobile agents may cause lack of identity traceability due to multiple transfers among networks. The security concerns relate to machine protection without artificially limiting agent access rights. Finally, there are issues surrounding performance and scalability, such as the performance effects that high levels of security would have on the network, as well as the effects of having multiple mobile agents in the same system. The emergence of intelligent mobile/software agents not only will change the way that we communicate across networks, but also have a profound impact on the way that we accomplish many tasks.

CONCLUSION

In conclusion, while intelligent agent technology has the potential for being useful to humankind, many fundamental issues remain unsolved. These problems are technical, social and/or ethical and require careful thought and consideration by developers. This discussion is critical of the current state of intelligent agent software technology and research, in the hope of encouraging developers to be aware of spillover effects. Unfortunately, issues raised by authors such as Lanier (1999) are often thrust aside as being extremist. Intelligent agent software technology has advanced, but greater progress must be made socially and ethically before these agents can be accepted as tools for the improvement of the quality of human life.

KEY TERMS

Agent: A program designed to provide specialized and well defined services. Agent can be *static* – executing on the computer where it was installed, or *mobile* – executing on computer nodes in a network.

Autonomous Agent: A system situated within and a part of an environment that senses that environment and acts on it, over time, in pursuit of its own agenda and so as to effect what it senses in the future.

Bottlenecks: A stage in a process that causes the entire process to slow down or stop.

Data Warehousing: A form of data storage geared towards business intelligence. It integrates data from various parts of the company. The data in a data warehouse are read-only and tend to include historical as well as current data so that users can perform trend analysis.

Decision Support Systems: A specific class of computerized information system that supports business and organizational decision-making activities. DSS is an interactive software-based system that compiles useful information from raw data, documents, personal knowledge, and/or business models to identify and solve problems and make decisions

Expert Systems: A computer system that facilitates solving problems in a given field or application by drawing inference from a knowledge base developed from human expertise. Some expert systems are able to improve their knowledge base and develop new inference rules based on their experience with previous problems.

Intelligent Agent: A program that gathers information or performs some other service without your immediate presence and on some regular schedule.

Turing Test (TT), for computational intelligence: In the test, a human judgment must be made concerning whether a set of observed behaviors is sufficiently similar to human behaviors that the same word - intelligent - can justifiably be used.

Intelligent Technologies for Tourism

Dimitris Kanellopoulos
University of Patras, Greece

INTRODUCTION

Nowadays, the tourism industry is a consumer of a diverse range of information (Buhalis & O'Connor, 2005). Information communication technologies (ICTs) play a critical role for the competitiveness of tourism organizations and destinations. According to Staab and Werthner (2002), ICTs are having the effect of changing:

- The ways in which tourism companies contact their business; reservations and information management systems;
- The ways tourism companies communicate; how customers look for information on, and purchase travel goods and services.

In the tourism industry, the supply and demand sides form a worldwide network in which tourism product's generation and distribution are closely worked together. Most tourism products (e.g., hotel rooms or flight tickets) are time constrained and nonstockable. Generally, the tourism product is both "perishable" and "complex," and itself is a bundle of basic products aggregated by intermediaries. Consequently, basic products must have well-defined interfaces with respect to consumer needs, prices, or distribution channels. In addition, a tourism product cannot be tested and controlled in advance. During decision-making, only an abstract model of the product (e.g., its description) is available. Besides, the tourism industry has a heterogeneous nature, and a strong small and medium-sized enterprises (SMEs) base. Undoubtedly, intelligent technologies are increasingly changing the nature of, and processes in, the tourism industry. This chapter reviews, in brief, such technologies applied to the e-tourism domain.

BACKGROUND

E-tourism is defined as the use of ICTs in the tourism industry. It involves the buying and selling of tourism products and services via electronic channels, such as the Internet, cable TV, and so forth. E-tourism includes all intranet, extranet, and Internet applications, as well as all the strategic management and marketing issues related to the use of technology. ICTs include the entire range of electronic tools that facilitate the operational and strategic management of organizations by enabling them to manage their information, functions, and processes, as well as to communicate interactively with their stakeholders for achieving their mission and objectives. Currently, e-tourism makes use of (syntactic) Web technology for tours, infrastructure, related interesting information, such as public transport, timetables, weather, online reservation, and so forth. However, the major barriers using the syntactic Web are:

- Creating complex queries involving background knowledge on tourism issues.
- Solving ambiguities and synonyms.
- Finding and using Web services for tourism

From another perspective, the characteristics of the tourism product require information on the consumers' and suppliers' sides, involving high information search costs and causing informational market imperfections. These outcomes sequentially lead to the establishment of specific product distribution information and value-adding chains. Given such a framework, Staab and Werthner (2002) state that intelligent Information Systems (ISs) should:

- Be heterogeneous, distributed, and cooperative.
- Enable full autonomy of the respective participants.
- Support the entire consumer life cycle and all business phases.
- Allow dynamic network configurations.
- Provide intelligence for customers (tourists) and suppliers as well as in the network.
- Be scalable and open.
- Focus on mobile communication enabling multichannel distribution.

Hereafter, we present intelligent technologies for tourism.

INTELLIGENT TECHNOLOGIES FOR TOURISM

Web intelligence combines two topics: (1) *Web analytics*, which examines how Web site visitors view and interact with a Web site's pages and features; and (2) *business intelligence*, which allows a corporation's management to use data on customer purchasing patterns, demographics, and

demand trends to make effective strategic decisions (Zhong, 2003). In tourism, the developments of artificial intelligence (AI) are at the cutting edge. Many applications are provided to the users, such as individualized pricing (http://www.priceline.com), reversed multiattribute auctioning (http://www.mytraveldream.com), recommendations in bundling products, and semantic Web, as well as mobile applications (Kanellopoulos, 2006; Kanellopoulos & Kotsiantis, 2006). Using the Web, travelers can get information on routes, timetables, seat availabilities, accommodations, rental cars, and restaurants to help them plan their travels. Remarkable progress has been made in the automation of travel planning with the help of the easily accessible information. There are also many semiautomated commercial service Web sites like travelocity.com, expedia.com, and orbitz.com (Paprzychi, Gilbert, & Gordon, 2002).

WEB SERVICES

The Web services technology is a set of standards that could allow Web applications for the tourism domain to "talk" to each other over the Internet. These standards are:

- XML (eXtensible Markup Language: http://www.w3.org/XML/) for driving applications services.
- SOAP (Simple Object Access Protocol: http://www.w3.org/TR/soap) for communication.
- WSDL (Web Services Description Language: http://www.w3.org/TR/wsdl/) as the service description language.
- UDDI (Universal Description, Discovery and Integration: http://www.uddi.org/) as the service discovery protocol.

The Web services technology offers distributed tourism services capability over a network (Ouzzani & Bouguettaya, 2004). The platform- and language-independent interfaces of Web services allow the easy integration of heterogeneous tourism ISs. Web services offer mechanisms for describing tourism-related Web documents, methods for accessing them, and discovery methods that enable the identification of relevant Web service providers. Recently, the OTA (Open Travel Alliance) has developed open data transmission specifications for the electronic exchange of business information for the travel industry, including but not limited to the use of XML.

SEMANTIC WEB

The *Semantic Web* is an extension of the current Web in which information is given well-defined meaning. It enables computers and users to work in cooperation, and allows the tourism content to become semantic annotated (Kanellopoulos, 2006). This characteristic allows users and software agents to query and infer knowledge from Web tourism information quickly and automatically. The semantic Web is based on formal domain models (ontologies) that define domain specific conceptualization and impose description on the domain knowledge structure and content. An ontology comprises the classes of entities, relations between entities, and the axioms that apply to the entities of the domain. Ontologies can provide a shared understanding of the tourism domain to sustain communication among users and software agents typically being represented in a machine-processable representation language like OWL (Web Ontology Language, http://www.w3.org/2004/OWL/). Through the use of metadata organized in several interrelated ontologies, information concerning tourism objects (e.g., hotels, attractions) can be tagged with descriptors that facilitate its retrieval, analysis, processing, and reconfiguration. Introducing semantics to Web services for tourism brings the following advantages:

- Ontologies offer a promising infrastructure to cope with heterogeneous representations of Web documents (Chandrasekaran, Josephson, & Benjamins, 1999). Semantically enriched Web services can handle the interoperability at the technical level, that is, they make Web applications "talk" to each other independent of their hardware and software platforms (Dell' Erba, 2004).
- Semantics can be used for the discovery and composition of Web services.
- The main mechanism for service discovery is *service registries,* and semantics can be used for the discovery of registries of Web services.

ONTOLOGIES FOR TOURISM

Tourism ontologies allow machine-supported tourism data interpretation and integration. The *e-tourism* ontology (http://e-tourism.deri.at/ont/) was deployed in the OnTour project, and describes the domain of tourism using OWL. It focuses on accommodation and activities, and it is based on an international standard: the "*Thesaurus on Tourism & Leisure Activities*" of the World Tourism Organization (WTO). This thesaurus is an extensive collection of terms related to tourism. The ISO 18513 standard ("tourism services–hotel and other types of tourism accommodation–terminology") defines terms used in tourism in relation to the various types of tourism accommodation and other related services. MONDECA's tourism ontology (http://www.mondeca.com) defines tourism concepts based on the WTO thesaurus. These concepts include terms for tourism object profiling, tourism and cultural objects, tourism packages, and tourism multimedia content. A reference ontology, named

COTRIN (Comprehensive Ontology for the Travel Industry) is presented in Cardoso and Lang (2007). The objective of COTRIN ontology is the implementation of the semantic XML-based OTA specifications. Major airlines, hoteliers, car rental companies, leisure suppliers, travel agencies, and others may use COTRIN to bring together autonomous and heterogeneous tourism Web services, Web processes, applications, data, and components residing in distributed environments.

From another perspective, a destination management system (DMS) provides complete and up-to-date information on a particular tourist destination. DMSs is a perfect application area for semantic Web and P2P (peer-to-peer) technologies. Kanellopoulos and Panagopoulos (2008) developed an ontology for tourist destinations in the LA_DMS (layered adaptive semantic-based DMS based on P2P technologies) project. The aim of LA_DMS project was to enable DMSs adaptive to tourists' needs concerning destination information. The LA_DMS system incorporates a metadata model to encode semantic tourist destination information in an RDF-based P2P network architecture. This metadata model combines ontological structures with information for tourist destinations and peers. Kanellopoulos and Kotsiantis (2007) proposed a semantic-based architecture in which semantic Web ontology is used to model tourist destinations, user profiles, and contexts. The semantic Web service ontology (OWL-S) is extended for matching user requirements with tourist destination specifications at the semantic level, with context information taken into account. Semantic Web rule language (SWRL) is used for inferencing with context and user profile descriptions. Their architecture enables DMSs to become fully adaptable to user's requirements concerning tourist destinations.

In the group package tour domain, an intelligent Web portal was proposed that helps people living in Europe to find package tours that match their personal traveling preferences (Kanellopoulos, 2008). For this purpose, the knowledge of the package tour domain has been represented by means of ontology.

The HARMONISE (http://www.harmonise.org) is an EU tourism harmonisation network (THN) established by the ECommerce and Tourism Research Laboratory, IFITT (International Federation for IT and Travel & Tourism), and others. The HARMONISE project allows participating tourism organizations to keep their proprietary data format and use ontology mediation while exchanging information (Fodor & Werthner, 2005). HARMONISE is an ontology-based mediation and harmonization tool that establishes the bridges between existing and emerging online marketplaces.

In the SATINE project (semantic-based interoperability infrastructure for integrating Web service platforms to P2P networks), a secure semantics-based interoperability framework was developed for exploiting Web service platforms in conjunction with P2P networks in the tourist industry (Dogac, Kabak, Laleci, Sinir, Yildiz, Kirbas, & Gurcan, 2004).

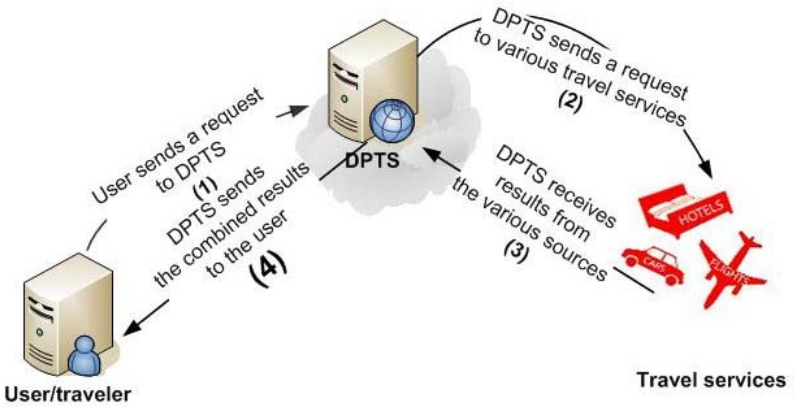
INTELLIGENT SOFTWARE AGENTS

The semantic Web includes intelligent software agents that "understand" semantic relationships between Web resources, and seek relevant information as well as perform transactions for users. Intelligent agents can provide various tourism products and services into an integrated tourism package that can be personalized to a tourist's needs. A variety of traveler, hotel, museum, and other agents can enhance the tourism marketing and management reservation processes (Kanellopoulos, 2006). There are many research prototypes of intelligent travel support systems based on software agent technology (Camacho, Borrajo, & Molina, 2001). Traveler software agents can assist travelers in finding sources of tourism products and services, and in documenting and archiving them. A set of agents can be deployed for various tasks including tracking visitor schedules, monitoring meeting schedules, and monitoring user's travel plans. For example, if the user specifies the travel itinerary and his/her required services, then a set of information agents can be spawned to perform the requested monitoring activities (Camacho et al., 2001). An additional capacity of the semantic Web is realized when intelligent agents extract information from one application and subsequently, utilize the data as input for further applications (Kanellopoulos, 2006). Therefore, software agents can create greater capacity for large-scale automated collection, processing, and selective dissemination of tourism data.

DYNAMIC PACKAGING SYSTEMS

A package tour consists of transport and accommodation advertised and sold together by a vendor known as a tour operator. Tour operators provide various services like a rental car, activities, or outings during the holiday. Consumers can acquire packages from a diversity of Web sites including online agencies and airlines. The objective of *dynamic packaging* is to pack all the components chosen by a traveler to create one reservation. Regardless of where the inventory originates, the package that is created is handled seamlessly as one transaction, and requires *only one* payment from the consumer. Cardoso and Lang (2007) proposed a framework and a platform to enable dynamic packaging using semantic Web technologies. A dynamic packaging application allows consumers and/or travel agents to bundle trip components. The range of products and services to be bundled is too large: guider tour, entertainment, event/festival, shopping, activity, accommodation, transportation, food and beverage,

Figure 1. The operation of DPTS



and so forth. Figure 1 depicts the operation of a dynamic packaging tour system (DPTS).

TRAVEL RECOMMENDER SYSTEMS

Recommender systems can predict what the user needs based on the information provided by the user (Ricci, 2004). A Web-based recommendation system was developed in the intelligent Recommendation for Tourist Destination Decision Making project (DieToRecs) (http://etd.ec3.at). This system helps the tourist destination selection process and accommodates individual traveler's preferences. Based on the user profiles, personalized recommendations are created to support potential tourists to choose their ideal destination. The Travel Recommender System (Trip@dvice) (http://tripadvise.itc.it) assists travelers in their search for tourism products and services. A prototype called NutKing (http://itr.itc.it) is available. Using the WAP (wireless application protocol), the Mobile Tourism Recommender System (mITR) (http://mobile.itc.it) implements mobile tourism services such as airlines (reservations, check-in, flight status, etc.), hotels and restaurants (reservations), maps, transportation (schedules, connections etc.), traffic, and weather conditions. Context-aware applications, such as mobile tourism guides, utilize contextual information, such as location, display medium, and user profile, in order to provide tailored functionality to the end-user.

MOBILE TOURISM GUIDES

A user interacts with a mobile tourism guide using a "map." Many mobile tourism guides have been deployed. The COMPASS (COntext-aware Mobile Personal ASSistant) guide provides tourists with context-aware recommendations and services (Van Setten, Pokraev, & Koolwaaij, 2004). The GUIDE system (Schmidt-Belz, Polsad, Nick, & Zipf, 2002) provides tourists with context-aware information about a city via a PDA (personal digital assistant). It is based on a client/server architecture and utilizes software agent technology, with a Fujitsu TeamPad 7600 used as a terminal. CRUMPET (CReation of User-friendly Mobile services Personalized for Tourism) is an EU project that developed a guide system that provides mobile services personalized for tourism. In the CRUMPET framework, tourism-related value-added services for nomadic users (across mobile and fixed networks) are provided. In most mobile guides, the characteristics of "context" are categorized into: (1) scope of context, (2) its representation and acquisition, as well as (3) the access mechanism used.

UBIQUITOUS COMPUTING AND AMBIENT INTELLIGENCE FOR TOURISM

Ubiquitous computing is a model of human-computer interaction in which information processing has been thoroughly integrated into everyday objects and activities. Recently, several projects have focused on ubiquitous computing. Such projects include Xeroz PARC's ubiquitous computing, IBM's pervasive computing, and MIT's Oxygen initiative. An interesting ubiquitous travel service delivery system is presented in O'Brien and Burmeister (2003).

Ambient intelligence is the convergence of ubiquitous computing and communication, and intelligent user-friendly interfaces. Ambient intelligent systems are embedded,

personalized, adaptive, and anticipatory, as well as they provide access for tourists, anywhere, at any time (Manes, 2003). In an ambient intelligent environment, tourists are surrounded by intelligent interfaces supported by computing and networking technologies that are embedded in everyday objects such as clothes, vehicles, and smart materials.

FUTURE TRENDS

In the near future, the mode of users' interaction will become laid-back (relaxed and enjoyable) in e-tourism. Users will enjoy computer interaction for travel planning, and technology will move to the background. In addition, users will become an integral part of tourism product creation. Therefore, personalized services and complex market mechanisms should be deployed and provided to the users. For that reason, researchers must consider nontechnical issues related to markets and users, such as dynamic market and network structures; pricing and market design; design and experimenting business models; user decision modeling; and usage analysis.

CONCLUSION

E-tourism is a decent area for Web and semantic Web technologies by assisting users and agencies with quick information searching, integrating, recommending, and various intelligent services. Semantic Web technology has an enormous potential for e-tourism by providing: (1) integration and interoperability, (2) personalized and context-aware recommendations, (3) semantically enriched information searching, and (4) internationalization. Staab and Werthner (2002) state that the requirements of intelligent tourism ISs will raise a number of important technical research issues such as (1) semantic interoperability and mediated architectures; (2) e-business frameworks supporting processes across organizations; (3) mobility and embedded intelligence; (4) natural multilingual interfaces and novel interface technologies; (5) personalization and context-based tourism services; (6) information-to-knowledge transformations, data mining and knowledge management. To these directions, much work has to be done.

KEY TERMS

CRS (Computerized Reservation System): A CRS enables travel agencies to find what a customer is looking for and makes customer data storage and retrieval relatively simple.

DMO (Destination Management Organization): It is an entity or a company that promotes a tourist destination such as to increase the amount of visitors to this destination. It uses a DMS to distribute its properties and to present the tourist destination as a holistic entity.

DMS (Destination Management System): A DMS provides complete and up-to-date information on a particular tourist destination. It handles both the pre-trip and post-arrival information, as well as integrates availability and booking service too. It is used for the collection, storage, manipulation, and distribution of tourism information, as well as for the transaction of reservations and other commercial activities. Well-known DMSs are TISCover, VisitScotland, and Gulliver.

GDS (Global Distribution System): A GDS provides travel information services, such as real-time availability and price information for flights, hotels, and car rental companies. Dominant GDSs are Sabre and Galileo.

IFITT (International Federation for IT and Travel & Tourism): The IFITT (http://www.ifitt.org/) is a not-for-profit organization aiming to promote international discussion about ICTs and tourism.

LA_DMS (Layered Adaptive Semantic-Based DMS Based on P2P Technologies): It is a DMS that is adaptive to tourists' needs for tourist destination information. It uses a metadata model to encode semantic destination information in an RDF-based P2P network architecture. Its metadata model combines ontological structures with information for tourism destinations and peers.

OTA (Open Travel Alliance): The OTA (http://www.opentravel.org/) is an organization that develops open data transmission specifications for the electronic exchange of business information for the travel industry, including, but not limited to the use of XML.

WTO (World Tourism Organization): The WTO (http://www.world-tourism.org/) is a global body concerned with the collection and collation of statistical information on international tourism. It represents public sector tourism bodies from most countries, and the publication of its data makes possible comparisons of the flow and growth of tourism on a global scale.

Interactive Television Context and Advertising Recall

Verolien Cauberghe
University of Antwerp, Belgium

Patrick De Pelsmacker
University of Antwerp, Belgium

INTRODUCTION

Interactive digital television (IDTV), the merging of the Internet and television, has the potential of reaching many consumers. Introducing interactivity in television content will replace lean-backward viewing with a more active lean-forward viewing (Van den Broeck, Pierson, & Pauwels, 2004). This new way of watching TV can have implications for the way people process the advertisements embedded in programmes. We examine the impact of two dimensions of interactivity induced by a TV quiz show, that is, user control and two-way communication (McMillan & Hwang, 2002) on the ad and brand recall of an embedded commercial. User control means the possibility of accessing extra information about the quiz show, the host, and the candidates with the remote control. Two-way communication allows the viewer to play along with the quiz using the remote control.

BACKGROUND

Advertising Context Effects

The impact of responses to programme context (e.g., mood, excitement, involvement) on embedded advertisements have been studied extensively (e.g., De Pelsmacker, Geuens, & Anckaert, 2002). This context can have either a stimulating or an inhibiting effect on the processing of an embedded advertisement. Mental processes evoked by the programme have an influence on the processing of the advertisement embedded in the programme. Positive or congruent context effects are caused by the "carry-over" principle of the programme-induced attention, liking, interest, or arousal toward the advertisement that follows (Moorman, Neijens, & Smit, 2005). Negative or contrasting relationships have been explained by the cognitive absorption of the programme, leaving less cognitive abilities for processing the advertisement (Lang, 2000).

Interactivity and Information Processing

Interactivity can be defined in different ways. Wu (2005) distinguishes between actual or feature-based interactivity and perceived interactivity. McMillan and Hwang (2002) define three underlying dimensions of interactivity: two-way communication, user control, and time delay.

A considerable amount of empirical studies have investigated the effects of the interactivity of a message vehicle on an individual's cognitive information processing in an Internet context. Some studies found a positive impact of interactivity on memory (Chung & Xinshu, 2004; Macias, 2003), while others found no impact or even a negative impact (Bezijan-Avery, Calder, & Iacobucci, 1998). The cognitive load theory (CLT; Van Merriënboer & Sweller, 2005) can be used to explain both. The CLT assumes that the human working memory is limited in processing novel information. There are broadly two types of cognitive load that can affect the working memory (Van Merriënboer & Sweller): intrinsic cognitive load, which is related to the intrinsic nature of the information (in this study the questions and answers of the quiz programme, and the content of the additional programme information), and extraneous cognitive load, which corresponds to the mental effort imposed by the way the information is presented (for instance, in this study, programme interactivity). According to the elaboration likelihood model (Petty & Cacioppo, 1981), extensive information processing only occurs when the consumer is motivated to process the information. When this prerequisite is accomplished, he or she must also have the ability (cognitive capacity) to do so. The amount of interactivity can have an influence on both mechanisms. Interactivity can increase involvement with the content (Fortin & Dholakia, 2005), which increases the motivation to process the information. However, following the CLT, interactivity can also increase the total cognitive load, and thus diminishes the ability to process information. Therefore, depending on the strength of the intrinsic cognitive load, the individual will or will not have enough ability to process the information (the interac-

tive programme), which will further influence the processing of the embedded advertisement.

In this study, we investigate the context effects of two dimensions of programme interactivity representing a low level of intrinsic load (user control regarding information about the programme, candidates, host) and a high level of intrinsic load (two-way communication involving the questions and answers in the quiz) on ad and brand recall.

User Control

User control is "the range of ways to manipulate the content" (Coyle & Thorson, 2002) and refers to the amount of possible interactions the user has to get the information in the order and pace he prefers (in this study the amount of hyperlinks in the additional programme information). Different levels of this user-control dimension could influence the motivation to process the programme. Because the intrinsic load (extra programme information) is low, we do not expect that the additional load imposed by the interactivity (user control) will lead to limited information processing capacity. Although the respondents have the ability to process the programme and the embedded advertisement when the programme has no user control, the involvement with the programme and thus the motivation to process it will be relatively low. This low processing motivation is expected to be transferred to the advertisement, leading to a superficial processing of the advertisement. At a moderate level of user control and no two way, the motivation to process the information and programme involvement increase, thus facilitating the processing of the programme. This attentive state is expected to be transferred to the subsequent advertisement. A high level of user control will increase the motivation to process the programme but, given the relatively low intrinsic cognitive load of the user control process, this motivation to process information may be higher than is required. This may lead to the development of negative thoughts, which may inhibit advertising processing. Also, more clicks lead to less information per click. This decrease in information complexity may also lead to the development of feelings of boredom and irritation. We expect the following.

H1: A moderate level of user control will lead to a higher ad and brand recall than a low or a high level of user control.

Two-Way Communication

This dimension of interactivity can be characterized as a mutual discourse or the capability of providing feedback (Ha & James, 1998). In this study, two-way communication is manipulated through the possibility of playing along with a quiz show. This implies that the interactivity leads to a high intrinsic load as a result of answering the quiz questions (multiple choices) on screen using the remote control. Although the individual may have a high motivation to process the programme when playing along, he or she may lack the ability to do so given the linear time flow of the programme, which demands the working memory to process the information very fast. This limited cognitive capacity to process the programme may lead to a cognitive capacity problem when the individual is exposed to the embedded advertisement. We expect the following.

H2: Programme embedded two-way communication (playing along) will lead to a lower ad and brand recall than no two-way communication (not playing along).

Interaction Effect between User Control and Two-Way Communication

It is unclear what the combined effect of two-way communication and user control in the program context will be on the recall of the embedded ad and brand. On the one hand, a combination of playing along and the availability of more user control could result in a higher cognitive load and less recall of the embedded ad. Following this argument, a combination of low user control and no two-way communication should lead to the highest recall, and high user control combined with two-way communication (playing along) to the lowest. On the other hand, when the viewer cannot play along with the quiz and has no user control, his or her motivation to process the programme will be low, and consequently also the motivation to process the ad. Earlier we also hypothesized that a moderate level of user control leads to the most optimal cognitive activation state to process the programme. This activation state will be transferred to the ad when the consumer has the ability to process the ad in depth. When the consumer does not play along with the game, he or she will have sufficient cognitive resources to process the programme, and thus we could expect that this combination of a moderate level of user control and two-way communication will lead to a positive effect on ad and brand recall. Given that playing along with the quiz absorbs a lot of cognitive resources, the additional cognitive load induced by the moderate level of user control, might lead to a limited capacity problem. Since the combined effect of user control and two-way communication is not clear, we formulate the following open research question.

Q1: What is the interaction effect of user control and two-way communication on ad and brand recall?

EMPIRICAL STUDY

Research Method

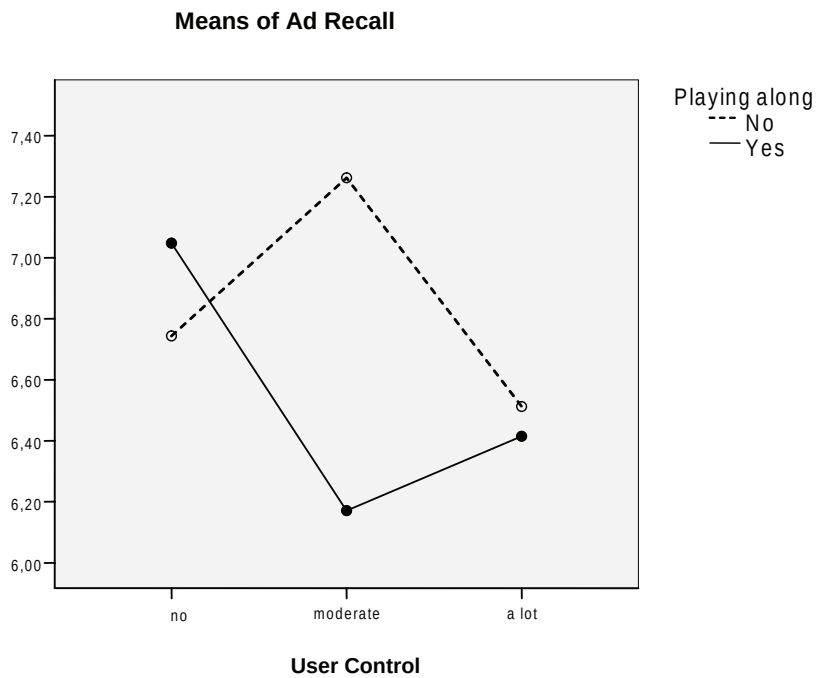
The hypotheses and research question were tested by means of a 3x2 (level of user control x level of two-way communication) between-participant experimental design. The programme context was an old episode of a well-known Belgian quiz show. User control was manipulated in the programme through the amount of clicks in the additional transparent information overlays that appeared automatically on screen during the sequence of the programme and that could be accessed by means of the remote control. Additional information about the host, candidates, quiz rules, and prizes was provided. The first level of user control did not enable any interactivity. Instead, the viewer got the extra programme information on paper. At the second level, a moderate amount of clicks (five clicks) was available during two moments in the programme. In the highest user-control condition, 26 clicks during four moments in the programme were available. The amount of information was kept constant across conditions. Two-way communication was varied on two levels. In the playing-along condition, for each question in the quiz, the viewer had the opportunity to make a choice out of three multiple choice answers using the remote control. In the not-playing condition, no interactivity was made possible. The advertisement and brand embedded in the program were unknown in Belgium at the time of the study to avoid confounding effects of existing knowledge and/or experience. We used a toothpaste advertisement from The Netherlands.

A sampling frame of 521 Flemish individuals was randomly selected by an Internet research company, taking age, gender, and education quota into account to be representative of the Belgian population. A net sample of 246 persons participated in the study. The average age of the participants was 38 years (range 21-56 years, 50% between 21-40 years old), 61.8% were males, 44.7% held a high school diploma, and 55.3% finished a higher education level.

The participants were individually invited to an experimental living-room setting. The participants were told that they were participating in a test viewing of an IDTV application. They were randomly assigned to one of the six experimental conditions. The participants viewed 15 minutes of the TV quiz show with an advertising break in the middle of the programme, after which they entered a computer-assisted questionnaire containing, amongst others, the recall measures. The experiment lasted 30 minutes in total. Each respondent received an incentive of €25

Advertisement recall was measured using 10 multiple-choice statements about content aspects of the advertisement (true vs. false). The scores were calculated by counting the

Figure 1. Interaction effect of user control and two-way communication on advertisement recall



number of correct answers (score between 0 and 10). Unaided brand recall was measured at two moments: immediately after the experiment and 10 days after the experiment. Of the 246 respondents, 168 cooperated in the delayed brand recall test (response rate of 68%).

Results

Advertising recall was measured as a score on a 10-point scale, and thus it was a ratio-scaled variable. The data met the conditions for parametric analysis. The ANOVA (analysis of variance) results indicate that user control ($p=.046$) has a significant main effect on ad recall. However, unexpectedly, the significance of this factor was driven by the difference between no user control ($M=6.90$) and high user control ($M=6.46$; $t=2.661$; $p=.009$), and not between the moderate level ($M=6.71$) vs. the high ($t=1.390$; $p=.167$) and low level ($t=.957$; $p=.341$), as expected. User control had no significant effect on brand recall measured immediately after the experiment (no=34.6%, moderate=36.1%, high=32.9%; $Chi^2=.189$; $p=.910$) or on delayed brand recall (no=28.8%, moderate=25.0%, high=27.7%; $Chi^2=.971$; $p=.896$). H1 is not supported.

Two-way communication also has a significant negative effect on ad recall ($p=.038$). Not playing along with the quiz resulted in a higher ad recall ($M=6.84$) than playing along ($M=6.55$, $t=2.011$; $p=.045$). As expected, two-way communication also had a significant negative effect on brand recall measured immediately after the experiment (40.2% vs. 29%; $Chi^2=3.370$; $p=.066$). This difference became even more significant after a delay of 10 days (36.7% vs. 18.1%; $Chi^2=7.992$; $p=.008$). H2 is accepted.

In Figure 1, the significant interaction effect between user control and two-way communication ($p<.001$) is shown. A moderate level of user control results in the highest ad recall rate when there is no play-along possibility ($M=7.26$) than when the consumer could play along. The lowest ad recall rate across all conditions results from the combination of a moderate level of user control and playing along ($M= 6.17$). This difference was significant ($t= 4.085$; $p<.001$). When there was no user control embedded in the programme, playing along had no effect on ad recall ($M= 6.74$ vs. $M= 7.05$; $t= -1.315$; $p=.192$). Also, when the level of user control was high, there appeared to be no difference in ad recall as a result of playing along or not ($M=6.51$ vs. $M=6.42$; $t= .416$; $p=.679$). The same interaction effect of user control and two-way communication was noticeable on immediate and delayed brand recall.

FUTURE TRENDS

Interactivity is assumed to be the major difference between new and traditional media. With IDTV, the viewer or user can interact with the TV content using the remote control, providing him or her with more control over the viewing experience (Van den Broeck, 2004). Requesting additional information about actors in a TV soap, participating in TV talk shows through on-screen chatting, and requesting a coupon in an advertisement are a few of the new possibilities made possible by this medium. This hypermultimedia content changes the way people watch TV, and thus can have implications on the way advertisements are perceived and processed.

The results of this study have implications for broadcasters, media planners, and advertisers. For broadcasters, the IDTV technology may increase the effectiveness of advertising in terms of ad and brand recall compared to traditional TV. The challenge for broadcasters is to reach enough viewers for their live interactive programming. Once this is achieved, our results demonstrate that IDTV compared to traditional TV can increase the brand recall up to 5.6% (difference between brand recall in the condition of no user control and no play-along possibility, and the condition with a moderate level of user control with no play-along possibility; 41% vs. 46.6%). For media planners and advertisers, the results may be of interest when the advertising goal of the campaign is to increase the awareness of the ad message or the brand. Placing an advertisement in an interactive programme might enhance ad and brand recall if the programme has a moderate level of interactivity. Too little programme interactivity might lead to boredom and to negative advertising results, whereas too much interactivity might load the respondent's cognitive abilities so much that he or she will no longer pay attention to the advertisements that appear during the commercial break. To achieve the most optimal recall results, programme interactivity should increase the motivation of the viewers to watch the content more in depth without overloading them. Therefore, a moderate level of user control without two-way communication would lead to the best results.

Further research should investigate the effects of less-cognitive-demanding two-way communication applications than the one used in this study. Perhaps imposing fewer questions on the viewers and giving them more time to respond might lead to this optimal IDTV experience for broadcasters and advertisers. In this study, we investigated memory-related aspects of processing the advertisement. Investigating the impact of programme interactivity on ad and brand attitudes would also be interesting. Further research is also warranted to study more in depth the effects of interactivity on memory and attitudes after a time delay. The results of the current study should be tested in a real-time (live) setting to corroborate the findings of this experimental context. Finally, research in larger samples is needed to reliably assess the differences in effects between different groups of viewers (e.g., by gender, age, education, etc.).

CONCLUSION

Both programme-induced user control and two-way communication had an influence on recall. However, the effect of user control was less outspoken than that of two-way communication. User control did not have a significant main effect on brand recall, and only had a weak negative effect on ad recall. Two-way communication (playing along with the TV quiz show) did have a strong and significantly negative impact on both immediate and delayed brand recall and on ad recall. The high motivation to process the quiz when playing along in combination with the high intrinsic load of the questions and answers apparently left little cognitive resources to process the embedded advertisement. The highest recall is obtained as a result of a moderate level of user control and playing along. In this condition apparently the viewer has both the ability and the motivation to process the programme, a processing state which is transferred to the embedded ad.

Besides the difference in cognitive intrinsic load, the fact that two-way communication is more likely to imply a limited-capacity problem compared to user control may also be explained by the fact that user control is a more voluntary interaction in terms of the time spent in the interactive information and the order in which viewers access the information. On the contrary, when playing along, the viewer has to follow the sequence and the order of the questions presented in the quiz programme. Past studies also found that time pressure increases the likelihood for cognitive overload to occur.

KEY TERMS

Carry-Over Advertising Context Effect: It is when psychological reactions evoked by a programme do not immediately disappear when the programme is interrupted by a commercial break, but have an influence on the processing of the advertisement embedded in the programme

Cognitive Overload: This occurs when the volume of information supply exceeds the information processing capacity of the individual.

Extrinsic Load: It is the cognitive load that is related to the representation of the information (form, style, etc.).

Interactive Digital Television (IDTV): IDTV is the merging of the Internet and television.

Intrinsic Load: It is the cognitive load that is related to the information content itself.

Two-Way Communication: It refers to mutual discourse, the capability of providing feedback, or the exchange of roles.

User Control: It is the range of ways to manipulate the content.

Interface Design Issues for Mobile Commerce

Susy S. Chan
DePaul University, USA

Xiaowen Fang
DePaul University, USA

INTRODUCTION

Effective interface design for mobile handheld devices facilitates user adoption of mobile commerce (m-commerce). Current wireless technology poses many constraints for effective interface design. These constraints include limited connectivity and bandwidth, diverse yet simplistic devices, the dominance of proprietary tools and languages, and the absence of common standards for application development.

The convergence of mobile Internet and wireless communications has not yet resulted in major growth in mobile commerce. Consumer adoption of m-commerce has been slow even in countries such as Finland, which have broadly adopted wireless technology (Anckar & D'Incau, 2002). An international study of mobile handheld devices and services suggests that mobile commerce is at a crossroads (Jarvenpaa, Lang, Takeda & Tuunainen, 2003). The enterprise and business use of wireless technology holds greater promise, but it demands the transformation of business processes and infrastructure. Poor usability of mobile Internet sites and wireless applications for commerce activities stands out as a major obstacle for the adoption of mobile solutions. For example, even with the latest 3G phones in Japan, consumers still find the small screen display and small buttons on these devices difficult to use (Belson, 2002).

BACKGROUND

Mobile Commerce

Mobile commerce broadly refers to the use of wireless technology, particularly handheld mobile devices and mobile Internet, to facilitate transaction, information search, and user task performance in business-to-consumer, business-to-business, and intra-enterprise communications (Chan & Fang, 2003). Researchers have proposed several frameworks for the study of m-commerce. Varshney and Vetter's framework (2001) presents 12 classes of m-commerce applications, ranging from retail and online shopping, auction, mobile office, and entertainment to mobile inventory emphasizing the potential of mobile B2B and intra-enterprise applications. The framework by Kannan, Chang, and Whinston (2001) groups mobile services into goods, services, content for consumer e-commerce, and activities among trading partners.

Waters (2000) proposes two visions for the potential and opportunities of m-commerce. One perspective argues that the mobile, wireless channel should be viewed as an extension of the current e-commerce channel or as part of a company's multi-channel strategies for reaching customers, employees, and partners. The second, more radical view suggests that m-commerce can create markets and business models.

Recent development in m-commerce has substantiated the first perspective. Major e-commerce sites have implemented their mobile Internet sites as an extension of wired e-commerce to support existing customers (Chan & Lam, 2004; Chan et al., 2002). Consumers have shown relatively low willingness to use m-commerce, but adopters of e-commerce are more likely to embrace this new technology (Anckar & D'Incau, 2002). Furthermore, perceived difficulty of use can affect consumers' choice of m-commerce as a distribution channel (Shim, Bekkering & Hall, 2002). These findings suggest that in a multi-channel environment, m-commerce *supplements* e-commerce instead of becoming a *substitute* for e-commerce.

Enterprise and business applications of m-commerce technologies seem to hold greater promise, because it is easier for companies to standardize and customize applications and devices to enhance current work processes. An Ernst & Young study (2001) of the largest companies in Sweden shows that, except for the retail industry sector, most industries have viewed m-commerce as being vital for growth and efficiency strategies, but not necessarily for generating new revenue. However, integrating the wireless platform in an enterprise requires significant structural transformation and process redesign.

Research on Wireless Interface Design

Several recent studies have examined interface design for mobile applications using handheld devices. Researchers have found that direct access methods were more effective for retrieval tasks with small displays (Jones, Marsden, Mohd-Nasir, Boone & Buchanan, 1999). Novice WAP phone users perform better when using links instead of action screens for navigation among cards, and when using lists of links instead of selection screens for single-choice lists (Chittaro & Cin,

2001). Ramsay and Nielsen (2000) note that many WAP usability problems echo issues identified during the early stage of Web site development for desktop computers, and could be alleviated by applying good user interface design. Such design guidelines for WAP applications include: (1) short links and direct access to content, (2) backward navigation on every card, (3) minimal level of menu hierarchy, (4) reduced vertical scrolling, (5) reduced keystrokes, and (6) headlines for each card (Colafigi, Inverard & Martriccian, 2001; Buchanan et al., 2001). Buyukkokten, Garcia-Molina, and Paepcke (2001) have found that a combination of keyword and summary was the best method for Web browsing on PDA-like handheld devices.

Diverse form factors have different interface requirements. The study by Chan et al. (2002) of 10 wireless Web sites across multiple form factors reveals that user tasks for the wireless sites were designed with steps similar to the wired e-commerce sites, and were primarily geared towards experienced users. Many usability problems, such as long download and broken connections, information overload, and excessive horizontal and vertical scrolling, are common to three form factors—WAP phone, wireless PDA, and Pocket PC. Interface design flaws are platform independent, but the more limitations imposed on the form factors, the more acute the design problems become.

Mobile users access information from different sources and often experience a wide range of network connectivity. Context factors have a particular impact on the usability of mobile applications. Based on a usability study conducted in Korea, three use context factors—hand (one or two hands), leg (walking or stopping), and co-location (alone or with others)—may result in different usability problems (Kim, Kim, Lee, Chae & Choi, 2002). Therefore, the user interface design has to consider various use contexts. Researchers also suggest a systems-level usability approach to incorporating hardware, software, "netware," and "bizware" in the design of user-friendly wireless applications (Palen & Salzman, 2002). Perry, O'Hara, Sellen, Brown, and Harper (2001) have identified four factors in "anytime anywhere" information access for mobile work: the role of planning, working in "dead time," accessing remote technological and informational resources, and monitoring the activities of remote colleagues.

Multimodal interfaces are gaining importance. The MobileGuiding project developed in Spain is aimed at building a European interactive guide network on a common, multimodal, and multilingual platform in which contributors will provide leisure information and cultural events in their locations (Aliprandi et al., 2003). Furthermore, there has been a study conducted in Finland that addresses the design and evaluation of a speech-operated calendar application in a mobile usage context (Ronkainen, Kela & Marila, 2003).

MAIN THRUST OF THIS ARTICLE

Five issues are essential to the interface design for mobile commerce applications, including: (a) technology issues, (b) user goals and tasks, (c) content preparation, (d) application development, and (e) the relationship between m- and e-commerce.

Technology Issues

Limitation of Bandwidth

Most mobile communication standards only support data rates that are less than 28.8 kbps. Connections to the wireless service base stations are unstable because signal strength changes from place to place, especially on the move. These constraints limit the amount of information exchanged between device and base station. Indication of the download progress and friendly recovery from broken connections are necessary to help users gain a better sense of control.

Form Factor

Mobile commerce services are accessible through four common platforms: wireless PDA devices using Palm OS, Pocket PCs running Microsoft Windows CE/Pocket PC OS, WAP phone, and two-way pagers. Within the same platform, different form factors may offer different functionalities. A developer should consider the form factor's unique characteristics when developing m-commerce applications.

User Goals and Tasks

Mobile users can spare only limited time and cognitive resources in performing a task. Services that emphasize mobile values, and time-critical and spontaneous needs, add more value for m-commerce users. These mobile services may include the ability to check flight schedules, check stock prices, and submit bids for auction (Anckar & D'Incau, 2002). In addition, mobile tasks that demonstrate a high level of perceived usefulness, playfulness, and security are the ones most likely to be adopted by users (Fang, Chan, Brzezinski & Xu, 2003).

Content Preparation

Constraints in bandwidth and small screen size demand different design guidelines. Most design guidelines for e-commerce (e.g., Nielsen, Farrell, Snyder & Molich, 2000) support the development of rich product information sets and a complete shopping process. In contrast, wireless Web sites have to simplify their content presentation.

Amount of Information

Content adaptation is necessary to convert information for the mobile Web (Zhou & Chan, 2003). However, users should have sufficient, if not rich, information to accomplish the goals for the application.

Navigation

Navigation systems vary from one form factor to another because the design of handheld devices differs. Currently, there is no consensus on which functions or features should be provided by the application, or built into the device itself.

Depth of Site Structure

Since mobile users have limited time for browsing wireless applications, the organization of information is critical. A flatter structure with fewer steps for wireless applications would allow users to review more options in the same step, and to locate the desired information more quickly.

Graphics or Text

Text is a better choice for displaying information on small screen browsers. However, better technology may improve the screen quality of handheld devices to display more complicated graphics. When determining the format of information to present, it is important to consider the form factor, because it may pose additional constraints on the format.

Development Environment

Mobile computing alters the assumption of "fixed" context of use for interface design and usability testing (Johnson, 1998). Traditional means of user interviews or usability testing in a laboratory environment cannot reveal insights into users' activities and mobility in real life. Contextual consideration is critical for gathering information about user requirements. For example, when developing and testing a mobile application for grocery shoppers, user requirement gathering and prototype evaluation should be conducted in a grocery store (Newcomb, Pashley & Stasko, 2003). The method of contextual inquiry can augment user interface design by exploring the versatility of usage patterns and usage context (Väänänen-Vainio-Mattila & Ruuska, 1998). While contextual inquiry may help developers gain a realistic understanding of contextual factors affecting user behaviors in motion, it is difficult to conduct non-obtrusive observations and inquiries. Developers for mobile applications need to consider the application context surrounding the relationship between the mobile device and user goals and tasks.

Relationship Between M-Commerce and E-Commerce

The wireless channel for e-commerce has raised many new questions regarding coordination between interactions with users across multiple channels. Some researchers suggest that because of the "transaction aware" and "location aware" characteristics of the wireless technology, mobile consumers may increase impulse purchases, especially in low-value, low-involvement product categories, such as books and CDs (Kannan et al., 2001). At present, many Web sites have extended the wireless channel to leverage relationships with exiting customers (Chan et al., 2002). The current state of technology and poor usability of mobile Web sites makes it difficult to expand m-commerce as an independent channel. Many analysts believe that the wireless channel is promising for customer relationship management (CRM) because of its ability to: (1) personalize content and services; (2) track consumers or users across media and over time; (3) provide content and service at the point of need; and (4) provide content with highly engaging characteristics (Kannan et al., 2001). The challenge is how to coordinate interface and content across multiple channels so that experienced users and repeat customers can handle multiple media and platforms with satisfaction.

FUTURE TRENDS

Technology Trends

User interface design for mobile commerce will likely be influenced by four trends. First, multiple standards for wireless communication will not be resolved quickly, especially in North America. Second, the high cost of third-generation (3G) technology may delay the availability of broadband technology for complex functionality and content distribution for mobile applications. Third, instead of the convergence of functionalities into a universal mobile handheld device, there may be a variety of communication devices operating in harmony to support users in their everyday lives. Fourth, input and output format may expand to incorporate voice and other formats, as well as expandable keyboards. The introduction of the voice-based interfaces may complement the text-based interface and remedy some of the information input/display problems of the handheld devices. These trends suggest opportunities to conceptualize wireless user interface beyond text-based interaction. The new challenges are to design better multimodal interfaces for inter-device communication in order to simplify tasks for mobile users.

Development Trends

Alternative methods for interface design and evaluation will be necessary to support m-commerce applications development. First, requirement analysis should focus on the context of mobile users' behaviors and tasks. Contextual inquiry and other methods may be developed to facilitate the understanding of interactions between mobility and usability. Second, usability testing should be conducted with an understanding of contextual variables beyond user behavior. Third, mapping form factors, user tasks, data needs, and content across multiple channels and platforms is necessary to synchronize content and coordinate functionality in a distributed system. Fourth, user-centered design guidelines for mobile applications will be important. These trends require a fresh look at current methodology and will help determine new ways of incorporating user interface design and usability testing for distributed wireless application development. The reference framework proposed by Lee and Benbasat (2003) may be useful in this regard. Their framework incorporates seven design elements for m-commerce interface: context, content, community, customization, communication, connection, and commerce.

M-Commerce Business Models

Wireless technology for m-commerce is likely to evolve in two areas. For intra-enterprise and business-to-business uses, wireless technology provides location-aware and mobility-aware solutions for mobile workers. There is a broad range of possibilities for B2B applications because such deployment can be controlled more easily. Content distribution may be integrated with the enterprise systems. Context-based applications, interfaces, functionality, and even devices can be customized according to the mobile tasks and user groups in the B2B context. This approach makes application development, deployment, and integration easier to manage. In contrast, it is far more challenging to manage the design, development, and deployment of wireless applications for customers. Wireless technology's capability for personalization seems to be the strongest argument for m-CRM services to enhance customer retention (Chan & Lam, 2004). A careful mapping of tasks, data, form factors, and the CRM process is essential for user interface design.

CONCLUSION

Wireless technology and the mobile Internet continues to evolve. Until the technology matures and bandwidth improves, wireless applications will be geared toward users requiring limited bandwidth, short exchange of data and text, and simple functionality. Two areas of wireless applications, CRM and enterprise efficiency, may reap greater success. Consumer e-commerce Web sites should focus on the selection of tasks that are most suitable for the wireless channel and demonstrate mobile values, especially for experienced users. Such mapping process requires a solid understanding of the CRM strategy, user preferences, and the constraints imposed by a mobile environment. For enterprise adoption, consolidating the wireless platforms and form factors will facilitate interface design. In either case, additional research to improve usability for mobile commerce is essential.

KEY TERMS

Contextual Inquiry: This interface design method employs an ethnographic approach such as observing user activities in a realistic context.

Fixed Context of Use: Traditional user interface design and testing assumes a single domain, with the users always using the same computer to undertake tasks alone or in collaboration with others.

Form Factor: This platform or operating system runs on a handheld device. Major form factors include Palm, Pocket PC, and WAP.

Interface Design: Design of the interactions between humans and computers.

Location-Aware Service: Mobile services that provide information based on a user's location through the support

of a global positioning system. Such services include mobile maps, weather, restaurants, and movie directories.

M-CRM: Interactions between a company and its customers for marketing, sales, and support services through the mobile Web and wireless channel.

Multimodal Interface: An interface that communicates with users through multiple modes.

Usability: Usability refers to how well an application is designed for users to perform desired tasks easily and effectively.

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 1612-1617, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

International Digital Studies Approach for Examining International Online Interactions

Texas Tech University, USA

INTRODUCTION

As global access to the Internet increases, so does the potential for miscommunication in international online interactions (IOIs). Unfortunately, many models for examining cross-cultural communication focus on conventional (offline) interactions or settings. As a result, researchers lack a mechanism for examining how cultural factors could affect online discourse.

This article presents an approach—international digital studies—for examining how cultural factors could affect IOIs. The purpose of this approach is to identify points of contention or areas where online media can create conflicts in cultural expectations associated with credibility. Once identified, these points of contention can serve as the subject of future research related to culture and communication.

BACKGROUND

Creating credibility, or ethos, is not a random process. Rather, audiences use certain factors, or *ethos conditions*, to develop a checklist for determining if a presentation is credible (worthy of attention). That is, audiences come to a particular presentation situation thinking, "This individual must do x, y, and z if I am to consider him or her credible/worth listening to." If all of these expectations are met (can be "checked off"), then the presenter and his or her ideas will be considered credible. If one or more ethos conditions are not met, then audiences will be less likely to view a presenter as credible (see St.Amant, 2002a, for a more in-depth discussion of this concept).

The ethos conditions one expects to encounter can vary from culture to culture, and such differences have been noted at a variety of levels (Campbell, 1998; Tebeaux, 1999; Lewis, 2001). Persons from different cultures, for example, often use different organizational structures (e.g., stated vs. implied conclusions) and different methods of citing sources to establish the credibility of a presentation (Woolever, 2001; Lewis, 2001; Hofstede, 1997). Cultures can also associate different credibility expectations with sentence length. Southern Europeans, for example, associate longer sentences with credible presentations, while Americans view shorter and more direct sentences as being more credible (Ulijn & Strother, 1995). Additionally, the kind of relationship associated with the use of a particular word can cause cross-cultural credibility problems (Li & Koole, 1998; Li, 1999).

Online media complicate cross-cultural interactions by creating conditions that affect credibility expectations. In many cases, online media reduce human interaction to typed words. Typed online messages, however, tend to follow patterns related to spoken discourse. This mix of written and spoken communication creates a new and interesting situation, for recipients of online text messages do not obtain nonverbal identity cues key to communicating in spoken exchanges. The sender of an online message therefore seems faceless and anonymous (Gauntlett, 2000; St.Amant, 2002b).

As a result, notions of authority, identity, and credibility take on new forms in cyberspace. As Fernback (1999) notes, in online exchanges, the markers of credibility—marks that draw others to listen to you—are not, "brawn, money, or political clout," but are rather "wit, and tenacity, and intelligence" (p. 213). Thus, wit, tenacity, and intelligence become ethos conditions individuals can use to appear more authoritative or more credible than other participants in an online exchange. These factors therefore become *digital ethos conditions*, for individuals come to expect them when assessing the credibility of online presentations. These digital ethos conditions, however, can conflict with the communication expectations of different cultural groups.

Understanding how cultural factors can affect online exchanges can be a complicated and seemingly overwhelming process. Yet, now that more of the world is getting online, it is becoming increasingly important to understand IOI situations so that miscommunications and mistakes can be avoided. (Such culture-related mistakes, moreover, could affect everything from online social exchanges to international outsourcing and international e-commerce activities.) For this reason, researchers can benefit from an approach that helps them focus their analysis of IOIs on a more manageable set of topics. The international digital studies approach is designed to establish such a focus.

MAIN THRUST OF THE ARTICLE

International digital studies is a research approach used to examine how cultural groups differ in their responses to digital ethos conditions. According to this perspective, the objective of the researcher is two-fold:

- First, the researcher must identify *actual* digital ethos conditions—presentation factors that actually contribute to a presenter's credibility in online exchanges. Once isolated, these digital ethos conditions can become variables used to evaluate how different cultures communicate online.
- Second, the researcher must determine if a digital ethos condition is also a factor that varies in relation to cultural communication expectations. That is, researchers need to determine if cultures would differ observably in how they responded to a particular digital ethos condition.

The key to this line of research becomes identifying variables that could affect communication in IOIs. To achieve this objective, researchers must use a two-part literature review involving the fields of Internet studies and intercultural communication.

The purpose of the dual-field literature review is to determine how factors of medium and of culture might create conflicting expectations of ethos conditions in IOIs. To identify these situations, individuals must first survey the research literature in Internet studies in order to identify digital ethos conditions in direct, two-way interactions online. The focus of this review is to isolate behavior resulting from online communication conditions vs. the transfer of communication patterns from more traditional media to an online setting. Name-dropping, for example, can be used to create credibility in both print and online media; the use of emoticons to create credibility, however, is more restricted to online communication.

After researchers identify digital ethos conditions, they must determine if these factors could cause confusion or conflict in cross-cultural exchanges. The goal then becomes evaluating if a particular digital ethos condition is also a *point of contention*—or a situation in which the communication patterns documented in the literature of one field (Internet studies) conflict with patterns noted in the literature of another field (intercultural communication).

To identify points of contention, the second part of the international digital studies process involves a review of the research literature in intercultural communication. In this second review, the researcher would look specifically for indications that digital ethos conditions identified in the initial (Internet studies) literature review relate to findings reported in the intercultural communication literature. If little or no mention of this factor is made, or if this variable appears to cause no real conflict in cross-cultural exchanges, then that variable would be a *weak* point of contention. If, for example, different cultural groups did not react differently to uses of wit (a key ethos condition noted in Internet studies), then uses of wit would be a weak point of contention, for there is little evidence of different cultural behavior related to this digital ethos condition. If, however, the intercultural literature review reports that the ethos condition noted in the Internet studies literature can cause problems in cross-cultural interactions, then that factor would be a *strong* point of contention that could affect IOIs.

Researchers must next determine if a strong point of contention could actually cause problems in IOIs. That is, just because the two-part literature review indicates a particular ethos condition could be a point of contention.

- Does that ethos condition actually affect discourse in IOIs?
- Do reactions to that ethos condition vary along cultural lines in IOI? (e.g., Do some cultures use it more than others? Are some cultures more confused by its use than others?)
- Can researchers develop a ranking system to compare how specific cultural groups vary in relation to uses of and responses to a particular ethos condition?

To answer these questions, researchers must use strong points of contention as the foundation for experiments that test if and how a strong point of contention can affect IOIs. In this way, the international digital studies approach helps researchers identify suitable topics for conducting further research into IOIs.

FUTURE TRENDS

An application of international digital studies indicates that the concept of identity could be a key problem area in future IOIs. For this reason, it is important that researchers understand how aspects and perceptions of identity could cause problems in online exchanges involving individuals from different cultures.

A review of the Internet studies literature reveals identity is a factor that affects discourse in online forums. Many researchers note that, in cyberspace exchanges, identity is neither fixed nor stable; rather, it can easily change because of online media that reduce interactions to typing words (Gauntlett, 2000; St.Amant, 2002b). By reducing identity to texts, online media allow individuals to create their online identity on their own terms (Arnold & Plymire, 2000).

Other researchers note that by limiting identity to texts, online media allow other users to co-opt or to change someone else's online identity by cutting and pasting another person's words into a different message (Warnick, 1998). Cutting and

pasting parts of a message allows individuals to separate what was said from who said it (Warnick, 1998). The ability to separate authors from their original online message gives presenters a great deal of liberty, for they can:

- attribute segments of forwarded messages to whomever they wish, thus altering the online identity of someone else;
- create new identities for themselves by co-opting the words or ideas of another;
- alter what another said, creating a new online identity for that author by "putting words in that person's mouth."

In all three cases, altering textual factors allows one individual to change the online identity of another person. The question then becomes: Could this plasticity of online identity result in reactions that vary along cultural lines? To answer this question, the researcher must review the intercultural communication literature in search of information relating to identity.

A review of the intercultural communication literature reveals that a fixed or verifiable identity is often essential to creating credible messages (Weiss, 1998; Ferraro, 2002; Ng & Van Dyne, 2001). In some cultures, one's identity is not based on the claims or the proof that the individual himself or herself presents, but is rather based on the claims of others. For example, in certain cultures, people interact within relatively large and complex social networks. These networks are often formed from long-term relationships developed between individuals over time, or from strong familial ties based on trust and senses of family duty and family honor (Hofstede, 1997; Weiss, 1998; Richmond, 1995).

In social network cultures, the identity of the presenter often determines if others will listen to or ignore information presented by that individual (Hofstede, 1997; Weiss, 1998; Richmond, 1995). The distinction is essentially one of in-group vs. out-group. If one can be identified as a member of the in-group as confirmed by someone else in the social network, then certain behaviors are expected and a certain level of credibility is awarded. Additionally, a special authority—or credibility—is given to the information that "identified" individual presents. If one is viewed as a member of the out-group (his or her identity cannot be confirmed by someone else in the social network), different behaviors are expected and different, more restricted levels of trust and disclosure are granted.

Also, in social network cultures, outsiders (members of a different culture) tend to be viewed with suspicion, and being "heard" or "listened to" often becomes a matter of having the proper introduction (Richmond, 1995; Hofstede, 1997; Scharf & MacMathuna, 1998). In such systems, if a person who is part of the network (has a known identity) says an outsider should be listened to, then that outsider is identified as "credible" by other members of the network. In this case, the identity of the outsider gains credibility by being associated with a particular individual who is known and is trusted by members of that system (Hofstede, 1997; Scharf & MacMathuna, 1998; Weiss, 1998). Success in such a cultural communication system becomes a matter of identity. That is, does the recipient of a message know the identity of the presenter and how do factors of identity affect perceptions of credibility?

Social network perspectives on identity might affect how individuals from such cultures use online communication technologies. For example, when an individual from a social network culture receives an e-mail message that lacks identity cues, will that individual trust the identity of the sender? Moreover, if individuals from such cultures (cultures in which a person's word is often that person's bond) see how easily online messages can be altered and reposted, would those individuals be willing to use online media to introduce new people or present new ideas? And how would resistance to disclosing information in cyberspace be perceived by individuals from cultures in which a fixed identity is not as important?

According to such cultural expectations, the identity of the presenter affects his or her credibility. This perceived credibility affects the degree of access an individual has to certain kinds of information in social network cultures. Persons with a solid and an easy-to-confirm identity are considered credible and gain access to information. Individuals with a limited/text-based identity, however, might be viewed as non-credible and would be limited in the information they could obtain. In such cases, identity = trust/credibility, and lack of identity = doubt.

The limited identity resulting from IOIs could therefore undermine the credibility of some participants in IOIs. This situation could lead to "unexpected" behaviors or reactions from members of social network cultures. (These behaviors might include ignoring important communiqués because the identity, and thus the credibility, of the sender is "suspect.") Such unexpected behavior could, in turn, lead to confusion or even offense.

This two-part literature review reveals instances where cultural perceptions of identity could cause problems in IOIs. As a result, identity appears to be a strong point of contention that merits further examination. From this point, researchers can use different methods to examine how this strong point of contention might affect discourse patterns in IOIs. For example, some researchers might conduct online case studies to observe how individuals from different cultural groups act and interact in online environments where identity remains restricted to texts. Other researchers might conduct controlled experiments in which different cultural groups interact in situations where identity is known and stable, and in situations where identity is limited and text based.

The purpose of these approaches would be to determine if identity actually affects how cultural groups interact in IOIs. Such research could also be used to establish a comparative system for determining how specific cultures differ according to this particular point of contention. The overall objective would therefore be to determine if a strong point of contention could allow for a relativistic comparison of cultural behavior according to a similar concept. The results of such research could provide important insights that could be used to shape everything from international e-commerce strategies to communication protocols used in international outsourcing projects.

CONCLUSION

The rapid evolution of online communication technologies is constantly changing how people think about space and time. Now, international communication often transpires in seconds or minutes, not days or weeks. This new degree of proximity, however, could lead to an increase in cross-cultural misunderstanding as many aspects of online interactions contradict the communication expectations of certain cultures. This essay has overviewed how the international digital studies approach can serve as a foundation for examining international online interactions. It now becomes the task of researchers to examine culture, technology, and communication in order to explore the true nature of IOIs.

KEY TERMS

Cross-Cultural: Situations where individuals from different cultures interact with or exchange information with one another; interchangeable with the term "intercultural."

Digital Ethos Conditions: Factors individuals use to assess the credibility or the worth of an online presentation of information.

Ethos Conditions: Factors individuals use to asses the credibility or the worth of a presentation.

Intercultural: Situations where individuals from different cultures interact with or exchange information with one another; interchangeable with the term "cross-cultural."

International Online Interaction (IOI): Situation in which individuals from two or more cultures use an online medium to interact directly with one another.

Literature Review: Reviewing the research findings reported by a certain field of research; the process usually involves the examination of articles published in the research journals of a particular field.

Point of Contention: A communication factor that is found to be positive (contribute to one's credibility) in the research of one field, but is found to be negative (detract from one's credibility) in the research of another field.

Presentation: The sharing of information with other via spoken, written, or online media.

INTRODUCTION

Only a few decades ago, the human-computer interaction was based on a rudimentary text user interface, a convenient method compared to the punch card era, but too tedious and not very appealing for the nonspecialist, and thereby, not suitable for the mass market. Later on, the multimedia era arrived, with personal computers and other devices having powerful graphic capabilities, plenty of full-coloured pictures shown to the user. Although images made more pleasant the interaction with computers, their use represented a new challenge for electronic engineers; while only a few bytes are needed to represent a text (typically one byte per character in extended ASCII), lots of data must be employed for images that, in a "raw" representation (i.e., uncompressed) for colour images, need as many as three bytes per single *pixel* (picture element, each dot forming an image). Thus, there was a clear urge to reduce the amount of bytes required to encode an image, mainly so as to avoid an excessive increase in both memory consumption and network bandwidth required to store and transmit images, which would limit or prevent their use in practice.

In general, in order to exploit the information system resources in an efficient way when dealing with images, compression is almost mandatory. Fortunately, most images are characterized by highly redundant signals (especially natural and synthetic images), since pixels composing an image present high homogeneity, and this redundancy, often called *spatial redundancy*, can be reduced through a compression process, achieving a more compact representation.

BACKGROUND

The main contribution of this chapter is a brief survey on ISO standards for image coding. This chapter is organised as follows. For continuous-tune still-image lossy compression, the chapter reviews the classic ISO JPEG standard and the newer ISO JPEG 2000, while for lossless compression, the ISO JPEG-LS is presented. In addition, the authors review the JBIG standard, which aims at binary image coding, being widely used for fax transmission.

For continuous tone images (e.g., those from a digital camera), each pixel takes a value in a (nonbinary) range; typically any value in the range $[0..2^8\text{-}1]$ for a greyscale image. Actually, for colour images, three bytes per pixel are commonly used (one byte per colour component, red, green, and blue, which is known as RGB colour space), where each pixel represents a colour from up to 2^{24} possibilities. The well-known standard, JPEG (JPEG, 1992), focuses on this type of image. Its sequential mode, widely used throughout the entertainment industry, is based on removing information that is hardly perceived by a human viewer (in particular, high-frequency components are less accurately encoded). Although the decompressed image is not equal to the original one if compared pixel by pixel, the perceptual quality could be nearly the same, provided that no heavy compression is applied. An evolution from this standard is the new JPEG 2000 standard (JPEG 2000, 2000), based on the same ideas, which is more efficient and flexible. However, the higher complexity of JPEG 2000 and the current widespread use

of JPEG make the success of this new version uncertain in the mass market.

This type of image coding process, where recovered data is not the encoded one, is called *lossy compression*. It is important to emphasise that the comparison of lossy encoders cannot be performed based on the final image size alone, but also on its visual quality, in a sort of cost/benefit ratio (usually represented as a rate/distortion curve).

If it is important to recover exactly the original image, for example, for legal reasons in medical imaging or in image editing, *lossless compression* can be done at the cost of lower compression performance (but no quality loss). Although JPEG 2000 has a lossless mode, specific standards, like JPEG-LS (JPEG-LS, 1997), offer better performance. Another famous lossless image encoder is GIF (CompuserveIncorporated, 1987). Frequently used on the Internet, it is intended for 256-colour images that are previously selected in a palette.

Finally, the authors deal with binary images where each pixel can take two different values. These images are typically employed in fax transmission, and are compressed using the JBIG standard (JBIG, 1993).

CONTINUOUS-TONE STILL-IMAGE COMPRESSION

The JPEG Standard

The most widely used algorithm for image coding is defined in the JPEG standard (JPEG, 1992). Introduced in the 1980s, and developed by the Joint Photographic Experts Group (from which the standard is named after), nowadays, it is the most common way of encoding pictures in a wide range of important applications, such as image transmission on the Internet and image storage for digital cameras. This algorithm is able to encode colour images with an average compression rate of 15:1 with good visual quality (Furth, 1995).

The JPEG standard provides four working modes, three of them are lossy and the other one is lossless (Pennebaker & Mitchell, 1992). All the lossy modes employ the two-dimensional discrete cosine transform (2D-DCT) to analyse the spatial-frequency features of the images so as to store with less precision (or even remove) those frequency components least important for a human observer (according to the human visual system). Another important role of the DCT is to achieve high compactness of the information: after the DCT is applied, a substantial part of the image information is concentrated in only a few transform coefficients, mainly the low frequency ones, and thus, it can be represented in an efficient way.

Among its four compression modes, the sequential mode is extensively used, being the simplest and most well known. In this mode, the input image can be a greyscale image or a colour image. Although a digital colour image is commonly represented in the RGB space by an image capture device, it can be stored more efficiently in YCbCr space, in which the luminance component (*Y*) is represented separately from the blue and red chrominance components (*Cb* and *Cr* respectively) (note that the remaining green component, *Cr*, is not needed because it can be inferred from the *Cb*, *Cr* and *Y* components). Since the human eye is more sensitive to brightness information than to colour, the YCbCr colour representation allows us to reduce the size of the chrominance components without a significant degradation of the perceptual image quality. Thereby, the first step of the JPEG algorithm for colour image coding is a colour space transform from the input colour space to YCbCr, followed by a chrominance downsampling, usually a 4:2:0 subsampling, where the chrominance components are reduced by two in both horizontal and vertical directions (other possible downsampling is 4:2:2, in which only the horizontal direction is reduced by two, or 4:4:4, where there is no subsampling at all).

In the sequential mode, each image component is divided into 8×8 nonoverlapping blocks, and they are compressed and transmitted (or stored) in scan order, from left to right, and from top to bottom, so that the decoder can recover the image sequentially, in the same order as it was encoded. Each block is then processed as follows:

1. The two-dimensional DCT is applied to the entire block (it can be separately applied by using a 1D-DCT, first on the rows and then on the columns). Details on how to compute the DCT can be readily found in the literature (Ghanbari, 2003; Pennebaker & Mitchell, 1992).
2. The transform coefficients are then quantised to reduce information, most of all in high frequency components. This step is responsible for introducing information loss in the encoding process. The quantization process is done by dividing each coefficient by an associated constant value from a quantization matrix, rounding the result obtained to the nearest integer. This matrix is defined in such a manner that the higher frequency a coefficient represents, the higher the denominator (quantization value) becomes, and thereby more information reduction takes place.
3. The DC component of the current block is differentially encoded by using, as a reference, the DC component of the previous block.
4. The rest of the components are scanned in zig-zag order, from lower to higher frequencies, and joint run-length and entropy coding is done. With the run-length coding, a count of zero-values is performed, while entropy coding is a statistical compression method that encodes symbols by using an amount of bits inversely

proportional to the probability of its appearance (i.e., more likely symbols are encoded with fewer bits, and vice versa).

In addition, the JPEG algorithm allows varying the compression ratio by increasing the value of elements in the quantization matrix, at the expense of reducing image quality. This process is called rate control.

The other two lossy modes are the progressive and hierarchical modes, and both are based on the sequential one, adding more features to it. In particular:

a. In the progressive mode, data from all the blocks is interleaved (by interleaving bit-planes, or coefficients, or both of them (Ghanbari, 2003)) so that a blurry full-resolution image can be displayed when the first bytes are received, and more bytes from the bitstream can be used to obtain more sharpened and defined versions of the image (this feature is known as quality scalability or SNR scalability).
b. In the hierarchical mode, the original image is first downsampled by two several times, and then encoded and transmitted as in the sequential mode. Then, the encoder transmits the error committed by upsampling by two the low-resolution version of the image, and it repeats this process successively until the original resolution is achieved. By this process, the decoder is able to reconstruct larger images as more bytes are received, approaching the original resolution (this feature is called resolution scalability).

The last operation mode in JPEG is the lossless mode. In this coding method, no block-division and transform is done, being completely different in concept and usage to the lossy modes. In fact, it was introduced as a late addition a few years after the JPEG standard was released.

The JPEG 2000 Standard

The JPEG 2000 standard (JPEG 2000, 2000) was proposed at the beginning of the new millennium, two decades after the JPEG standard was released, aiming at replacing it. Much research had been done in the field of image coding, and this new standard was intended to collect and apply much of it. During these years, a new mathematical tool, called discrete wavelet transform (DWT), had aroused great interest in the field of image coding, mainly because it achieves high compactness of energy in the lower frequency sub-bands for natural images, which is extremely useful in image compression. Moreover, it allows resolution scalability in a natural way, since more wavelet sub-bands are used to progressively enlarge the low frequency sub-bands (Mallat, 1989). For these reasons, the JPEG 2000 standard replaced the use of the DCT by the DWT.

Another advantage of the DWT compared to the DCT is that there are computationally efficient algorithms to apply the two-dimensional transform to the entire image as a whole, with no need to partition it into smaller blocks. One of the side effects of the block processing in the DCT, and perhaps the main problem of JPEG, is that blocking artifacts appear with moderate to high compression ratios. According to the human visual system, block edges are easily identified and, hence, the visual image quality is highly degraded. Moreover, when small blocks are independently encoded, spatial redundancy is not optimally removed from the image. The use of the wavelet transform also solves these problems.

As a result of the replacement of the DCT by the DWT, the JPEG 2000 standard offers superior coding performance, especially at high compression rates, where blocking artifacts are more noticeable. Despite the bit rate saving of the new standard, maybe its main feature is a different one: it produces an extremely flexible and versatile bitstream. First, the user can indicate exactly the desired file size of the compressed image, while in the original JPEG, only a quality parameter can be used (and the final file size is unknown a priori). Besides, after encoding the wavelet coefficients, the bitstream is reorganised to achieve different types of resolution and quality scalability, with almost no loss of coding performance (observe that the progressive and hierarchical modes are less efficient than the sequential one in JPEG).

Let us now briefly describe the image coding process of JPEG 2000. After a colour space transform (if needed), each image component is transformed by the DWT, which is applied to the entire component as a whole (unless there are memory limitations), and the resulting transform coefficients are quantized to obtain integer values. Then, the embedded block coding with optimized truncation (EBCOT) algorithm (Taubman, 2000) is used to encode the coefficients in blocks (typically of 64×64 coefficients each block). Although block coding is also used in JPEG 2000, blocking artifacts do not appear because the image transform and quantization is applied to the entire image, and the block size is considerably bigger than in JPEG. The EBCOT algorithm consists in a bit-plane encoder (with three passes per bit-plane), followed by an optimization algorithm based on the Lagrange multiplier method (Everett, 1963), which is used to achieve the target file size in an optimal way, and a bitstream reorganization to fulfil the desired scalability.

Moreover, the original JPEG 2000 algorithm is able to work in lossless mode, as described previously, simply by utilizing a reversible integer-to-integer wavelet transform that ensures the exact reversibility of the transform coefficient (avoiding possible rounding errors), and by skipping the quantization stages.

Specific Lossless Image Encoders

Most lossless coders are based on entropy coding and predictive techniques. Predictive schemes try to calculate every sample from the previously encoded samples that are available to the encoder and the decoder. In lossless image coding, prediction is usually done from nearby pixels. After computing a prediction, the residual pixel is entropy encoded as the difference between the prediction and the original value. Basically, this is how the lossless mode of the JPEG standard works, a process that differs significantly from the lossy modes defined by that same standard.

Clearly, the better a prediction is, the lower the residual error becomes. In order to improve the prediction, the CALIC scheme (Wu & Memon, 1996) uses a very large amount of contexts (i.e., different statistics for the entropy coding depending on the neighbour pixels), achieving one of the best coding performances among the continuous-tone still-image lossless encoders. The high number of contexts makes CALIC quite complex and therefore, a simplification of CALIC was adopted as the JPEG-LS standard (JPEG-LS, 1997), which aims at improving and replacing the lossless mode of the original JPEG standard. The core algorithm of JPEG-LS is a simplified version of CALIC called LOCO-I (Weinberger, Seroussi, & Sapiro, 2000), whose performance is close to CALIC with lower complexity. It is able to provide both lossless and "near lossless" image compression. Moreover, it is more efficient and much faster than JPEG 2000 working in lossless mode.

Lossless image coding is also used to transmit bitmaps on the Internet in well-known services, such as the World Wide Web. Thus, the graphics interchange format (GIF) (CompuserveIncorporated, 1987) was introduced to losslessly encode images formed by 256 colours that are previously selected and stored in a colour table (also known as colour palette) from 2^{24} different possibilities (all the colours generated from a 24-bit RGB colour space). GIF images are compressed with the Lempel-Ziv-Welch (LZW) lossless encoder (Welch, 1984). The fact that LZW was a patented algorithm caused the PNG format to be proposed as a royalty-free alternative to GIF, with an additional support for palettes of 24-bit RGB colours (PNG, 2003).

BINARY IMAGE COMPRESSION

The JBIG standard (JBIG, 1993) was released by the Joint Bi-level Image Experts Group as an efficient solution to encode images with only two possible values for each pixel (known as binary or bi-level images). One of the main applications of this standard is fax transmission. JBIG uses a special entropy coder, the Q-coder (Pennebaker, Mitchell, Langdon, & Arps, 1988), as a basis to transmit the bi-level pixels in a lossless way.

An advanced version of this standard, called JBIG 2 (JBIG 2, 2001), was released in 2001. This new version is suitable for lossless, lossy, and perceptually lossless compression, and provides large increases in coding performance. This new standard is able to take advantage of image segmentation by separating an image into text, picture, graphical regions, and so forth, and encoding each different segment with the most appropriate algorithm.

FUTURE TRENDS

One of the greatest doubts about the future of image compression is if JPEG 2000 will be able to become a widespread standard, as occurred with the previous JPEG standard. At the time of writing this chapter, in early 2008, the support of images encoded with JPEG 2000 was not generalised in the World Wide Web, mainly because the most popular browsers (such as Internet Explorer and Firefox) do not support them yet. In order to improve the use of JPEG 2000 in interactive networks with client/server protocols, a new part of this standard has been recently released. This is Part 9, and is called JPIP. In this extension, a client can control and optimise the data flow downloaded from the server to meet the needed requirements.

Other new parts of the JPEG 2000 standard include Part 8 (JPSEC), which addresses security and content protection issues, Part 10 (JP3D), dealing with volumetric and 3-D image coding, and Part 11 (JPWL), for image transmission on wireless networks, including (a) protection of the bitstream against transmission errors (Part 1 only conceals errors), (b) detection of sensible areas of the bitstream, which will be protected more intensively, and (c) detection of errors that could not be corrected by the error protection decoder.

As for digital cameras, an increase of the native support of JPEG 2000 is expected because the specific hardware is becoming cheaper (e.g., Analog Devices, Inc. has recently lowered the price of their JPEG 2000 chip from USD 30 to USD 8). On the other hand, JPEG 2000 is the standard adopted by the digital cinema industry for media content distribution (each movie frame is encoded with a JPEG-2000-based encoder).

The main drawback of JPEG 2000 implementations is that they are computationally intensive and need a lot of memory to work, especially if compared to the sequential mode of JPEG. Thereby, alternative methods have recently been proposed (Cho & Pearlman, 2007; Oliver & Malumbres, 2006) to reduce the computational requirements while trying to preserve coding efficiency, many times at the cost of a less flexible bitstream than in JPEG 2000.

CONCLUSION

The main contribution of this chapter is a survey of the main existing standards for digital image compression. First, the authors have focused on current standard solutions for continuous-tone image coding, JPEG being the most commonly employed compression method, widely used in digital cameras and on the web. Then, the JPEG 2000 standard has been presented. The JPEG 2000 standard aims at replacing JPEG, although its use in common fields is still limited, and its success in the mass market is an open question. On the other hand, lossless coding is required at times (e.g., in medical imaging for legal issues, or in image editing, to avoid the accumulative errors from successive editions progressively damaging the image quality). Hence, both JPEG and JPEG 2000 have lossless modes, though it has been shown that JPEG-LS, the specific standard for lossless image coding, is a better option in most cases because it is faster and more efficient. Finally, if the image to encode is not continuous toned but binary instead, the standard solution is JBIG, which has been employed in several important applications, like fax transmission.

KEY TERMS

Chrominance: The difference between a certain colour component and the luminance component is called chrominance. The *Cb* and *Cr* components refer to the blue and red chrominances, increased by 0.5 and rescaled by 2 and 1.6, respectively (Pennebaker & Mitchell, 1992)

DC Component: When the two-dimensional discrete cosine transform is computed, the DC coefficient refers to the mean value of the pixels in the block, usually scaled according to the normalization used in the transform (in the

DCT transform applied in JPEG, the DC is the mean value multiplied by 8).

Entropy Coding: An entropy coder is a general lossless data compression method that encodes symbols by using an amount of bits inversely proportional to the probability of the symbols.

Human Visual System (HVS): In order to improve coding performance, a lossy encoder removes the information that is not seen by the human eye. The human visual system is the part of the nervous system that allows us to see. It has been modelled to determine its behaviour, and hence, to identify the information that can be removed without noticeable artifacts.

Lossless Coding: In lossless image compression, the decoded pixels are exactly the same as those that were encoded. For this reason, it is considered that there is no loss of data.

Lossy Coding: An image encoder can modify a source image in order to achieve higher compression ratios, while trying to keep the perceived quality unaltered. This is the case of lossy image compression, in which the decoded pixels do not maintain the same values as when they were encoded.

Luminance: The brightness of an image is determined by the luminance component (usually referred to as *Y*). It is the main component in a YCbCr colour space because the HVS is more sensitive to this component than to chrominance components. It can be computed from the RGB components as $Y = 0.2126\ R + 0.7152\ G + 0.0722\ B$.

Internet Abuse and Addiction in the Workplace

Mark Griffiths
Nottingham Trent University, UK

INTRODUCTION

As with the introduction of other mass communication technologies, issues surrounding Internet use, abuse and addiction have surfaced. This article has a number of objectives. It will first introduce readers to the concept of Internet addiction before going on to look at the wider issue of Internet abuse in the workplace. In this section, generic types of Internet abuse will be described, in addition to further examination of the reasons why Internet abuse occurs. The chapter ends with some guidelines and recommendations for employers and human resources departments.

BACKGROUND: INTERNET ADDICTION

There have been a growing number of academic papers about excessive use of the Internet. These can roughly be divided into four categories:

- Studies that compare excessive Internet users with non-excessive users (e.g., Brenner, 1997; Young, 1998)
- Studies that have examined vulnerable groups of excessive Internet use; for example, students (e.g., Nalwa & Anand, 2003; Scherer & Bost, 1997)
- Case studies of excessive Internet users (Catalano, Catalano, Embi & Frankel, 1999; Griffiths, 2000a; Tsai & Lin, 2003; Young, 1996)
- Studies that examine the psychometric properties of excessive Internet use (e.g., Armstrong, Phillips & Saling, 2000; Charlton, 2002; Pratarelli et al., 1999).
- Studies examining the relationship of excessive Internet use with other behaviors; for example, psychiatric problems, depression, loneliness, academic performance and so forth (e.g., Kubey, Lavin & Barrows, 2001; Nie & Ebring, 2000; Shapira, Goldsmith, Keck, Khosla & McElroy, 2000)

Despite the predominance of drug-based definitions of addiction, there is now a growing movement that views a number of behaviors as potentially addictive, including those which do not involve the ingestion of a psychoactive drug (e.g., gambling, computer game playing, exercise, sex, and now the Internet) (Orford, 2001). Research has suggested that social pathologies are beginning to surface in cyberspace. These have been termed "technological addictions" (Griffiths, 1996a) and have been operationally defined as non-chemical (behavioral) addictions that involve excessive human-machine interaction. They can thus be viewed as a subset of behavioral addictions (Marks, 1990) and feature core components of addiction (Brown, 1993; Griffiths, 1996a); that is, salience, mood modification, tolerance, withdrawal, conflict and relapse. Young (1999) claims Internet addiction is a broad term that covers a wide variety of behaviors and impulse control problems. This is categorized by five specific subtypes:

- Cybersexual addiction: compulsive use of adult Web sites for cybersex and cyberporn
- Cyber-relationship addiction: over-involvement in online relationships
- Net compulsions: obsessive online gambling, shopping or day-trading
- Information overload: compulsive Web surfing or database searches.
- Computer addiction: obsessive computer game playing (e.g., Doom, Myst, Solitaire, etc.)

In reply to Young, Griffiths (2000a) has argued that many of these excessive users are not "Internet addicts" but just use the Internet excessively as a medium to fuel other addictions. Put very simply, a gambling addict or a computer game addict who engages in their chosen behavior online is not addicted to the Internet. The Internet is just the place where they engage in the behavior. However, in contrast to this, there are case study reports of individuals who appear to be addicted to the Internet itself (e.g., Young, 1996; 2000b). These are usually people who use Internet chat rooms or play fantasy role playing games - activities that they would not engage in except on the Internet itself. These individuals to some extent are engaged in text-based virtual realities and take on other social personas and social identities as a way of feeling good about themselves.

In these cases, the Internet may provide an alternative reality to the user and allow them feelings of immersion and anonymity that may lead to an altered state of consciousness. This in itself may be highly psychologically and/or physiologically rewarding. There are many factors that make the Internet seductive. It is clear from research in the area of computer-mediated communication that virtual environments

have the potential to provide short-term comfort, excitement, and/or distraction (Griffiths, 2000a). These reasons alone provide compelling reasons alone why employees may engage in non-work related Internet use. There are also other reasons that are outlined in more detail in the next section on Internet abuse.

Case study accounts (e.g., Griffiths, 2000b; Tsai & Lin, 2003; Young, 1996) have shown that the Internet can be used to counteract other deficiencies in the person's life (e.g., relationships, lack of friends, physical appearance, disability, coping, etc.). Internet addiction appears to be a bona fide problem to a small minority of people but evidence suggests the problem is so small that few employers take it seriously. It may be that Internet abuse (rather than Internet addiction) is the issue that employers should be more concerned about.

TYPES OF WORKPLACE INTERNET ABUSE

It is clear that the issue of Internet abuse and Internet addiction are related but they are not the same thing. Furthermore, the long-term effects of Internet abuse may have more far-reaching effects for the company that the Internet abuser works for than the individual himself or herself. Abuse also suggests that there may not necessarily be any negative effects for the user other than a decrease in work productivity.

As seen in the previous section, Young (1999) claims Internet addiction is a broad term that covers a wide variety of behaviors and impulse control problems categorized by five specific subtypes. These can be adapted and refined to produce a typology of Internet abuse within the workplace. These are cybersexual Internet abuse, online friendship/relationship abuse, Internet activity abuse, online information abuse, criminal Internet abuse, and miscellaneous Internet abuse. These are examined in more detail below.

- Cybersexual Internet abuse: this involves the abuse of adult Web sites for cybersex and cyberporn during work hours. Such online sexual services include the conventional (e.g., Internet versions of widely available pornographic magazines like Playboy), the not so conventional (Internet versions of very hardcore pornographic magazines) and what can only be described as the bizarre (various discussion groups). There are also pornographic picture libraries (commercial and free-access), videos and video clips, live strip shows, live sex shows and voyeuristic Web-cam sites (Cooper, 2000; Griffiths, 2001).
- Online friendship/relationship abuse: this involves the conducting of an online friendship and/or relationship during work hours. Such a category could also include the use of e-mailing friends and/or engaging in discussion groups, as well as maintenance of online emotional relationships. Such people may also abuse the Internet by using it to explore gender and identity roles by swapping gender or creating other personas and forming online relationships or engaging in cybersex (see above) (Griffiths, 2001; Whitty, 2003).
- Internet activity abuse: this involves the use of the Internet during work hours in which other non-work related activities are done (e.g., online gambling, online shopping, online travel booking, online computer gaming, online day-trading, etc.). This may be one of the most common forms of Internet abuse in the workplace.
- Online information abuse: this involves the abuse of Internet search engines and databases. Typically, this involves individuals who search for work-related information on databases and so forth but who end up wasting hours of time with little relevant information gathered. This may be deliberate work-avoidance but may also be accidental and/or non-intentional. It may also involve people who seek out general educational information, information for self-help/diagnosis (including online therapy) and/or scientific research for non-work purposes.
- Criminal Internet abuse: this involves seeking out individuals who then become victims of sexually-related Internet crime (e.g., online sexual harassment, cyberstalking, paedophilic "grooming" of children). The fact that these types of abuse involve criminal acts may have severe implications for employers.
- Miscellaneous Internet abuse: this involves any activity not found in the above categories such as the digital manipulation of images on the Internet for entertainment and/or masturbatory purposes (e.g., creating celebrity fake photographs where heads of famous people are superimposed onto someone else's naked body) (Griffiths, 2001).

WHY DOES INTERNET ABUSE OCCUR?

There are many factors that make Internet abuse in the workplace seductive. It is clear from research in the area of computer-mediated communication that virtual environments have the potential to provide short-term comfort, excitement, and/or distraction (Griffiths, 2000a). These reasons alone provide compelling reasons why employees may engage in non-work related Internet use. There are also other reasons (opportunity, access, affordability, anonymity, convenience, escape, disinhibition, social acceptance, and longer working hours), which are briefly examined next:

- Opportunity and access – Obvious pre-cursors to potential Internet abuse include both opportunity and access to the Internet. Clearly, the Internet is now commonplace and widespread, and is almost integral to most workplace environments. Given that prevalence of undesirable behaviors is strongly correlated with increased access to the activity, it is not surprising that the development of Internet abuse appears to be increasing across the population.
- Affordability - Given the wide accessibility of the Internet, it is now becoming cheaper and cheaper to use the online services on offer. Furthermore, for almost all employees, Internet access is totally free of charge and the only costs will be time and the financial costs of some particular activities (e.g., online sexual services, online gambling, etc.).
- Anonymity - The anonymity of the Internet allows users to privately engage in their behaviors of choice in the belief that the fear of being caught by their employer is minimal. This anonymity may also provide the user with a greater sense of perceived control over the content, tone, and nature of their online experiences. The anonymity of the Internet often facilitates more honest and open communication with other users and can be an important factor in the development of online relationships that may begin in the workplace. Anonymity may also increase feelings of comfort since there is a decreased ability to look for, and thus detect, signs of insincerity, disapproval, or judgment in facial expression, as would be typical in face-to-face interactions.
- Convenience - Interactive online applications such as e-mail, chat rooms, newsgroups, or role-playing games provide convenient mediums to meet others without having to leave one's work desk. Online abuse will usually occur in the familiar and comfortable environment of home or workplace, thus reducing the feeling of risk and allowing even more adventurous behaviors.
- Escape - For some, the primary reinforcement of particular kinds of Internet abuse (e.g., to engage in an online affair and/or cybersex) is the sexual gratification they experience online. In the case of behaviors like cybersex and online gambling, the experiences online may be reinforced through a subjectively and/or objectively experienced "high". The pursuit of mood-modifying experiences is characteristic of addictions. The mood-modifying experience has the potential to provide an emotional or mental escape and further serves to reinforce the behavior. Abusive and/or excessive involvement in this escapist activity may lead to problems (e.g., online addictions). Online behavior can provide a potent escape from the stresses and strains of real life.
- Disinhibition – Disinhibition is clearly one of the Internet's key appeals, as there is little doubt that the Internet makes people less inhibited (Joinson, 1998). Online users appear to open up more quickly online and reveal themselves emotionally much faster than in the offline world. What might take months or years in an offline relationship may only takes days or weeks online. As some have pointed out (e.g., Cooper & Sportolari, 1997), the perception of trust, intimacy and acceptance has the potential to encourage online users to use these relationships as a primary source of companionship and comfort.
- Social acceptability – The social acceptability and perception of being online has changed over the last 10 years (e.g., the "nerdish" image of the Internet is almost obsolete). It may also be a sign of increased acceptance as young children are exposed to technology earlier and so become used to socializing using computers as tools. For instance, laying the foundations for an online relationship in this way has become far more socially acceptable and will continue to be so. Internet interaction takes away the social isolation that we can all sometimes feel and there are no boundaries of geography, class or nationality.

FUTURE TRENDS: GUIDELINES FOR MANAGERS AND HUMAN RESOURCES DEPARTMENTS

As has been demonstrated, being able to spot someone who is an Internet addict or an Internet abuser can be very difficult. However, there are some practical steps that can be taken to help minimize the potential problem.

- Develop an "Internet Abuse At Work" policy. Many organizations have policies for behaviors such as smoking or drinking alcohol. Employers should develop their own Internet abuse policies by liaison between personnel services and local technology councils and/or health and safety executives.
- Take the issue of Internet abuse/addiction seriously. Internet abuse and addiction in all their varieties are only just being considered as potentially serious occupational issues. Managers, in conjunction with personnel departments, need to ensure they are aware of the issues involved and the potential risks it can bring to both their employees and the whole organization. They also need to be aware that for employees who deal with finances, the consequences of some forms of Internet abuse/addiction (e.g., Internet gambling) for the company can be very great.

- Raise awareness of Internet abuse/addiction issues at work. This can be done through e-mail circulation, leaflets, and posters on general notice boards. Some countries will have national and /or local agencies (e.g., technology councils, health and safety organizations, etc.) that can supply useful educational literature (including posters). Telephone numbers for these organizations can usually be found in most telephone directories.
- Ask employees to be vigilant. Internet abuse/addiction at work can have serious repercussions not only for the individual but also for those employees who befriend Internet abusers and addicts, and the organization itself. Fellow staff need to know the basic signs and symptoms of Internet abuse and addiction. Employee behaviors such as continual use the Internet for non-work purposes might be indicative of an Internet abuse problem.
- Give employees access to diagnostic checklists. Make sure that any literature or poster within the workplace includes a self-diagnostic checklist so that employees can check themselves to see if they might have (or be developing) an Internet problem.
- Monitor Internet use of your staff that you suspect may have problems. Those staff with an Internet-related problem are likely to spend great amounts of time engaged in non-work activities on the Internet. Should an employer suspect such a person, they should get the company's IT specialists to look at their Internet surfing history, as the computer's hard disc will have information about everything they have ever accessed. The fact that specific individuals may be monitored should be outlined in the organization's "Internet Abuse At Work" policy so that employees are aware they may be monitored.
- Check Internet "bookmarks" of your staff. In some jurisdictions across the world, employers can legally access the e-mails and Internet content of their employees. One simple check is to simply look at an employee's list of "bookmarked" Web sites. If they are spending a lot of employment time engaged in non-work activities, many bookmarks will be completely non-work related (e.g., online dating agencies, gambling sites).
- Give support to identified problem users. Most large organizations have counseling services and other forms of support for employees who find themselves in difficulties. In some (but not all) situations, problems associated with Internet use need to be treated sympathetically (and like other more bona fide addictions such as alcoholism). Employee support services must also be educated about the potential problems of Internet abuse and addiction in the workplace.

CONCLUSION

In this chapter, major issues that surround Internet abuse/addiction issues in the workplace have been highlighted. Internet abuse/addiction can clearly be a hidden activity and the growing availability of Internet facilities in the workplace is making it easier for abuse to occur in lots of different forms. Thankfully, it would appear that for most people Internet abuse is not a serious individual problem, although for large companies, small levels of Internet abuse multiplied across the workforce raises serious issues about work productivity. For those whose Internet abuse starts to become more of a problem, it can affect many levels including the individual, their work colleagues and the organization itself.

Managers clearly need to have their awareness of this issue raised, and once this has happened, they need to raise awareness of the issue among the work force. Knowledge of such issues can then be applied individually to organizations in the hope that they can develop an Internet abuse policy in the same way that many organizations have introduced smoking and alcohol policies. Furthermore, employers need to let employees know exactly which behaviors on the Internet are reasonable (e.g., the occasional e-mail to a friend) and those that are unacceptable (e.g., online gaming, cybersex, etc.). Internet abuse has the potential to be a social issue, a health issue *and* an occupational issue and needs to be taken seriously by all those employers who utilize the Internet in their day-to-day business.

KEY TERMS

Conflict: This refers to the conflicts between the addict and those around them (interpersonal conflict), conflicts with other activities (job, social life, hobbies and interests) or from within the individual themselves (intrapsychic conflict) that are concerned with the particular activity.

Cybersex: The act of computer-mediated sex either in an online or virtual environment. Examples include two consenting adults engaging in an e-mail or real-time chat sex session. The advantages to this are that two people who are at opposite ends of the globe can maintain a relationship.

Internet Addiction: This is a term used to describe excessive Internet use and has been also been referred to as Internet addiction disorder (IAD), Internet addiction syndrome (IAD) and pathological Internet use. As with other addictions, Internet addiction features the core components of other addictive behaviors (salience, mood modification, tolerance, withdrawal, conflict and relapse) and can be defined as a repetitive habit pattern that increases the risk of disease and/or associated personal and social problems. It is often experienced subjectively as "loss of control" and these habit patterns are typically characterized by immediate gratification (short-term rewards), often coupled with delayed, deleterious effects (long-term costs). Attempts to change an addictive behavior (via treatment or by self-initiation) are typically marked by high relapse rates (see also technological addictions).

Mood Modification: This refers to the subjective experiences that people report as a consequence of engaging in the particular activity and can be seen as a coping strategy (i.e., they experience an arousing "buzz" or a "high" or paradoxically, tranquilizing feel of "escape" or "numbing").

Relapse: This is the tendency for repeated reversions to earlier patterns of the particular activity to recur and for even the most extreme patterns typical of the height of the addiction to be quickly restored after many years of abstinence or control.

Salience: This occurs when the particular activity becomes the most important activity in the person's life and dominates their thinking (preoccupations and cognitive distortions), feelings (cravings) and behavior (deterioration of socialized behavior). For instance, even if the person is not actually engaged in the behavior they will be thinking about the next time they will be.

Technological Addictions: These addictions are operationally defined as non-chemical (behavioral) addictions that involve human-machine interaction. They can either be passive (e.g., television) or active (e.g., computer games, Internet), and usually contain inducing and reinforcing features which may contribute to the promotion of addictive tendencies. Technological addictions can be viewed as a subset of behavioral addictions and feature core components of addiction, that is, salience, mood modification, tolerance, withdrawal, conflict and relapse.

Tolerance: This is the process whereby increasing amounts of the particular activity are required to achieve the former effects. For instance, a gambler may have to gradually have to increase the size of the bet to experience a euphoric effect that was initially obtained by a much smaller bet.

Withdrawal Symptoms: These are the unpleasant feeling states and/or physical effects that occur when the particular activity is discontinued or suddenly reduced, for example, the shakes, moodiness, irritability and so forth.

Panayotis Pintelas
University of Patras, Greece

INTRODUCTION

Multimedia communications involve digital audio and video and impose new quality of service (QoS) requirements on the Internet (Lu, 2000). Different multimedia applications have different QoS requirements. For example, continuous media types such as audio and video require hard or soft bounds on the end-to-end delay, while discrete media such as text and images do not have any strict delay constrains. In addition, video applications require more bandwidth than audio applications. QoS requirements are specified by the following four closely related parameters: (1) bandwidth on demand; (2) low end-to-end delay; (3) low delay variation (or delay jitter); and (4) acceptable error or loss rate without retransmission, as the delay would be intolerable with retransmission. Multimedia applications are classified into the following three categories:

- *Two-way conversational applications*, which are characterized by their stringent requirement on end-to-end delay that includes total time taken to capture, digitize, encode/compress audio/video data, transport them from the source to the destination, and decode and display them to the user.
- *Broadcasting services* where the source is live. The main dissimilarity from the conversational applications is that it is one-way communication and it can stand more delay.
- *On-demand applications* (e.g., video on demand) where the user requests some stored items and the server delivers them to the user.

In designing and implementing multimedia applications, the characteristics of these application types should be used to provide required QoS, but using network and system resources efficiently. Even though we say that QoS should be guaranteed, the user states the degree of guarantees. Usually, there are three levels of guarantees:

- *Hard guarantee*, where user-specified QoS should be met absolutely. Reserving network and system resources based on the peak-bit rate of a stream achieves hard guarantees.
- *Soft guarantee*, where user-specified QoS is supposed to be met to a certain precise percentage. This is suitable for continuous media, as they usually do not need 100% accuracy in playback. This type of guarantee uses system resources more efficiently.
- *Best effort*, where no guarantee is given and the multimedia application is executed with whatever resources are available. More networks function in this mode.

These different types of guarantees may all be needed in a multimedia session established using proper association control protocols such as C_MACSE (Kanellopoulos & Kotsiantis, 2006). Different levels of guarantee are used for different types of traffic and the user determines which type of guarantee to use. Besides, the charging policy is related to the level of guarantee and the most expensive is the hard guarantee, while the best effort is the cheapest. At the source, multimedia data are either captured live or retrieved from storage devices. The transport module accepts these data, packetizes and passed them on to the Internet. At the destination (sink), multimedia data are reassembled and passed to the application for playback of audio/video. Packet processing time differences, network access time differences, and queuing delay difference can cause delay jitter, which has to be removed at the destination before data being played out.

BACKGROUND

Through a number of subsystems multimedia data flows. For example, an audio segment is encoded at the audio server program, sent through the underlying transport network, and decoded at the receiving application. In a multimedia multiparty call, the end-user issues diverse QoS parameters values,

which are interpreted onto specific performance parameter values in the communication subsystem and the operating system frameworks. To provide end-to-end QoS guarantees, an intensive effort is necessary from all subsystems, including end-subsystems, network hardware, and communication protocols, of a multimedia system.

Bandwidth On Demand

The speed of network links and routers in the next generation Internet will be improved radically so that network congestion will be uncertain and QoS guarantees will be provided by design. This endeavor will include optical wavelength-division multiplexing (WDM) technologies, being considered by Next Generation Internet (NGI) initiative (http://www.ccic.gov/ngi/).

Multicast Support

It is a common requirement of multimedia communication to send data from one source to multiple destinations. Efficient multicasting protocols can reduce bandwidth requirements (Paul, 1998). Given the multireceiver nature of video programs, real-time video distribution has emerged as one of the most important IP multicast applications and it requires bandwidth adaptability. Real-time video multicast applications have to adapt to the dynamic network conditions, but still offer reasonable playback quality to the receivers. Liu and Zhang (2003) present a survey on adaptive video multicast solutions. Because video and shared data are essential to many distributed tasks, audio of sufficient quality is a necessary condition for almost any successful real-time interaction.

Synchronization

Continuous media are characterized by well-defined temporal relationship between subsequent presentation units to be played. A presentation unit is a logical data unit that is perceivable by the user. *Multimedia synchronization* is the process of preserving the temporal order of one or more media streams. The problem of maintaining continuity within a single stream is referred as *intra-stream synchronization*; where as the problem of maintaining continuity among the streams is called *inter-stream synchronization*. These two types of synchronization are necessary for both live streams and for stored media streams presentations. Manvi and Venkataram (2006) proposed an agent-based synchronization framework to handle three synchronization mechanisms (point, real-time, and adaptive) at application service level depending on the life/run-time presentation requirements of the multimedia applications.

Adaptive Media Coding

Multimedia data should be coded in a way such that acceptable audio/video playback quality is still achieved, when some data packets are delayed extremely or lost. Coding multimedia data into multiple layers is the basic suggestion. Some layers are assigned high priority and they contain essential data to generate basic acceptable basic play out audio/video quality. Extra layers contain data that add additional details (or quality) to the basic quality and are assigned low priority. In the case of system overloading, low priority data are dropped first, leading to little effect to play out quality. This effect is named *graceful quality degradation*, and it can be obtained by the use of error control techniques such as forward error correction (FEC).

End System Support

End systems must offer mechanisms to handle multimedia data efficiently and effectively such as to provide end-to-end QoS guarantees (Lu, 1996). The end-system support for multimedia communications is required for two reasons. Firstly, the communications protocol stack is implemented mainly in software and it has thousands of instructions executed by the end system. If, for these instructions, the end system cannot guarantee the execution time, there will be no real-time communications system regardless of how well networking support is offered. Secondly, if the media data need to be compressed and decompressed before presentation, the processing time should be predictable. If not, a meaningful presentation is not obtained.

Hardware: Multimedia applications impose the following requirements on the hardware architecture:

- Digital audio and video are very data intensive, and therefore the hardware must have high data transfer throughput and high processing power.
- Parallel hardware architectures are preferred, as a lot of multimedia applications have to access several input/output devices simultaneously. In addition, multimedia host computers have usually I/O buses, which support lower transfer rates than of those of high-speed networks. This situation leads to the problem called "*mismatch in bandwidth.*" For the solution of this problem various network interface units must be implemented.
- The hardware architecture must be scalable to accommodate new input/output devices and applications.
- To support different types of data and applications, the architecture should be versatile and programmable.

Multimedia operating systems: They should meet the following requirements (Steinmetz, 1995).

- Multimedia operating systems should use the hardware resources efficiently so that use of these resources is maximized.
- QoS requirements of multimedia applications should be guaranteed by using proper resource management and process scheduling. At the operating system level, one of the main QoS requirements is the guaranteed processing time for each task.
- The multimedia operating system should execute multimedia applications as well as conventional applications. This has two implications. Firstly, the conventional application-programming interface (API) should be maintained. Secondly, the conventional applications should not be starved of resources, while QoS requirements of multimedia applications are guaranteed.

Mobility Support

The advent of wireless and cellular networks has improved multimedia applications with mobility. Mobility aspect has added another dimension of complexity to multimedia networks. It opens up questions on a host of complex issues like routing to mobile terminals, maintaining the QoS when the host is in motion, interworking between wireless and wired networks. Kanellopoulos, Pintelas, and Giannoulis (2006) provide an overview of key QoS issues required to support end-to-end QoS guarantees for wireless multimedia communications.

PROPOSED APPROACHES FOR QoS GUARANTEES OVER THE INTERNET

Supporting multimedia communications over the Internet introduces two major problems: *fairness* and *useless packet transmission* (UPT). In current Internet, a single FIFO-based queue is used to multiplex both adaptive and nonadaptive traffic at routers. When multimedia applications cross the same router, this may cause fairness problems. UTP is based on the fact that for packetised audio and video, packet loss rate must be preserved under a given threshold for any meaningful communication. Wu and Hassan (2004) have proposed two different management policies for UPT.

ITU-T has developed a series of recommendations together comprising the *H.323 system* (Toga & Ott, 1999) that provides for multimedia communications in packet-based (inter)networks. The H.323 series of recommendations explain systems, logical components, messages and procedures that enable real-time, multimedia calls to be established between two or more parties on a packet network.

Giordano, Salsano, Van den Berghe, Ventre, and Giannakopoulos (2003) describe the current evolution of QoS architectures, mechanisms, and protocols in the Internet, as it is ongoing in the framework of the European Union funded research projects (AQUILA, CADENUS, TEQUILA) on premium IP networks.

The Internet provides the best-effort service to applications and thus cannot meet the QoS requirements of multimedia communications. However, many research efforts have been made toward providing QoS guarantees. Communication architecture of the Internet is altered or improved to provide QoS guarantees. Three main architectures have been proposed: (1) integrated service model (IntSer); (2) differentiated service model (DiffServ); and (3) multiprotocol label switching (MPLS). Bhargava, Wang, Khana, and Habib (2005) developed an adaptable network architecture (ADNET) which allows different QoS provision schemes such as active networks, integrated services and differentiated services to co-exist.

Integrated Service Model

The integrated service model (IntServ) is based on resource reservation (Braden et al., 1994). An appropriate amount of resources is reserved for each flow to meet its requirements. Resources including bandwidth and memory are reserved to meet QoS requirements of an application or communication session (Braden, Zhang, Berson, Herzog, & Habib, 1997). The following fundamentals are needed to provide QoS guarantees:

- A QoS specification mechanism for applications to specify their requirements;
- Admission control to determine whether the new application should be admitted without affecting the QoS of other ongoing applications;
- A QoS negotiation process so that as many applications as possible can be served. During the QoS negotiation phase (Figure 1), each peer computer must determine whether it can support the desired QoS. If so, certain resources are reserved for this session. If the user is satisfied with the suggested QoS, the session is established. Otherwise, the session is rejected.
- Resource allocation and scheduling to meet the QoS requirement of accepted applications; and
- Traffic policing to make sure that applications generate the correct amount of data within the agreed specification.

A QoS renegotiation mechanism is required so that applications can request changes in their initial QoS specifications. The actual QoS provided to the ongoing sessions should be monitored (Figure 2) so that suitable actions can be taken in case of any problem in providing specified QoS guarantees. Media scalability and graceful quality degra-

Figure 1. QoS negotiation

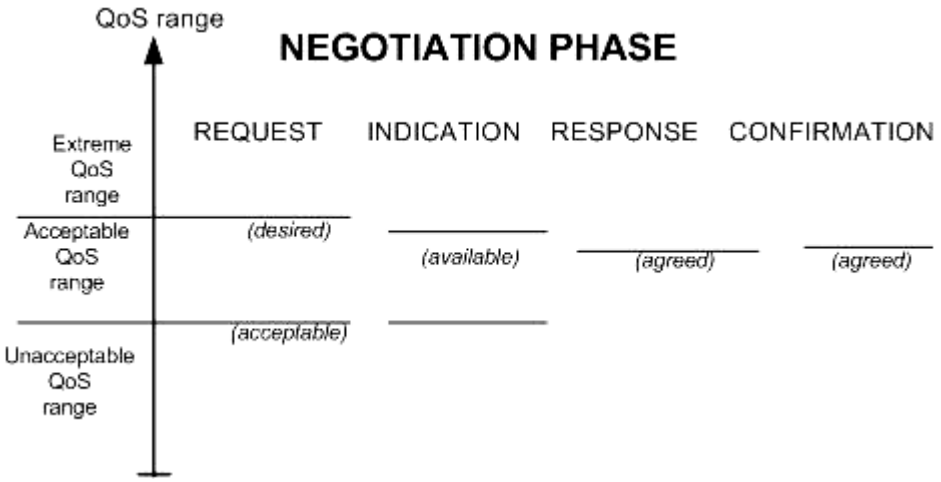

Figure 2. QoS monitoring

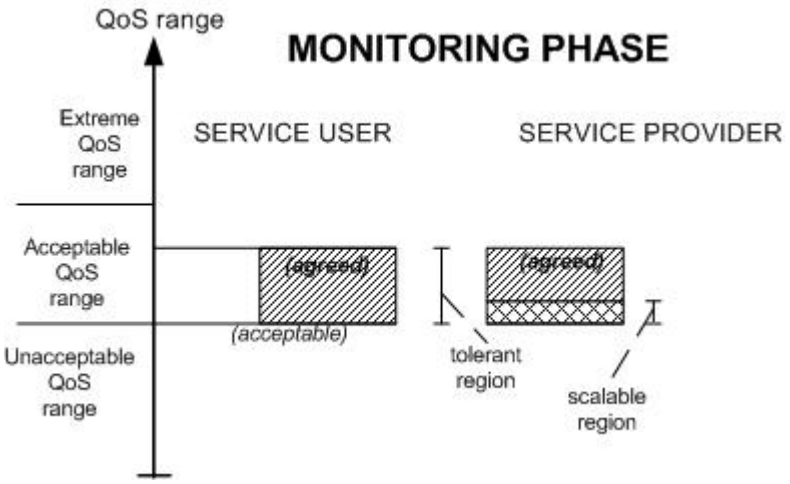

dation techniques should be used together with the above mechanisms to provide satisfactory services to multimedia applications.

Traffic-shaping schemes. Traffic shaping regulates a stream's traffic so that it is simple to describe and police. Traffic-shaping schemes are used when the traffic pattern is too complicated to describe directly or the traffic is not appropriate for networks to support directly. For example, when video is variable bit rate coded, it may be hard to characterize the coded bit stream.

Admission control, QoS negotiation and renegotiation. When a connection with specified QoS is established, QoS parameters are translated and negotiated among all relevant subsystems. Only when all subsystems are in agreement with and guarantee the specified QoS parameters, the end-to-end QoS requirements can be met.

Resource reservation protocols. A vital part of the IntServ model is the resource reservation protocol at the network layer. A resource reservation protocol transfers information about resource requirements and negotiates the QoS values that users desire for their end-to-end applications. In the current IntServ model, only RSVP (Braden et al., 1997) is used as the reservation protocol.

IntServ uses RSVP to make per-flow reservations at routers along a network path. While this allows the network to provide service guarantees at the flow level, it suffers from scalability issues. RSVP is a soft-state protocol, which means that the router's state has to be refreshed at regular intervals,

and this adds to traffic overhead. The service classes offered by IntServ are: (1) guaranteed service class, (2) controlled load service, and (3) best-effort service.

Differentiated Services

The main problem of the currently best effort model on the Internet is that all packets are treated the same, although different types of service can be determined in the IPv4 header. The main problem of the IntServ is that there is potentially an infinite number of different types of traffic so each router has to store essential information to provide QoS guarantees to each type of traffic. Differentiated services (Black, 1998) take a middle ground between the best-effort service and IntServ. It defines a *fixed* number of packet classes. All traffic types/packets are aggregated into these classes and the network/routers provide different services to different packet classes.

Service classification. IPv4 has an underused type-of-service byte in its header. The newer IPv6 has a header byte called *traffic class*. In DiffServ, the type-of-service (traffic class) byte is redefined as a *differentiated service* (DS) field. The first six bits of the DS field is called *DS CodePoint*, which indicates the behavior each router is required to apply to the individual packet. Packets with the DS CodePoint set to zero receive the same service as they get in the best effort service. Values between one and seven are defined to be backward compatible with the original IP precedence mechanism, to ensure that DiffServ technology can be deployed in the operational Internet progressively. The DS filed can be assigned by the customer (the transmitter process) to indicate the desired service. Alternatively, the ingress router marks the DS field based on *multifield* (MF) *classification*. MF classification classifies packets based on the contents of multiple fields such as source address, destination address, type-of-service byte, protocols ID, source port number and destination port number. As a packet moves from one Internet Service Provider (domain) to another, it may be reclassified. Many service classes can be defined. The Internet Engineering Task Force (IETF) working group has defined the following two new services.

- *Expedited* or *premium service*: to provide virtual leased line service to applications requiring low-delay and low delay jitter.
- *Assured service*: to provide better-than-best-effort services to applications.

In the past decade, Hou et al. (2000) proposed a Diffserv architecture for multimedia streaming applications in next generation Internet.

MULTIPROTOCOL LABEL SWITCHING (MPLS)

In an IP network, each router analyzes the packet's header and runs a network layer routing algorithm. Each router separately chooses a next hop for the packet, based on its analysis of the packet's header and the results of running the routing algorithm. This process introduces some latency, as the routing tables are very big and table lookups take time. Choosing the next hop consists of two steps. The first step classifies the entire set of possible packets into a set of *forwarding equivalence classes* (FECs). The second step maps each FEC to a next hop. As far as the forwarding decision is concerned, different packets, which are mapped into the same FEC, are indistinguishable and travel in the same path. In MPLS, the assignment of a particular FEC is done just once at the ingress router (Armitage, 2000). The FEC to which the packet is assigned is encoded as a short fixed length value known as a *label*. This label is inserted into the packet by the ingress router. At subsequent hops, there is no further analysis of the packet's network layer header. Instead, the label is used as an index into a table that specifies the next hop and a new label. The old label is replaced with the new label and the packet is forwarded to its next hop. The path taken by the packet is specified by a sequence of labels and is called a *label switched path* (LSP). The routers that support MPLS are called *label-switching routers* (LSRs). MPSL is a forwarding scheme and is much faster than IP routing. The label can represent a combination of a FEC and a precedence or class of service. Routers to provide differentiated QoS to different types of traffic can treat packets with different labels differently.

FUTURE TRENDS

In the future, high-speed multimedia networks will be mainly wireless at the edges, with access to a high-speed optical backbone infrastructure, including optical switches. One can imagine a network that consists only of wireless access to an optical backbone. Fourth-generation mobile wireless networks will emerge to offer capacities up to 150 Mb/s to fully mobile users in various environments. In such environments, resource management will remain an important issue. Efficient resource management is a hot issue due to: the rapid increase in size of the wireless mobile community; its demand for high-speed multimedia communications; and the limited resources.

CONCLUSION

This chapter provides an overview of technologies required to support end-to-end QoS guarantees over the Internet. Besides the network layer architectures, proper transport protocols such as RTP (Schulzrinne, Cassner, Frederick, & Jacobson, 1996) and application dependent protocols such as Session Initiation Protocol (SIP) (Johnston, 2000) are required for multimedia communications. To achieve end-to-end QoS guarantees an effort from all subsystems including end systems and all networking components is required. The communication architectures IntServ, DiffServ and MPLS will inter-operate with each other in the Internet environment. IntServ will be implemented in edge networks where the number of flows is small, while DiffServ will be putted into practice in the core of the Internet where the number of flow is high (Lu, 2000). MPLS together with DiffServ will provide differentiated services and QoS guarantees.

KEY TERMS

ACSE (Association Control Service Element): In the Open Systems Interconnection Reference Model (OSI-RM), an element of the application layer, which is responsible for the establishment, termination and control of associations between two or more communication parties (programs).

Bandwidth on Demand: It refers to data rate measured in bit/s (channel capacity or throughput-bandwidth consumption), which is required in order to transfer continuous media data (e.g., video).

Delay Variation (or delay jitter): It is a loose term for the variation of end-to-end delay from one packet to the next packet within the same packet stream (connection/flow).

End-to-end Delay: It is a significant parameter affecting the user's satisfaction with the application. It includes capturing, digitizing, encoding/compressing media data,

transporting them from the source to the destination, and decoding and displaying them to the user.

Multicast: The capability of a network to transmit data simultaneously to many receivers with no need to replicate the data.

Multimedia Data: It refers to data that contain various media types such as text, graphics, animation, audio, and video.

QoS (Quality of Service): It refers to the capability of a networked system to provide scalable service to selected network traffic.

The Internet and SMEs in Sub-Saharan African Countries: An Analysis in Nigeria

Princely Ifinedo
University of Jyväskylä, Finland

INTRODUCTION

The Internet is a global network of interconnected computers using multiple Internet protocols (IP). Increasingly, it is being used to enhance business operation by both small and medium-sized enterprises (SMEs) and large organizations around the world (Bunker and MacGregor, 2002; Turban, Lee, King, & Chung, Lee, J., King, D. & Chung 2004). One reason is that the Internet, when used to facilitate e-commerce and e-business, offers several benefits for the adopting organizations (Walczuch, den Braven, & Lundgren, 2000; Turban, et al, 2004). Such benefits include the following: 1) reducing distance barrier, 2) the development of new products and services, 3) opening direct links between customer and suppliers, and 4) enhancing communication efficiency. Our study of the relevant literature reveals that the diffusion of the Internet among businesses in Sub-Sahara Africa (SSA), including SMEs, is the lowest in the world at around 2% (ITU, 2005). A recent report shows that the whole of Africa has only 1% of the total international Internet bandwidth (UNCTAD, 2005). Thus, it is to be expected that businesses in the region with such poor connectivity and use will be unable to fully reap the benefits of the technology. Against such unfavorable situations, it would seem reasonable for research efforts to uncover why such unfavorable conditions prevail in the region. Sadly, very few studies exist that have investigated such issues. Little is known about the perceptions of the Internet or the factors inhibiting its spread among SMEs in SSA. To fill this gap in research, this article aims at adding to knowledge by presenting a summary of the findings of a preliminary study designed to investigate the perceptions of the Internet and the sorts of barriers facing SMEs in SSA desiring to adopt Internet in their operations or for commerce. The study used SMEs in Nigeria, a Sub-Saharan African country. The country was chosen for illustration proposes as it is the most populous country in Africa and has favorable indicators for the use of information and communication technologies (ICT) compared to other SSA countries (Ifinedo, 2005). Importantly, researchers, for example, Ojukwu (2006) have discussed use of ICT among Nigerian SMEs and it is hoped that this present effort will complement similar research efforts.

BACKGROUND

SMEs and Economies

SMEs can be described in several ways, for example, the European Parliament's definition of SMEs refers to a business with up to 250 employees. de Klerk and Kroon (2005), writing from the perspectives of the Republic of South Africa, divided SMEs into three main subcategories: micro (< 5 people), small (between 5-50 people) and medium-sized (51-200 people). Nonetheless, we accept SMEs as businesses characterized by informal planning, strong owner's influence, lack of specialists, small management teams, heavy reliance on few customers, and limited knowledge, amongst others (Bunker and MacGregor, 2002; Ifinedo, 2006). It is generally accepted that SMEs are the engine of growth of all economies (Bunker and MacGregor, 2002), including those in Africa. According to Ojukwu (2006), 97% of all businesses in Nigeria employ less than 100 employees, and the same is true in many African countries (Ifinedo, 2006). That said, SMEs in developed nations have been able to use ICT products such as the Internet in establishing e-commerce and e-business initiatives (Bunker and MacGregor, 2002; Turban, et al., 2004) and have subsequently benefited from such exercises. On the contrary, little or no progress has been made on such fronts in many developing countries, including SSA ones due to a variety of reasons, including inadequate know-how and a lack of resources (Ifinedo, 2005, 2006; Ojo, 1996; Ojukwu, 2006; Okoli, 2003).

SSA and Internet Commerce

Africa, with its population of about 1 billion people, is the poorest continent in the world (World Bank, 2005). In terms of geography, Africa tends to be described as being comprised of two regions - North Africa and SSA. The Northern part is comparable to the Middle East economically and culturally (Ifinedo, 2005). Further, South Africa (also known as the Republic of South Africa (RSA)) tends to be excluded from the rest of SSA because of its relatively high socio-economic indicators. The conditions in SSA are different from those in the excluded regions, and the region of SSA

Figure 1. Nigeria on the map of Africa

Source: Worldcountries.info (2006).

typifies perceptions of Africa more than do the excluded regions. The map Africa highlighting Nigeria, the chosen SSA country for this study is shown in Figure 1.

According to the latest World Bank (2005) reports Africa continues to be the only continent with worsening socio-economic indicators. In particular, SSA lags behind on the adoption and use of ICT products such as the Internet. Africa has the lowest diffusion rates for ICT products (for example, computers and telephones) (UNCTAD, 2005). Further, ITU (2005) shows that there were only 4.9 Internet hosts per 10, 0000 Africans in 2004 and the statistics are unchanged two years. When ICT products are lacking, it is not surprising that Internet commerce (also known as e-commerce) is relatively low on the African continent compared to the rest of the world (Economist Intelligence Unit, 2003; Gateway, 2003; UNCTAD, 2005; Ifinedo, 2005, 2006). Reports by Gateway (2003) state that "E-commerce is concentrated in South Africa and Egypt (regions not considered in this article), while B2B (business-to-business) outside South Africa remains negligible." As noted above, few have investigated why the penetration rates of ICT products such as the Internet and other ICT products are relatively low in Africa in general and SSA in particular. The available few studies suggest that the slow diffusion can be attributed to the unavailability of technological/technical expertise and other know-how in the region (de Klerk and Kroon, 2005; Ojukwu, 2006; Ifinedo, 2006) while others attribute it to unfavorable cultural influences (Ojo, 1996; Okoli, 2003). Yet others trace the poor penetration rates to a lack of financial resources in the SSA region (Duncombe and Heeks, 1999; Beliamourne-Lutz, 2003). In particular, Duncombe and Heeks (1999) highlighted the factors below as the main reasons why the adoption of the Internet among SMEs in Botswana - an SSA country – is very low.

- Lack of money.
- Lack of skills or knowledge.
- Lack of technological infrastructure, for example, telecommunications, electricity supply.
- Lack of awareness of the business environment and how to take advantage of it.
- Lack of "critical mass": Few local people/organizations use computers/email; thus most are unable to engage in any meaningful Internet commerce.

As mentioned above, the focus of this article is to present the perception of the Internet and barriers for not using it by Nigerian SMEs. The issues relating to the perceptions of the Internet were adapted from the work of Duncombe and Heeks (1999), and with regard to the factors militating against the use of the Internet in Nigerian SMEs, we adapted the variables from Walczuch, den Braven, & Lundgren (2000) to suit the SSA context. That said, we conducted a survey in Nigeria using the judgmental or purposive sampling approach in selecting our respondents (Neuman, 1997). With the approach, the researcher selects his or her respondents given their suitability for the study's theme. We collected data from SMEs in three Nigerian cities, namely, Lagos, Ibadan, and Port-Harcourt. The chosen cities are among the largest commercial cities in the country. (There is an "urban-rural divide" with regard to the use of ICT facilities in Nigeria which suggests that SMEs in larger cities are more likely to use ICT products in their operations than those in other parts of the country (Ifinedo, 2006). The SMEs selected follow the definitions provided above. Overall, 63 usable questionnaires were obtained for analysis. The views of 22 (35%) proprietors and 41(65%) supervisory/managerial employees are used. Our respondents came from wide ranging industries, including Agro-based business, light engineering (metal works), constructions, retail, and IT consultancy. The majority of the respondents are aged between 26 and 55 years and more than half have university degrees. Our respondents classified according to the sub-classifications offered by de Klerk and Kroon (2005) are as follows: 32 (50.8%), 19 (30.2%), and 12 (19%) respectively for micro, small, and medium-sized organizations. Participation was voluntary and respondents were motivated with a promise that their responses will be kept anonymous. We used a five-point Likert scale to represent the issues, please see Table 1.

A summary of the results is shown in Table 1. Only 5 (7.9%) of the SMEs in our sample have their own Web pages. Many of the SMEs - 81% - plan to have their own Web pages at some future time. E-mail is the commonest Internet facility used by the Nigerian SMEs. The Internet (e-mail) is accessed more from Cybercafés than anywhere else which suggests that the SMEs do not have their own extranets and intranets. 35% of the sampled SMEs agree to using e-mails regularly. About 90% of the respondents "surely" accept that the Internet could be a source of business and business information. Finally, while all of the respondents noted that they prefer conducting business transactions face-to-face, only 22% indicated that the Internet could serve as an alternative transaction platform.

Table 2 shows the barriers or reasons for not using the Internet by SMEs in Nigeria. We briefly discuss the top ten issues due to space limitations. The "lack of IT skills for e-commerce development" placed as the topmost barrier. This harks back to the general limitations confronting the SSA region with respect to the availability of technological/technical expertise and know-how (Ifinedo, 2005; Ojukwu, 2006). The next barrier relates to the "general lack of finance", which researchers such as Beliamourne-Lutz (2003) and Duncombe and Heeks (1999) contend is the most prominent inhibitor to ICT (including the Internet) diffusion in developing countries. The third highly ranked barrier relates to the costs of buying computers. Feedback from one manager in an Agro-based business reads: "To do buying and selling online, our company needs facilities (computers, telephones, and so forth); we're a small business, we can't afford to invest such huge sums when apparently our business stands to benefit from any spare cash." The majority of the feedback received echo similar sentiments.

The next barrier concerns "Technical complexity of using IT in business". This, in some respects, is related to the topmost barrier on the list. The lack of technical know-how continues to be among the most cited inhibitors facing SMEs both in developed and developing countries in their use of ICT-enabled services (Ifinedo, 2006). High costs of using and subscribing to telephone services ranked fifth. This is

Table 1. Perception of the Internet among Nigerian SMEs

	Number (N)	Percent (%)		Number (N)	Percent (%)
Preference for conducting business:			***Are you planning having a Web page in the near future?***		
Face-to-face	63	100	Yes		
Telephone / fax	29	43	No	51	81
The Internet	14	22.2	Undecided	4	6.3
Others	11	17.5	Missing data	4	6.3
				4	6.3
Does your business have a Web page?			***Does your business have Internet access?***		
Yes	5	7.9	Yes	57	90.5
No	58	92.1	No	4	6.3
			Missing data	2	3.2
Which one in particular?			***How often do you use the Internet (e-mail, WWW etc.)?***		
E-mail	53	84.1	Very often	35	56.5
WWW (Web page)	5	7.9	Often	23	37.1
Others	4	6.4	Sometimes	3	4.8
Missing data	1	1.6	Never used it	1	1.6
Where do you (and your business) access the Internet?			***Accepting the Internet as a source of business and business information***		
Own business premises	8	12.9			
Cyber cafés	49	79	Surely	56	88.9
Public places (library etc.)	1	1.6	Not too sure	5	7.9
Friend's	2	3.2	It cannot be a source…	1	1.6
Other places	2	3.2	No comment	1	1.6

Table 2. Reasons for **NOT** *having the Internet used by SMEs in Nigeria*

Reasons or barriers	N	Min	Mean	Std dev.	Max
Lack of IT skills for e-commerce development	63	2	4.84	0.54	5
General lack of finance	63	3	4.43	0.78	5
Too expensive to buy computers	63	3	4.25	0.74	5
Technical complexity of using IT in business	63	3	4.11	0.79	5
Telephone costs is too high	63	3	4.10	0.89	5
Internet subscription fee is too high	63	2	3.97	1.08	5
Not clear government policy and support	63	2	3.97	1.15	5
Poor energy (power) supply	63	2	3.87	1.11	5
Not many of many our customers use the Internet	63	1	3.60	1.01	5
Not suitable for our business	63	1	3.49	1.03	5
The Internet is not safe for our business	63	1	3.32	0.76	5
Does not lead more efficiency or lower costs	63	1	3.14	1.12	5
Lack of time	60	2	3.08	0.79	5
The Internet is too slow	63	1	2.89	1.32	5
The Internet is too difficult to use	63	1	2.75	1.29	5
Does not lead to more sales in our business	63	1	2.62	0.73	5
Never thought about it	57	1	2.25	0.93	5

Likert scale ranging from strongly agree (5) to strongly disagree (1)

not surprising given the poor statistics for Africa on ICT use and diffusion (ITU, 2005). Apparently, the sixth placed barrier is related to the preceding one. The lack of clear government policy and support for e-commerce (and the use of the Internet for business in Nigerian SMEs) ranked seventh. Poor energy supply came in eighth in the ranking order of barriers. Feedback from a manager/co-owner of a Business Centre reads "If you do business with the Internet, would NEPA [National Electric Power Authority] understand and improve power supply?" She emphasized that due to the poor power supply, her business has had to procure a generating plant to supplement the services provided by the state through NEPA. Indeed, the EIU (2003) noted poor power generation in Nigeria as one of the impediments to e-business growth in the country.

The lack of critical mass among SMEs with the technology which is captured by the barrier of "not many of our customers use the Internet" came in ninth place. Finally, the last of the top-ten reasons that the Internet is not used by SMEs in Nigeria is related to the suitability of the technology for local business initiatives. To illustrate this point, a proprietress of a small confectionary business responded that "I make wedding cakes and also participate in the [wedding] ceremonies; my presence is a must for my business…. The Internet can't help my business", when asked why she has not considered the use of the Internet for business. Some scholars have suggested that the socio-cultural contexts in developing countries, especially those in SSA, might not be conducive for Internet commerce. Okoli (2003, p.16) comments that "Africans do not have the culture of buying a product without [having] tactile contacts.

CONCLUSIONS AND FUTURE STUDY

The findings of this preliminary study have added to our understanding of the perceptions and use of the Internet among SMEs in SSA. It is easy to notice that a lack of resources (that is, technological, financial, and human) explains the poor state of affairs with regard to the use of the Internet among SMEs in SSA. The general lack of IT skills among SMEs in Nigeria can be attenuated through well-planned schemes and programs. For instance, governments in SSA could follow cues from other developing countries in Asia where cooperation between states and SMEs has started yielding encouraging results with regard to how SMEs in those parts of the world perceive and use of the Internet in their business operations. For example, in Thailand, the Ministry of Commerce arranged free homepages for SMEs. In addition to paying for the homepages, the Thai govern-

ment helped to provide relevant technical skills and training for some of these SMEs. Our study shows that SMEs in Nigeria may be able to benefit from the Internet as well as if their infrastructural, human, and financial capabilities are improved. To assist SMEs in SSA make progress with the use of the Internet for their operations and commerce, SSA governments could consider the types of assistance being offered in Thailand or grant soft loans and subsidies to those showing interest in adopting the Internet in their businesses. The availability of funding (finance) is vitally important in redressing the poor use of ICT among SMEs in SSA (Beliamourne-Lutz, 2003; Duncombe and Heeks, 1999; Ifinedo, 2006), and this should be accorded great attention. Efforts need to be directed toward sensitizing SMEs in SSA about modern business practices and technologies. Norms, traditions, or culture must not be allowed to stand in the way of progressive development. This study provides a basis for further investigations. For example, studies could be commissioned to investigate the perceptions of the Internet and the sorts of factors that might be limiting its use among large organizations in SSA. Future studies could consider the perceptions of the Internet among SMEs located in rural communities in SSA; a comparative study between the two parts (rural vs. urban) could enrich the discourse of Internet use among SMEs in SSA.

KEY TERMS

Cybercafé: This a place where one can use a computer with access to the Internet for a fee; it may or may not serve as a regular café serving food and drinks.

Business-2-Business (B2B): This refers to the commercial activities between firms online.

Business-2-Customer (B2C): This refers to the commercial activities between firms and customers online.

E-Business: This refers to the sharing of business information, collaborating with business partners as well as conducting business transactions by means of the telecommunication networks.

E-Commerce: This term is used to describe the buying and selling of goods and services online.

Information and Communications Technology (ICT): These include technological products such as telephones, computers, the Internet, and so forth which are used to convert, store, protect, process, transmit, and retrieve information.

The Internet: This is a global network of interconnected computers using multiple Internet protocols.

The Internet Protocol (IP): This is a unique number that devices use in order to identify and communicate with each other in a computer network.

Small and Medium Sized Enterprises (SMEs): These are businesses characterized by informal planning, strong owner's influence, lack of specialists, small management teams, heavy reliance on a few customers, limited knowledge, and often employ less than 250 workers.

Sub-Saharan Africa (SSA): This is the region of Africa excluding the Northern part of the continent and the Republic of South Africa.

The Internet and Tertiary Education

Paul Darbyshire
Victoria University, Australia

Stephen Burgess
Victoria University, Australia

INTRODUCTION

For many years, information technology (IT) has been used to find ways to "add value" for customers to entice them to purchase the products and services of a business. This article examines the possibility of translating the benefits of "added value" to the use of the Internet by tertiary educators for subject and course delivery. Many educators use the Internet to supplement existing modes of delivery. Importantly, the Internet is providing a number of "added value" supplemental benefits for subjects and courses delivered using this new, hybrid teaching mode. There are two aspects to subject delivery to where "added value" benefits may be applied, and that is in the *administrative tasks* associated with a subject and the *educational tasks*. In both instances, IT solutions can be employed to either fully or partially process some of these tasks. Given the complex and often fluid nature of the education process, it is rare that a fully integrated solution can be found to adequately service both aspects of subject delivery. Most solutions are partial in that key components are targeted by IT solutions to assist the subject coordinator in the process. If we examine closely the underlying benefits gained in the application of IT to these tasks, there is a strong parallel to the benefits to be gained by business organizations with similar applications of IT. While the actual benefits sought by academics depend on the motivation for the IT solution, the perceived benefits can be classified using standard categories used to gauge similar commercial applications. However, from an *educational* viewpoint online technologies provide educators with new challenges, especially in relation to dealing with issues related to plagiarism and class attendance. These need to be considered by educators when deciding how, and if, to incorporate the Internet into their curriculum.

BACKGROUND

In order to investigate the benefits of using Web-based techniques to supplement traditional teaching in terms of business efficiencies, the reasons that commercial organizations use IT are examined. The different aspects of subject delivery also need to be considered in order to determine the ultimate benefits to be gained.

Information Technology: Efficiency and Added Value

There are a number of reasons for using IT in organizations (O'Brien, 1999):

- **For the support of business operations:** This is usually to make the business operation more efficient (by making it faster, cheaper and more accurate).
- **For the support of managerial decision making:** By allowing more sophisticated cost benefit analyses, providing decision support tools and so forth.
- **For the support of strategic advantage:** This refers to the use of Porter and Millar's (1985) three generic strategies as a means of using information technology to improve competitiveness by adding value to products and services.

It has been recognized for a number of decades that the use of computers can provide cost savings and improvements in efficiencies in many organizations. Porter et al. (1985) have generally been credited with recognising that the capabilities of information technology can extend further to providing organizations with the opportunity to add value to their goods. Value is measured by the amount that buyers are willing to pay for a product or service. Porter et al. (1985) identify three ways that organizations can add value to their commodities or services (known as *generic strategies for improving competitiveness*):

- Be the lowest cost producer
- Produce a unique or differentiated good (providing value in a product or service that a competitor cannot provide or match, at least for a period of time). If an organization is the first to introduce a particular feature, it may gain a competitive advantage over its rivals for a period. Some ways in which information technology can be used to differentiate between products and/or services are (Sandy & Burgess, 1999):

  - Improved quality
  - Superior product support
  - Time (delivering products or services faster)

- Provide a good that meets the requirements of a specialised market

The next sections examine the possibility of translating the benefits of "added value" to a particular application of IT, the use of the Internet by tertiary educators to assist with subject and course delivery.

Aspects of Course and Subject Delivery

There are two overall aspects to course and subject delivery, the educational and administrative components (Darbyshire & Wenn, 2000). Delivery of the educational component of a subject to students is the primary responsibility of the subject coordinator, and this task is the most visible from a student's perspective. However, the administration tasks associated with a subject form a major component of subject coordination, but these responsibilities are not immediately obvious or visible to the students.

It is essential that all aspects of subject delivery be carried out as efficiently as possible. To this end, IT, and in particular, Web-based solutions can be applied to both aspects of subject delivery. That Web-based solutions are a suitable vehicle to use has been almost universally accepted by students, teachers, and academic administrators (Scott Tillett, 2000). Other advantages are the ease with which information can be disseminated, its interactivity, its use as a real-time communication medium and the ability to use text, graphics, audio, and video (Kaynama & Keesling, 2000).

There are a number of administrative tasks associated with subject coordination for which IT solutions can be applied in the application. These include (Byrnes & Lo, 1996; Darbyshire et al., 2000):

- **Student enrollment:** While most universities have a student enrolment system administered at the institute level, there are often local tasks associated with enrolment such as user account creation and compilation of mail lists etc. Some of these tasks can be automated (Darbyshire et al., 2000).
- **Assignment distribution, collection, and grading:** The written assignment remains the basic unit of assessment for the vast majority of educators, and there have been many initiatives to computerize aspects of this task. Some of these include *Submit* (Hassan, 1991), *NetFace* (Thompson, 1988), *ClassNet* (Boysen & Van Gorp, 1997) and *TRIX* (Byrnes et al., 1996).
- **Grades distribution and reporting:** Techniques for this range from e-mail to password protected Web-based database lookup.
- **Informing all students of important notices:** Notice boards and sophisticated managed discussion facilities can be found in many systems. Examples include products such as *TopClass*, *Learning Space*, *Virtual-U*, *WebCT*, and *First Class* (Landon, 1998)

Many of the tasks viewed as educational can also employ IT solutions in order to gain perceived benefits. Some of these include *online class discussions, learning, course outline distribution, seminar notes distribution, and answering student queries*. Just how many of these are actually implemented will relate to a number of factors such as the amount of face-to-face contact between lecturers and students. However, using the Internet for many of these can address the traditional problems of students misplacing handouts, and staff running out of available copies.

Discussion management systems are being integrated into many Web-based solutions. These are usually implemented as threaded discussions, which are easily implemented as a series of Web pages. Other tools can include chat rooms or listserv facilities. Answering student queries can take place in two forums, either as part of a class discussion or privately. Private discussions online are usually best handled via an e-mail facility, or in some instances, *store and forward messaging systems* may replace e-mail.

Implementing IT solutions to aid in the actual learning process is difficult. These can range from intelligent tutoring systems (Cheikes, 1995; Ritter & Koedinger, 1995), to facilitated online learning (Bedore, Bedore, & Bedore, 1998). However, the major use of IT solutions in the learning process is usually a simple and straight forward use of the Web to present hypertext based structured material as a supplement to traditional learning.

Using Internet Technologies to Improve Efficiency and Add Value

With the recent explosion in Internet usage, educators have been turning to the Internet in attempts to gain benefits by the introduction of IT into the educational process. In this article, subject delivery at the university level is only considered. The benefits sought from such activity depend on the driving motivation of the IT solution being implemented. While many may not perceive a university as a business (and it is not advocated here), it is nonetheless possible to match the current uses of the Internet in tertiary education with traditional theory related to the reasons why firms use IT.

Internet technologies in education, which are used for the learning process itself, target the student as the main stakeholder. While the motivation may be the enhancement of the learning process to achieve a higher quality outcome, we can loosely map this to the "*support of managerial decision making*" concept identified earlier. Such technologies allow educators to obtain a far more sophisticated analysis

of individual student's learning progress, and thus provide them with decision support tools on courses of action to take to influence this process.

Technology solutions, which target the academic as the stakeholder (Darbyshire et al., 2000), implement improvements or efficiencies that can be mapped to the *support of the business operation* previously identified. Improvements or efficiencies gained from such implementations are usually in the form of automated record keeping and faster processing time, ultimately resulting in lower costs in terms of academic time, and added value to the students.

By default, the university also becomes a stakeholder in the implementation of either of the previous types of technology enhancements. Benefits gained by students and staff by such uses of technology translates ultimately to lower costs for the institution or the provision of more and/or better quality information. The benefits of such systems can be mapped onto the *support of strategic advantage* concept (as Porter et al's low cost and differentiation strategies), previously identified as a reason for using technology in business. If these institutions are to regard themselves as a business, then the successful use of IT in subject delivery could give the university a strategic advantage over other universities, which it would regard as its business competitors. Most of the reported advantages gained from online supplementation of teaching relate to cost savings in terms of efficiency, flexibility, and/or convenience. These represent the traditional added value benefits of lower cost and faster access to goods in the commercial world. Thus, we can use the measures of *money savings*, *time savings*, *improved quality*, and better *product information* as categories to measure the benefits gained from the introduction of IT to supplement teaching.

VALUE ADDED ACHIEVED BY ACADEMICS

The authors were interested to investigate the extent of appreciation of the "value added" benefits that the Internet can offer to tertiary educators, institutions, and their students. In the first instance, a simple survey was conducted in 2001 through the IS world discussion list to gain an initial idea of the level of appreciation that existed (Darbyshire & Burgess, 2005a).

The most common benefit for administrative uses was to *save time* for the institution and for students. Most administrative benefits were similar for both groups except for *save money* (where more than twice the respondents felt that the institution saved money than students). The *information provision* administrative usages were the most commonly used (important notices, schedules/timetables, assignment, and grade distribution). Less common were the more *interactive* options, assignment collection, and student enrolment. Educational uses of the Internet were seen as providing slightly more benefits for students than institutions. Their uses were seen as providing more information and improving quality more on average than the administrative uses. As with administrative usages, the easiest educational features to set up were the most commonly used (distribute course/subject notes, provide external links). Less common were the more *interactive* options, discussion lists, and online chat groups. About three quarters of respondents used the Internet to answer student queries (probably by e-mail). As with administrative uses, most of the benefits are similar for students and the institution, with (again) some differences for instances where the benefits save money more for the institution than students. More respondents saw the differences in the benefits of educational uses flowing to students than to institutions than with administrative uses. In three of the uses, saving time *was not* the most common benefit identified. These were the provision of external links to additional resources, discussion lists, and online chats, where improved quality of information and more information were more commonly identified. More recently, there have successful trials of automatically generated online examinations. For instance, Patterson (2006) reports on the conversion of a four-hour examination delivered online to almost 200 students. The examination consisted of 100 randomly generated questions—so the test was different for each student. The vast majority of students found the examination easy to access and complete online.

ISSUES FOR ONLINE TEACHING

Having decided to adopt the Internet as part of their curriculum, academics are faced with a number of issues in dealing with the new paradigm. Two of these are *plagiarism* and *class attendance*.

Plagiarism has long been a problem for educators, but recent discussions seem to indicate that incidents of plagiarism are increasing. The easy access of information via the Internet has been blamed for this perceived rise in plagiarism. However, while there is no direct evidence that plagiarism is occurring more often since the introduction of the Web into classrooms, anecdotal evidence suggests this is so. But is the Internet to blame? According to Tribe & Rendell (2003), there were very few publications dealing with plagiarism prior to 1995, although by the year 2000 it seems to have become a very serious problem. Tribe et al. provide a number of explanations for this including student commitment, lifestyle, organizational skills, and confusion. What the Internet offers is the ability to find vast amounts of information very quickly with basic mastery of a search engine and some carefully selected key words. There are a number of strategies available to combat plagiarism. McLafferty and Faust (2004) suggest that the best strategy

to combat plagiarism is to prevent its occurrence and that when students are given appropriate instructions and/or particular types of assignments, plagiarism is minimized or even eliminated completely. Online plagiarism detection systems can be used as a deterrent beforehand, as well as for detecting plagiarism of online materials (Martin, 2005). In Darbyshire and Burgess (2005b), we outlined two vastly different techniques to combat plagiarism in two subjects offered by the School of Information Systems at Victoria University, Melbourne Australia. Each take a different approach by concentrating on the learning required of the assessment tasks and combating plagiarism at a different phase of the task. In one case students are encouraged to embrace the diversity offered by the Internet and shown how to find materials online and how to reference materials found on the Internet. In the other case, students were presented with an ungraded assignment, for which they could research information on the Internet, with a test on that assignment then being set. Each technique was effective in its own way in reducing the level of plagiarism by students. The eventual conclusion was that an evolution in procedures for assessment tasks is underway, and as academics we should view the Internet as a tool to be used rather than an adversary aiding and abetting plagiarists. Plagiarism occurs for many reasons, and there are many things we can do combat this. We are operating in a new landscape and traditional assessment methods are open to abuse in this environment.

Another problem to consider in the teaching environment is that of class attendance. Over the last few years, we seem to be experiencing a phenomenon of dropping attendance rates in classes. It is unclear whether this phenomenon is linked to increasing student employment rates or some other societal direction not yet evident, but the trend is a matter of concern. There is some doubt as to whether there is a direct correlation between attendance rates and success rates in university courses. However, students run the risk of significantly increasing their chances of poor performance and (or) failure by missing vital information due to non-attendance. Policy makers are putting pressure on universities to be more accountable in their management of public funds. One of the methods universities can adopt to do this is to more closely monitor student progression rates (Dancer & Fiebig, 2004). Trying to reverse this trend is difficult, and it seems that at best we need to closely monitor attendance and warn those at risk as early as possible. Alternatively, we can build attendance into the grading scheme, a practice which is common in online courses due to the nature of the paradigms utilized, and the importance of attendance in this environment. In Burgess and Darbyshire (2006), we examined two separate cases related to tertiary student attendance—one in a traditional face-to-face environment and one in an online environment. In the *face to face* example, student attendance in lectures had been quite poor for a few semesters, with students apparently relying on online lecture notes and copying noted from friends to survive. Unfortunately, this reflected in some poor student final results. The lecturer introduced a number of strategies, including weekly polls in lectures related to the lecture topic in which students were identified in their responses, and a regular reinforcement via e-mail to students with a poor attendance rate. Eventually, the student attendance rates and overall performance improved. In the second case, one of the advantages of the online paradigm became apparent. For students to succeed in a solely online course offering they are virtually **required** to "attend" class (online) on a regular basis. In this instance, the case showed that students that attended poorly tended to be identified early on and often did not remain enrolled in the course.

FUTURE TRENDS

The use of the Internet has become ubiquitous in tertiary education. It has now become commonplace as a tool for administration and learning both to supplement traditional techniques and in the form of new online paradigms. The lessons are still being learned as to how to best employ online technologies to improve the overall tertiary experience. New initiatives, such as randomly generated online tests delivered to large numbers of students in different locations, will continue to be trialled. It is also a time to look for future developments in the manner in which plagiarism, and the strategies used to deal with it, are developed. We anticipate this battle to continue for a while yet.

CONCLUSION

The majority of tertiary educators use the Internet to supplement existing modes of delivery. Importantly, the Internet is providing a number of *added value* supplemental benefits for subjects and courses delivered. There are two aspects to subject delivery to where *added value* benefits may be applied, and that is in the *administrative tasks* associated with a subject and the *educational tasks*. Most of the reported advantages gained from online supplementation of teaching relate to cost savings in terms of efficiency, flexibility, and/or convenience. These represent the traditional added value benefits of lower cost and faster access to goods in the commercial world. The measures of *money savings*, *time savings*, *improved quality*, and better *product information* can be used as categories to measure the benefits gained from the introduction of IT to supplement teaching.

A 2001 survey of tertiary educators revealed similar usage levels of administrative and educational features to aid tertiary education on the Internet. The administrative uses showed slightly more benefits for the institution than for students and vice-versa for educational uses. In both types of uses, their adoption seemed to be based upon how

difficult the feature was to set up as well as the added value benefits it provided. More recently, the use of the online paradigm for educational delivery has introduced new issues in relation plagiarism and online attendance, which need to be confronted by academics intending to head down the online or hybrid delivery paths.

KEY TERMS

Administrative Tasks: The tasks that support educational tasks (such as enrolment, recording results, and so forth).

Class Attendance: In the case of "face to face" classes this refers to the physical presence of students in class. In the case of "online" classes this refers to student participation occurring with the timelines as imposed by the course lecturer.

Educational Tasks: Those tasks directly associated with the delivery of the educational component to students (e.g., lecturers, tutorials, assessment, and so forth).

Efficiency: From an IT viewpoint this usually relates to improvements within the business, so for a business it may mean IT systems that reduce costs or perform tasks more reliably or faster.

Internet Technologies: That group of technologies that allow users to access information and communication over the World Wide Web (Web browsers, ftp, e-mail, associated hardware, Internet service providers, and so forth).

Plagiarism: Using the words or ideas of others and presenting them as your own without acknowledgment.

Value: The amount a "buyer" is willing to "pay" for a product or service. A business can "add" value by being a low cost providing, providing a unique or differentiated product or service, or filling a niche market.

Internet Auctions

Kevin K.W. Ho
The Hong Kong University of Science and Technology, Hong Kong

INTRODUCTION

Year 2005 marks the 10th anniversary of eBay (http://www.ebay.com), the most successful online marketplace for Business-to-Consumer (B2C) and Consumer-to-Consumer (C2C) Internet auctions in this decade. As of December 2005, eBay has a major auction Web site and 26 sister Web sites operating all over the world and is enjoying a 37% quarter-to-quarter growth in revenue (eBay, 2005).

Before eBay existed, Internet auctions were mainly held in Internet forums and newsgroups (Lucking-Reiley, 1999, 2000). Nowadays, people can auction goods in cyberspace through Web sites such as eBay, Yahoo! auction (http://auctions.yahoo.com), and Amazon auction(http://s1.amazon.com). Designated Web sites for niche markets, such as antiques or electronic products are also established.

With the rapid growth of Internet auctions, economists and information systems (IS) researchers are using these Web sites to conduct field experiments and to collect transaction records to support their research more and more frequently. They are also interested in analyzing new features developed by these Web sites, such as Peer Review System and Buy-It-Now (BIN) auction, and bidders' behaviors, such as snipping. This article aims to provide a brief review of the Internet auction research conducted in the past few years and to explore the future research trends in this area.

BACKGROUND

Auction is one of the most popular business activities in the world. Each year, goods worth hundreds of billions of dollars are auctioned online and off-line. The types of goods auctioned range from very expensive items such as land and properties, government permits/licenses, and antiques to relatively minor items such as used stuffs, toys, and food (McAfee & McMillian, 1987; Lucking-Reiley, 2000). Recently, even job openings are being auctioned via the Internet (see, Job Dumping, http://www.jobdumping.de.)

Before the Internet boom, people already auctioned goods on the Internet via forums and newsgroups (Lucking-Reiley, 1999, 2000), as well as in private networks (for example, AUCNET, http://www.aucnet.com) (Lee, 1997, 1998). On the contrary to the argument that the "frictionless" nature of electronic commerce would reduce the profit of sellers (Bakos, 1997), AUCNET shows that electronic marketplaces can bring a win-win situation to both sellers and buyers. AUCNET has, on the one hand, increased sellers' profit, and on the other hand, provided an efficient market for auction participants with the help of information technology and other supporting features (Lee, 1998).

In response to customers' suggestions and to improve its usability, new features have been developed in Internet auction Web sites in the past few years. While some of them are brand new auction mechanisms, others are new features which aim to build up the trust between auction participants. Among them, Buy-It-Now auction and Peer Evaluation System are the most important ones.

Before we start our discussion, readers are reminded that the terminologies used by auction Web sites are sometimes different from auction literature. The most significant difference is the definition of a "Dutch auction." Dutch auction is a descending auction commonly used for the auction of perishable goods such as fish and cut flowers (McAfee & McMillian, 1987). However, auction Web sites use the same term to describe multiple-item English auction (Bapna, Goes, & Gupta, 2001). Hence, readers are reminded to check with individual Web sites on the terminologies if they are in doubt.

CURRENT TOPICS IN INTERNET AUCTION RESEARCH

In this section, we will review the latest research findings in Internet auctions, including research on the Peer Evaluation System and Buy-It-Now auction, as well as how economists and IS researchers employ Internet auction Web sites to conduct field experiments.

Peer Evaluation System

Peer Evaluation Profile is a reputation profile of auction participants based on his/her behaviors in his/her previous transactions on the Web site. After each transaction, the auction Web site will invite auction participants to evaluate each other. Nowadays, nearly all Internet auction Web sites have developed their own feedback system to allow their users to evaluate each other. Most of them use a 3-point scale (e.g., eBay and Yahoo!) and the others use a 5-point scale (e.g., Amazon) to record participants' performance, supplemented with notepads to provide further comments

Figure 1. A sample of user profile of Internet auction

Bidder Profile: Auctioner (112)				
Feedback Score: 112 **Positive Feedback: 93.8%**	Recent Rating:			
		Past Month	Past 6 Months	Past 12 Months
	Positive	20	120	140
	Neutral	2	5	5
	Negative	0	8	8

on the Web. Figure 1 is a hypothetical user profile of an Internet auction Web site. A lot of research studies have been conducted to examine whether the feedback system can bring benefit to auction participants.

One of the earlier studies on the Peer Evaluation System was conducted by Lee, Im, and Lee (2000). Through regression analysis using auction data of monitors and printers collected from eBay, they observe that the negative feedback score of a seller will have negative impact on the final auction price. This effect is more significant to used and refurbished products than to brand new items. Standifird (2001) used eBay auction data of 3Com Palm Pilot V to show that while both positive and negative feedback scores affect the final price, negative feedbacks are more influential than the positive ones. McDonald and Slawson's study (2002) suggests that the peer evaluation profile could be used to measure the expected performance of the seller whereas Ba and Pavlou (2002) suggest that the profile can induce and build up trust between bidders and sellers.

A comprehensive review has been conducted by Dellarocas (2003). He suggests that Peer Evaluation System provides an opportunity for sellers and bidders to build up their word-of-mouth profiles in electronic marketplaces. Yoo, Ho, and Tam (2006) propose that as there is a large number of positive feedback when compared with the number of negative feedbacks, the per-unit effect of negative feedback becomes more influential when bidders evaluate the reputation of sellers. This may explain why some Web sites highlight the net feedback (i.e., the number of positive feedback minus negative feedback) of auction participants as this can minimize the adverse effect of negative feedbacks.

In conclusion, as shown in Table 1, the Peer Evaluation Profile can induce and build up trusts between buyers and sellers. For bidders, they can use the profile to evaluate the trustworthiness of sellers before they decide whether they should join the bidding competitions. On the other hand, sellers can use this system to boost up the auction price by building up their word-of-mouth profile.

Buy-It-Now and Buy-Price Auctions

BIN auction and Buy-Price (BP) auction are two similar variations of English auction developed by eBay and Yahoo! respectively, in the late 1990s. In BIN auction, the seller posts a BIN price and indicates that he/she is willing to close the auction at this preset price. This BIN price is valid until a bidder submits a bid which is higher than the reserve price. After that, it will disappear and the auction will convert to an English auction. BP auction operates in a similar way except it will not convert to English auction in any circumstances. This counter-intuitive arrangement, that is, capping the maximum profit of an auction by sellers themselves, creates an interesting research topic. Table 2 summarizes the result of several representative studies on BIN and BP auctions.

Most of the analytical studies are developed based on the assumption that bidders are risk averse. For example, Budish and Takeyama (2001) show that with risk averse bidders, BP auction can generate more revenue than First-Price Sealed Bid and Dutch auctions. Mathews (2004), on the other hand, shows that BIN auction is useful only when either bidders, sellers, or both of them are time impatient. Onur and Tomak (2003) also analyze whether bidders would prefer to use the BIN option or to snipe in an Internet auction. Their model, supported with empirical data, shows that the low value bidders prefer to snipe, and the high value bidders prefer to exercise the BIN option in a BIN auction.

To compare the difference between BIN and BP auctions, Reynolds and Wooders (2003) develop an analytical model to examine their differences. Similar to Budish and Takeyama's (2001) model, their model also predicts that both BIN and BP auctions will not bring any additional benefit to sellers if bidders are risk neutral. However, if bidders are risk averse, BIN and BP auctions will raise the revenue when compared with English auction. Furthermore, BP auction will have a better performance, that is, generate more revenue, than BIN auction. More recently, Hidvegi et al. (2006) have further extended the discussion and show that the social welfare and utilities of all participants can be improved if BP is properly set.

Empirical and experimental studies have also been conducted to examine the property of these auctions. Standifird et al. (2005) conducted a field experiment on eBay using American Eagle silver dollars. They observe that some eBay users do not exercise the BIN options even when they are set at a price lower than the market price. Hence,

Table 1. Result of studies on peer evaluation profile

Authors	Web site studied	Item studied	Result
Lee et al.(2000)	eBay	Printer Monitor	Negative feedback will decrease the final auction price.
Standifird (2001)	eBay	Palm Pilot V	Positive feedback will increase the final auction price. Negative feedback will decrease the final auction price. Negative feedback has a stronger influence than positive feedback.
McDonald and Slawson (2002)	eBay	Doll	The higher the net feedback score, the higher the final auction price.
Ba and Pavlou (2002)	eBay	Digital products, CD and software	Positive feedback has a stronger positive impact on the final auction price.
Yoo et al.(2006)	eBay Yahoo!	Digital Camera	Positive feedback will increase the final auction price. Negative feedback will decrease the final auction price. Negative feedback has a stronger influence than positive feedback.

Table 2. Result of studies on Buy-It-Now and Buy-Price auctions

Authors	Auction studied	Result
Budish and Takeyama (2001)	BP	If bidders are risk averse, revenue of BP > D and FP.
Onur and Tomak (2003)	BIN	Low value bidders prefer to snipe and high value bidders prefer to use BIN.
Reynolds and Wooders (2003)	BIN and BP	If bidders are risk averse, revenue of BP > BIN > E.
Mathews (2004)	BIN	BIN is useful when either bidders, sellers, or both of them are impatient.
Standifird, Roelofs, and Durham (2004-5)	BIN	Bidders are interested in the hedonic effect of Internet auctions. Hence, they will not exercise BIN option even if it is set below the market price.
Yoo et al. (2006)	BIN and BP	The revenue of BP > BIN > E. Besides, even if BP and BIN are not exercised, their performances are still better than E.
Hidvegi, Wang, and Whinston (2006)	BP	The revenue of BP > E. Social welfare of all participants can be improved if BP is properly set.

Key: BIN: Buy-It-Now auction BP: Buy-Price auction D: Dutch auction E: English auction FP: First-Price Sealed Bid auction

they propose that bidders may only be interested in taking part in the bidding competition. Another empirical study conducted by Yoo et al. (2006) using digital camera data obtained from eBay and Yahoo! auction Web sites shows that BIN and BP posted by sellers can provide additional information to bidders. This effect can probably help to improve the auction performance even when the BIN or BP option is not being exercised.

Field Experiments on the Internet

Experimental economics also benefits from the boom of the Internet. Before the Internet Age, most economic experiments were conducted in laboratories using student subjects. It is always arguable that whether the results obtained from student subjects can be generalized to the real world setting. Thus Internet auction provides an opportunity for researchers to conduct field experiments more easily. One of the early experiments using the Internet was conducted by Lucking-Reiley (1999) in an Internet newsgroup. In his study, he auctioned game cards in the newsgroup and examined whether the *revenue equivalence theory* proposed by Vickrey (1961) is held in cyberspace. He observed that Dutch auction outperforms first-price sealed bid auction and he suggests that the Dutch clock may have an anchoring effect to bidders' valuation on the product.

Hossain and Morgan (2006) also conducted a field experiment in eBay. They auctioned matched pairs of CDs and Xbox games with different combinations of reservation price and shipping and handling costs. Even though the opening offers, that is, reservation price plus shipping and handling costs, are the same for both settings, they observe that a combination of high shipping and handling costs and low opening price attracts more bidders than a combination of low shipping and handling costs and high opening price. They propose that mental accounting maybe one of the reasons to explain this phenomenon. Besides, Standifird et al. (2004-5) conducted another field experiment to examine the impact of BIN option on the auction price.

Other Studies on Internet Auctions

Other studies on Internet auctions include the study on the reputation of auction Web sites. Standifird (2002) conducted

Table 3. Result of experimental studies on Internet auctions

Authors	Web site studied	Item studied	Result
Lucking-Reiley (1999)	Internet newsgroup	Game Cards	Dutch auction outperforms First-price sealed bid auction.
Standifird et al. (2004-5)	eBay	Silver Coins	Bidders are interested in the hedonic effect of Internet auctions.
Hossain and Morgan (2006)	eBay	CDs Xbox Games	A combination of high shipping and handling cost and a low opening price will attract more bidders than a combination of low shipping and handling cost and a high opening price.

an empirical study to examine whether the brand name of the Web site will have any effect on the auction final price. He shows that using the auction of Iomega Zip Disks, eBay generates more revenue than CNET (a niche auction Web site for digital products) and Amazon auction as well. Moreover, the revenue generated from CNET is higher than Amazon. Onur and Tomak (2003) and Roth and Ockenfel (2002) both studied the sniping behavior of bidders, that is, last minute bidding for an auction with hard close. While the former study proposes that the type of bidders will determine the selection between sniping and using BIN option, the latter study concentrates on the effect of the closing method of the auctions on the sniping behavior.

FUTURE TRENDS

From our review of the literature we notice that Internet auction study is a very interesting research topic in economic and IS. It is because Internet auction research is one of the few research areas which can allow researchers to construct analytical models which are ready for validation using both empirical and experimental methods. These analytical models developed can be implemented in the real business world, and hence, practitioners can also benefit from the result of this area of research.

Concerning future research areas, it is expected that more research will be conducted on the development of new auction mechanisms which can either improve the trust between bidders and sellers or resolve the information asymmetry problem. Trust building is important as this can reduce the perceived risk associated in Internet auctions. This can in turn increase the number of participants in the electronic marketplace and increase the revenue. New mechanisms targeted to resolve information asymmetry will also help to reduce the perceived risk and improve the auction performance. The building of these new mechanisms will definitely bring benefits to the sellers (by increasing the revenue) and bidders (by reducing the perceived risk in participating in Internet auctions).

Moreover, it is also expected that more field experiments will be conducted using the Internet as it can provide a test bed for auction research. It can also provide a platform for practitioners to discover the pricing of new products.

CONCLUSION

As one of the most successful e-businesses in the world, eBay tells us that Internet auction can be one of the "killer" applications in the real world. Apart from financial reward for stockholders as well as sellers using their service, it also provides opportunities for researchers to conduct new economic and IS research. It is foreseeable that more and more e-business research will be conducted in this area in the near future.

KEY TERMS

Auction With Hard Close: It is an Internet auction with a fixed end time. This closing method provides an opportunity for bidders to snipe in an auction.

Auction With Soft Close: It is an Internet auction with an extendable end time. The end time of auction will be extended if a new bid submitted within the last few minutes of the auction.

Buy-it-Now (BIN) Auction: It is a variation of English auction developed by eBay. The seller posts a BIN price and agrees to close the auction at this preset price. The BIN option will disappear and the auction will convert to an English auction when a bidder submits a bid which is higher than the reserve price of the auction.

Buy Price (BP) Auction: It is a variation of English auction developed by Yahoo! auction. Its setting is similar to BIN auction. Unlike BIN auction, BP auction will not covert to English auction in any circumstances.

Dutch Auction: It is a common descending auction for perishable goods. However, some Internet auction Web sites used this term to describe a multiple-item English auction.

Peer Evaluation Profile: It is a reputation profile of the auction participants based on her/his behaviors in her/his previous transactions on the Web site.

Snipping: It is a jargon for "last-minute bidding." It is only possible if the auction Web site is having a fixed end time (or "hard close").

Internet Diffusion in the Hospitality Industry

Luiz Augusto Machado Mendes-Filho

Anatália Saraiva Martins Ramos
Universidade Federal do Rio Grande do Norte, Brazil

INTRODUCTION

Tourism is the most important industry in the world in terms of the numbers of employees and its effect on the social and economical development of a region or country. Holjevac (2003) believes that, by the year 2050, tourism will by far be the largest industry worldwide, with 2 billion tourists and US$24 billion in domestic and international receipts. Moreover, the major tourist destinations will be India, China, Indonesia, and Brazil.

The use of information technologies for basic functions—conferences, business meetings in distant places, training, designed routes and airlines, reservations and tickets purchased through computer systems, tourist shops, restaurants—is becoming usual in tourism. All these services have led tourist companies to adopt more updated methods in order to increase competition. Consumers, who are already becoming familiar with new technologies, demand more flexible, interactive, and specialized products and services, bringing new management techniques from the intelligent use of IT used to accomplish tour company business processes (Buhalis, 2000).

The hotels depend progressively on the resources of new information technology to follow and update the tools which allow an efficient development of activities in each section of the company, leading to better results for its management (Mendes-Filho & Ramos, 2003a). To Phillips and Moutinho (1998), information technology (IT) is one of the critical factors of success in the hotel industry.

According to studies and data, the use of technological tools will allow a bigger competitiveness for hotels (Cline, 1999). Technology will be the catalyst of change, a source of growing connectivity and one of the most important factors in distinguishing success among hotel companies. Few issues have greater importance to the business of hospitality than the technological decisions that will be made in the coming years (Buhalis, 2000; Mendes-Filho & Ramos, 2004; Olsen & Connoly, 2000).

The hotel industry is one of the most important kinds of Web commerce. The data shows that all major companies linked to the tourism industry (hotels, agencies, air companies, and rentals) possess some kind of e-commerce activity through the Web (O'Connor, 1999; Scottish Executive, 2000; Werthner & Klein, 1999).

BACKGROUND

Decades ago, before the use of the computer in the accommodation sector, those charged with making reservations performed their service by checking availability tables exposed on the wall or in large, updated, hand-written lists (O'Connor, 1999). The hotels received innumerous telephone calls, letters, and telex from potential clients, sometimes larger than that of the hotel's reception, and worked to select correspondence, type letters, send telegrams, and deal with other demands. The delays were frequent, the cost of correspondence writing went sky-high, and specialized typists were in demand (World Tourism Organization, 2003).

A way found by the American hotel chains to streamline the reservation services was to centralize this function in a main office, serving the consumer better and offering a valuable service to the hotels belonging to that chain. O'Connor (1999) states that the reservation process in hotels in the USA was made even easier with the introduction of free telephone services in the mid-'60s, which permitted potential clients to perform an only call to obtain information or make reservations in any of the hotels of that chain in the world.

Although the reservation area became faster and more efficient, two large costs remained, those of telecommunications (free telephone service payment) and labor costs of the reservation agents necessary to answer the phones. With the increase in trips during the 1960s, the airline companies developed the computer reservation system (CRS), which pressured the hotel sector to develop its own (O'Connor, 1999).

The main focus in hotel and restaurant management has always been the maximization of consumer satisfaction and personalized attention. The use if IT has, at times, seemed incompatible with this objective, and the hotel sector has, in a way, delayed the application of IT in its operations. The technology has been viewed as a hindrance to personalized service because it creates an impersonal, mechanical, and cold environment with the clients.

However, the change of this belief is being changed within the hotel sector. Nowadays, according to Sheldon (1997), the establishments are noticing that IT can bring efficiency to the hotel, besides reducing costs and offering a great potential to increase the levels of personalized service to the clients.

In a survey performed by financial managers of American hotels, all stated that IT increased the hotel's productivity (David, Grabski, & Kasavana, 1996). The motives used to justify this statement were the following: Technology reduces the administration costs, decreases the amount of paperwork between sectors, minimizes operational errors, increases the earnings/profits of the hotel, and makes the reservation management more efficient. This same survey proved that IT is not only used to increase the hotel's productivity but also to improve the service, as well as to offer new services to the guests.

According to Namasivayam, Enz, and Siguaw (2000), IT can also be employed to reach business objectives. American and European hotel executives have plans to use the technology to reduce operational costs, increase sales, improve the service to the client, increase employees' productivity, and increase hotel earnings.

In research performed by Van Hoof et al. (1995), 550 American hotel managers answered questions about their perceptions of the use and implementation of technology in their establishments. Those responding identified the front office (reception and reservations) of the hotel as the sector that can benefit the most from the use of the technology, followed by sales and marketing, accounting, and the food and drink sector. According to Van Hoof et al. , having a quality service is a challenge to the hotel industry, which has high employee turnover indexes, employee salary increase, and low age of the most qualified people. Consequently, technological applications have been developed in hotels to increase this quality in the services and improve the interaction of the hotel employees with the guests.

IMPACTS OF THE INTERNET IN HOTEL INDUSTRY

During the '80s and '90s several authors from companies and universities had already foreseen that as new technologies were increasingly used, hotels could benefit from that in a great range of situations, for example: better qualified services for customers, increased sales and profits, efficiency in operation and integration of hotel sectors, rapid communication, and cost reduction (Laudon & Laudon, 1999).

Technological applications enable information and knowledge to bring a competitive advantage to the future profile of the hotel. The "Information Age" idea is that the most modern companies will build their success upon the amount of knowledge they have about their clients as well as information on their products and services and how they will make a profit in this new environment (Olsen & Connoly, 2000).

With the Internet being used as a means of communication, this brings several advantages or benefits compared to other vehicles. Flecha and Damiani (2000) state that when it comes to the tourist area, the main points are: the new relationship between consumers and companies, marketing for actively participating consumers, the importance of detailed information, self-service application, credibility, and agility of communication.

The use of the Internet and World Wide Web is spreading quickly in most consumer access areas to travel database developments. There are hundreds of thousands of suppliers' homepages, associations, e-news, newsgroups, and chats for the travel and tourism community. This group of technologies provides many opportunities for the industry to interact with its consumers and suppliers. It is also possible that, through information technology, products and services may be personalized according to the tourist's needs and thus may become a differential feature for those who adopt it (Buhalis, 2000; Sheldon, 1997).

The purchase of products and services through the Internet is revolutionizing the world of business and people's lives as well. For some clients it is more comfortable to book an e-ticket through the company home page rather than going to the travel agency (Franco, 2001).

As the Internet began and grew, the use of such technologies at home or work and also the new opportunities that arose from the lower costs in telecommunication equipment made it possible for suppliers to distribute information to their clients and process reservations directly with the clients (O'Connor, 1999).

According to Jeong and Lambert (2001), the Internet has already modified the competitive strategy of some hotels. It is through the Internet that the client can have a "self-understanding" in a service that is being offered to him in a more efficient way. In hotels, check-in processes can already be totally automatic, from the Internet booking until the moment the client takes his keys in an automatic dispenser. The result is that clients can become more informed and willing to have quick answers from the orders online. Though many experts and businessmen agree that the Internet is probably the most important technological tool, it is still relatively new and misused in the hotel industry (Van Hoof & Verbeeten, 1997).

Several authors have identified impediments to the growth of the Internet in the industry and, hence, have reservations about the willingness of hotel operators to adopt the Internet wholeheartedly (Wei et al., 2001). These problems include user-friendliness, the quality and accuracy of information obtained from the Web, and the issue of data security (Wei et al.). Here are other difficulties found by Lituchy and Rail (2000) in their research: problems in updating new

information in hotel Web pages, annoyance expressed at inaccessible Webmasters by managers, hard to find hotel Web sites, lack of knowledge on the employees' part of how to use the technology, and the impersonality of the medium. Because of these, consumers have been slow to adopt the Internet as a means of making hotel reservations. Only 4% of reservations are made online (Maselli, 2002).

Namasivayam et al. (2000) summarize that almost 60% of the hotels in their study had few technologies. To Feiertag (2000), a lack of proper training, high turnover rates, and limited financial resources were major barriers to the successful use and implementation of new technologies.

In addition to this, many hotels still believe that conventional means of advertising, such as radio, television, and printed material, are the most effective way of promoting their properties. The share of reservations received through the Internet remains minute compared to reservations received through conventional means, such as phone, fax, or mail (Van Hoof & Combrink, 1998). However, these problems are diminishing with the increase of the number of Internet users. And if customers become accustomed to browsing for rooms and making reservations through the Internet, more and more properties will be forced to get on the Internet as well (Mendes-Filho & Ramos, 2002).

In a specific way, the Internet provides an expansion of hotel services, changing this industry and giving new opportunities to clients, thus being a new channel to be developed. Besides online reservation services, the Internet allows hotels to sell their services and charge them electronically as well as offer new products through the World Wide Web (Blank, 2000; Laudon & Laudon, 1999).

Through the Web the customer can check hotel location, compare rates, see pictures and watch videos, get information about tourist destinations and other facilities, check room availability, and book and confirm reservations for the amount of time he wants to stay, among other services. Hence, the interactivity of the Web provides an ideal medium for distributing accommodations online, consolidating itself as a very adequate platform for bringing information and services to the client in a very straightforward, efficient, and quick way (Flecha & Damiani, 2000; Hotels, 2001).

Marriot, Hospitality Services of America, and Hilton are some of the hospitality industry's members that have successfully used marketing on the Internet to reach new markets, track customers, take online reservations, and offer information about their products and services (Lituchy & Rail, 2000).

FUTURE TRENDS

A hotel chain's success has always depended on excellent services performed by operation, marketing, and human resources sectors. For Withiam (2000) in the 21st century an essential factor will be technological support, making it possible for computers to process information of reservation systems, affinity programs, and marketing data banks.

Improvements in integration, centralized data banks, and the use of Web sites are some of the tendencies in the development of software for hotels (Adams, 2001). Therefore, the connection of a hotel system to the Internet will integrate information of the internal system with the Web site, and this will make a lot of information available to managers. The new systems are being developed with this integration with the Web site.

With the increasing demand of information in the tourist sector, the importance of IT use in this industry will only tend to increase in the future. Therefore, the tourist businesses must understand, incorporate, and use IT strategically to serve the target markets, improve their efficiency, maximize profitability, perfect services, and maintain the profitability in the long term (Buhalis, 2000).

To Olsen and Connoly (2000), the volume of information about the guests collected electronically is too large for the directors to be able to manage without the help of technology. Data warehousing and data mining are technologies that are gaining popularity to analyze information about clients. These technologies may be used to help hotel keepers construct good relationships with their guests, increasing their loyalty to them.

Using the Internet in the hotel industry has good prospects of growth, though in many hotels the use of such technology is still moving slowly. On the other hand, there are some hotels using and steadily setting the trend. It will be an important and strategic issue for businessmen to stimulate such Internet use policies inside the tourist trade so that they become wired to this new reality and can work on even terms with their competitors.

CONCLUSION

The Internet has decreased expenses and enabled small businesses to conduct international business from home (Lituchy & Rail, 2000). Small inns and bed and breakfasts are advertising on the Web and are therefore becoming a presence in the global market. So, they face the likelihood of serving foreign customers that may have different hospitality expectations.

Despite the fact that Internet use is very common, the proportion of reservations received from the Internet is small. The public could still be concerned about issues of

security for financial transactions or could not be satisfied with its inability to synchronize inquiries. A low reservation rate from the Internet may also be partly attributed to the lack of certain relevant information, such as room availability and virtual tours of the property not commonly included in the homepage (Wei et al., 2001).

In general, the Internet does enable tourist companies to increase their competitiveness. IT can improve the efficiency of suppliers and provide tools for the development and delivery of different tourist products (Mendes-Filho & Ramos, 2003b). One of the benefits reached is the reduction of the dependence on the middlemen in the distribution of tourist products. Hotel owners should invest more money in technology besides concentrating more time and attention to subjects in that area. IT affects all aspects of a hotel chain's value, going far beyond sectors and departments. As technology will be intrinsically linked to hotel business, its executives will insert technology in all their strategic decisions for the facility. That implies all the employees (including managers and directors) need to have enough knowledge to extract the potential the technology provides.

KEY TERMS

Bed and Breakfast: An establishment (as an inn) offering lodging and breakfast.

Computer Reservation System: A computer system that manages the distribution of the tourist products to transportation, lodging, and entertainment companies.

Data Mining: The process of analyzing data to determine relationships undiscovered by previous analyses.

Data Warehouse: A data warehouse is a central repository for all or significant parts of the data that an enterprise's various business systems collect.

E-Ticket: An e-ticket (electronic ticket) is a paperless electronic document used for ticketing passengers, particularly in the commercial airline industry. Virtually all major airlines now use this method of ticketing.

Front Office: The department of the hotel that deals directly with clients. Normally, it involves the reception and the reservation sector of the hotel.

Middleman: A dealer or agent intermediate between the producer of goods and the consumer or retailer.

Internet Work/Play Balance

Pruthikrai Mahatanankoon
Illinois State University, USA

INTRODUCTION

Productivity gain can be achieved through utilitarian use of the Internet. Networked organizations foster intra- and inter-organizational communications, which amplify team collaborations, information sharing, and relationship building. The Internet also provides linkage to external global information sources, allowing organizations to analyze market trends, predict competitors' movements, and search for competitive advantages. However, Internet usage in the workplace is also a double-edged sword that can bring liabilities to modern workplaces. Employees can utilize their Internet connectivity and e-mail accounts for a variety of purposes. Publicized cases of Internet abuse in the workplace (i.e., pornography, employee harassment, information leakage, software piracy, etc.) have generated different ethical and legal concerns for many organizations.

To prevent such occurrences, practitioners utilize several strategies to deter Internet abuses (e.g., training of proper Internet usage, communicating Internet usage policy, installing Internet monitoring, and filtering software, etc.). These strategies have been effective against such behaviors, but they often decrease employees' job satisfaction and motivation. Understanding the underlying determinants of workplace Internet usage can bring balance to organizational work and play, and allow practitioners to apply the most effective Internet usage policies to increase job satisfaction.

A feasible balance between proper behavioral controls and employee motivation is attainable through the equilibrium of organizational and individual psycho-socio-technical factors. The ultimate goal of this balance is to maintain and improve employee satisfaction and organizational well-being. To identify the appropriate balance, this article examines different perceptions of Internet usage activities and suggests three Internet management strategies.

ASPECTS OF INTERNET USAGE

Any Internet behavior can be classified as a productive, personal, or pathological Internet usage. This article defines these perceptions as the 3Ps of Internet usage. These perceptions have a direct influence on social/technological/psychological situations of individuals and organizations. Studies of Internet usage behaviors are interdisciplinary in nature; therefore, the stimuli behind each perception still require extensive research that involves a different set of determinants and outcomes.

Productive Internet usage provides a utilitarian view of Internet technologies. Research on information technology adoption, information systems success factors, and technology-task fit all contribute to increase productive Internet use. Studies in this area include creating positive employees' attitude, establishing organizational/social usage norms, and lowering the psychological barriers of Internet usage. Ideally, productive Internet usage occurs at work. With today's networked organizations, productive work also can be performed at various virtual offices.

Personal Internet usage involves a recreational use of the Internet. This type of usage occurs privately at home and occasionally at work. Anandarajan and Simmers (2002) define these behaviors as voluntary online Web behaviors during working time in which employees use any of the organization's Internet resources for activities outside current customary job/work requirements. These activities include any personal use of the Internet at work such as searching for news and entertainment information, conducting electronic commerce, booking a vacation, and using personal e-mail (Mahatanankoon, Anandarajan, & Igbaria, 2004). Most people who engage in such behaviors are aware of their environment, social norms, and organizational policies. The consequences of personal Internet usage also have contradictory ramifications. Some studies suggest that these behaviors lead to productive work life (Stanton, 2002) and organizations should encourage a balance between and work and play (Belanger & Van Slyke, 2002; Oravec, 2002). Other studies find that these behaviors can lead to cyberloafing (Lim, 2002). Table 1 summarizes the benefits and potential risks of personal Internet usage.

The norms of Internet usage in the workplace are "co-evolving" (Kraut & Kiesler, 2003) and it is difficult for organizations to associate the relationships between personal Internet activities with any individual and organizational outcomes. However, excessive personal Internet usage is counterproductive. Internet abuse is a general term that often refers to any wrongful or improper use of the Internet in the workplace. Behaviors related to Internet abuse often are more severe in nature such as viewing pornography, harassing other employees, downloading illegal software, excessive gaming, etc. Extreme cases of Internet abuse habitually result in many negative, uncontrollable psychological consequences.

Table 1. Benefits and potential risks of personal Internet usage

Benefits	Potential Risks
Information sharing	Cyberloafing
Team collaboration	Productivity loss
Job satisfaction/performance	Social disintegration
Stress reduction	Wasted network bandwidth
Work-life balance	Possible legal liability
Empowerment and motivation	Information leakage
Social networking	Cyber-workplace deviance
Relationship building	
Organizational learning	

Pathological Internet usage or Internet addiction involves excessive Internet usage as a way to cope with personal problems or difficulties (David, 2001; Greenfield, 1999; Young, 1998). Pathological Internet users have low self-esteem and are socially suppressed (Niemz, Griffiths, & Banyard, 2005). Mood-altering, denial of responsibilities, guilt, and craving are the common symptoms of Internet addicts (Morahan-Martin & Schumacher, 2000). Other symptoms include loneliness, boredom, salience, and lack of control (Nichols & Nicki, 2004; Widyanto & McMurran, 2004). They have a higher tolerance level, withdrawal symptoms, and a craving for the Internet as compared to normal Internet users (Brenner, 1997). Occurrences of Internet addiction are rare in the workplace, and most organizations have taken harsh measures to punish Internet addicts including workplace reprimand, employee termination, and pressing criminal charges (Warden, Phillips, & Ogloff, 2004).

The next section explains how a proper balance of Internet usage can occur, and suggests potential strategies for effective Internet management in the workplace.

BALANCING OF WORK-PLAY

Work/play balance is based on the equilibrium between employee extrinsic and intrinsic motivations. Extrinsic motivation is related to productive Internet use. That is, employees utilize the Internet to achieve work-related rewards such as monetary, promotion, and/or recognition. Intrinsic motivation is related to personal Internet usage at work. Occasionally, such activities can lead to both positive and negative outcomes, as indicated earlier. Self-determination theory suggests that people seek out stimulating and challenging activities in order to fulfill their interests and enjoyment. When they do, these activities generate the sense of competence and self-determination (Deci & Ryan, 1985), which can facilitate positive emotional experience (Matsumoto & Sanders, 1988) and individual learning (Pintrich & Schrauben, 1992).

As personal Internet usage influences the well-being of employees, Internet usage policy (IUP) must be examined carefully so it will not decrease any positive motivation or work morale. The policy should include training and education, which can be used as a tool for effective communication between management and employees. When Internet monitoring is necessary to enforce appropriate behavioral norms, the policy should be based on maintaining employee job performance. To achieve work/play balance, the article recommends three Internet management strategies.

- **Individual-organizational Internet behavioral alignment:** Employees' perceptions of proper Internet activities need to be aligned with organizational policy. The act of alignment is not as straightforward as it seems, because the 3Ps of Internet usage also asserts its "weight" on individual and organizational psycho-socio-technological situations. In other words, increasing an individual's "productive" Internet usage will reduce the occurrence of personal/pathological Internet usage. However, the increase in productive Internet usage also is related to the ways in which a person behaves socially, technically, and psychologically.

  A proper balance occurs when there is a fit among psycho-socio-technological factors of an individual and those of an organization. Figure 1 shows the intricacies of various concepts described earlier. To create a balance, (1) organizations must have sufficient technological support and infrastructure that match the knowledge and efficacy of their employees; (2) the need for social relationships of an individual must equal the general social norms and culture in the workplace; and (3) organizational psychology (e.g., the organizational analyses of job, career paths, personality, ethics, morale, and attitudes its employees) must adhere to individuals' psyche and motivation. Once there is a mutual understanding of psycho-socio-technological factors, an adaptive internet monitoring and filtering policy (AIMF) can be implemented.

Figure 1. Internet work/play balance framework

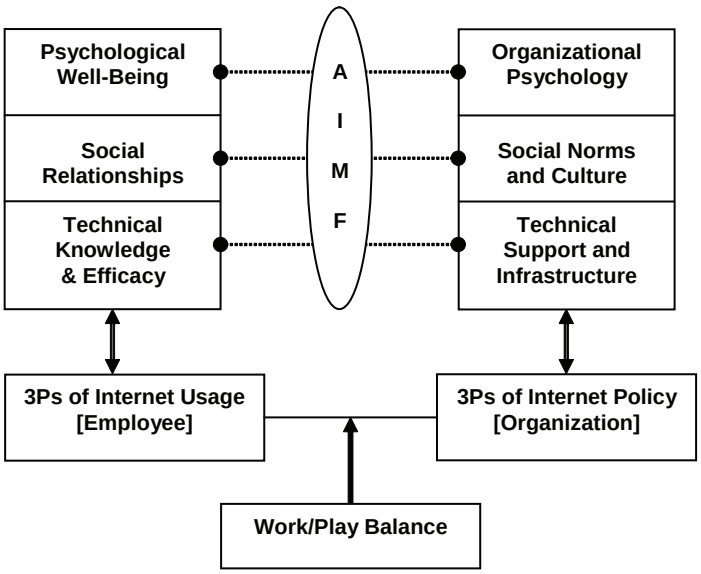

Table 2. Workplace Internet monitoring and filtering policy

Well-being	Performance	Types of Internet Activities	Restriction
+	+	• Learning about educational training classes related to work. • Visiting professional Web sites. • Reading current news/events to fulfill a career or promotional goal. • Searching for new business tools.	LOW/ MODERATE
-	-	• Visiting pornography sites. • Downloading music or illegal software. • Escaping from job responsibilities. • Excessive gaming and chatting. • Any pathological activities.	HIGH
+/-	+	• Accessing organizational intranet/extranet sites. • Sending and sharing information with co-workers. • Visiting customers, suppliers and/or competitors Web sites, etc.	LOW
+	-	• Researching personal hobbies. • Booking travel vacation. • Chatting with co-workers. • Engaging in minor leisure activities. • Surfing without any purpose or to reduce stress. • Reading general news and sport scores.	MODERATE/ HIGH

- **Adaptive Internet monitoring and filtering policy (AIMF):** This strategy requires a reciprocal sense of respect and fulfillment of an organizational—employee psychological contract (Mahatanankoon, 2005). Organizations may allow non-work-related Internet usage as long as employees satisfy their job requirements. Nevertheless, organizations need to provide adequate ethical education for their employees and establish Internet usage norms through informal peer influence. The psycho-socio-technical needs and job characteristics dictate the amount of Internet usage activities performed by the employees (see Figure 1); therefore, organizations must take these factors into consideration before implementing this strategy.
- **Workplace Internet monitoring and filtering policy:** This strategy examines Internet activities based on job satisfaction and job performance dimensions (Mahatanankoon & Igbaria, 2004). These dimensions are related to employee well-being and job performance, which can be used to develop a monitoring/filtering policy for personal Internet usage.

Employee well-being = *f* (job satisfaction, intrinsic motivation, quality of work life)
Job performance = *f* (productivity, extrinsic motivation)

The quality of any personal internet usage is based on its effects on well-being and job performance. Again, it is equally important to acquire the proper understanding of the 3Ps of Internet usage and the impact on individual and organizational psycho-socio-technological situations. In other words, an Internet monitoring/filtering policy should rely on general norms, cultural fits, and the objectives of each organization. Table 2 defines the type of Internet activities and the potential organizational policies.

FUTURE TRENDS

Management must decide on the tradeoffs between employee work/play balance and organizational liability. Some Internet activities can increase an employee's job satisfaction by amplifying his or her intrinsic motivations while reducing stress; however, such behaviors also can lead to higher organizational risks and monitoring costs. The new challenge for Internet-enabled workplaces is to find the right balance between work and play. Future studies need to examine:

- Relationships among the 3Ps of Internet usage and job satisfaction/motivation
- Suitable education and training to enhance work and IT ethics
- Filtering strategies to identify problem employees
- Strategies to reprimand valued employees
- Moderating effects of demographic and cultural differences on the 3Ps of Internet usage
- Possible psychological, social, and technical factors that could lead to the 3Ps of Internet usage

CONCLUSION

The Internet has become one of the most essential technological tools in today's workplace. The broad scope of its usefulness and ease of use makes the Internet beneficial to work and play activities. This article identifies the impact of the 3Ps of Internet usage on individual and organizational psycho-socio-technical factors, and recommends several management strategies to create a balance between work and play. These strategies will help researchers and practitioners better understand the Internet usage patterns of employees and assist them in implementing better Internet usage policies that fit the workplace environment, employees' personal agendas, and management goals.

KEY TERMS

Cyberloafing: Any production-deviant act in which of employees use their organization's Internet access and e-mail accounts during work hours for non-work-related purposes.

Internet Abuse: Any wrongful or improper use of the Internet in the workplace.

Internet Filtering and Monitoring Software: Software tools used to reduce occurrences of Internet abuse by blocking inappropriate Web sites and identifying frequently visited Web sites.

Internet Usage Policy (IUP): An organizational policy given to employees that governs the use of the Internet in a specific workplace. The goals of an IUP, if properly written and implemented, are to help organizations communicate proper Internet usage behaviors lessen employees' perceived expectation of privacy, and reduce costly litigation that may occur from the use of Internet monitoring and filtering software.

Pathological Internet Use: Excessive Internet usage by people as a means of coping with their personal problems or current personal difficulties.

Personal Internet Usage: Voluntary online Web behavior during working time in which employees utilize any of the organizations' resources for activities outside current customary job/work requirements.

Psycho-Socio-Technical: Factors that contribute to the impact of psychological, social, and technological aspects.

Quality of Work Life: Workplace factors that support the well-being and job satisfaction of employees.

Work/Play Balance: The balance between work and play that increases the quality of work life.

Interoperability between Distributed Systems and Web-Services Composition

Christophe Nicolle
Université de Bourgogne, France

INTRODUCTION

An information system is a multi-axis system characterized by a "data" axis, a "behavioral" axis, and a "communication" axis. The data axis corresponds to the structural and schematic technologies used to store data into the system. The behavioral axis represents management and production processes carried out by the system and corresponding technologies. The processes can interact with the data to extract, generate, and store data. The communication axis relates to the network used to exchange data and activate processes between geographically distant users or machines. Nowadays, technologies required for interoperability are extended to deal with the semantic aspect of the information systems. The aim of the semantic axis is to take into account new aspects of the sharing of the data and the processes, such as the understanding of the data and the processes, the access security, and owner rights (OWL Services Coalition, 2006).

Information system interoperation has emerged as a central design issue in Web-based information systems to allow data and service sharing among heterogeneous systems. Data heterogeneity stemming from the diversity of data formats or models used to represent and store information in the Web is a major obstacle to information systems interoperability. These data models range from the structured data models (network, relational, OO) found in traditional databases to flat files and emerging Web oriented semi-structured models. Information system interoperability aims at supporting the amalgamation autonomous heterogeneous systems to create integrated virtual environments or architectures in which information from multiple disparate sources can be accessed in a transparent and efficient manner. As an example of such integrated virtual systems, consider an airline reservation system based on the integration of a group of airlines reservation and ticket sale information systems. The specific airline systems provide various types of fares and

special discount trips. That can be searched and compared to respond to user queries for finding the best available prices for specified flights.

BACKGROUND

Database interoperability issues have been extensively studied in the past. Several approaches, including database translation, distributed systems, federations, language based multidatabase, ontology, and mediation, have been proposed to bridge the semantic gaps among heterogeneous information systems.

The *database translation* approach is a point-to-point solution based on direct data mappings between pairs of information systems. The mappings are used to resolve data discrepancies among the systems (Yan & Ling, 1992). The database translation approach is most appropriate for small-scale information processing environments with a reduced number of participants. The number of translators grows with the square of the number of components in the integrated system. For example, consider two information systems, IS1 and IS2 in the earlier travel agency example. The corresponding translators must be placed between the information systems as shown in Figures 2 and 3. Information in IS1 is represented by vertical lines, while the information in IS2 is shown as horizontal lines.

In the *standardization* approach, the information sources use the same model or standard for data representation and communication. The standard model can be a comprehensive metamodel capable of integrating the requirements of the models of the different components (Atzeni & Torlone, 1997). The use of a standard metamodel reduces the number of translators (this number grows linearly with the number of components) to resolve semantic differences. However, the construction of a comprehensive metamodel is difficult; the manipulation of high-level languages is complex; and there are no unified database interfaces. In our example, the travel agencies must define a common model to export their data. A centralized information system can be built to replace the original information systems (IS1, IS2). The global centralized schema is a combination of the entire data (horizontal and vertical lines) contained in IS1 and IS2.

Federated systems consist of a set of heterogeneous databases in which federation users can access and manipulate data transparently without knowledge of the data location (Sheth & Larson, 1990). Each federation database includes a federated schema that incorporates the data exported by one or more remote information systems. There are two types of federations. A tightly coupled federation is based on a global federated schema that combines all participant schemas. The federated schema is constructed and maintained by the federation administrator. A loosely coupled federation includes one or more federated schemas that are created by users or the local database administrator. The federated schema incorporates a subset of the schema available in the federation. This approach becomes rapidly complex when the number of translators required becomes large. In our example, the existing information systems are completely operational for local users. Only the shared data

Figure 6. Ontology approach

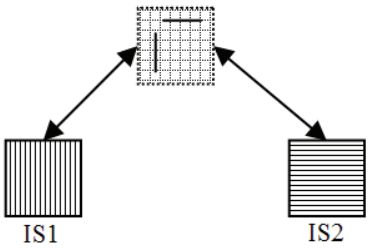

Figure 7. Mediation approach

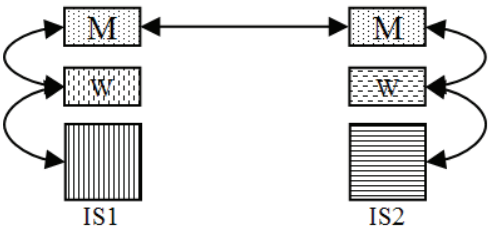

are integrated in the federated schema. The federated system is only made of horizontal and vertical lines that IS1 and IS2 want to exchange.

Language-based *multi-base systems* consist of a loosely connected collection of databases in which a common query language is used to access the contents of the local and remote databases (Keim, Kriegel, & Miethsam, 1994). In this approach, in contrast to the distributed and federated systems, the burden of creating the federated schema is placed on the users, who must discover and understand the semantics of the remote databases. In our example, the various companies have to define a global common language (Q) to query their information systems (IS1, IS2). This solution is well adapted for information systems that are based on the same family of data models and does not require complex query translators.

The *ontology*-based interoperability approach uses ontology to provide an explicit conceptualization of the common domain of a collection of information systems (Benslimane, Leclercq, Savonnet, Terrasse, & Yétongnon, 2000). An ontology defines a common vocabulary that can be used by users from different systems. The construction of an ontology for a domain is a difficult task and often requires merging existing overlapping ontologies. The interoperability solutions based on ontology describe the semantics of information rather than their organization or their format. In our example, the companies have to define ontology to capture the semantics of their domain of activity.

The *mediation* approach is based on two main components: mediator and wrapper. The mediator is used to create and support an integrated view of data over multiple sources. It provides various services to support query processing. For instance, a mediator can cooperate with other mediators to decompose a query into sub queries and generates an execution plan based on the resources of the cooperating sites. The wrapper is used to map the local databases into a common federation data model. The wrapper component provides the basic data access functions (Hammer et al., 1995). In our example, a translator, which acts as a wrapper, is placed between the conceptual representation of the mediator and the local description of each information source.

As new data models are developed for Web-based information systems, there is a need to extend interoperability solutions to take into account requirements and specifications of the new models. For instance, *XML* (XML, 2004) has emerged recently as an important model for describing and sharing Web-based data. This importance stems from two major factors. First, XML is becoming a de facto data standard supported by many software vendors and applications developers. Second, XML is based on a relatively simple structure that is both user- and machine-readable and that can be used by non-expert database administrators. The existing Web technologies are not initially intended to address some of the issues involved in database integration. For instance the Web-browsing paradigm is efficient for data look up in large environments, but is inadequate for database integration support. To use this paradigm to locate and merge data requires costly applications that are often tailored to specific integration needs. New challenges have arisen from the development of Web-based information systems. One of the challenges is the need to develop Web-oriented tools to support information integration and allow access to local as well as remote information sources.

Since 2000, *Web services* have been proposed as a method to address some of the challenges of Web-based integrated systems. A Web service can be viewed as a set of layers contained in a stack. The layers are dynamically defined

Figure 8. WS approach

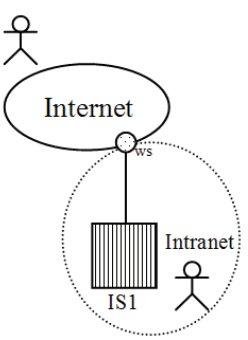

Table 1. Overview of architectures for interoperable information systems

Systems	Advantage	Limits	Tools or methods used	Level
Translation	• Better control of point-to-point translation.	• Requires a large number of translators in open environments. • Adding a new information system requires 2(n-1) translators.	Required n*(n-1) translators	☑ D ☐ B ☐ C
Standardization	• Use of pivot, canonical model or metamodel. • Reduce the number of translators.	• Definition of a common standard accepted by all ISs. • The construction of a comprehensive metamodel is difficult.	Required 2n translators	☑ D ☐ B ☐ C
Federation	• Derived from standardization. • Local IS are autonomous.	• Use of a global, static federated schema. • The construction of an integrated federal schema is difficult. • New addition requires redesign of federated schema.	Required 2n translators	☑ D ☐ B ☐ C
Multi-base	• Used of a single language for many IS.	• The common interoperate language does not export local system semantics. • Users need to discover and understand the semantic of remote IS.	Query Based	☑ D ☑ B ☐ C
Ontology	• Semantic-oriented solution.	• Extensive ontologies are voluminous. • Requires meta-level translation.	Semantic	☑ D ☐ B ☐ C
Mediation	• Combine translation and semantic. • Local ISs are autonomous.	• Difficult to construct automatic mediator process.	Required 2n semantic translators	☑ D ☑ B ☐ C
Web services	• Resolved format level. • Resolved process translation. • All levels of IS are managed. • Normalized solution. • Developed by both industrials and researchers.	• Security mechanism not finalized. • Combination of Web services not resolved.	Protocol SOAP, WSDL, UDDI	☑ D ☑ B ☑ C

Note: D = Data level, B = Behavioral level, C = Communication level.

following user needs and are called through a set of Internet protocols. The protocols are different; those propose for various network architectures. However, in all Web service architecture, a base set of protocols is always used (W3C, 2002). This base set is composed of SOAP (SOAP, 2003), WSDL (WSDL, 2004), and UDDI (UDDI, 2003). They allow the discovery, description and information exchanges between Web services.

SOAP is a mechanism that uses XML for the exchange of structured and typed information between several actors in a decentralized and distributed environment. SOAP does not define the semantics of the application, but provides a mechanism for expressing semantics by proposing a modular template and mechanisms for data coding.

WSDL uses XML syntax to describe the methods and parameters of Web services. These parameters include protocols, servers, ports, input and output messages format, and exceptions format. With WSDL, an application using SOAP can auto-configure the Web services exchanges, masking the majority of the low-level technical details.

UDDI is a Web-based company world directory combining "white pages" (information such as name, address, telephone number, and other contact information of a given business), "yellow pages" (information that categorizes businesses), and "green pages" (technical information about the Web services provided by a given business.). UDDI allows Web service references by automating all search procedures. Table 2 presents the advantages and limits of Web services.

In our example, a set of Web services can be built from each information system independently from the other information systems. The Web services become a standard interface to access the local information system. These Web services can be used by customers and partners via the Internet and by local users via an intranet. This solution is very flexible and reduces the complexity of the heterogeneity problem.

Industrial Development Platforms

To achieve Web service architecture, several industrial tools have been developed. Four main actors in the industrial world share the market. The solutions proposed by Microsoft and SUN are language oriented, while the solutions proposed by IBM and BEA are platform oriented.

Microsoft.NET proposes a software platform on which companies can exchange data and services on the Internet based on an ASP model (Application Provider Service). Most Microsoft products can be extended to use Web services developed with the *.NET*. The philosophy of this solution can be resumed by "one OS, many languages."

The *SUN J2EE* was developed by the Java Community Process. It is a set of services and specification containing JDBC (Java Data Base Connector), JMS (Java Message Services), JSP (Java Server Pages), EJB (Enterprise Java Beans), and so forth. J2EE 1.4 includes Web service specifications using an open source framework called AXIS (used by *IBM WebSphere*). In response to the *Microsoft .NET* solution, SUN proposes *ONE*, which groups the set of SUN Web services propositions. The philosophy of this solution can be resumed by "many OS, one language."

IBM WebSphere is a set of components allowing the creation of interoperable information systems based on Web services. These components include Interchange Server, which allows process integration; MQ Integrator Broker, which allows data integration; MQ Workflow, which allows processes management; and so forth. *IBM WebSphere* uses the SUN JAVA language for the development of its Web services.

The *BEA WebLogic Server* is based on the Java Connectors Architecture. This tool uses the notion of components and connectors that can be integrated between them. The integration of the connectors is carried out by the Application Integration framework and the Adapter Development Kit. To manage the resulting architecture, a Business Process Management is used in coordination with the B2B integration tool. This tool exploits standards such as XML, HTTP, or SSL and semantic solutions such as RosettaNet, cXML, ebXML, or EDI.

Table 1 summarizes the various architectures for the interoperation of information systems. In this table, a brief presentation of the advantages and limits of each approach is given.

FUTURE TRENDS

The next major challenge in the Web service world is to construct adaptive distributed applications that only exist for the time of their use and that are constructed according to the end user's waiting. This is possible by merging researches from the interoperability area and from the adaptive hypermedia systems.

CONCLUSION

For the past 20 years or so, the need to exchange information between various partners pushed researchers to develop architectures for the interoperability of information systems. The proposed architectures have addressed several key interoperability issues, ranging from the resolution of data format heterogeneity using translations-based architecture and the reduction of the number of required translators in standardization-based architecture to the resolution of semantic heterogeneity based on ontology and the resolution of process heterogeneity with mediation-based architecture.

Nowadays, information systems can be integrated or disassociated depending on the market trends of enterprise mergers. The Web service-based architecture allows the development of this type of interoperability by proposing a standard data format with XML, standard communication architecture based on the SOAP protocol, and a standard description of processes using WSDL and UDDI.

Nevertheless, the creation of distributed applications made of combined Web services is not really resolved. Since three years many researcher focus their works in the definition of a global framework to combined Web services. These frameworks are based on semantics characterization of services, orchestration languages, workflows, and so on (Agarwal et al., 2005).

KEY TERMS

eXtensible Makrup Language (XML): A language for creating markup languages. There are two kinds of XML documents: well-formed and valid. The first respects the XML standard for the inclusion and the names of the tags. The second must well-be formed and uses a grammar to define the structure and the types of the data described by the document.

Interoperability: The ability of heterogeneous software and hardware to communicate and share information.

Ontology: An explicit formal specification of how to represent the objects, concepts, and entities existing in some area of interest and the relationships among them.

Simple Object Access Protocol (SOAP): An XML-based message protocol used to encode information in Web service requests and response messages before sending them over a network. SOAP messages are independent of any operating system or protocol and may be transported using Internet protocols (SMTP, MIME, and HTTP).

Universal Description, Discovery, and Integration (UDDI): A Web-based distributed directory for discovery of Web services offered by companies. It is similar to a traditional phone book's yellow and white pages.

Web Service: A software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-readable format (specifically WSDL). Other systems interact with the Web service in a manner prescribed by its description using SOAP-messages, typically conveyed using HTTP with an XML serialization in conjunction with other Web-related standards.

Web Services Language Description (WSDL): An XML-formatted language used to describe a Web service's capabilities as collections of communication endpoints capable of exchanging messages.

Interventions and Solutions in Gender and IT

Amy B. Woszczynski

Janette Moody
The Citadel, USA

INTRODUCTION

The role of women in technology-related fields began with promising contributions from pioneers like Grace Hopper. In recent years, women have moved away from information technology (IT) fields, and the number of women selecting IT majors in universities continues to decline. Likewise, the number of women employed in the IT workforce remains low and declining.

Researchers have recognized the problem and have investigated the many reasons for low participation of women in IT-related fields. Researchers have proposed various interventions to fill the pipeline and retain women in computing.

In this chapter, we provide an overview of the current state of women in IT. We focus on girls and women at various life stages, from early education to the IT workplace. We also provide a discussion of the various methods and appropriate interventions that may be employed to encourage women to become empowered users of technology worldwide.

We use a broad definition of IT, which includes computer science (CS), computer engineering, information systems (IS), information technology (IT), and related professional fields. By examining research from multiple technology-related fields, we gain a clearer picture of the many ways that women may participate in IT.

Recent research on gender and IT has used an interdisciplinary approach, which has greatly expanded our potential for understanding why women decide not to pursue IT-related fields and how to implement appropriate interventions. Researchers from topics as diverse as IS, psychology, social sciences, education, and feminism, have taken a distinctive approach to understanding why women are not better represented in the IT workplace. We believe this broad, interdisciplinary approach has great potential to understand motivations for women pursuing IT-related careers. As Trauth & Niederman (2006, p. 8) said, "…the IT profession is challenged with meeting the demand to enlarge the IT workforce by recruiting and retaining personnel from historically underrepresented groups." This chapter looks at women in IT, shedding light on one historically underrepresented group.

BACKGROUND

Previous literature on women in IT has focused on education and the IT workforce. More recent research pursuits have focused on feminism as a lens through which to view gender and IT. The following sections discuss these areas.

Primary and Secondary Education

To increase the pipeline of women pursuing IT-related majors in universities, we must reach girls at a young age. Many factors, both structural and social, influence career choices of both genders, as seen in Adya & Kaiser's (2005) model. Generally speaking, social influences come from role models and influences by family members, peers, and the media; whereas structural influences are found in the support provided by educational institutions. One ubiquitous and early influence on a young girl's perceptions of computers comes through the mass media and its gendered implications, as reported by Gannon (2007). For example, magazines that appeal to teenage girls, including those with global editions for other cultures, consistently fail to portray women in professional careers using technology (Adya & Kaiser, 2005), but, rather, focus on beauty, fashion, and relationship items. Even as young women expand their readings and increase their exposure to home computing magazines, they will find images of women as novices when dealing with technology, in contrast to technologically competent and powerful males (Johnson & Lynch, 2006).

Although there has been little advice regarding how to counteract the media influences, researchers have made multiple suggestions on how to modify structural influences, one of which is the use of single-sex schools. However, a recent study showed that girls in single-sex schools did no better than their counterparts in coeducation schools in deciding to major in CS (Olivieri, 2005). Olivieri proposes that the lack of computer knowledge and understanding are more common reasons that girls do not choose to major in CS rather than the presence of mostly men in IT courses.

Some researchers have advocated exposing girls to programming as early as possible to increase their comfort and skill in developing simple programs on their own, be-

lieving this exposure will give girls an edge when they take the first programming course in college. However, Katz, Allbritton, Aronis, Wilson & Soffa (2006) note that girls who develop programming skills in high school may do so at the expense of advanced math skills. Clearly, that outcome is not satisfactory since math skills are highly correlated with success in CS.

Post-Secondary Education

Student perceptions of IT are "moderately gendered with a greater emphasis on masculine traits and abilities" (Joshi & Schmidt, 2006, p. 38). Students pursuing university degrees often do not understand IT-related fields and the diversity of career opportunities available. In fact, when college students are asked to draw a computer scientist, they usually draw a geeky, smart person, often with glasses, eating junk food and invariably male (Martin, 2004). Moreover, stereotypes associated with CS tend to be associated with IT in general, at least until undergraduate students are exposed to IT careers in introductory college courses. At that time, students begin to see the diversity in IT and how CS is uniquely different from IS (Joshi & Schmidt, 2006).

Most studies show that there are few significant differences for the variables of gender, persistence in IT-related courses, and achievement (Ilias & Kordaki, 2006). However, Katz, et al. (2006) showed that men who earned a grade below "B" in an early CS course were more likely to persist in CS than were their female counterparts. Perhaps average performing males have higher levels of self-confidence and believe they can succeed in subsequent courses as compared to their female colleagues. Interestingly, Ilias & Kordaki (2006) found that female graduate computer engineering students in Greece completed their studies faster than their male counterparts.

Researchers have recommended that university professors use care when integrating group projects and online learning tools into the classroom. Wolfe & Alexander (2005) showed that when coeducational project teams form, a single male often emerges as the resident computer expert. Then women do not learn how to effectively use technology tools, and men receive great credit for being the technical expert, thus perpetuating the myth of the masculine-dominated IT field. Moreover, when professors use technology tools in male-female classes, they should ensure that online tools allow equal participation by all students (Huynh & Schuldt, 2005).

Research has also shown that another factor affecting the retention of IT students is the type of assignments given in CS classes. For example, female students prefer to work on real-world applications, while males prefer to work on game problems. Yet, current textbooks continue to provide a large percentage of math problems (Wilson, 2006).

The IT Workforce

For those females who successfully persist to complete an IT degree, other challenges await them in the professional world. One of the major issues affecting women's job satisfaction is work-family life balance (Gallivan, 2004). Most women realize that IT careers require them to constantly re-train and learn new technologies. Much of the dissatisfaction with work-family life balance may be explained in how companies approach professional development opportunities. For example, in a company that paid for employees to undertake training on company time, women had lower levels of stress, as compared to women at a company that expected employees to undertake professional development on their own time (Gallivan, 2004). Since women are typically the primary caregivers for children and older parents, the work-family life balance issue may be more important to them than their male counterparts.

Another important issue related to work-family life balance is flexibility in scheduling. Armstrong, Riemenschneider, Allen & Reid (2007) found that women were concerned about the lack of consistency and equality in corporate policies regarding flexible work schedules. As the primary caregivers, women may need more flexible scheduling options than their male counterparts. As Tapia (2006, p. 94) notes, companies should develop organizational policies that are "sensitive, especially with regard to training and professional career development of a diverse IT staff."

Ironically, while medium and large corporations may not have been able to accommodate the work-family life balance requirements of women, women entrepreneurs have excelled in using IT to set up their own companies, thereby customizing how technology can help balance home and work needs. Computers and the Internet have enabled female small business owners to become independent and highly effective in developing new ways to meet market demands (Martin & Wright, 2005). Clearly the passive and novice role of women with respect to computers as portrayed in computer advertisements (Johnson, Rowna & Lynch, 2006) is not indicative of reality.

Global Issues

For issues related to IT education and the IT workforce, research needs to include a global perspective. There may be differences in groups not because of gender, but because of culture (Sagi, Carayannis, Dasgupta, & Thomas, 2004). When attempting to fill the pipeline and ultimately populate the IT workforce with women and other underrepresented groups, careful consideration of cultural and local contexts must be understood for successful development of interventions.

For example, the NetCorps Jordan Project, an IT training project in Jordan, found that culture, context, and gender

all play a significant role in who gets to do what with IT (Wheeler, 2005). These types of considerations may be particularly relevant in Middle Eastern and other countries where women do not typically work outside the home and usually have very traditional roles based on cultural contexts. In this case, offering IT training in primary and secondary schools has to be considered in the context of relevant social norms for the country in question. Much of the research on women in IT, however, has focused on a narrow view that considers mostly United States women. We cannot design interventions to help women break the IT glass ceiling without understanding the global environment.

We may need to develop training programs based on the particular culture and country situation. Understanding issues such as country infrastructure, availability of the Internet, and women's roles in society, is important to make an impact on the number of women who enter the IT workforce. Wheeler (2005) suggests using local people for IT training as a way to overcome cultural/country issues.

Unlike the United States, some countries may not have a gendered impression of IT. For example, women in Malaysia, who often outnumber men in undergraduate and graduate programs in CS, did not perceive IT as a masculine field (Othman & Latih, 2006). Of particular note, the universities studied employed a substantial number of women faculty in CS, with women in prominent positions such as Dean or Department Chair. Clearly, the success of women in IT-related programs in Malaysia demonstrates the importance of female mentors.

Feminist Research on Women in IT

Of interest to researchers is the recent emergence of feminist study as it relates to gender and IT. This research stream shifts the lens through which the topic of women and IT is viewed. As recounted by Trauth & Howcroft (2006), it is important to add the critical research approach to the well-entrenched positivist and interpretive research approaches of the past. Positivist research looks at the gender issue in order to quantify the dichotomy of the genders so that management can harness all of the firm's resources with the goal of "optimizing efficiency and enhancing corporate effectiveness." (p. 274). Interpretive research on gender issues looks at the why of these differences, investigating social influences and national cultures as they relate to gender identities. Such research has been seen as simply documenting the influences rather than confronting them for the purpose of change. In contrast to these two approaches, critical feminist research looks at and challenges the social and political power relations that create gender inequality.

Liberal feminist study looks to IT to put women on equal footing with their male counterparts (Rosser, 2005). Cyberfeminists note women's approximately equal use of the Internet as compared to their male counterparts, which coupled with women's lower interests in and development of hardware, illustrate a female's desire to remain connected (Rosser, 2005). Therefore, women may choose different types of career paths in IT, but they need to know about the diversity of options available to them in IT. As Miller (2005, p. 164) notes, "Integrating feminist models with traditional models may produce a computer science or cognitive science that reflects not only experiences associated with males but all the experiences associated with females." We believe this recent and emerging approach to studying women in IT shows promise for improving the understanding of women's motivations for pursuing IT-related degrees and the design of possible interventions to increase representation of women in IT.

INTERVENTIONS AND SOLUTIONS

One basic impediment to increasing the number of persons pursuing an IT career is the pernicious stereotype of the work itself and those entering it. Thus, we characterize the field of IT itself as having a diversity problem. Many women believe that IT is associated with masculine traits, epitomized by the geeky male without a social life who works 24 hours a day while sitting in front of a computer. That homogenous view of IT does not allow women to see the various career options for IT fields. We must design interventions to encourage girls to enter the IT pipeline, mentor women in universities to persist in IT, and support women as they move through life stages in the IT workplace. We also must consider context, culture, and global issues when trying to better understand women and IT. Specifically, the following interventions can increase the number of women in IT globally:

- Educate people about the nature of IT and the variety of career choices available. Start these programs early, reaching girls in primary and secondary school programs.
- Teach teamwork explicitly in the university classroom environment (Wolfe & Alexander, 2005) to avoid a division of labor that allows men to dominate the technology portion of projects.
- Allow time for professional development to better balance personal and career-related needs of women in IT.
- Encourage the use of flexible scheduling in the IT workplace to balance work-family life.
- Develop organizational policies and professional codes of ethics in organizations that encourage professional career development of a diverse IT staff. Doing so should help prevent the hostile work environments that emerged from the dot-com era when young white men

developed new companies consisting of a homogenous staff (Tapia, 2006).
- Increase the use of mentoring to encourage women to enter and persist in the IT pipeline. These mentoring endeavors should also extend into the IT workplace (Othman & Latih, 2006).
- On a global scale, educate men on how women can use IT to develop culturally appropriate businesses or to manage the home. The use of same-sex trainers may make it easier for women to participate in training programs in other countries.
- Consider the many faces of women in the IT profession (Trauth, 2002) and provide research that avoids characterizing all women as the same. Research needs to be expanded beyond its traditional focus on white, middle class, college educated women who are very different from other women.

FUTURE TRENDS

We see the future of research on women in IT as having an interdisciplinary approach, including perspectives from CS, information sciences, social sciences, women's studies, feminism, psychology, and education. We believe this interdisciplinary approach will allow us to better understand women and IT. We see future research as considering multiple interacting variables in addition to gender. Adya & Kaiser (2005) have provided a comprehensive and testable model of factors that influence female career choices as an excellent starting point for this research. By focusing on the many faces of women at various life stages, we will be able to provide a richer discussion of how to increase the number of women in the pipeline and who persist in IT careers.

CONCLUSION

The decreasing number of girls and women participating in IT education and employment continues to be a concern. Today's global economy presents opportunities and challenges for women in their choices of careers. This chapter has presented highlights of recent research into the causes of this decline and suggested interventions to reverse it. Clearly, the research and interventions must continue to adapt to the changing landscape of the IT field, and cross-cultural knowledge must be shared to provide a complete understanding. The future for women in IT looks brighter, broader, and more global.

KEY TERMS

Computer Science: More traditional IT curriculum whose focus is technical and theoretical concepts rather than applied.

Critical Research: Methodological research perspective that approaches a research question with a stated point of view.

Feminist Research: Large body of research that seeks the "ideal of emancipation" of women (Trauth & Howcroft, 2006, p.273), including their relationship to technology.

Interpretive Research: Methodological research perspective that attempts to describe, from a neutral perspective, the factors observed in exploring the research question under consideration.

Information Systems: Curriculum which integrates technical skills and knowledge with applied business and organizational knowledge.

Information Technology: Term that encompasses a range of professional positions requiring at least a baccalaureate degree in CS, IS, or closely related majors.

Positivist Research: Methodological perspective extensively used by physical scientists and some social scientists that considers the researcher separate from the research object(s); best documented through quantitative analysis.

An Intranet within a Knowledge Management Strategy

Udo Richard Averweg
eThekwini Municipality and University of KwaZulu-Natal, South Africa

INTRODUCTION

An Intranet (or internal Web) is a network designed to serve the internal informational needs of an organisation (e.g., a municipality) using Internet concepts and tools (Averweg, 2007; Turban, McLean & Wetherbe, 2004). The cost efficiency of utilizing Internet technology has opened the door for organizations to use this same technology to share information within the organization (Botha, 2004). Information technology (IT) thus plays an important role in organizations. Given that advances in IT have made it easier to acquire, store and disseminate knowledge than ever before, many organizations are employing IT to facilitate sharing and integration of knowledge (Kankanhalli, Tanudidjaja, Sutanto & Tan, 2003). An Intranet is an application of technology within an organization for the purpose of information dissemination, communication, integration, and collaboration (Telleen, 1997).

Knowledge Management (KM) describes "the primary focus of these efforts has been developing new applications of information technology to support digital capture, storage, retrieval and distribution of an organization's explicitly documented knowledge" (Zack, 1999). In this chapter it is argued that, when aligned, organizational strategy and technical resources (e.g., IT) provide a sound framework to support KM within an organization. However, the question arises as to whether an organization is making the best investment in its IT resources and whether it is managing knowledge in the right way. One technical IT resource in an organization is an Intranet.

Every major organizational process should be regularly evaluated and the evaluation should be *purposeful* and *completed* (Debowski, 2006). One method of evaluation is a survey. Debowski (2006) suggests that survey "evaluations take a number of forms … and may be conducted via telephone, e-mail or mailouts". In this study the evaluation selected by the author is e-mail since the purpose and benefits of an e-mail survey justify the cost.

BACKGROUND

There is a need for KM practices in the workplace to enable managers to promote the sharing of knowledge and allow the organization to acquire and retain intellectual capital. For example, eThekwini Municipality in South Africa is "committed to using Information Technology to make a real difference … municipal decisions have to be based on sound research and information management in order to ensure [service] delivery" (eThekwini Municipality, 2006). KM initiatives in organizations are increasingly becoming important as organizations are making significant IT investments in deploying KM systems (Hahn & Subramani, 2000).

INTRANET AND INTRANET TECHNOLOGY

Tiwana and Ramesh (2001) contend that the Intranet is well suited for use as a strategic tool within the domain of KM owing to its ability to support distribution, connectivity and publishing. According to these authors, the Intranet should be seen as integral to an organization's KM system and should therefore be designed and tailored to enhance an organization's knowledge-sharing activities. This rationale raises the question whether an organization's existing Intranet facilitates knowledge-sharing and KM processes. The exploration of this question creates an opportunity for research within a field of application that seems particularly appealing: a metropolitan municipality – eThekwini Municipality in Durban, South Africa. The appropriate context and appeal arose from the fact that the author is situated within the organization's Information Services Department. Furthermore, given eThekwini Municipality's Integrated Development Plan (IDP), this study was considered pertinent and relevant. In surveying the parameters of the question, the overriding premise was established as follows: If knowledge is used effectively, it may well provide meaningful utility to the organization. Clark (2001) notes that "knowledge management initiatives are unlikely to be successful unless they are integrated with business strategy."

Intranets create a common communications and information-sharing system. Brelade and Harman (2003) suggest Intranets can be used on a "push" basis, where information is presented to employees, and on a "pull" basis, where employees may seek out and retrieve information for themselves. These mechanisms are described more fully as follows:

- "Push" technology is used when it is important that certain material is presented to employees at their

workstation. It ensures that no other function takes place until all the information is correctly accessed; and
- "Pull" technology allows employees to decide when to pull down information from the Intranet that they wish to view. The "views of the end users are more important than in most other studies" (Skok & Kalmanovitch, 2005).

To provide a seamless experience between viewing pages on the Web and viewing information on an Intranet, access is usually via a standard Internet browser. The commonly used Internet browser in eThekwini Municipality is Microsoft Internet Explorer.

WHAT IS KNOWLEDGE?

The question of defining knowledge has occupied the minds of philosophers since the classical Greek era and has led to many epistemological debates (Alavi & Leidner, 2001). Given the differing views of knowledge (e.g., a state of mind, an object, a process, a condition of having access to information or a capability), Carlsson, El Sawy, Eriksson, and Raven (1998) suggest that this leads to different perceptions of KM.

Many current theories and practices indicate that knowledge (and the management thereof) may prove useful if the scope and utility of knowledge is aligned with an organization's strategy. For this reason KM must have a business focus. It is therefore critical that KM aligns with the organization's business strategy and that it is structured in such a way that it articulates with the organization's purpose and goals. It may be further argued that knowledge should be viewed as a resource in the business, and that it should therefore tie in with the resource-based approach to strategy.

Although this chapter seeks to review the role of the Intranet and its contribution to a KM strategy, it also proposes that KM should be set on a broader scale than merely IT, that is, it is argued that the management of knowledge should go beyond a narrow technical focus and encompass other less tangible themes within an organization. Zack (1999) clarifies the intangible "as the knowledge existing within people's heads, augmented or shared via interaction and social relationships". This chapter draws together the technology, the notion of shared interaction and the creation of an opportunity for knowledge transfer.

Knowledge Management (KM)

Precisely what is KM? Kwalek (2004) suggests that "the literature on knowledge management is disjointed and disconnected". Pfeffer and Sutton (2000) indicate that KM "tends to treat knowledge as a tangible thing, as a stock or quantity, and therefore separates knowledge as some *thing* from the use of that thing". While there are different views on what KM is, Nomura (2002) suggests that the "objective of KM is to directly enhance corporate value according to business strategy." From a review of the literature and for the purposes of this chapter, the following definition of KM will be adopted: "KM is the organizational process for acquiring, organising and communicating both tacit and explicit knowledge (so that people may use it to be more effective)" (Gray, 2006). The argument for this selection is based on the recognition that the combined knowledge and expertise of people within an organization is what makes an organization unique.

The basic role of technology in KM can be briefly summarised in functional terms into the areas of:

- Facilitating communication;
- Enabling collaboration
- Collecting information;
- Storing information;
- Analysing information;
- Disseminating information; and
- Updating information (Brelade & Harman, 2003).

KM is not a centralized database that contains all the information known by an organization's workers. It is the idea of gaining business insights from a variety of sources – including databases, Websites, employees, and business partners – and cultivating that information wherever it resides into corporate value. Business insight emanates from capturing information and giving it greater meaning via its relationship to other information in the organization. It should be stated that KM is not about making plug-and-play workers dispensable because all they know is recorded for the next person who fills their shoes – it is about delivering information to knowledge workers, business processes and technology to make organizations and people successful and effective. The Intranet, the in-house version of the World Wide Web (the Web) browser based on Internet technology, creates a common corporate communications and information-sharing system (Brelade & Harman, 2003).

eThekwini Municipality in South Africa

eThekwini Municipality comprises six clusters/service units (Office of the City Manager, Treasury, Governance, Sustainable Development and City Enterprises, Corporate and Human Resources and Health, Safety and Social Services) and employs approximately 20,000 employees. The Information Services Department is located in the Office of the City Manager. eThekwini Municipality has some 6,000 networked desktops (personal computers, thin clients and laptops) and electronic communication (i.e., e-mail) takes place via Novell's GroupWise (Client version 6.5). A total of

6 654 GroupWise accounts exist in eThekwini Municipality. There are approximately 1,500 Internet accounts utilising either Microsoft Internet Explorer or Netscape Navigator Web browsers.

Research Methodology and Survey

Since research is varied, disparate approaches are taken. For this research, a mixed-methods research approach is adopted:

- Knowledge claim – pragmatism;
- Strategy of inquiry – transformative procedures; and
- Methods of data collection and analysis – secondary data and analysis are used. The data for eThekwini Municipality's Intranet have recently been collected by an independent research company, Ask Africa. The rationale for using secondary data is that (1) they are considered relevant to the study; and (2) there are savings of time and money by using available data rather than collecting original data.

On June 13, 2006, eThekwini Municipality employees were invited – by e-mail invitation from the Communications Department – to participate in an online Intranet survey. The aim of the survey was "to identify areas where the Intranet may need improvements" and "to allow positive user experiences to be obtained". eThekwini Municipality employees who expressed an interest in participating in this survey received an online questionnaire, which was e-mailed to them by Ask Africa's research partner, MicroIces. Data collation was handled by Ask Africa. The data used in this research are sourced from the eThekwini Municipality Intranet Research Report (July 2006), which was compiled by Ask Africa. The reported findings inform this study.

From the 150 e-mails sent to eThekwini Municipality employees, 39 responses were received. This represents 26 per cent of the total number of employees who originally expressed interest in participating in the survey. Debowski (2006) suggests that response "rates as low as 20% may still provide some sense of the issues". The author did not participate in this online survey.

Extracted from the eThekwini Municipality Intranet Research Report (Ask Africa, 2006), the results are now presented. The ranking in ascending order of Agree/Strongly Agree responses to benefits the Intranet holds is reflected in Table 1.

From Table 1, the greatest perceived benefit that the Intranet holds for employees using it is as a platform to share and access interdepartmental (i.e., clusters/service units) information. The second highest reported benefit was as "an effective way to conduct organizational interaction". Van der Walt, van Brakel, and Kok (2004) emphasized the importance of evaluating an organization's Intranet to ascertain its contribution to potential knowledge-sharing in an organization. The third highest reported benefit was as the quickest "focal point to disseminate and get organizational communication". The lowest reported benefit was for employees to use the Intranet for their daily work functions.

The ranking in ascending order of Agree/Strongly Agree responses to the design of the Intranet is reflected in Table 2.

From Table 2, it appears that most respondents surveyed (86 per cent) were satisfied with the text, font and colours used, but there was some disagreement on the images, pictures and overall design of the Intranet Website. For respondents surveyed, this suggests that images and pictures used on the Website require improvement for eThekwini Municipality employees to obtain user satisfaction (Ask Africa, 2006).

Table 1. Ranking in ascending order of Agree/Strongly Agree responses to benefits the Intranet holds

	Percentage (%) of Respondents (N=19)		
Statement	**Agree/ Strongly Agree**	**Neutral**	**Disagree**
Useful platform to share and access inter-departmental information	87%	9%	4%
The Intranet is an effective way to conduct organizational interaction	81%	14%	5%
Quickest focal point to disseminate and get organizational communication	77%	14%	9%
Enhances departmental communication 7	2% 5	%	24%
Helps the organization improve its service to customers	65%	15%	20%
Helps with productivity	63%	14%	23%
Using the Intranet is necessary for employees to perform daily work functions	50%	5%	45%

(Adapted from eThekwini Municipality Intranet Research Report compiled by Ask Africa (2006: 26))

Table 2. Ranking in ascending order of Agree/Strongly Agree responses to design of Intranet

Statement	Percentage (%) of Respondents (N=21)		
	Agree/ Strongly Agree	Neutral	Disagree
I am happy with the text and font used on the site	86%	5%	10%
I am happy with the colours used on the site	81%	10%	10%
I am happy with the layout and organization of the site	67%	19%	14%
I am happy with the images and pictures used on the site	62%	19%	19%
Overall I am happy with the design of the Intranet Website	57%	33%	10%

(Adapted from eThekwini Municipality Intranet Research Report compiled by Ask Africa (2006: 34))

Table 3. Ranking in ascending order of Agree/Strongly Agree responses to the usability of the Intranet

Statement	Percentage (%) of Respondents (N=20)		
	Agree/ Strongly Agree	Neutral	Disagree
The drop down menus are easy to use	70%	20%	10%
Overall I am happy with the functionality/usability of the site	67%	10%	24%
I am happy with the site labeling	62%	19%	19%
I am happy with the speed of the site	62%	14%	24%
I am able to navigate quickly and easily	50%	20%	30%
The site is self-explanatory – it indicates where I need to go to find the information I am looking for	43%	29%	29%

(Adapted from eThekwini Municipality Intranet Research Report compiled by Ask Africa (2006: 39))

The ranking in ascending order of Agree/Strongly Agree responses to the usability of the Intranet is reflected in Table 3.

From Table 3, it appears that navigation improvements are required. Furthermore, while respondents surveyed agreed that they are able to navigate the Intranet Website quickly and easily, they felt that there was no clear direction provided. This suggests the navigation needs to be improved for beginner users so that they have a better indication of where to go to find the information they are seeking (Ask Africa, 2006).

The ranking in ascending order of Agree/Strongly Agree responses to the content of the Intranet is reflected in Table 4.

From Table 4, it appears that respondents surveyed felt that the information on the Intranet is relevant and reliable. However, improvements in the updating of information and the quality of information-seeking are required. This suggests that while the information on the Intranet Website is generally seen to be reliable, the regular updating of content and finding information that an employee is looking for needs to be improved (Ask Africa, 2006). An important use of most

Table 4. Ranking in ascending order of Agree/Strongly Agree responses to the content of the Intranet

Statement	Percentage (%) of Respondents (N=18)		
	Agree/ Strongly Agree	Neutral	Disagree
The information and content on the Website is relevant	63%	11%	26%
The information on the Website is reliable	61%	17%	22%
Overall I am happy with the quality of content on the Website	57%	14%	29%
I am happy with the quality of the search process	57%	14%	33%
The content on the site is regularly updated	53%	11%	38%
There is a high likelihood of finding information I am looking for even though I do not know where to find it	52%	10%	38%

(Adapted from eThekwini Municipality Intranet Research Report compiled by Ask Africa (2006: 44))

Intranets is to find documents that "point" to employees who have knowledge and expertise. Wells, Sheina, and Harris-Jones (2000) indicate that less than 5 per cent of employee knowledge is actually captured and accessible across the organization. Intranet satisfaction is directly influenced by having the right content, features, and design factors (Kaplan, 2001).

From the survey results, there appear to be areas for improvement in the Intranet design, usability and content areas. The author's evaluation therefore appears to be both purposeful and completed.

FUTURE TRENDS

An Intranet may be classified as a KM application since it is capable of distributing knowledge. An Intranet is seen as a tool for the more efficient sharing and creation of knowledge within organizations, using both "push" and "pull" technologies. However, in the case of eThekwini Municipality's Intranet, it appears that far greater use is made of the "pull" technology (as opposed to "push" technology). This current trend will need to be addressed so that the "pull" technology is also facilitated.

The reported results tend to suggest that there is limited knowledge-sharing and/or KM in eThekwini Municipality. The trend will also need to be addressed so that "knowledge management [is] a planned structured approach to manage the creation, sharing, harvesting and leveraging of knowledge as an organizational asset … [and] should be in line with its business strategy" (Du Plessis & Boon, 2004).

CONCLUSION

Organizations generally make use of one of a variety of methodologies, or a combination of these, for strategy formulation when planning their longer-term interaction with the environment. Knowledge-based strategy places the organization's primary intangible asset, namely the competence of its people, at the centre. Given eThekwini Municipality's IDP and its overall intent to respond to social and economic needs of citizenry, the value of knowledge to organizational effectiveness is crucial at this point. IT, with the enabling role of Intranet technology, should be seen as significantly important to enhance the management of knowledge within eThekwini Municipality. By being aligned to the organizational strategy, the Intranet will provide a sound framework to support KM within the organization and become a strategic tool within a KM strategy.

KEY TERMS

Information Systems (IS): A combination of technology, people and processes to capture, transmit, store, retrieve, manipulate and display information.

Information Technology (IT): The technology component of an IS.

Intranet: A network designed to serve the internal informational needs of an organisation using Internet concepts and tools.

Knowledge: The understanding, awareness or familiarity acquired through education or experience.

Knowledge Management (KM): KM is the organisational process for acquiring, organising and communicating both tacit and explicit knowledge.

Pull technology: An IT network communication where the initial request for data originates from the client and then is responded to by the server.

Push technology: An IT network communication where the request for data originates with the server.

World Wide Web (the Web): An information space consisting of hyperlinked documents published on the Internet.

Introduction to Basic Concepts and Considerations of Wireless Networking Security

Carlos F. Lerma
Universidad Autónoma de Tamaulipas, Mexico

Armando Vega
Universidad Autónoma de Tamaulipas, Mexico

INTRODUCTION

Local networks have been, from the beginning, a controversial topic. The organizations that have implemented these types of networks have shown their concern about their levels of security. Ever since the discovery of vulnerabilities among first-generation wireless networks (Borisov, Goldberg, & Wagner, 2001), analysts and security companies have tried to understand and mitigate those risks. Some of those efforts have contributed towards the study of wireless security. Other efforts have failed, presented a different group of vulnerabilities, or require expensive proprietary software and hardware. Finally, other efforts try to mitigate the problem piling up a complex group of security technologies, like virtual private networks.

Despite the benefits they bring, a great number of concerns related to security have limited the massive adoption of wireless networks, particularly in sectors that are highly aware of the existing security risks such as the financial and government sectors. Even though there are a significant number of risks inherent to the mass transmission of data to any individual within the boundaries of a wireless network, a good amount of these are installed without any security measure at all. However, the majority of businesses that have implemented some sort of wireless security measures have done so in the most rudimentary way, bringing a false sense of security to users.

When the first IEEE 802.11 wireless standards were in the phase of development, security was not as important as it is today. The level of complexity of network threats was much lower and the adoption of wireless technologies was still in an introductory phase. It was under these circumstances that the first standard for wireless network security, known as wired equivalent privacy (WEP), was originated. WEP underestimated the necessary means to turn air security into an element equivalent to the security provided by a cable. In contrast, the security methods of modern wireless networks are designed to work in hostile environments where there is a lack of well-defined physical network perimeters.

BACKGROUND

Every network environment is susceptible to risks, and wireless networks are not the exception. According to a survey by the Federal Bureau of Investigation of the United States, the only category of threats that shows a significant increase in number of attacks and/or possibility of misuse in the last few years is "wireless network abuse." The broadcasting nature of these networks has turned them into perfect targets for nonauthorized users.

According to Arbaugh (2001), these problems are exacerbated by the myriad of free security-threatening tools widely available for download on the Internet and because of the inherent vulnerabilities of wireless networks themselves. One of the most exploited vulnerabilities is the WEP protocol (Fluhrer, Mantin, & Shamir, 2002; Peikari & Forgie, 2002), which is such a severe problem that many companies have decided to abandon the wireless business.

On the other hand, a good amount of the deployment strategies of wireless networks lack a cohesive and effective integration with the authentication services infrastructure of the organization in which they are implemented (Arbaugh & Shankar, 2002). This common mistake is easy to mitigate, and its correction is evident almost immediately by closing the gap between the number of authorized and unauthorized users. This is evident because authorized users are checked against a database with secure access methods inside the wired network.

In other cases, security problems go beyond the merely technological element (National Institute of Standards and Technology, 2007). Commonly, the lack of planning of the wireless network is a decisive coverage and placement factor. Other elements, such as security policies, access procedures, internal policies governing the use of and access to resources and guidelines governing confidentiality and protection of information serve as a complementary regulatory framework that provides support to the technological infrastructure, establishing limitations related to the way in which information is and/or should be used.

TECHNOLOGICAL ANALYSIS

Wireless networks have experienced a rising trajectory in the last 8 years. Basically, access to wireless technology (access points, wireless network cards) has become easier due to relatively low equipment prices and easiness to set up equipment. Many pieces of network equipment are advertised under the commercial designation SOHO (small office home office), whose installation in inherently simple to carry out due to the fact that the people who purchase those pieces of equipment are relatively new to network equipment installations or users with basic computer skills.

Current advantages of implementing a wireless network include (Planet3 Wireless, 2005):

- Availability: Members of an organization can have access to information resources anywhere without depending on a wired infrastructure.
- Mobility: A user can go from one place to another inside a building or between buildings without leaving the network's coverage area while still having access to network resources. This characteristic trait poses one of the main advantages and threats to wireless networks.
- Productivity: Due to the fact that wireless networks can provide a connection virtually anywhere, this feature enables users to keep working no matter where they are. This feature gains a significant value when wireless networks are implemented in the business sector, due to factors like access to business information and management information systems.
- Ease of installation: A wireless network can be deployed in a matter of minute,s and can be transferred from one place to another as fast as it was set up in the first place. Basically, this advantage tends to be more noticeable in networks with a steady level of permanence and low level of complexity. However, ease of installation does not mean that important security and planning aspects should be omitted, such as carrying out a site survey, and the configuration of security protocols and authentication methods.
- Scalability: Wireless networks can rapidly adapt to an increasing population of users. To achieve this, a network administrator needs less pieces of wireless equipment than wired equipment. Scalability should also be determined before installation of a network, due to the fact that an administrator needs to know an estimated number of the users that will be connecting to the network and the number of pieces of equipment that will support those users, as well as the applications that will be supported by the network.
- Cost: Even though wireless network equipment is more expensive than their wired counterparts, their prices are still reasonable for the home user. Enterprise-scale equipment tends to be extremely expensive, but it comes preloaded with advanced security and management features, is built to be used outdoors, and can support a bigger amount of users.

On the other hand, wireless networks have clear disadvantages that are a result of their own nature (LaRocca & LaRocca, 2002). Generally, they can be:

- Security: Aided with proper equipment and pertinent knowledge concerning the basic operation of a wireless network, any person can capture information that travels through the air, product of a wireless transmission. For an intruder, it is only needed to position oneself within a relative close distance to the network from which one can have an acceptable level of signal reception and possess the tools needed to perform the decryption of the information.
- Distance: The coverage area of wireless networks used today is considered in tens of meters (taking into account that most networks used in infrastructure mode are part of the 802.11 standard). It is necessary to acquire and install accessories and equipment, such as antennas and repeaters, in order to further enhance the coverage area of the network.
- Reliability: Wireless technology is subject to the effects of interference, the environment, and terrain features. Most of the times, an administrator can deal with these phenomena, but it is an undeniable fact that their effects are strongly felt, producing unpleasant results and undermining network performance (in different degrees).
- Speed: Wireless network speed is low by nature, and it is not comparable to those of wired networks, which offer speeds and transfer rates much more advanced than wireless networks. Even though special components can be used to increase the speed and performance of a wireless network, this cannot be translated to higher transfer rates and increased speed, which is still a major disadvantage.

By analyzing disadvantages, it can be concluded that security is, without a doubt, the most important of them all when it comes to wireless networks, and is the one factor that originates the higher amount of challenges. Even though reliability is an area where antenna design and other important areas are put to better use, and are of extreme importance to the development of new generations of networks, security takes a more dynamic posture. A solution has not fully matured when there is a new problem to solve and a new countermeasure to develop. Wireless security is seen as a modular problem, that is, or can be solved by integrating several technologies.

This "integral solution" must be designed according to the security needs of the organization and the information and services that it handles or needs.

The search for solid security mechanisms that allow networks to be deployed in a safe manner is, and will always be, a priority, both for the industry and for researchers around the globe. Currently, the emphasis of wireless security has focused its efforts towards a framework that includes the following key areas (Federal Trade Commission, 2002):

1. General security: The wireless world differs greatly from its wired counterpart. Because wireless devices tend to be shared, and interact with exterior networks and users, passwords have ceased to be an effective method of authentication because of the fact that they are constantly in contact with dangerous and insecure resources. In this sense, wireless networks can benefit from a bipartite method of authentication in which the user makes use of an element he/she has and other element he/she knows. In this case, a USB device, an authentication token or its own fingerprint (read through a biometric device) are elements he/she possesses, while a password is an element he/she knows.
2. Encryption: Wireless networks must be able to support encryption schemes that provide that service in a solid manner, and along the entire communication path, in order to get to its destination. Previously, solutions such as WEP and WPA (Wi-Fi protected access) were proposed to alleviate the security problems that plagued wireless networks, but eventually, they turned out to be vulnerable when the attackers analyzed their mechanisms and published tools that crippled them (Peikari & Forgie, 2002). Currently, WPA2 seems like a viable solution, but it is evident that, with time, a new solution (or solutions) will be necessary (Mehta, 2001).
3. Digital signatures: From the beginning, wireless networks have been (and are already still, up to a certain extent) vulnerable to attacks that replicate or insert forged and/or altered packets in transmission sessions in order to lure users into traps to obtain their confidential information. It is evident that schemes like public key infrastructure (PKI), where integrity and reliability of data can be assured, have been deemed necessary to avoid "man-in-the-middle" type of attacks, where a third party hijacks a communication session and obtains data packets that traverse that communication's channel, forging or altering the information contained in the packets and then fooling the user who was intended to be the final destination of those packets.
4. Interoperability: Due to the fact that options like the exclusive use of WEP or WPA leaves important security holes open to a possible attack, it is evident that security solutions are built by integrating many products (which use, in most cases, proprietary technologies) that must interact with one another to alleviate the different and possible security threats that a network might encounter (Bhagyavati Summers, & DeJoie, 2004). Frequently, there is a possibility that, due to the proprietary nature of the aforementioned technologies, they might not be able to interact one with another in a correct way. This fact has focused the efforts of regulatory bodies and standards all over the world in order to guide the wireless networking industry towards the development of applications and solutions that can operate between them in a native way, and in any IP network platform.

Technological Integration

The implementation of a secure wireless network is founded on the integration of elements that can be classified inside two groups:

- Native 802.11 Security Solutions: Comprised by those solutions that conform, in a natural way, the standards established by IEEE's 802.11 workgroup: WEP, TKIP, 802.1x/EAP, WPA and WPA2 (Giller & Bulliard, 2004).
- Independent 802.11 Solutions: Comprised by all those technologies that are implemented "on top" of natural 802.11 solutions. Generally, they are proprietary, third-party solutions with different degrees of interoperability: VPNs, LDAP-based directory services (Microsoft, 2007), captive portals, physical configurations, and physical network design considerations (site surveys).

Once again, final wireless network implementations depend heavily on the privacy and confidentiality requirements of the organization, product of a previous network analysis. The possibility of mitigating multiple problems with a single tool is very distant from becoming a reality.

FUTURE TRENDS

Even though the future trends, in regards of security for the next generation of wireless networks, is very promising, companies need to continue the implementation of security countermeasures in order to guarantee the efficacy of their security programs aimed at wireless networks. Future work should be aimed towards standardization of security solutions in such a way that, any security solution can operate in an integral way with other solutions without altering the basic essence of any standard or protocol.

The basic security component inside SOHO equipment is also a security niche that should be addressed in the future. Since most security breaches happen in SOHO networks, manufacturers should aim their efforts into security solutions that are easy to implement, and whose complexity level is low. A solution to this issue is an area where the industry should focus its research, since it represents a good market opportunity and eventual future strategic advantage, as we see that enterprise equipment is hard to provide with quite hardened security countermeasures. However, since the industry is shifting towards more affordable types of equipment, this should be a priority in terms of security design and features in the near future.

CONCLUSION

The security-related concerns that have plagued wireless networks in both the enterprise and SOHO sectors finally seem to dissipate with security schemes that range from encryption methods using static keys, all the way through several improvements in dynamic encryption keys, and authentication solutions carried out in free software platforms (open source) and extensive solutions like VPN or captive portals. The security capabilities and levels of wireless networks are finally matching those provided by wired networks, due to the adoption and use of current available standards, certifying organisms like IEEE and the Wi-Fi Alliance, and integrated solutions, whether they might be open or proprietary, providing access control and encryption of the information that travels through the air.

Even though the first versions of wireless networks were not designed with security in mind (IEEE, 1999), the amount of security methods and solutions is growing extremely fast. With newly introduced solutions like 802.1x and 802.11i, there are now readily available and secure solutions in terms of encryption and authentication standards. These security features must be implemented in order to assure the integrity of the information inside a wireless network. With careful planning and analysis phases carried out well in advance of its implementation, a wireless network can be as secure as one of its wired alternatives. It is here where the human factor is as important as the technological.

KEY TERMS

802.11: Set of standards, established by the IEEE (Institute of Electrical and Electronics Engineers, a worldwide standardization body), that govern the functioning and design of wireless networks communicating in the 5GHz and 2.4 GHz unlicensed bands. It has evolved into many other specifications, but 802.11 still dictates the basic standards for what should be considered as a wireless network.

Access Point: A network device that serves as a central point of connection for devices with wireless networking capabilities. Similar to a network hub, it performs similar functions, being the difference that a wired hub uses a medium access control based in collision detection and an access point uses a collision avoidance method.

LDAP: Acronym for lightweight directory access protocol. A protocol used to send queries to user databases organized through directory services. Wireless networks use this protocol to communicate with servers housing user databases in a secure way, thus providing a consistent method of user authentication on wireless networks whose access is restricted.

SOHO: Acronym for small office home office. Types of network equipment intended for home use or offices with small amounts of employees. Generally, they offer most of the features and functionalities found in enterprise-class hardware, but are limited in certain aspects, and their price is much cheaper and competitive.

VPN: Acronym for virtual private network. Secure communication channels established from one network to another or inside one network. VPNs provide dedicated communications channels that offer higher levels of security and encryption. They can be established using a VPN server (software) or through a VPN concentrator (hardware). They assure that communications are somewhat free from eavesdropping.

WEP: Acronym for wired equivalent privacy. An encryption algorithm intended to secure the first generation of wireless networks. It uses a 40-bit key alongside a 24-bit initialization vector, originating an RC4 key. It proved to be useless in 2001, when it was cracked, and the cracking tools were made available on the Internet.

WPA: Acronym for Wi-Fi protected access. An encryption algorithm created by the Wi-Fi Alliance. Like WEP, it uses an RC4 encryption key, but WPA's key is longer: a 128-bit key alongside a 48-bit initialization vector. WPA also comes in two variations: enterprise and personal. The difference relies on the fact that enterprise is a method that relies in an 802.1x server to provide authentication services, while personal relies on a preshared key scheme.

WPA2: Acronym for Wi-Fi orotected access 2. It is also known as 802.11i. It is basically the same as the WPA standard, improved with a new algorithm to distribute encryption keys.

Intrusion Detection Based on P2P Software

Zoltán Czirkos
Budapest University of Technology and Economics, Hungary

Gábor Hosszú
Budapest University of Technology and Economics, Hungary

INTRODUCTION

The importance of the network security problems come into prominence by the growth of the Internet. The article presents a new kind of software, which uses just the network, to protect the hosts and increase their security. The hosts running this software create an *Application Level Network* (ALN) over the Internet. Nodes connected to this ALN check their operating systems' log files to detect intrusion attempts. Information collected is then shared over the ALN to increase the security of all peers, which can then make the necessary protection steps by oneself.

The developed software is named *Komondor* (Czirkos, 2006), which is a famous Hungarian guard dog. The novelty of the system Komondor is that Komondor nodes of each host create a *Peer-To-Peer (P2P) overlay network*. Organization is automatic; it requires no user interaction. This network model ensures stability, which is important for quick and reliable communication between nodes. By this build-up, the system remains useful over the unstable network.

The use of the peer-to-peer network model for this purpose is new in principle. Test results proved its usefulness. With its aid, real intrusion attempts were blocked. This software is intended to mask the security holes of services provided by the host, not to repair them. For this it does not need to know about the security hole in detail. It can provide some protection in advance, but only if somewhere on the network an intrusion was already detected. It does not fix the security hole, but keeps the particular attacker from further activity.

BACKGROUND

The P2P networks comprise hundreds of thousands or millions of peers. That is why they are characterized by large dynamism, with a continuous process of nodes joining or leaving the P2P overlay.

Such large scale dynamism introduces several development problems. Neither a central authority nor a fixed communication topology can be employed to control the different components. Instead, a dynamically changing overlay topology is maintained and the maintenance is completely decentralized. The overlay is defined by links among nodes that are created and deleted based on the requirements of the particular application (Montresor, 2004).

Variability of P2P networks can be leveraged by implementing virtual networks based on super-peers. In the meantime, widely-used file-sharing systems such as Kazaa have applied the use of super-peers to enhance their search performance. In the field of the super-peer networks, the main focus is on centralized design of such networks (Yang & Garcia-Molina, 2003).

Until recently, most of the P2P applications deployed on the Internet had not any sophisticated mechanism for enforcing a particular overlay topology. The consequence of this was the adoption of simple communication models, such as flooding. Currently the situation has changed; many research projects have proved the importance of selecting, and proposed constructions and maintenance of appropriate topologies for robust P2P systems (Rowstron, & Druschel, 2001). Even popular file-sharing applications have started to consider more structured topologies (Kan, 2001). By introducing the concept of super-peer, their topologies are now organized through a two-level hierarchy. Nodes that are faster and/or more reliable than the ordinary nodes take on server-like responsibilities and provide services to a set of clients. A good example for this is the case of file sharing, where a super-peer builds an index of the files shared by its clients and participates in the search protocol on their behalf, leveraging them from participating in complicated protocols and reducing the overall traffic by forwarding queries only among super-peers.

The super-peer concept allows decentralized networks to run more efficiently by exploiting heterogeneity and distributing load to machines that can handle the burden. Also, it does not inherit the flaws of the client-server model, as it allows multiple, separate points of failure, increasing the robustness of the P2P network.

The applicability of the super-peer model is not limited to file-sharing, that is, it is possible to envisage distributed game systems (Smed, Kaukoranta, T., & Hakonen, 2003). In this case, multiple locations of a simulated virtual environment can be maintained by a distributed set of super-peers that control the virtual environment on behalf of their clients. Grid management systems and distributed storages are other

good possibilities for the usages of this architecture (Foster & Kesselman, 1999).

The construction and maintenance of a super-peer topology is, however, a difficult task. The extreme scale and dynamism call for robust and efficient protocols, capable to self-organize and self-repair a super-peer overlay in spite of both voluntary and unexpected events like joins, leaves and crashes. Another problem arises that in a P2P gaming, nodes must be clients of a single super-peer, and the sub-topology of super-peers must reflect the characteristics of the particular virtual environment that is simulated.

In order to avoid some problems that arise according to the super-peer model, Montresor (2004) proposed an enhanced protocol for the construction and management of super-peer-based overlay topologies. This protocol is based on the so-called gossip paradigm (Eugster, Guerraoui, Kermarrec, & Massoulié, 2003). In this case, every node periodically initiates an information exchange with a peer node selected randomly. The nodes involved in the exchange send each other information about their current status; whether they are super-peers or simply clients, the number of clients they are serving, and so on. Based on this information, role changes and/or client transfers can occur. A client may decide to become a super-peer and take responsibility for some of the clients of the other node to alleviate its load. Alternatively, a super-peer may decide to move all its clients to the other node and become a client by itself, to reduce the number of super-peers and, thus, the traffic generated by communication between super-peers.

THE SECURITY PROBLEMS OF P2P COMMUNICATION

The popular software, the *Instant Messaging* (IM) is the fastest increasing communications medium with an estimated 300 million consumer and enterprise IM users in 2005 (IMlogic, 2005). Global services such as AOL Instant Messenger, MSN Messenger, and Yahoo! Messenger each report over 1 billion messages sent per day, and IM traffic is expected to exceed email traffic by the end of 2006. As one of the most successful and widely-deployed applications on the Internet, IM has increasingly become the target for attackers to distribute IM-borne viruses, spyware software, worms, *SPam over IM* (SPIM), and malware attacks. Though widespread in adoption, IM is usually not protected and in user and corporate environments, leaving it vulnerable to attacks and exploits. These threats have grown exponentially over the past few years, increasing the need for real-time threat response for IM and P2P systems. As use of instant messaging clients and P2P networking increases, new viruses and other malware software are increasingly applying these mechanisms to disseminate.

Recently, the IM worms are more and more sophisticated and cross over from one network to another. In 2005, worms have been detected that are propagating over the Microsoft MSN public network and are crossing over into internal enterprise IM deployments, including Microsoft Live Communications Server environments (IMlogic, 2005). The growing prevalence of public to private network hopping by IM malware and worms will most likely increase in the near future, especially as IT organizations leverage public IM or connectivity to the public IM networks. The threats of multilingual worms are also growing, indicating a large sophistication for disseminating IM worms across geographic areas.

In order to monitor the network and to recognize the activity of the malware applications, a lot of different monitoring systems have been developed. One of them is the Netmon, which is a comprehensive network monitoring appliance that gives a complete perspective of the user's network (Netmon, 2005). Using Netmon, many kinds of malware can be identified, including worms, browser toolbars and plug-ins, and so forth. The Netmon can identify the activity of other types of network software, for example, P2P file sharing applications like KaZaA, E-Donkey and BitTorrent.

The Netmon apply the *Simple Network Management Protocol* (SNMP) to monitor the usage of many types of core network devices, including routers, gateway, firewalls, and switches. The implementation of the SNMP has two parts: one is the SNMP manager, and the other is the SNMP agent. While the SNMP manager is used by the network administrator, the SNMP agents are resided in the network devices to be monitored. The main task of the SNMP is extracting information from the *Management Information Bases* (MIB), which are maintained by the SNMP agents.

SNMP can also be applied for monitoring a lot of other kinds of devices, including network printers, hubs, and more. From the security viewpoint, the Netmon has an important feature, namely, its flexible port scanning tools. It can determine which ports are open for requests. The user is able to compare earlier scan results with the latest ones to spot newly opened ports.

TYPES OF PROTECTION

Security of a system can be increased with strict rules of usage. Applications doing this locally are Bastille-Linux (2006) and SeLinux (2006). These applications provide security mechanisms built in to the operating system or the kernel. Network security is also enhanced with these, but that is not the main purpose of them.

Protection of Host

No system can be completely secure. The literature defines the term of a properly skilled attacker (Toxen, 2001), a theoretical person, who by his infinite skills, can explore any existent security hole. We know that a completely secure system cannot be built. Every hidden bug of a system can be found, either systematically, or accidentally.

An average user has not much to do about the security of his system. Storing sensitive and valuable data (for example a bank company) demands dealing with security problems. Several companies offer *security management* to customers (Bauer, 2003). It is important to know that the more secure a system is, the more difficult the use it, and the less usability it has. A trade-off between security and usability has to be made (Bauer, 2005). Before initiating medium and large sized systems it is worth making up a so-called *security policy*.

Protection of Network

The simplest style of network protection is a firewall**.** This is a host which provides a strict gateway to the Internet for a subnetwork, checking traffic and maybe dropping some network packets. The three main types of firewalls are the following:

1. **Packet level firewalls**
   In this one, filtering rules are based on packet hearers, for example, the address of the source or the destination.
2. **Application level firewalls**
   These examine not only the header, but also the content of the network packets, to be able to identify unwanted input. They can also be used for an adaptive supervision of an application program.
3. **Personal firewalls**
   It is used usually for workstations and home computers. With these, the user can define access to the network for which running applications should be granted.

Intrusion Detection

Computer intrusion detection has three main types, which are the following:

- Traffic signatures (data samples) implying an intrusion,
- Understanding and examining application level *network protocols, and*
- Recognizing signs of *anomalies* (non-usual functioning).

Unfortunately, not every attack comes along with easily, automatically detectable signs. For example, the abusing of a system by an assigned user is hard to notice.

Data Acquisition

For accurate intrusion detection, authoritative and complete information about the system in question is needed. Authoritative data acquisition is a complex task on its own. Most of the operating systems provide records of different users' actions for review and verification. These records can be limited to certain security events, or can provide a list of all system calls of every process. Similarly, gateways and firewalls have event logs of network traffic. These logs may contain simple information like opening and closing network sockets, or may be the contents of every network packet recorded, which appeared on the wire.

The quantity of information collected has to be a trade-off between expense and efficiency. Collecting information is expensive, but collecting the right information is important, so the question is which types of data should be recorded.

Detection Methods

Supervising a system is only worth this expense if the intrusion detection system also analyzes the collected information. This technology has two main types: *anomaly detection* and *misuse detection*.

Anomaly detection has a model of a properly functioning system and well behaving users. Any deviation it finds is considered a problem. The main benefit of anomaly detection is that it can detect attacks in advance. By defining what is normal, every break of the rules can be identified whether it is part of the *threat model* or not.

The disadvantages of this method are frequent false alerts and difficult adaptability to fast-changing systems.

Misuse detection systems, practically speaking, define what is wrong. They contain intrusion definitions and alias *signatures*, which are compared with the collected supervisory information, searching for the signs of the known threats.

The advantage of these systems is that investigation of already known patterns rarely leads to false alerts. At the same time, it can only detect known attack methods, which have a defined signature. If a new kind of attack is found, the developers have to model it and add to the database of signatures.

ALGORITHMS USED IN THE DEVELOPED SYSTEM

This section describes basic security concepts, dangers threatening user data, and computers. We describe different means of attacks and their common features one by one, and also show the common protection methods against them. For the demonstration of the overlay network used in the Komondor, we also review the theory of P2P networks and the newest results of its research. Computers connected to networks are to be protected by different means (Kemmerer & Vigna, 2002), described in detail as follows.

Information stored on a computer can be personal or business character, private or confidential. An unauthorized person can, therefore, steal it. Its possible cases are shown in the *Table 1*.

We have to protect not only our data, but also our resources. Resources are not only hardware. A typical type of attack is to gain access to a computer to initiate other attacks from it. This is to make the identification of the attacker more difficult, because this way the next intruded host in this chain sees the IP address of the previous one as its attacker.

Intrusion attempts, based on their purpose, can be of different methods. But these methods share things in common, scanning networks ports or subnetworks for services, and making several attempts in a short time. This can be used to detect these attempts and to prepare for protection.

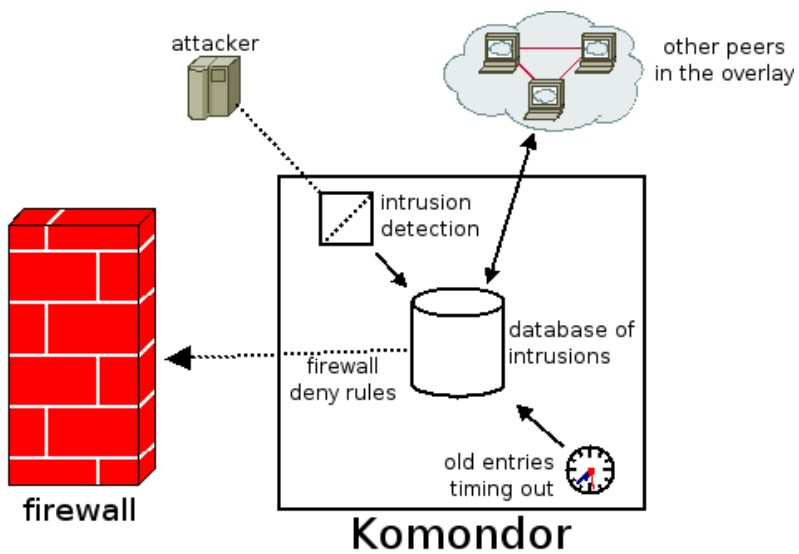
Through security holes, the attacker can also be trying to find resources. With this type of action, whole ranges of network addresses are scanned for a particular service having a bug or just being badly configured. The port number is fixed here. An example for this is scanning for an open e-mail (SMTP) relay to send junk mail anonymously.

The inner architecture of Komondor is presented on Figure 1. Different hosts run the uniform copies of this program, monitoring the occurring network intrusion attempts.

Table 1. The types of the information stealth

• An unauthorized person gains access to a host. • Monitoring or intercepting network traffic by someone. • Abuse of an authorized user.

Figure 1. Architecture of the Komondor system



Komondor nodes protect each other this way. If an intrusion attempt was recorded by a node, the other ones can prepare for the attack in advance.

Information about intrusion attempts is collected by two means: intrusion detected by this node, or intrusion detected by another node. The first working version of Komondor monitors system log files to collect information. These log files can contain various error messages, which may refer to an intrusion attempt. Possible examples are login attempt with an inexistent user name, or several attempts to download an inexistent file through a HTTP server.

Figure 2. Algorithm of the Komondor entity

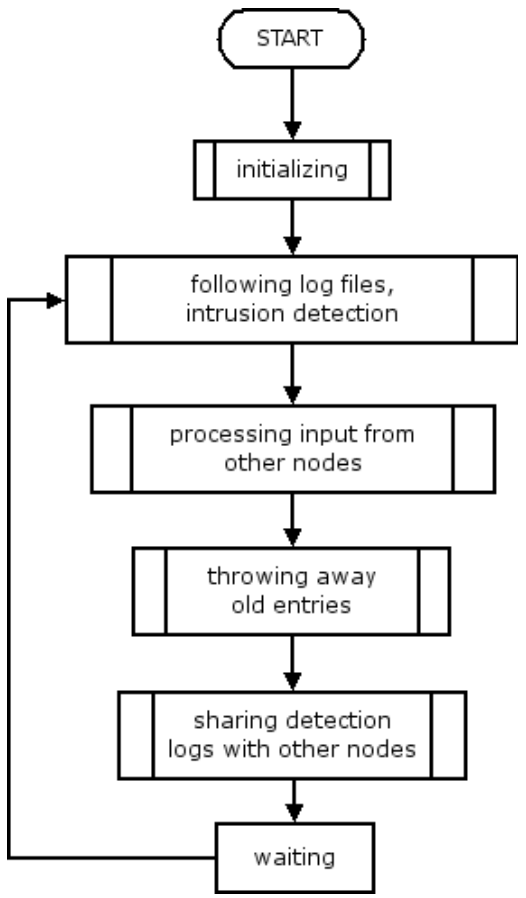


Figure 2 presents the algorithm of the software Komondor. It checks the log files every second, while the database should be purged only on an hourly or daily basis (Czirkos, 2005).

If a node has an empty connection slot, it tries to find other connection points (Hosszú, 2005). A list of active nodes can be downloaded from an anchor point. From this list, a connection is chosen randomly and the ones already tried to connect are deleted from the list. If it becomes blank, the node requests more addresses from the anchor server.

Each peer connects to *at least three; at most five* other nodes. These parameters can be easily adjusted in the program, to set the density of the overlay mesh. The denser the overlay is, the faster the database share and the more stable the system is.

Running of this module is continuous. After starting a Komondor process, it does not wait to connect to the overlay. Following system log files should be begun as soon as possible to be able to detect intrusions. If the node cannot connect to the overlay before the first intrusion is detected, the entry in the database is labeled as "unpublished." When at least one connection is up, then it is possible to send data to the overlay.

RATING OF THE NEW SYSTEM

The first version of Komondor network aided security enhancement system was under extensive testing for months. Parts of these examinations were simulated, and others were real intrusion attempts. This chapter is about some real intrusion attempts, which were averted by the Komondor system. *Table 2* summarizes some of the results achieved.

Effectiveness of the Komondor system is determined by the diversity of peers. Intrusion attempts attacking security holes are software and version specific. Daemons providing services (SSH, Web) could be of different versions on hosts running Komondor. An attempt detected on any (either buggy or not) system can also protect vulnerable ones. Three possible cases in which this can occur are listed in the *Table 3*.

Table 2. Results

Time of attack	Service under attack	Answer
2005-10-17	Secure shell	blocked IP
2005-06-17	Apache httpd	blocked IP
2005-09-20	Monkey httpd	blocked IP

Table 3. Examples of the heterogeneity of the Komondor's environment

• Hosts running the same software, but different version (Apache 2.0.54 and Apache 2.0.30). • Hosts providing the same service, but with means of different software (web server Apache and Zeus). • Hosts are based on different operating systems (Linux and Windows for example).

FUTURE TRENDS

In the second half of 2005, 54 day elapsed between the disclosure of a vulnerability and the release of a patch by the vendor. Security threats tend to emerge, as *exploits* are published in a much shorter time (Symantec, 2005). Development of firewall tools like Komondor is therefore important, while through blocking initiated attacks, they can even enable a vulnerable application to run safely.

We plan enhancing efficiency of the Komondor overlay by merging it with Snort. Also algorithms of present *P2P networks* mainly aim distributing resources and finding specific peers in the overlay. In contrast to this, our application demands a fast broadcast of information: data of detected intrusions. Therefore, we conduct research on selection of a particular P2P topology for this task.

CONCLUSION

This novel application of P2P theory helps the users of this system to increase security of their hosts. The system is easy to use; the nodes organize the P2P overlay automatically, and do not need any user interaction. The intrusion protection of the networked computers has obvious importance and introducing the cooperation among the hosts to be protected is a promising approach.

After reviewing the most important features of the P2P networks and their security related problems, the article presented the most common intrusion detection methods. Finally, a novel approach and the results of an ongoing research were introduced to utilize together the advantages of the P2P paradigm and the enhancements in the security methods of the operating systems. The presented experimental results proved the usefulness of the proposed method.

KEY TERMS

Application Level Network (ALN): The applications, which are running in the hosts, can create a virtual network from their logical connections. This is also called *overlay network* (*see below*). The operations of such software entities are not able to understand without knowing their logical relations. The most cases this ALN software entities use the *P2P model (see below)*, not the *client/server* (*see below*) one for the communication.

Client/Server Model: A communicating way, where one host has more functionality than the other. It differs from the *P2P model* (*see below*).

Exploit: A small program which is designed specifically to attack a certain vulnerability in a system. These are dangerous, while their use requires no skills, and they are usually published shortly after a disclosure of a vulnerability.

Firewall: This is a host or router which provides a strict gateway to the Internet for a subnetwork, checking traffic and maybe dropping some network packets.

Overlay Network: The applications, which create an *ALN (see above)* work together and usually follow the *P2P communication model (see below)*.

Peer-to-Peer (P2P) Model: A communication way where each node has the same authority and communication capability. They create a virtual network, overlaid on the Internet. Its members organize themselves into a topology for data transmission.

Security Management: It means the calculation of the damage caused by a certain attack in advance so one can decide if a particular security investment as buying new devices or training employees is worth it or not.

Security Policy: It means a set of rules in which the expectations and provisions of usage for the users, and the administrators also, is made up. It is worth making up before initiating medium or large sized systems.

Simple Network Management Protocol (SNMP): It is a network management protocol used primarily for IP networks. Using it, the networked devices as routers and host, can be monitored and managed.

Intrusion Tolerance in Information Systems

Wenbing Zhao
Cleveland State University, USA

INTRODUCTION

Today's information systems are expected to be highly available and trustworthy — that is, they are accessible at any time a user wants to, they always provide correct services, and they never reveal confidential information to an unauthorized party. To meet such high expectations, the system must be carefully designed and implemented, and rigorously tested (for intrusion prevention). However, considering the intense pressure for short development cycles and the widespread use of commercial off-the-shelf software components, it is not surprising that software systems are notoriously imperfect. The vulnerabilities due to insufficient design and poor implementation are often exploited by adversaries to cause a variety of damages, for example, crashing of the system, leaking of confidential information, modifying or deleting of critical data, or injecting of erroneous information into a system.

This observation prompted the research on intrusion tolerance techniques (Castro & Liskov, 2002; Deswarte, Blain, & Fabre, 1991; Verissimo, Neves, & Correia, 2003; Yin, Martin, Venkataramani, Alvisi, & Dahlin, 2003). Such techniques can tolerate intrusion attacks in two respects: (1) a system continues providing correct services (may be with reduced performance), and (2) no confidential information is revealed to an adversary. The former can be achieved by using the replication techniques, as long as the adversary can only compromise a small number of replicas. The latter is often built on top of secrete sharing and threshold cryptography techniques. Plain replication is often perceived to reduce the confidentiality of a system, because there are more identical copies available for penetration. However, if replication is integrated properly with secrete sharing and threshold cryptography, both availability and confidentiality can be enhanced.

BACKGROUND

In this section, we introduce some basic security and dependability concepts and techniques related to intrusion tolerance. A secure information system is one that exhibits the following properties (Pfleeger & Pfleeger, 2002):

- **Confidentiality:** Only authorized users have access to the information.
- **Integrity:** The information can be modified only by authenticated users in authorized ways. Any unauthorized modification can be detected.
- **Availability:** The information is available whenever a legitimate user wants to access it.

Confidentiality is often ensured by using encryption, authentication, and access control. Encryption is a reversible process that scrambles a piece of plaintext into something uninterpretable. Encryption is often parameterized with a security key. To decrypt, the same or a different security key is needed. Authentication is the procedure to verify the identity of a user that wants to access confidential data. Access control is used to restrict what an authenticated user can access.

Information integrity can be protected by using secure hash functions, message authentication code (MAC), and digital signatures. For data stored locally, including the application binary files, a checksum is often used as a way to check data integrity. The checksum can be generated by applying a one-way secure hash transformation on the data. Before the data is accessed, one can verify its integrity by recomputing the checksum and comparing it with the original one. The integrity of a message transmitted over the network can be guarded by a MAC. A MAC is generated by hashing on both the original message and a shared secret key. If it is tampered with, the message can be detected in a way similar to that for the checksum. For stronger protection, a message can be signed by the sender. A digital signature is produced by first hashing the message using a secure hash function, and then encrypting the hash using the sender's private key.

High availability is achieved by using replication, checkpointing, and recovery techniques. Replication is a technique that relies on running redundant copies of an application so that if one copy fails, the services can be provided by the remaining copies. Checkpointing means to take a snapshot of the state of a replica. The saved state can be used to bring a new or a restarted replica up to date. Checkpointing is also useful to avoid log buildup (when a checkpoint is taken, all previous logs can be garbage collected). Recovery techniques concern the tasks of removing faulty replicas, repairing them, and reintegrating them back to the system.

INTRUSION TOLERANCE TECHNIQUES

Intrusion tolerance is built on two fundamental techniques: replication and secret sharing/threshold cryptography (Deswarte et al., 1991). In the context of intrusion tolerance, a very general fault model must be used because a compromised replica might exhibit arbitrary faulty behaviors. Such a fault model is often termed as Byzantine fault (Lamport, Shostak, & Pease, 1982).

Byzantine Fault Tolerance

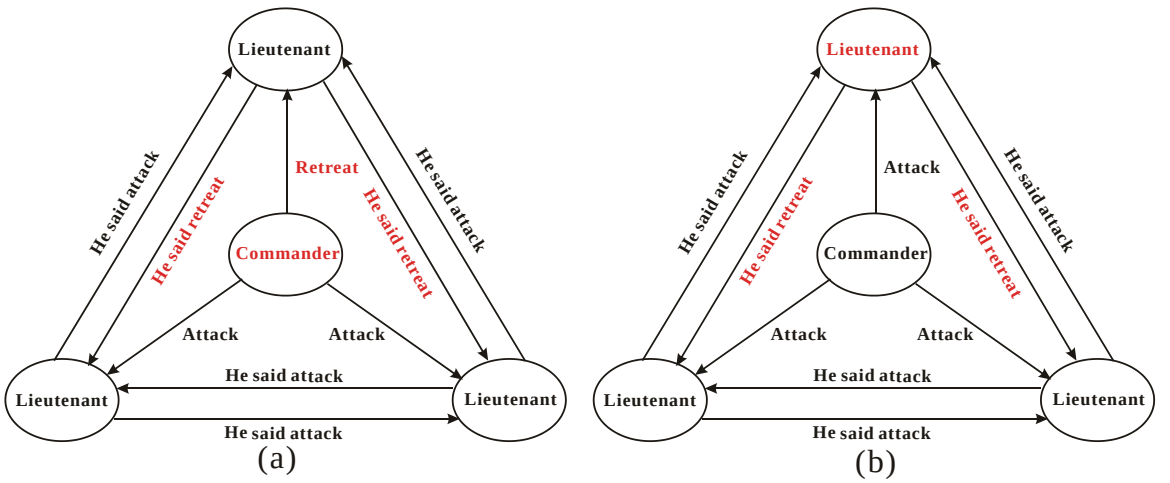
An intrusion attack might bring a service down or compromise the integrity of a service. An effective defense is to introduce redundancy into the system — that is, to replicate critical components in the system. Assuming that an intrusion attack can only penetrate a small fraction of the replicas, the service availability and integrity can be preserved by the remaining correct replicas. However, achieving this goal is not trivial — we must ensure consistent execution of all correct replicas despite the attacks launched by faulty replicas.

A Byzantine faulty replica may use all kinds of strategies to prevent the normal operations of the replicated service, in particular, it might propagate conflicting information to other replicas or components that it interacts with. To tolerate f Byzantine faulty replicas in an asynchronous environment, we need to have at least $3f+1$ number of replicas (Castro & Liskov, 2002). An asynchronous environment is one that has no bound on processing times, communication delays, and clock skews. Internet applications are often modeled as asynchronous systems. Usually, one replica is designated as the primary and the rest are backups.

There are two different approaches to Byzantine fault tolerance. In a Byzantine quorum system (Malkhi & Reiter, 1997), read and write operations issued by some clients are applied on a set of data items (which consists of the state of a service). It is assumed that the read and write operations are synchronized. A read operation retrieves information from a quorum of correct replicas, and a write operation applies the update to a quorum of correct replicas. In a system with $3f+1$ replicas, a quorum can be formed by $2f+1$ replicas so that any two quorums overlap by at least $f+1$ replicas, among which at least one is not faulty. This guarantees the correct operations of the quorum-based system.

A more general method is the state-machine-based approach (Schneider, 1990), in which a replica is modeled as a state machine. The state change is triggered by remote invocations on the methods offered by the replica. This approach is applicable to a much wider range of applications. Consider a client server application where the server is replicated using the state-machine-based approach (Castro & Liskov, 2002). The client first sends its request to the primary replica. The primary then broadcasts the request message to the backups and also determines the execution order of the message. To prevent a faulty primary from intentionally delaying a message, the client starts a timer after it sends out a request. It waits for $f+1$ identical replies from different replicas. Because at most f replicas are faulty, at least one reply must come from a correct replica. If the timer expires before it receives a correct reply, the client broadcasts the

Figure 1. The Byzantine agreement problem: To tolerate a single Byzantine fault, four replicas are needed. (a) If the commander (i.e., primary replica) is faulty, he may send conflicting information to its lieutenants (i.e., backup replicas). However, the lieutenants can exchange information regarding what they heard from the commander and reach the correct decision (attack) based on majority voting. (b) On the other hand, if a lieutenant is faulty, he may lie to other lieutenants regarding the information he has heard from the commander. Other lieutenants can still reach a correct decision based on majority voting. Reducing the number of replicas to three cannot guarantee an agreement among the correct replicas.



request to all server replicas. This enables the correct replicas to detect the primary failure so that a new primary can be elected (this is often called a view change).

All correct replicas must agree on the same set of input messages with the same execution order. In other words, the request messages must be delivered to the replicas reliably in the same total order. To understand this better, consider two replicas R1 and R2 and two requests M1 and M2 from two different clients. Let M1 be an update request and M2 be a read-only request. If R1 processes M1 and then M2, and R2 processes M2 and then M1, the reply messages for M2 from R1 and R2 would be different because one reflects the latest update while the other does not.

Furthermore, replicas may not process the same request deterministically — that is, given the same request (delivered in the same order to all replicas), they may not produce identical reply. There are many factors that can cause non-deterministic execution of a request, for example, differences in local clocks, process identifiers, and many other local resources that might be referenced by the replicas, and multi-threading. These factors must be controlled properly so that the replicas appear to execute deterministically. This is a rather difficult task in the face of Byzantine fault. So far, this issue has been addressed in a very limited fashion. Current solutions often assume that the replicas are single-threaded, and all non-deterministic operations are known *a priori*. The primary replica determines the values to be used for all replicas and disseminates them to the backups. The backups subsequently verify the proposed values. If the primary is detected to be faulty, a view change is initiated.

Byzantine fault tolerance mechanisms tend to suffer from scalability problems. Amir et al. (2006) have tackled the size scalability problem by using a hierarchical replication architecture so that Byzantine fault tolerance can be achieved in large-scale application running over wide area networks. Aiyer et al. (2005) considered the challenges faced by ensuring Byzantine fault tolerance over multi-administrative domains (administration scalability problems) and invented mechanisms to cope with selfish members, in addition to arbitrary faulty members.

Secrete Sharing and Threshold Cryptography

Another aspect of intrusion tolerance is to protect confidential information (e.g., security keys) even if some replicas have been penetrated (Deswarte et al., 1991). If all the secrets are maintained by a single process, an adversary can obtain these secrets by compromising the process. To defend against such an attack, each secret is divided into multiple shares, and each share is stored in a separate process. To obtain the secret, an adversary must now break into a significant number of processes. This is the basic objective of *secret sharing.*

A popular secret sharing scheme is the *(k, n) threshold scheme*, where *n* is the total number of shares and *k* is the minimum number of shares needed to reconstruct the secret. No useful information can be obtained as long as the number of shares collected is less than *k*, the threshold. This scheme was first proposed by Shamir (1979) and implemented using polynomial interpolation. In this scheme, each share is of similar size to the original secret, and shares can be dynamically added or deleted.

The (k, n) threshold scheme is quite expensive computationally and space-wise. Therefore, it is used only to protect the most crucial secret such as security keys. It might not be practical to apply the scheme to file systems or databases. Consequently, a more cost-effective scheme, called Fragmentation-Replication-Scattering (FRS), is proposed (Deswarte et al., 1991). It was initially designed to provide intrusion tolerance for file systems and was later extended to object-based systems (Fabre & Randell, 1992). The FRS scheme involves three steps. First, a file is partitioned into many smaller pieces. (To enhance the confidentiality, the file can be encrypted prior to the fragmentation step.) Second, each piece is replicated. Finally, the pieces are distributed pseudo-randomly according to some algorithm to the storage sites. The fragmentation and scattering protect data confidentiality against intrusion attacks, because to obtain the file, an adversary must first find out the locations of the fragments belonging to the file and then penetrate all the sites that store the fragments. The replication protects the availability of the file so that even if some pieces are destroyed by an adversary, there are enough copies left to reconstruct the original file.

Despite the elegancy of the secret sharing schemes, the secret must be reconstructed before it can be used. This poses a security threat because if the process that performs this task is compromised, the secret may be exposed. This prompted the development of threshold cryptography (Desmedt & Frankel, 1989). In threshold cryptography, security operations such as encryption, decryption, signature generation, and verification can be performed by a group of processes without reconstructing the shared secret. Threshold cryptography has been applied primarily to public key-based security services by sharing the private key among a group of processes (Zhou, Schneider, & van Renesse, 2002). The shares can be proactively updated to further enhance the security. By sharing the private key, each process can produce a partial signature. If a client obtains enough partial signatures, it can compute the complete signature. During this process, the private key is never reconstructed.

PROTECTING BOTH AVAILABILITY AND CONFIDENTIALITY

Byzantine fault tolerance ensures service high availability, but it does not protect data confidentiality against intrusions. Threshold cryptography guarantees both confidentiality and

high availability of some security operations, but not general services one might use. All secret sharing schemes require the reconstruction of the secret at a trusted site, which may be vulnerable to intrusion attacks.

COCA (Zhou et al., 2002) is the first attempt to integrate a Byzantine quorum system with threshold cryptography in the context of a certificate authority (CA) service. In COCA, the most critical state — that is, the service private key, used to generate signatures for the certificates issued to clients — is shared among the replicas to prevent an adversary from stealing it. There are other states in a CA service, such as the certificate issued to the clients. A client can query and update the certificate information through the CA services. The high availability of the CA services is provided by the group of CA replicas. To enhance failure resiliency, the replicas are periodically restarted proactively with a correct binary image and the latest state collected from other correct replicas. The server keys (used to communicate securely among the replicas) are also periodically refreshed.

FUTURE TRENDS

Even though there is moderate success in applying intrusion tolerance techniques to a few specific applications, it remains to be seen how to introduce intrusion tolerance to other types of information systems, such as credit card processing systems, online banking systems, and e-commerce systems. The lack of effective solutions has left many mission-critical systems vulnerable. This is evidenced by the increasingly frequent reports of high-impact security breaches that resulted in massive disclosure of confidential information, such as the break-in of CardSystems Solutions, which exposed the confidential data of more than 40 million credit card holders (Dash & Zelle, 2005), and the Veteran Affairs incident, which has caused the potential loss of personal data of more than 26.5 million veterans to the hands of adversaries (Dunhm, 2006).

There are many open issues to be resolved before we see widespread adoption of intrusion tolerance techniques. The most interesting research problem seems to be the design of a systematic methodology that allows direct operation on the shared secret that is dispersed among a number of processes. This will eliminate the vulnerability introduced by relying on a trusted process to reconstruct the secret. Another urgent issue is how to address the replica non-determinism problem, especially that caused by multi-threading. Practical information systems are very complicated and contain extensive non-deterministic operations. Unfortunately, all Byzantine fault tolerance strategies require deterministic execution of replicas. Even though the non-determinism resulting from a replica's accessing of some local resources (such as clock values and file descriptors) can be easily controlled if the access pattern is known in advance (Yin et al., 2003), there is no straightforward solution to render a multi-threaded application deterministic without significantly impacting the application's performance and correctness (Zhao, Moser, & Melliar-Smith, 2005). Furthermore, intrusion tolerance favors design diversity to avoid common vulnerabilities among the replicas. N-version programming was proposed as a potential solution by Chen and Avizienis (1978). However, it might not be an economically viable solution due to its heavy software development cost. Alternative, less costly solutions are needed to diversify the replica implementations. Code randomization appears to be a good approach to achieve replica diversity (Forrest, Somayaji, & Ackley, 1997).

Intrusion tolerance design does not conflict with the effort of intrusion prevention and intrusion detection (Verissimo et al., 2003). In fact, they are all indispensable techniques for building secure and dependable systems. Without applying good intrusion prevention techniques, the application would contain too many vulnerabilities for the replication strategy to take effect. Similarly, intrusion detection plays an essential role in intrusion tolerant systems. To remove a faulty replica and to recover it subsequently, the fault must be detected as quickly as possible. Intrusion detection also helps deter future intrusion attacks if there is enough information logged that can be used to prosecute the intruders (Dunlap, King, Cinar, Barsai, & Chen, 2002).

CONCLUSION

We believe that the research and development of intrusion tolerant systems will gain more momentum as more and more services are offered online. The expectation of such services is high, considering their essential roles in everyday operations of businesses and individuals as well. The impact of service unavailability and security breaches will only be more serious. In this chapter, we have surveyed the state-of-the-art techniques for building intrusion tolerant systems. We also illustrated a few most urgent open issues for future research. Finally, we pointed out that to build secure and dependable systems, we need a concerted effort in intrusion prevention, intrusion detection, and intrusion tolerance.

KEY TERMS

(k, n) Thread Scheme: A secret is divided into *n* shares. To reconstruct the secret, at least *k* shares are needed. No useful information can be obtained from *k-1* shares.

Byzantine Fault: Used to model arbitrary fault. A Byzantine faulty process might send conflicting information to other processes to prevent them from reaching an agreement.

Byzantine Fault Tolerance: A replication-based technique used to ensure high availability of an application subject to Byzantine fault.

Byzantine Quorum System: A system offering read and write services to its clients on a set of replicated data items. A read operation retrieves data from a quorum of correct replicas, and a write operation applies the update to a quorum of correct replicas. Any two quorums must overlap by at least one correct replica.

Fragmentation Redundancy Scattering: A secret sharing scheme that involves the following three steps: fragmenting a file, replicating each fragment, and distributing the replicated fragments to different storage sites.

Replica Consistency: The states of the replicas of an application should remain identical at the end of the processing of each request. Replica consistency is necessary to mask a fault in some replicas.

Threshold Cryptography: Security operations such as encryption, decryption, signature generation, and verification can be performed by a group of processes without reconstructing the shared secret. Threshold cryptography utilizes (k, n) threshold schemes internally.

Inventing the Future of E-Health

José Aurelio Medina-Garrido
Cadiz University, Spain

María José Crisóstomo-Acevedo
Jerez Hospital, Spain

INTRODUCTION

E-health involves the use of information and communications technologies to improve health in general and the healthcare system in particular (Alvarez, 2002; Chau & Hu, 2004; Roger & Pendharkar, 2000).

Healthcare, one of the largest industries in the world, suffers from some inefficiencies and inequities in both service provision and quality. Some of these problems are due to the poor management of the information flows (Kirsch, 2002). In this respect, there are business opportunities for e-health. But to understand what the future holds for e-health, we need to find a precise definition of the concept and identify the possible sources of business.

This article is structured as follows. The second section, the background, defines the concept of e-health. The third section outlines some of the business opportunities in the area of e-health based on the communications platform that is the Internet, and discusses some practical guidelines for e-health businesses to create value. The fourth section discusses the low level of adoption of e-health at present, as well as the future trends, in which e-health will presumably grow. e-health is also expected to be used to reduce the disparities in the population in access to healthcare, and for the treatment of the chronically ill. The fifth section is dedicated to the final conclusions.

BACKGROUND

The term *e-health* is relatively recent and refers to healthcare practice that is supported by electronic processes and communications. The term has many definitions, depending on the functions, stakeholders, context, or the theoretical framework referred to. It includes a wide range of medical informatics applications, both specific (for example, decision support systems, citizen health information) and general (for example, management systems, healthcare services provision, etc.). But the increased importance of the communication function in e-health, and the use of electronic networks (particularly the Internet), differentiate e-health from traditional medical informatics (Pagliari, 2005).

Thus, e-health goes beyond healthcare informatics and incorporates the most advanced information technologies to medicine and healthcare. Among the most significant applications of the technologies to healthcare are the following:

- *Electronic Medical Records*, which allow different healthcare professionals to share information about a particular patient.
- *Telemedicine*, which uses information and communications technology (ICT) to enable physician-patient contact at a distance.
- *Evidence-based Medicine*, in which a system updates information about the most appropriate treatments for each patient, thereby enhancing physicians' treatment possibilities.
- *Citizen-oriented Information*, through which citizens are provided with information about health topics.
- *Specialist-oriented Information*, whereby a system distributes information to specialists about medical journal articles, practices and protocols in the area of health, new medical advances, epidemiological alerts, etc.
- *Virtual healthcare teams*, made up of healthcare professionals sharing information about patients electronically to improve their knowledge and decision-making.
- *Health e-commerce*, which involves providing value-added electronic services to both professionals and citizens, and economically exploiting some or all of the services. In this respect, e-health is supported by the Internet and related technologies and combines medical informatics, public health, and business. This type of e-health does not exclude the previous ones. To the contrary, it includes them or complements them. The following section discusses the concept of Health e-commerce, indicating what types there are, what they consist of, and how they obtain their revenues.

Some authors go further than the concepts explained in this section and predict a change of mentality and culture among both citizens and practitioners. One author goes so far as to argue that e-health "..characterizes not only a technical development, but also a state-of-mind, a way of

thinking, an attitude, and a commitment for networked, global thinking, to improve healthcare locally, regionally, and worldwide by using information and communication technology" (Eysenbach, 2001).

BUSINESS OPPORTUNITIES BASED ON E-HEALTH

As we mentioned above, the inadequate management that a large part of the healthcare sector makes of its information flows (Kirsch, 2002) and processes, as well as the new advantages offered by present-day ICT, mean that e-health opens up significant business opportunities.

One of the most notable business opportunities offered by e-health is e-commerce. The most important forms that *e-commerce* can adopt on the Internet include (Parente, 2000): portals, connectivity sites, business-to-business applications, and business-to-consumer applications.

Portals dedicated to health tend to provide all types of information, guidance, and medical advice to consumers and professionals. Portals generally represent starting points for consumers, offering them various online activities as well as diverse information. Their general objective is to be the first place that customers go to when they are looking for something on the Internet. For this, they need to establish a brand that attracts visits and creates loyal customers. Their main sources of income come from the advertising they contain and occasionally from users' subscriptions.

Sites dedicated to facilitating connectivity in the healthcare sector have the objective of linking and integrating the various information systems seamlessly. The income of this business model comes from the company's external users, who pay fees to obtain information. Health e-commerce connectivity initiatives involve accessing electronic medical records on the Internet, evaluating the quality of providers according to their clinical results, and using quality information in the selection of physicians. For example, some hospitals provide their patients with directories of their physicians on the Internet, which are searchable by zip code and clinical specialty (Coile, 2000). Because these sites obtain their revenues from the fees generated by each information transaction, their objective is to maximize the number of transactions. These companies obtain transaction fees from health plan providers, physicians, hospitals, clinical laboratories, pharmacies, consumers, and companies offering financial, marketing, or delivery services in the healthcare sector.

Business-to-business (B2B) e-commerce involves selling products and services to other firms on the Internet. The income from this business model comes from the sale of the product or service itself. *B2B Health e-commerce* includes businesses dedicated to selling refurbished medical equipment or pharmaceutical refills on the Internet. Indeed, pharmaceutical refills are a large market with a high turnover, and are ideally suited to be traded on the Internet at competitive prices offering next-day home delivery (Coile, 2000). Apart from the products sold in this way, some companies are now beginning to offer services such as online management consultancy.

Business-to-consumer (B2C) e-commerce sells products and services directly to the consumer via the Internet. As in the previous model, the income comes from the sales themselves. The B2C business model in the healthcare area allows consumers to acquire products and services such as health insurance, prescription drug refills, over-the-counter drugs, medical supplies for the chronically ill, vitamins, homeopathic medicines, and home fitness equipment (Coile, 2000).

Table 1 shows examples of some of the most important firms in the e-health sector. The firms are classified under the business model that most closely matches their main activities or sources of income. But the limits are often hazy, and the firms can often be classified in more than one category.

After the bursting of the Internet bubble it became clear that an e-business, such as one based on e-health, should in the first place be a business venture, and not just a technological one. e-health firms are businesses, and so they must seek to create value. In this respect, some authors offer *practical guidelines to e-businesses* about how to generate value (Earle

Source: Adapted from Parente (2000).

and Keen, 2000; Shapiro and Varian, 1999), and these are also valid for the particular case of e-health:

- Cultivate stable relationships with customers. Building a critical mass of loyal customers allows firms to avoid customer acquisition costs for each transaction. The idea is to build solid relationships with strong ties. For this reason, some firms offer some services for free on their Web sites.
- Build a powerful brand. The concept of brand is redefined on the Internet. It is a relationship brand. Customers cannot see the product or service until they pay for it. Thus, e-health firms need to have a good reputation. This reputation, which takes substantial time and money to build, can be quickly acquired working together or allying with another firm that already has a good reputation.•
- Improve the logistics. This is important for e-health firms that distribute physical products such as medical equipment or drugs. Logistics capabilities are critical for the generation of value. But some firms have opted to focus on those core activities they know how to do well, in order not to spread efforts or resources too thinly, and have allied with top logistics firms that can undertake this function.
- Harmonize the channels in the name of the customer. Customers choose the communication channel that offers them most advantages. Firms need to provide the option that best helps to build and maintain the relationship, and that choice is for the customer to make, not the firm. In this respect, customers need to be offered a number of communications channels (Web forms, e-mail, telephone, fax, post, cell phone SMS, personal digital assistants (PDAs), a combination of physical and virtual branches, etc.).
- Become an intermediary that provides value, or use one that does. Business on the Internet is dominated by nerve centers such as portals with powerful brands and other intermediaries that bring the supply and the demand together. These will control the interaction between providers and customers, and will advise customers about the Web sites they should visit when looking for a particular product or service. Only the intermediaries that offer consumers or firms value will survive and prosper. Intermediaries that do not provide value must use one that does if they wish to be profitable.
- Analyze how much the firm invests in producing and selling information. Information is expensive to produce, but extremely cheap to copy. In this respect, trading data electronically allows firms to distribute information enjoying economies of scale, which means they can cut unit costs and consequently the price of their product or service.
- When firms compete in commodity markets they need to create economies of scale that cut costs (and prices), be flexible to adapt to any change and quick, both to enter a market and exploit the business opportunity and to exit when this is no longer profitable.

FUTURE TRENDS

E-health tools show plenty of potential, but they are relatively undeveloped and have not yet been adopted to a great extent (Wilson, 2005). Some authors have predicted that some of the new technologies applicable to e-health will be adopted very quickly and massively (for example, telemedicine or PDAs), but there remain problems in this respect. Occasionally, the main *source of income of the business model* has seen undermining. This has been the case, for example, of the supply of information to the consumer, as they are not used to paying for this. On the other hand, some technologies do not have a large enough potential market to grow very quickly, for example, applications for supply-chain management (SCM) or procurement. Consequently, firms do not find them so attractive to invest in (Kirsch, 2002).

Electronic medical records are also expected to take off in the future. No paperless hospitals can be found just yet, but some authors predict that some hospitals will be completely paperless in the not-too-distant future (Coile, 2000). If these predictions prove right, extreme care will be needed to protect patients' privacy and interests.

A proper implementation of *e-health will require political commitment*, an adequate legal framework, and R&D and Innovation (Wilson, 2005). The political commitment should be reflected in the development of electronic health cards and health information networks and online health services. The legal framework must offer adequate coverage in terms of data protection, digital signatures, e-commerce regulations, and the professional qualifications required to use telemedical applications. The R&D and Innovation needs to promote the development of new technological tools and help to spread best practices in this new field.

Another potential future trend for *e-health is to apply information and communications technologies to reduce the disparities in the population* in access to the healthcare system (Ahern, Kreslake, & Phalen, 2006; Cashen, Dykes, & Gerber, 2004; Gibbons, 2005). Demographic and socioeconomic factors are arguably behind these disparities, such as: ethnic origin (whites vs. minorities), geographic (urban vs. rural) (Galea & Vlahov, 2005), gender (masculine vs. feminine) (Mcgrath & Puzan, 2004; Quinn & Overbaugh, 2005), income level (poor vs. non-poor) (Federico & Liu, 2003), and age (elderly vs. non-elderly) (Pyle & Stoller, 2003).

In the future, *e-health is also expected to increasingly facilitate the treatment and monitoring of patients with chronic illnesses* (Ahern, Kreslake & Phalen, 2006). This

will reduce the constant and inconvenient traveling to and from medical centers that these patients are subjected to, not to mention the healthcare system's work overload in this respect.

CONCLUSION

E-health will lead to a behavior change in the area of healthcare, through which the use of information technologies, the Internet and communications technologies enable improved and more effective healthcare (Eng, 2002).

One of the main areas of interest in e-health is to improve health communications by using technologies. In this respect, both healthcare organizations and public healthcare agencies are increasingly using the Internet in their communications and to transfer information.

These efforts are generating various socio-economic phenomena, in particular e-health as a business opportunity – the chance to create an e-business. Four models familiar from traditional e-businesses have also been adopted by e-health businesses: portals, connectivity sites, business-to-business applications, and business-to-consumer applications.

Although more attention is commonly paid to technological questions, we must also remember that an e-business is first of all a business. E-health businesses, as businesses, need to create value for their customers. In this respect, they are advised to cultivate stable relationships with their customers, build a powerful brand, consider the logistics carefully, offer a number of channels to their customers, be an intermediary that provides value, seek economies of scale when they produce and sell information, and be quick and flexible and create economies of scale when they compete in commodity markets.

At present, e-health activities are defusing only gradually, and have been slow to be accepted. But a greater development is forecast for the future; in particular, we will conceivably see phenomena such as paperless hospitals and a more complete coverage of the population's healthcare needs (education about health, treatment of chronically ill patients, and reduction in the disparities in access to healthcare).

KEY TERMS

Business-to-Business (B2B) E-Commerce: Economic transactions between firms using information systems and technologies.

Business-to-Consumer (B2C) E-Commerce: Commercial transactions and activities between firms and the end-consumer using information systems and technologies.

Commodities: Raw materials, unfinished products, or products sold loose, or any other product characterized by being undifferentiated. Such products cannot be differentiated from other products in function of the producer that manufactures them or the supplier that sells them.

E-Health: The provision of any healthcare service that is supported by electronic processes and communications.

Electronic Medical Records: Computer-based patient medical records. Patient medical records are a systematic documentation of a patient's medical history and care.

Evidence-Based Medicine: Medical practice involving the sharing, updating and consultation of a system containing information about the most appropriate treatments for each patient. This helps to improve the treatments chosen by the physicians who use this system.

Health E-Commerce: E-business based on the economic exploitation of health-related information and services.

Health Plan: An individual or group plan that provides, or pays the cost of, medical care.

Over-the-Counter (OTC) Medicine: A medicine that can be bought without a doctor's prescription, such as some analgesics.

Telemedicine: The use of information and communications technologies to exchange information between practitioners, or to deliver medical services to a patient remotely.

Virtual Healthcare Teams: Teams made up of healthcare professionals that share information about patients electronically in order to improve their knowledge and decision-making.

Investigating Internet Relationships

Monica T. Whitty
Queen's University Belfast, UK

INTRODUCTION

The focus on Internet relationships has escalated in recent times, with researchers investigating such areas as the development of online relationships (e.g., McCown, Fischer, Page, & Homant, 2001; Parks & Roberts, 1998; Whitty & Gavin, 2001), the formation of friends online (Parks & Floyd, 1996), representation (Bargh, McKenna, & Fitzsimons 2002), and misrepresentation of self online (Whitty, 2002). Researchers have also attempted to identify those addicted to accessing online sexual material (Cooper, Putnam, Planchon, & Boies, 1999). Moreover, others have been interested in Internet infidelity (Whitty, 2003a, 2005) and cybersex addiction (Griffiths, 2001, Young, Griffin-Shelley, Cooper, O'Mara, & Buchanan, 2000). Notwithstanding this continued growth of research in this field, few researchers have considered the new ethical implications of studying this topic area.

While it is acknowledged here that some of the discussions in this article might be equally applied to the study of other Internet texts, such as religious or racial opinions, the focus in this article is on the concomitant ethical concerns of ongoing research into Internet relationships. Given that the development and maintenance of online relationships can be perceived as private and very personal (possibly more personal than other sensitive areas), there are potential ethical concerns that are unique to the study of such a topic area (Whitty, 2004; Whitty & Carr, 2006). For a broader discussion of virtual research ethics in general, refer to Ess and Jones (2004) and Whitty and Carr (2006).

BACKGROUND

Early research into this area has mostly focused on the similarities and differences between online and off-line relationships. Researchers have been divided over the importance of available social cues in the creation and maintenance of online relationships. Some have argued that online relationships are shallow and impersonal (e.g., Slouka, 1995). In contrast, others contend that Internet relationships are just as emotionally fulfilling as face-to-face relationships, and that any lack of social cues can be overcome (Lea & Spears, 1995; Walther, 1996). In addition, researchers have purported that the ideals that are important in traditional relationships, such as trust, honesty, and commitment, are equally important online, but the cues that signify these ideals are different (Whitty & Gavin, 2001). Current research is also beginning to recognize that online relating is just another form of communicating with friends and lovers, and that we need to move away from considering these forms of communication as totally separate and distinct entities (e.g., Wellman, 2004). Moreover, McKenna, Green, and Gleason (2002) have found that when people convey their "true" self online they develop strong Internet relationships and bring these relationships into their "real" lives.

Internet friendships developed in chat rooms, newsgroups, and MUDs or MOOs have been examined by a number of researchers. For example, Parks and Floyd (1996) used e-mail surveys to investigate how common personal relationships are in newsgroups. After finding that these relationships were regularly formed in newsgroups, Parks and Roberts (1998) turned to examine relationships developed in MOOs. These researchers found that most (93.6%) of their participants had reported having formed some type of personal relationship online, the most common type being a close friendship.

Researchers have also been interested in how the playful arena of the Internet impacts on the types of relationships formed in these places (e.g., Whitty, 2003b; Whitty & Carr, 2003, 2006). Turkle's (1995) well-known research on her observations while interacting in MUDs found that the role-playing aspect of MUDs actually creates opportunities for individuals to reveal a deeper truth about themselves. Whitty and Gavin (2001) have also contended that although people do lie about themselves online, this paradoxically can open up a space for a deeper level of engagement with others.

Importantly, some researchers are now starting to realize that cyberspace is not a generic space that everyone experiences in the same way. New theories are currently being developed to explain how individuals present themselves in different spaces online. For instance, Whitty (in press) devised the BAR theory to explain presentation of self on online dating sites, which she believes is different to other spaces within cyberspace. The BAR theory purports that most online daters find the best strategy for developing a "successful profile" is to create a balance between an "attractive self" and a "real self." The online daters Whitty and her research assistants interviewed (see Whitty, in press; Whitty & Carr, 2006) talked about the need to re-write their profiles if they were attracting either people they did not desire, or if they were attracting no one, or if their date appeared disappointed with them when they met face-to-face (given that they did not live out to their profile). Therefore, it would seem that

a successful profile has to appear attractive enough to stand out and be chosen, but also one that individuals could live up to in their first face-to-face date (which often took place within a couple of weeks of meeting online).

Cybersex addiction and the available treatment for these cybersex addicts and their partners has been an area of research and concern for psychologists (e.g., Schneider, 2000; Young, Pistner, O'Mara, & Buchanan, 1999). Research has also focused on what online acts might be considered as an act of infidelity. For example, Whitty (2003a) found that acts such as cybersex and hot-chatting were perceived as almost as threatening to the off-line relationship as sexual intercourse. In addition to these concerns, Cooper et al. (1999) identified three categories of individuals who access Internet erotic material, including recreational users, sexual compulsive users (these individuals are addicted to sex *per se*, and the Internet is but one mode where they can access sexual material), and at-risk users (these individuals would never have developed a sexual addiction if it were not for the Internet).

ETHICAL ISSUES PERTINENT TO THE STUDY OF INTERNET RELATIONSHIPS

Much of the research, to date, on Internet relationships and sexuality has been conducted online—either through interviews, surveys, or by carrying out analysis on text that is readily available online. There are many advantages to conducting research online as well as collecting text or data available online for analysis in one's research (see Table 1).

In spite of the numerous advantages to conducting research online, investigators also need to be aware of the disadvantages (see Table 2).

What all studies that research Internet relationships have in common is that they are researching a sensitive topic, which requires individuals to reveal personal and often very private aspects of themselves and their lives. Given the sensitive nature of this topic area, it is crucial that researchers give some serious thought to whether they are truly conducting research in an ethical manner.

Table 1. Practical benefits of conducting research online

- Easy access to a population of individuals who form relationships online and who access sexual material
- Internet provides researchers with a population that is sometimes difficult to research (e.g., people with disabilities, agoraphobia)
- Contact people in locations that have closed or limited access (e.g., prisons, hospitals)
- Requires relatively limited resources
- Ease of implementation

Photographs, video, sound bites, and text produced by individuals online are sometimes examined by researchers. The text can be produced in a number of different forums, including chat rooms, MUDs, newsgroups, MySpace, Bebo, and online dating sites. One way researchers collect data is by lurking in these different spaces in cyberspace. The development of online relationships (both friendships and romantic) and engaging in online sexual activities, such as cybersex, could easily be perceived by those engaging in such activities as a private discourse. Given the nature of these interactions, social researchers need to seriously consider if they have the right to lurk in online settings in order to learn more about these activities—despite the benefits of obtaining this knowledge.

There are fuzzy boundaries between what constitutes public and private spaces online, and researchers need to acknowledge that there are different places within cyberspace. For example, a chat room might be deemed a more public space than e-mail. It is contended here that lurking in some spaces online might be ethically questionable. We must, as researchers, debate how intrusive a method lurking potentially is. As Ferri (1999, cited in Mann & Stewart, 2000) contends, "who is the intended audience of an electronic communication—and does it include you as a researcher?" (p. 46).

Researchers also need to consider how the participant perceives the various online spaces. As Ferri suggests, private interactions can and do indeed occur in public places. It has been theorized that the Internet can give an individual a sense of privacy and anonymity (e.g., Rice & Love, 1987; Whitty & Carr, 2006). The "*social presence theory*" contends that "social presence" is the feeling one has that other persons are involved in a communication exchange (Rice & Love, 1987). Since computer-mediated-relating (CMR) involves less non-verbal cues (such as facial expression, posture, and dress) and auditory cues in comparison to face-to-face communication, it is said to be extremely low in social presence. Hence, while many others might occupy the space online, it is not necessarily perceived in that way. As researchers we need to ask some questions: Can researchers ethically take advantage of these people's false sense of privacy and security? Is it ethically justifiable to lurk in these sites and download material without the knowledge or consent of the individuals who inhabit these sites? This is especially relevant to questions of relationship development and sexuality, which are generally understood to be private

Table 2. Disadvantages of conducting research online

- Security issues
- Possible duplication of participants completing surveys
- Difficult to ascertain how the topic area examined impacts on the participant
- Restricted to a certain sample

matters. Therefore, good ethical practice needs to consider the psychology of cyberspace and the false sense of security the Internet affords.

It is suggested here that researchers need to maintain personal integrity as well as be aware of how their online investigations can impact the Internet relationships they study. For example, given researchers' knowledge of online relationships, interacting on online dating sites, chat rooms, and so forth could potentially alter the dynamics of these communities.

While it might be unclear as to how ethical it is for lurkers to collect data on the Internet, there is less doubt as to whether it is acceptable to deceive others online in order to conduct social research, especially with respect to online relationships and sexuality. Ethical guidelines generally state that deception is unethical because the participant is unable to give free and fully informed consent. For example, according to the Australian National Health and Medical Research Council (NHMRC), which set the ethical guidelines for Australian research:

As a general principle, deception of, concealment of the purposes of a study from, or covert observation of, identifiable participants are not considered ethical because they are contrary to the principle of respect for persons in that free and fully informed consent cannot be given. (NHMRC, 1999)

Generally, ethical guidelines will point out that only under certain unusual circumstances deception is unavoidable when there is no alternative method to conduct one's research. However, in these circumstances individuals must be given the opportunity to withdraw data obtained from them during the research that they did not originally give consent to.

FUTURE TRENDS

As with any other research conducted within the social sciences, some important ethical practices need to be adhered to when we conduct research on Internet relationships and sexuality (see Table 3).

Informed consent requires researchers to be up front from the beginning about the aims of their research and how they are going to be utilizing the data they collect. In off-line research individuals often sign a form to give their consent; however, this is not always achievable online. One way around this is to direct participants to a Web site that contains information about the project. This Web site could inform the participants about the purpose of the study, what the study entails, as well as contact details of the researcher, and the university Human Ethics Committee.

In some cases, spaces on the Web are moderated. In these instances, it is probably also appropriate to contact the moderators of the site prior to contacting the participants. This is analogous to contacting an organization prior to targeting individuals within that organization. Wysocki (1998), for instance, asked permission from the moderator of a sadomasochist bulletin board called the "pleasure pit."

Researchers also need to be aware that some European countries require written consent. If written consent is required, then the participant could download a form and sign it off-line and then return it by fax or postal mail (Mann & Stewart, 2000).

In research about relationships and sexuality, in particular, there is the risk that the interview or survey will stress the participant too much for them to continue with the study. As with off-line research, researchers need to consider up until what point a participant can withdraw consent. The end point of withdrawal of consent might be, for instance, after the submitting of the survey, or at the conclusion of the interview the interviewer might find confirmation that the participant is happy to allow the researcher to include the transcript in the study. Social scientists should also be aware that the lack of social cues available online makes it more difficult for them to ascertain if the participant is uncomfortable. Thus one should tread carefully and possibly make an effort to check at different points in the interview if the individual is still comfortable with proceeding.

There are other issues unique to Internet research in respect to withdrawal of consent. For example, the computer could crash mid-way through an interview or survey. Mechanisms need to be put into place to allow that participant to re-join the research if desired, and consent should not be assumed (Buchanan & Smith, 1999). In circumstances such as the computer or server crashing, we might need to have a system to enable debriefing, especially if the research is asking questions of a personal nature. Nosek, Banaji, and Greenwald (2002) suggest that debriefing can be made available by providing a contact e-mail address at the beginning of the study. They also suggest providing "a 'leave the study' button, made available on every study page, [which] would allow participants to leave the study early and still direct them to a debriefing page" (p. 163). In addition, they state that participants be given a list of FAQs, since they argue that there is less opportunity to ask the sorts of questions participants typically ask in face-to-face interviews.

There are various ways we might deal with the issue of confidentiality. As with off-line research we could elect to

Table 3. Ethical practices

• Informed consent
• Withdrawal of consent
• Confidentiality
• Psychological safeguards

use pseudonyms to represent our participants or even request preferred pseudonyms from them. However, a unique aspect of the Internet is that people typically inhabit the Web using a screen name, rather than a real name. Can we use a screen name given that these are not real names? While they may not be people's off-line identities, individuals could still be identified by their screen names if we publish them—even if it is only recognition by other online inhabitants.

As mentioned earlier in this article, research into the areas of relationships and sexuality is likely to cause psychological distress for some. It is perhaps much more difficult to deal with psychological distress online and with individuals in other countries. Nevertheless, it is imperative that we ensure that the participant does have counseling available to them if the research has caused them distress—which sometimes might be delayed distress. This could mean that there are limits to the kinds of topics about which we interview participants online or that we restrict our sample to a particular country or region where we know of psychological services that can be available to our participants if required.

Given that research into Internet relationships and sexuality is a relatively new area, future research might also focus on how to improve ethical practices. For instance, future studies might interview potential participants about how they would prefer social scientists to conduct research. Moreover, gaining a greater understanding of how individuals perceive private and public space could also influence how we conduct future studies in this topic area.

CONCLUSIONS

In concluding, while this article has provided examples of ways forward in our thinking about virtual ethics in respect to the study of online relationships, it is by no means prescriptive or exhaustive. Rather, it is suggested here that debate over such issues should be encouraged, and we should avoid setting standards for how we conduct our Internet research without also considering the ethical implications of our work. The way forward is to not restrict the debate amongst social scientists, but to also consult the individuals we would like to and are privileged to study.

KEY TERMS

Bebo: A social networking site where members can communicate with school and university friends, connect with friends, share photos, comment on others sites and photos, and write a blog.

Blog: Online diaries on a Web page, where the blogger updates entries, typically fairly regularly, in reverse chronological sequence.

Chat Room: A Web site, or part of a Web site, that allows individuals to communicate in real time.

Cybersex: Two or more individuals using the Internet as a medium to engage in discourses about sexual fantasies. The dialogue is typically accompanied by sexual self-stimulation.

Hot-Chatting: Two or more individuals engaging in discourses that move beyond light-hearted flirting.

Lurker: A participant in a chat room or a subscriber to a discussion group, listserv, or mailing list who passively observes. These individuals typically do not actively partake in the discussions that befall in these forums.

MUDs and MOOs: Multiple-user dungeons, or more commonly understood these days to mean multi-user dimension or domains. These were originally a space where interactive role-playing games could be played, very similar to Dungeons and Dragons.

MySpace: A social networking site where members can communicate with school and university friends, connect with friends, share photos, comment on others' sites and photos, and write a blog.

Online Sexual Activity: Using the Internet for any sexual activity (e.g., recreation, entertainment, exploitation, education).

Screen Name: A screen name can be an individual's real name, a variation of an individuals' name, or a totally made-up pseudonym. Screen names are especially required on the Internet for applications such as instant messaging.

IS Project Management Contemporary Research Challenges

Maggie McPherson
University of Sheffield, UK

INTRODUCTION

Although project management is often said to have its roots in other traditional fields, such as construction, Morris (2002) asserts that modern project management practices have their origins in the 1950s US aerospace agencies. Much has been written about Information System (IS) / Information Technology (IT) project initiatives in both the public and private sectors. In fact, many information systems frequently fall short of their requirements, and are, more often than not, costlier and arrive later than anticipated, if indeed they are completed at all. For instance, according to a report for the Organization for Economic Co-operation and Development (2001), failures of major IT investments and key systems development projects have raised concerns for the achievement of service improvement through information technology. Additionally, it has been argued that failures in IT projects are more common than failures in any other aspect of modern business (Nulden, 1996). The widely-cited Standish Group (1994) study, carried out in the US, classified IT projects as follows:

- **Resolution Type 1 (Project Success)**: The project is completed on-time and on-budget, with all features and functions as initially specified.
- **Resolution Type 2 (Project Challenged)**: The project is completed and operational but over-budget, over the time estimate, and offers fewer features and functions than originally specified.
- **Resolution Type 3 (Project Impaired)**: The project is cancelled at some point during the development cycle.

The report estimated the success rate was only 16.2%, while challenged projects accounted for 52.7%, and impaired projects (cancelled) amounted to 31.1%. Since large complex projects in any area are difficult to organize, it could be said that the level of abstraction required often leads to a lack of understanding between all stakeholders involved with the project. Callahan and Moretton (2001) describe software design as being "in the code". They assert that since it is not visible, it makes it hard to use software design as a focal point for development project coordination and integration, unlike many physical designs which can be made visible to all project participants. As a result of this "invisibility", managing the development of an IS project is arguably more problematic than project management within the manufacturing sector because software development is often a highly conceptual and complex process.

Indeed, a lack of adequate project management knowledge could be said to be a major contributing factor to unsuccessful IS projects. For instance, as project managers should be aware, unless specific objectives and clear-cut end points have been set, it can be difficult to know if a milestone has been reached and indeed if the required end-product has been produced. However, making use of proprietary tools such as Microsoft™ Project is sometimes mistakenly thought of as project management, whereas real project management expertise goes beyond the mere production of Gantt or Pert (Program Evaluation Review Technique) charts, which simply represent project activities in the form of bar charts or flow diagrams. As Mandl-Striegnitz et al. (1998) point out, important project management techniques include estimation of costs and explicit identification of risks. Clearly, there is a need for more in-depth research to gain a better understanding relating to the complex role of project management within the whole IS design and development process. This discussion considers how these problems affect contemporary IS project management research and explores the methodological approaches open to researchers carrying out investigations in this area.

BACKGROUND

In order to better understand the challenges facing researchers of Information Systems Project Management (ISPM), it is necessary to explore what is meant by some of these terms. As stated by the American National Standard for Telecommunications (2000), an IS is "an organized assembly of resources and procedures united and regulated by interaction or interdependence to accomplish a set of specific functions, whether automated or manual, that comprises people, machines, and/or methods organized to collect, process, transmit, and disseminate data that represent user information". In its simplest terms, an IS can be described as a human activity or social system, which may or may not involve the use of computer systems; although, these days the former is more likely. According to Stoner et al. (1994), management can be regarded as a process of planning, organizing, leading and controlling the efforts of staff and other resources in order to

achieve organizational goals, and the Association for Project Management (2000) describes a project as a distinct set of coordinated activities "… with definite starting and finishing points, undertaken by an individual or organization to meet specific objectives within defined time, cost and performance parameters". By combining these terms, a definition for ISPM could be said to be the process of managing the creation of an IS through the establishment of project goals; organizing, leading, co-coordinating the efforts of staff processes and tasks; and controlling other resources to achieve a set of agreed objectives.

Since IS projects are frequently comprised of multi-disciplinary teams of people, a definition of what is meant by a team in this particular context is called for. Geddes et al. (1993), regard a team as comprising those individuals who have a significant contribution to make to the successful achievement of the project, whether this is through technical or specialist expertise; sponsorship, political support or sponsorship; or expectation of, and interest in, outcomes. Programmers and associated staff are often selected according to their ability to demonstrate the appropriate technical knowledge, which does not guarantee proficiency in managing successful projects. Despite the emphasis on team leadership ability, senior developers/project managers are often promoted from the programming team, with a continued emphasis on technical expertise (Mandl-Striegnitz et al., 1998).

In reality, IS project managers must not only be able to plan and break activities down into components that can be understood and to control tasks and monitor risks, but must additionally be able to consider people and process issues requiring significant team-building skills. Although IS may be implemented by staff with technical competence, they may well lack the necessary abilities to evaluate organizational contexts and analyze corresponding behaviors.

Nevertheless, since 1994 there has been an improvement in project management outcomes. By 2001, the Standish Group published another report stating that project time and cost overruns had reduced significantly. Although this improvement in project results was confirmed by a UK-based survey (Saur & Cuthbertson, 2004), the authors acknowledged that their sample could have been unrepresentatively experienced, signifying a continued need for further research.

CRITERIA FOR ISPM SUCCESS

Referring to the Standish Group report "Extreme Chaos" (2001), it seems that lessons can be learned from the successes and failures of past projects which warrant further study. From extensive research, the Standish Group identified ten criteria for project success:

1. Executive support
2. User involvement
3. Experienced project managers
4. Clear business objectives
5. Minimize scope
6. Standard software infrastructure
7. Firm basic requirements
8. Formal methodology
9. Reliable estimates
10. Other criteria such as small milestones, proper planning, competent staff and ownership

In the UK based study, Sauer and Cuthbertson (2004) reported a higher project success rate than the US Standish Report (1994). Nevertheless, Sauer and Cuthbertson suggested that in order to continue this general improvement, the following recommendations ought to be adhered to:

- Project managers should:
  - Structure projects into smaller units
  - Select the right team and involving them in decision making
  - Invest time and effort in self-development
- Senior IT managers should:
  - Establish a project management focus in the organization
  - Identify the right person for project management role
  - Create appropriate career paths
  - Be accountable through more effective performance management
- Senior business managers/sponsors should:
  - Develop client understanding of project management
  - Engage more actively with projects for which they have responsibility

Some reasons for the improvements described above were costs being cut, better tools being created to monitor and control processes and, not least, project managers becoming better skilled with better management processes being used, giving rise to optimism for the future of project management. Despite the change for the better as highlighted above, the Standish Group (2001) considered "Nirvana" still to be a long way off, indicating a need for continued research. In order to select more appropriate research approaches to investigate ISPM, it is necessary to explore some of the issues specifically related to this particular field.

INFORMATION SYSTEMS PROJECT MANAGEMENT RESEARCH ISSUES

Prior to the 1950s, computing was primarily associated with scientific applications. Even after computer installation began in business environments for data-processing tasks, associated research had a tendency to be dominated by scientific approaches. Thus, despite the increasing importance of IS within modern businesses, for historical reasons the close association of IS development with IT induced many researchers to consider IS problems using methods from the natural sciences (Baskerville & Wood-Harper, 1996; Garcia & Quek, 1997) that are more suited to science laboratories. As a consequence of this scientific tradition, investigations within the field of IS appear to have had a predominance of both positivist and technical points of view, despite major criticisms (op.cit.) that may these research methods might be not always be wholly appropriate.

Keen (1984) stressed that IS is not simply the installation of a technical system in an organization. He suggested that successful implementation needs to consider institutional issues affecting its use in the ongoing context of jobs, formal and informal structures, as well as personal and group processes. Hughes and Wood-Harper (2000) concurred, rejecting the notion that the process is exclusively technical and rational. In their view, IS research should not merely pay attention to the technology and called for IS development to be understood in its situated context, i.e. to consider the domain, the organizational constraints, the social actors and the politics in situ.

ISPM RESEARCH METHODS

The debate as to whether to adopt quantitative or qualitative research methods is well-documented and will only be touched on lightly here. However, as described by Wilson (2002), one of the most contentious debates is whether to adopt the positivist view of the nature of social reality, in which social facts can be known with certainty and in which laws of cause and effect can be discovered, or whether to apply humanistic approaches which generally see social reality as constructed through social action on the part of people who undertake those acts because they have meaning for them. Conventional "scientific" research can run the risk of being reductionist (Lincoln & Guba, 1985), since complex problems are condensed in order to produce models that can provide a simplified simulation of reality. Bryman (1988) suggests that the basic choice of methodological approach is largely influenced by the type of research question being asked and according to Yin (1994) a researcher's choice of methodological approach depends on the problem at hand and the control that the researcher has over the behavioral events. Given that many researchers now believe IS to be socially constructed in particular contexts, it is thought to be important to extend research methodologies for ISPM problems beyond the positivist paradigm in order to uncover rich qualitative data.

FUTURE TRENDS

Mumford et al. (1985) argued for a methodological pluralism within IS research domains, asserting that scientific proof was being regarded as the only valid method despite the fact that many IS problems were not susceptible to these systematic methods. A decade later, Allen (1995) agreed that research methods from different paradigms can be used simultaneously or consecutively and are equally valid. Despite the historical emphasis on positivist methods in IS research, there is increasing support for developing this type of methodological mix and this is equally applicable to project management research. This is demonstrated by the fact that although the data for the Standish Group (1994) project management research was primarily collected through a survey, focus groups were conducted to augment the survey results.

In fact, Myers (1997) argues that all studies are based on some underlying assumptions about what constitutes "valid" research and it is this which should dictate which research methods are appropriate. Avegerou (2000), writing about alternative reasoning for IS, notes that the development literature argues that developing societies need to recognize the limitations of the validity of techno-economic rationality and that they ought to pursue rationalities stemming from their own value systems. IS professional roles have been based and legitimated mostly on technocratic logic, without an obligation to consider the validity of the requirements, which are normally based on the social context (Avegerou, 2000). Morris (2002) concurs, stating that project management is not a science in the full or proper sense of the word. This is contrary to the view of Khazanchi and Munkvold (2000) who believe that methodological and philosophical diversity do not preclude researchers from making scientific inquiries into the fundamental nature of IS phenomena.

Nevertheless, Morris believes that it is a discipline worthy of theoretical study, with various questions susceptible to the methods of scientific enquiry, whilst other areas will always have a large element of unpredictability. He therefore considers that some knowledge of this field will always be personal and experiential. Following this line of reasoning, prominent researchers such as Galliers (1992) have proposed that an interpretative stance for IS research would be wholly applicable. Correspondingly, other researchers have explored and recommended various interpretivist approaches as being particularly suitable. These methodologies include case study research (Yin, 1994), where the researcher interprets data

without direct involvement, and action research (Baskerville, 1999), where the researcher is actively involved.

However, Garcia and Quek (1997) stress the need for further critical awareness, stating that importing methods into the IS field is not a simple task. They warn that without critical awareness, there is a danger of methods becoming stereotyped or distorted. Nonetheless, they supported the use of multiple methods to correspond with the complexity of research investigation which will allow a better understanding of the different aspects involved in the constitution of the object under investigation.

CONCLUSION

If one accepts that IS are socially constructed, as many researchers now appear to do, then it follows that evaluative research of IS projects needs to be situated in contextualized and authentic settings. It would therefore seem highly appropriate to set aside the positivist versus interpretivist debate, since Marcella and Knox (2004) suggest that "…it is only based upon a much fuller and more precise understanding of the complex and multifaceted needs of all users, internal and external, in all functional areas of the institution, that systems will be developed which are truly responsive and which function to meet overall … objectives". With this in mind, it seems reasonable to suggest that it is worthwhile combining diverse research methods, as endorsed by Fitzgerald and Howcroft (1998), with a view to maximizing their complementary strengths. This would seem to be particularly appropriate to address many of the concerns and issues relating to ISPM as highlighted in this discussion.

KEY TERMS

Case Study Research: An in-depth investigation that attempts to captures lessons learned through studying the environment, procedures, results, achievements, and failures of a particular project or set of circumstances.

Development Literature: Literature about impoverished countries of the world that are trying to modernize or to find different ways of supporting their populations.

Focus Group: A small group interview, conducted by a moderator, which is used to discuss one or more issues.

Humanism: A philosophical approach that focuses on human value, thought, and actions.

Information Systems Project Management: The process of managing the creation of an IS through the establishment of project goals; organizing, leading, co-coordinating the efforts of staff processes and tasks; and controlling other resources to achieve a set of agreed objectives.

Interpretivism: A research approach that attempts to reach an understanding of social action in order to arrive at a causal explanation of its course and effects.

Positivism: A belief that natural science, based on observation, comprises the whole of human knowledge.

Project Team: All individuals who have made a significant contribution to make to the successful achievement of the project.

Project: A distinct set of coordinated activities with definite starting and finishing points, undertaken by an individual or organization to meet specific objectives within defined time, cost and performance parameters.

Techno-Economic Rationality: Logical justification for making a connection between technical advances and economic growth.

INTRODUCTION

A multimedia system is characterized by the integrated computer-controlled generation, manipulation, presentation, storage, and communication of independent discrete and continuous media data. The presentation of any data and the synchronization between various kinds of media data are the key issues for this integration (Georganas, Steinmetz, & Nakagawa, 1996). Clearly, multimedia systems have to precisely coordinate the relationships among all media that include temporal and spatial relationships. Temporal relationships are the presentation schedule of media, and spatial relationships are the location arrangements of media. Multimedia synchronization is a process of maintaining these relationships by employing appropriate synchronization mechanisms and algorithms. Multimedia synchronization is traditionally challenging, especially in distributed environments.

Three types of multimedia synchronization can be distinguished: intrastream synchronization, interstream synchronization, and intermedia synchronization (Crowcroft, Handley, & Wakeman, 1999). The approaches used for interstream synchronization can also be used for intermedia synchronization.

The word *synchronization* refers to time. The easiest way of synchronizing between streams at different sites is to use a single time reference. There are several ways to provide this time reference.

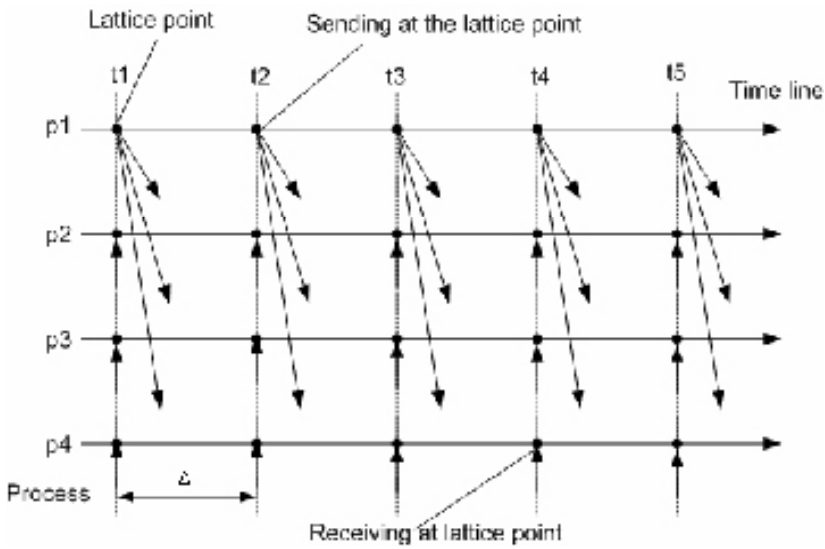
- The network will have a clock serve as a single reference. This approach is used in H.261/ISDN- (integrated services digital network) based systems. A single clock time is propagated around a set of codecs and multipoint control units (MCSs).
- The network deploys a clock-synchronization protocol, such as NTP (the network time protocol; Mills, 1993). The time stamps of media packets will be derived from the globally synchronized clocks. The isochronous synchronization approach as described in this article heavily relies on this time reference.

AN ISOCHRONOUS SYNCHRONIZATION APPROACH

The isochronous synchronization approach employs a clock-driven protocol for achieving multimedia synchronization (any one of three types of synchronization; Yang, Gay, Sun, Siew, & Sattar, 2002). This approach is particularly suitable for distributed collaborative multimedia environments where many-to-many multimedia communication is the basic interaction pattern. In this approach, multimedia synchronization is based on the use of synchronized physical clock time instead of any form of logical clock or sequence numbers, and thus clock synchronization across the distributed system is assumed. A real-time (synchronized) clock is incorporated in the system as a mechanism used for initiating significant events (actions) as a function of real time.

With globally synchronized clocks that satisfy the granularity condition, we can construct an *action lattice* (or *event lattice*; Kopetz, 1992). One dimension of this lattice represents the progression of time, the other dimension is the processes in the system (Figure 1). Processes in the system are designed to execute a simple *clock-driven protocol*, which requires that the events of sending and receiving messages are restricted to only occur at the lattice point of the globally synchronized space-time lattice (Figure 1). Thus, whenever an action has to be taken, it has to be delayed until the next lattice point of the event lattice.

Figure 1. Lattice structure



This lattice structure greatly simplifies multimedia synchronization and readily maintains the temporal and causal relationship among the media.

The idea behind the clock-driven, isochronous synchronization is very simple and intuitive in that the easiest way to synchronize processes is to get them all to do the same thing at the same time. Using the simple mechanism based on the synchronized clock without requiring complex algorithms, the approach can equally well be applied to various multimedia applications in distributed environments, including live multimedia applications (live teleconferencing and CSCW) and stored media applications.

THE ORDERING PROPERTIES OF THE SYNCHRONIZATION PROTOCOL

In essence, what is really required for distributed multimedia synchronization is *order*; that is, a synchronization protocol must ensure that multimedia messages or streams are sent, delivered, and presented in an order that is consistent with the expected behavior of the distributed multimedia system as a whole. Clearly, multimedia systems have to precisely coordinate the relationships among all media. These relationships include temporal and spatial relationships. Temporal relationships are the presentation schedule of media, and spatial relationships are the location arrangements of media.

There are two specific cases concerning temporal order: *causal order* and Δ-*causal order*. These ordering concepts are derived from a happens-before relation, which is a more fundamental notion in distributed computing. The expression $a \rightarrow b$ is read as "*a* happens before *b*" and means that all processes agree that first, event *a* occurs, then afterward, event b occurs. The happens-before relation can be observed directly in two situations in a distributed environment: (a) If *a* and *b* are events in the same process and *a* occurs before *b*, then $a \rightarrow b$ is true, and (b) if *a* is the event of a message being sent by one process and *b* is the event of the message being received by another process, then $a \rightarrow b$ is also true. Obviously, a message cannot be received before it is sent or even at the same time it is sent since it takes a finite, nonzero amount of time to arrive. Note that happens-before is a transitive relation, so if $a \rightarrow b$ and $b \rightarrow c$, then $a \rightarrow c$.

The notion of causal order, as introduced by Birman and Joseph (1994), states that for any process, the order in which it delivers messages must respect the happens-before relation of the corresponding sending of the messages. More formally, a distributed computation *E*, all of whose messages is denoted as a set $M(E)$, respects causal order if for any two messages $m1$ and $m2$ and corresponding message-sending events $send(m1)$ and $send(m\_2)$, $send(m1) \rightarrow send(m2)$. If $m1$ and $m2$ have the same destination process, then for the message delivering events, $deliver(m1) \rightarrow deliver(m2)$.

In the definition of causal order, nothing is mentioned about the time at which the messages are delivered; also, it does not prescribe what to do with the cases of message loss and late arrival. However, in a distributed multimedia system, messages have limited *validity time*, after which the

messages become useless and are allowed to be discarded. Messages that arrive at its destination within its validity time must be delivered within the expiration of its validity time and in its causal order. This motivates the notion of Δ-causal order, introduced in Yavatkar (1992) and formalized in Baldoni, Mostefaoui, and Raynal (1996). The Δ-causal order is defined as follows. A distributed computation respects Δ-causal order if (a) all messages in $M(E)$ that arrive within a time interval Δ are delivered within Δ and all the others are never delivered (they are lost or discarded), and (b) all delivery events respect causal order. That is, for any two messages $m1$ and $m2$ in $M(E)$ that arrive within Δ we have, if $send(m1) \rightarrow send(m2)$ and $m1$ and $m2$ have the same destination process, then $deliver(m1) \rightarrow deliver(m2)$.

The clock-based isochronous synchronization protocol requires the following ordering property be respected.

- **Same order:** The multimedia messages are delivered to the destinations in the same order.
- **Temporal order:** Different destinations see the different messages in the temporal order.
- **Simultaneity:** Different destinations see the same messages at about the same time.

Note that the temporal order is a prerequisite for the causal order. If and only if the occurrence of an event e_1 has preceded the occurrence of an event e_2 in the domain of real time, it is possible that e_1 has an effect on e_2. On the other hand, if it can be established that e_2 has occurred after e_1, e_2 cannot be the cause of e_1.

The basic mechanism is to use clock values as event time stamps to preserve temporal ordering of events and to achieve synchronization, and clocks in the system must have sufficient granularity or resolution. The granularity g of a synchronized clock is defined as the real-time duration between two consecutive global ticks. Obviously, the temporal order of two or more events, which occur between any two consecutive ticks of the synchronized clock, cannot be reestablished from their time stamps. This is a fundamental limit when using clock time for temporal ordering.

With globally synchronized clocks having sufficient granularity, we can construct an action lattice (or event lattice) as described above; that is, one dimension of this lattice represents the progression of time, and the other dimension is the processes in the system (Figure 1). Processes in the system are designed to execute a simple clock-driven protocol (an isochronous protocol below), which requires that the events of sending and receiving messages are restricted to only occur at the lattice point of the globally synchronized space-time lattice. Thus, whenever an action has to be taken, it has to be delayed until the next lattice point of the event lattice. This delay is the price we have to pay for the simple and intuitive synchronization protocols.

This lattice is a basic mechanism for the isochronous approach to multimedia synchronization. The lattice interval, Δ, is an important design parameter for the synchronization protocols. The following factors will affect how to choose Δ.

- The bounded end-to-end communication delay
- The validity time of multimedia, beyond which the multimedia objects become useless
- The granularity g and precision p of clock synchronization

As a general guideline, Δ must be large enough to accommodate all these factors; it must also be small enough not to unduly delay events.

AN ISOCHRONOUS SYNCHRONIZATION PROTOCOL

We now describe a general clock-driven, isochronous protocol to achieve desired multimedia synchronization. The protocol seeks to guarantee that in a time period, a set of processes will deliver the same messages at the same time and in the same temporal order. Here, "same time" must be understood to be limited by the clock skew (clock-synchronization precision) as much as π, meaning that two processes undertaking to perform the same action at the same time may in fact do so as much as π time units apart.

The protocol executes its events on every clock tick (i.e., at the lattice point), and executes a *No-Op* event by doing nothing if there is no communication event to take place on a clock tick. In practice, operations on a clock tick can be implemented by an interrupt-driven program; for example, the receipt of a message time-stamped T causes the setting of a clock interruption for $T+\Delta$, which in turn will cause the message to be processed at that time. When a process disseminates a message, it will not do so immediately; rather, it will wait until the next tick (i.e., next lattice point) on its clock and then time-stamp the message using its clock reading and send out the message. When the message arrives at its destination, it is not sufficient for the destination process to handle messages that have been received in ascending order by time-stamp. We must ensure that a process delivers messages only if no message with a smaller time stamp can be subsequently received. We say that a message is *stable for p* once no message with a lower time stamp can be delivered to the process p. Clearly, a message should be processed only after it becomes stable.

The lattice structure for the protocol operation provides a convenient way of establishing message stability. Here, testing the stability of a message can be accomplished by exploiting the bounds on delivery delays (i.e., the next lattice point) and process clocks. A message time-stamped T by

process p will be received by $T+\Delta$ at every other process in the system according to each process' local clock, which is synchronized with the others. The message that arrives later than $T+\Delta$ is considered useless and discarded (because the multimedia message is beyond its validity time).

The isochronous synchronization protocol follows the following rules.

- **Sending Rule:** A process sends out the message at every clock tick; if there is no message to send, the process will do nothing (or you can think of it as sending out a null message) at the clock tick.
- **Stability Rule:** A message is stable at process p_i if the time stamp on the message is T and the clock at p has a value equal or greater than $T+\Delta$.
- **Delivery Rule:** Stable messages are delivered to the application in ascending order by time stamp.
- **Tie-Breaking Rule:** Two messages with the same time stamp from different processes are ordered according to the process ID, which is assumed to be unique.

Note that the ordering properties as required by the synchronization are guaranteed by executing this protocol. Noticeably, the temporal order, causal order, and Δ-causal order are all respected without requiring additional sophisticated algorithms. In executing this protocol, all processes have a consistent behavior toward messages.

The isochronous synchronization approach assumes globally synchronized clocks in distributed systems. The improved NTP (version 3) enjoys synchronization to within a few tens of milliseconds in the global Internet of today; the clock synchronization for LANs (local area networks) can obtain accuracy as high as a few microseconds. The introduction of the Global Positioning System (GPS) in the 1990s has further advanced the clock-synchronization technique (Herring, 1996). GPS has introduced an inexpensive way to obtain accurate information (including time information) using a radio receiver, which consists of nothing more than a GPS receiver and a network interface. Time obtained in this manner is accurate to a few tens of microseconds. Accuracy such as this is adequate for even the most demanding real-time applications. With this development and such an accurate timing source in place, we believe that the clock-based isochronous distributed synchronization, as advocated by Lamport (1984), provides a promising yet simple and intuitive alternative.

ACHIEVING ISOCHRONOUS SYNCHRONIZATION USING RTP/RTCP

RTP (a transport protocol for real-time applications) is the real-time transport protocol within an Internet integrated-service architecture, which is designed to provide a quality-of-service guarantee beyond the current TCP/IP (transmission-control protocol/Internet protocol) best-effort service model. RTP provides end-to-end network transport functions suitable for applications transmitting real-time data (e.g., audio, video, or simulation data) over multicast or unicast network services. The data transport is augmented by a control protocol (RTCP) to allow monitoring of the data delivery in a manner scaleable to large multicast networks, and to provide minimal control and identification functionality. RTP and RTCP are designed to be independent of the underlying transport and network layers.

The noticeable feature associated with media synchronization is the 32-bit time stamp field in RTP data packets, the 64-bit NTP time stamp field, and the 32-bit RTP timestamp field in RTCP control packets. Although RTP does not mandate running the NTP to provide clock synchronization, running NTP is very useful for synchronizing streams transmitted from separate hosts. The mechanisms incorporated in RTP/RTCP enable the isochronous synchronization protocol.

One of primary functions of RTCP is to provide feedback in RTCP control packets (sender report, SR, and receiver report, RR) on the quality of the data distribution and information for intermedia synchronization. The RTP standard requires that the NTP time stamp (based on synchronized clocks) and corresponding RTP time stamp (based on data-packet sampling) are included in RTCP packets by data senders. This correspondence between the RTP time stamp and NTP time stamp may be used for intra- and intermedia synchronization for sources whose NTP time stamps are synchronized. Using the time-stamp mechanisms in RTP/RTCP and the lattice structure described in this chapter, our isochronous approach can be readily applied to multimedia systems, particularly in distributed many-to-many conferencing environments.

CONCLUSION

In distributed multimedia systems, there exist two approaches to protocol design, event driven and clock driven, and most protocols have taken an event-driven approach. While using physical time based on globally synchronized clocks for obtaining synchronization was advocated a long time ago, the clock-driven approach has not been popular in the distributed-system research community. In conjunction with the lattice structure, the isochronous protocol achieves the required synchronization, which guarantees the temporal order, including causal order and Δ-causal order, without additional sophisticated algorithms for respecting causality. The only assumption of the isochronous protocol is the synchronized clocks in a distributed system and the known bounds of the network communication delays. These assumptions can readily be satisfied with the deployment

of modern networks. The mechanisms incorporated in the Internet standard real-time protocols such as RTP/RTCP make the isochronous synchronization approach readily applicable.

KEY TERMS

Clock Synchronization: Physical clocks in a network are synchronized to within certain precision and accuracy. The precision refers to the difference between readings of clocks, and the accuracy refers to the difference between the clock reading and the universal standard time.

Intrastream Synchronization: This, also called play-out synchronization, ensures that the receiver plays out the medium a fixed time after it was generated at the source and it experienced variable end-to-end delay. In other words, intrastream synchronization assures that a constant-rate source at the sender again becomes a constant-rate source at the receiver despite delay jitter in the network.

Intermedia Synchronization: This is concerned with maintaining the requirements of the temporal relationships between two or more media. Lip synchronization between video and audio is an example of interstream synchronization where the display of video must synchronize with audio.

Interstream Synchronization: This ensures that all receivers play the same segment of a medium at the same time. Interstream synchronization may be needed in collaborative environments. For example, in a collaborative session, the same media information may be reacted upon by several participants.

Isochronous: The term refers to time-dependent processes where data must be delivered within certain time constraints. For example, multimedia streams require an isochronous transport mechanism to ensure that data is delivered as fast as it is displayed, and to ensure that the audio is synchronized with the video. Isochronous processes can be contrasted with asynchronous processes, which refers to processes in which data streams can be broken by random intervals, and synchronous processes, in which data streams can be delivered only at specific intervals. Isochronous service is not as rigid as synchronous service, but not as lenient as asynchronous service.

Multimedia: This term is used to indicate that the information and data being transferred over the network may be composed of one or more of the following media types: text, images, audio, and video.

NTP: NTP stands for network time protocol, and it is a standard Internet protocol used to synchronize the clocks of computers to some time reference.

Stream: This technique is for transferring data such that it can be processed as a steady and continuous stream. Streaming technologies are becoming increasingly important with the growth of the Internet because most users do not have fast-enough access to download large multimedia files quickly. If the stream is for transferring multimedia data, it is called a *multimedia stream*.

Validity Time: This is a time interval within which the message remains valid, available, and useful to its recipients. After the validity time of a message, the message becomes

useless and may be discarded. The notion of validity time is important in multimedia communication.

Issues in Using Web-Based Course Resources

Karen S. Nantz
Eastern Illinois University, USA

Norman A. Garrett
Eastern Illinois University, USA

INTRODUCTION

Education over the Internet is going to be so big it is going to make e-mail usage look like a rounding error.

John Chambers, Cisco Systems, New York Times, November 17, 1990

Web-based courses (Mesher, 1999) are defined as those where the entire course is taken on the Internet. In some courses, there may be an initial meeting for orientation. Proctored exams may also be given, either from the source of the Web-based course or off-site at a testing facility. The Internet-based course becomes a virtual classroom with a syllabus, course materials, chat space, discussion list, and e-mail services (Resmer, 1999). Navarro (2000) provides a further definition: a fully interactive, multimedia approach. Current figures indicate that 12% of Internet users in the United States use the Internet to take an online course for credit toward a degree of some kind (Horrigan, 2006). That number is indicative of the rapid proliferation of online courses over the past several years.

The Web-enhanced course is a blend with the components of the traditional class while making some course materials available on a Web site, such as course syllabi, assignments, data files, and test reviews. Additional elements of a Web-enhanced course can include online testing, a course listserver, instructor-student e-mail, collaborative activities using RSS feeds and related technologies, and other activities on the Internet.

One of the biggest concerns about Web-based courses is that users will become socially isolated. The Pew Internet and America Life Project found that online communities provide a vibrant social community (Horrigan, Rainie, & Fox, 2001). Clearly, students are not concerned or feel that other benefits outweigh the potential drawbacks. According to government research (Waits and Lewis, 2003), during the 2000-2001 academic year alone, an estimated 118,100 different credit courses were offered via distance education (with the bulk of that using Internet-based methods) by 2- and 4-year institutions in the United States. Over 3 million students were registered in these courses.

Navarro (2000) suggests that faculty members are far more likely to start by incorporating Internet components into a traditional course rather than directly offering Web-based courses. These Web-enhanced courses might be considered the transition phase to the new paradigm of Internet-based courses. Rich learning environments are being created, with a shift from single tools to the use of multiple online tools, both to enhance traditional courses and to better facilitate online courses (Teles, 2002).

BACKGROUND

A 1999 research study showed that 27.3% of the faculty members thought they used the Internet for the delivery of course materials, but only 15.6% actually did so. Of this group, the major use was simply the substitution of a Web page for the printed page. Most faculty members (73.8%) updated their sites so infrequently that the sites only served to replicate printed handouts. In a follow-up study at the same university, the number of faculty who used Web pages to enhance their courses showed a decrease from the previous year (Garrett, Lundgren, & Nantz, 2000). In the same study, 22% of the faculty were never planning to use a Web site for delivery of any portion of their courses. Less than 5% were truly incorporating Web technology into their courses in a meaningful way. Lee Raines, Director of the Pew Internet and American Life Project notes that the role of experts, such as teachers, has changed. The Internet has empowered amateurs. New teaching models and methods have developed as educators try to adjust to changing student attitudes (Rainie, 2006). The new educational model becomes "the net-savvy, well-connected, teacher-independent end-user" (Castells, p. 20).

Overall, Internet penetration for U.S. adults is up to 73% as of April 2006, up 9% in just one year. In addition, "… the 40% in home broadband adoption from March 2005 to March 2006 is double the 20% rate of increase that occurred from March 2004 to March 2005" (Horrigan, 2006). For college age degreed adults, 91% go online regularly (Rainie, 2006). Researchers at Ball State University found that 30% of a waking day is spent with media as the sole activity with an additional 39% spent with media combined with some other

activity ("Average…", 2005). Fully one third of all Internet users in the U.S. say that the Internet has greatly improved the way they pursue hobbies and interests (Madden, 2006) and each day 44% of all Americans are online at some point, up from 36% in 2002 (Horrigan & Rainie, 2006).

Part of the expectation of the current college population is that two-way technologies are the norm (instant messaging, Weblogs, and online journaling, for example) and that online communities provide a rich environment for information sharing. According to Pew data, almost half of Internet users access listservs, RSS feeds, and bulletin boards to stay engaged. This shift to more collaborative tools provides new opportunities but creates numerous challenges. Learning management systems (LMS) are adding collaborative tools to reflect the changing habits of Internet users. All of the popular LMS tools, such as WebCT, Blackboard, and Moodle provide for online discussions, information posting, group assignments, synchronous chats, interactive quizzes, and a closed e-mail system. Students perceive collaborative activities, both synchronous and asynchronous, as cutting edge. Castell and Wellman refer to this synchronous and asynchronous environment as "networked individualism" (Castells, p. 20). In Figure 1, Garrett (2006) presents a breakdown of the myriad tools available in various combinations of synchronous/asynchronous and interactive/non-interactive. With these tools available in an almost endless variety of combinations, classroom experiences can be tailored to suit the content as well as the student learning styles (see Baggaley, 2003, for some examples).

Clearly, there are many compelling reasons to use Web-based resources in a course including greater efficiency in the delivery of materials, providing up-to-the-minute content, enhanced status for the course and faculty, fostering student-to-student collaboration, and the use of technologies with which the students are increasingly familiar and comfortable.

Despite the quantum leap in Internet technology adoption, some of the familiar problems still exist. Faculty still must adapt to a looser teaching environment. No longer are lectures delivered from a raised lectern, enough. The expectation by students is that the classroom paradigm has shifted, and faculty must adapt to a looser, more flexible teaching environment. Some of the issues inhibiting the use of Web-based resources include: lack of faculty knowledge of Web page design, html, server sites, and file transfer protocols (Nantz & Lundgren, 1998); perceived need for Web glitz to provide entertainment along with content such as highly interactivity, animation, audio, and video streaming; lack of accessibility to Web resources for both faculty and students (Rao & Rao, 1999); sufficient training for faculty (Rups, 1999); and compensation for cyberprofs who typically spend twice as much time developing and teaching Web-based courses for no extra pay (Navarro, 2000).

Carr notes that the high drop rates in online courses may result from faculty inexperience with the new classroom paradigm (Carr, 2000). Also, the need to continually retool to stay even with the student use of technology is daunting.

Illinois State University identified five major issues driving Web-delivered courses:

- Technology needs to be driven by sound pedagogical goals.
- Technology tools need to address a specific pedagogical task with technical expertise available.
- Faculty want and need to interact with peers who are doing similar tasks.
- Hardware must support teaching without frustrating students and faculty.
- Faculty need recognition for technology adoption ("Average…". 2005).

A Course Web Site Classification

Courses using Web-based resources can be classified in six different levels. At the top levels are the Internet-based classes (i.e., the course was created and organized to be Web delivered). The middle levels involve a Web class that uses the Internet for delivery of content and communication among the course registrants, but also uses face-to-face meetings for some classes, orientation, and testing. At the lowest level,

Figure 1. Instructional Communication (Adapted from Garrett, 2006)

	Non-interactive	***Interactive***
Synchronous	Lecture Web casts Videos	Discussion Managed Meetings IRC Chat Internet Messaging (IM) Webinars
Asynchronous	Podcasts / Vodcasts Webcasts Wikis	Discussion Boards Weblogs RSS Feeds / Syndication Cellular Text Messaging (SMS)

Table 1. Classification of academic Web pages

Level	Description	Typical Content	Maintenance Level Required
1	Traditional course presentation, basic-level course materials on Web—internal links	Instructor data (name, phone, office hours, e-mail address) course materials (syllabus, generic schedule, assignments); non-interactive	Low—static pages after initial upload. Low-volume e-mail correspondence.
2	Traditional course presentation—intermediate-level course materials on Web—external links	All Level 1 Some external links, such as textbook and reference sites; non-interactive.	Low—mostly static pages with occasional updates and checking of external links. Low-volume e-mail correspondence.
3	Traditional enhanced course presentation—intermediate-level course materials on Web and Web content delivery	All Level 2 All traditional course materials posted. Web access in class used for delivery of some course content. Some assignments/requirements involve interaction, e.g., e-mail submissions, listserv postings.	Weekly updates to schedule, FAQ, course materials, notes to students. Medium-volume e-mail correspondence.
4	Traditional enhanced course presentation—complete Web content and materials	All Level 3 Course Presentations and lectures dynamically available on Web. Data files, links, programs on Web for students. Forms for student "reply" assignments, course evaluations, etc. Link to course grades.	2-3 times per week. Regular updating of grades. Medium-volume e-mail correspondence.
5	Web-delivered course with orientation and testing meetings	All Level 4 plus any additional materials to allow for full Web delivery of course including audio and video augmentation; multimedia CD's. Few or no regular classes—orientation meeting may be necessary. Testing may be proctored off-site or unproctored on the Web.	Daily maintenance and access by instructor. High-level of e-mail correspondence. Regular updating of grades and course materials.
6	Virtual class	All Level 5 plus online testing and orientation. Discussion, chat groups, list serve, e-mail, and other interactive tools;. Teleconferencing. No class meetings.	Substantial daily maintenance (average 1-3 hours) by instructor including all course aspects. High-level of e-mail correspondence.

some course materials are simply presented in a hypertext format that replace traditional printed handouts. Table 1 shows the classification levels of academic Web pages by typical content and maintenance levels.

The six levels previously presented indicate progression from the most basic Web-enhanced course to a course delivered fully on the Internet. Faculty would likely proceed through the levels to reach level 4 for traditional classes unless limited by resources, expertise, and administrative factors. Levels 5 and 6 require significant changes in the academic structure and considerable support of the academic computing environment. The following table summarizes the resources that would be involved in the process of moving courses to the Web.

Although Table 2 shows a summary of the typical resources faculty need to develop Web course materials at varying levels, there are other elements that will be just as important in achieving a specific level of Web course expertise. The following list illustrates some of the issues involved. For a more comprehensive discussion, see Nantz and Lundgren (2003).

Issues Inhibiting Web-Enhanced Courses and Recommendations

- Be realistic about your own level of expertise and the instructional support you have available. Convert print-based materials to html using Word or some other

Table 2. Resources involved in moving to the Web

Level	Description	Resources Needed
1	Traditional course presentation, basic-level course materials on Web—internal links	Basic computer literacy, Web browsing experience. Course site can be created by the faculty member, professional designers, by use of Web course applications such as BlackBoard, WebCT, or the open-source Moodle.
2	Traditional course presentation—intermediate-level course materials on Web—external links	Experience with preceding level. Web application packages can be extended or with additional training, a general Web development package like MS FrontPage or DreamWeaver can be used.
3	Traditional enhanced course presentation—intermediate-level course materials on Web and Web content delivery	Experience with preceding level. Commitment to regular maintenance. Knowledge of e-mail attachments, listserv maintenance, or other interactive Web applications. Both Web application and general Web development packages can be extended for this level.
4	Traditional enhanced course presentation—complete Web content and materials	Experience with preceding level. Professional Web applications may not be able to accommodate this level without considerable difficulty. Usually requires considerable expertise with general Web development packages and some knowledge of HTML and programming concepts include Javascript, ASP, and XML. In addition, a working knowledge of social networking tools such as blogs and wikis, RSS feeds, and XML might be helpful.
5	Web-delivered course with orientation and testing meetings	All of the above. No additional faculty resources required; academic structural change to allow for registration and other student activities online.
6	Virtual class	Use of a sophisticated commercial Web course package that allows for secure online testing; considerable administrative support and faculty expertise in the selected package.

familiar software. Once a comfort level is achieved, incorporate other html code using simple programs like Netscape Composer. Cut and paste code from sample Web pages. Extend knowledge to knowledge of common gateway interface (CGI) scripts, Java, or XML (Extensible Markup Language). Use university's instructional support personnel to help you set up simple Web pages that are at your comfort level for maintenance.

- Be realistic about the cost in time and money to maintain course Web sites. The development of a full Web-delivered course may be as high as $115,000 (Navarro, 2000). Marchese (1998) suggests a range of $12,000 to $90,000 per credit hour. Any Web platform provider will charge a licensing fee, which may be based on the number of students. The equivalent of a 1-hour lecture may require 24 hours for writing, recording, and editing and up to 162 hours for full multi-media support.
- Be realistic about your access and the students' access to technology. Any administration who wants Web-delivered coursework must provide adequate technology to support it, either through on-campus servers or an off-campus Web host. Do not assume that all students have broadband connections at home, or their own computers on which to install specialized software.
- Be realistic about converting paper-based content to Web content. A direct conversion usually doesn't work well. The visual indicators on printed materials (headers, footers, page numbering) don't convert well to html. Content and access must be re-evaluated. Powerpoint slides can be posted, but good slide design means key points only. Substantial notes must be provided to expand on the slides. Some students see the notes as ancillary and don't get the depth of content. Text-based sites are seen as boring. An academic course site that simply creates text on a Web page defeats the purpose of using Web pages—of having the ability to create links to interesting sites, to provide graphics, to provide sound and video. Providing hundreds of pages of text is the death knell for a Web class.
- Be realistic about the use of Web-based multimedia materials. Unless these are professionally developed by staff that are familiar with the software, they are often viewed by students as low-quality even through they can be extremely time-consuming to produce. Overuse of multimedia can be counterproductive and can also become a storage and transmission burden, as multimedia can consume large amounts of storage and bandwidth. A good balance of quality multimedia

with other materials can significantly enhance learning in a class, but great care must be taken in the selection and application of the media.

- Be realistic about your expectations of a Web-enhanced course. Our research shows that when course content is placed on the Web, student attendance will drop by as much as 50%. Students see printing Web pages as a substitute for class attendance (Lundgren & Lundgren, 1996).
- Keep in mind that students may be more familiar with the technologies than you are. Many of them have grown up with technology and are more used to it than their older instructors. Recent statistics (Hitlin & Rainie, 2005) show that 87% of people in the U.S. aged 12 to 17 use the Internet and 78% of those have used it at school. Students, for example, are used to social networking and peer-to-peer collaboration, and studies show that they prefer synchronous interaction (such as instant messaging) to asynchronous interaction, such as e-mail (Lenhart, Madden, & Hitlin, 2005). You can use that to your advantage in a course if you use such tools as blogs, wikis, and RSS feeds (Harrsch, 2003), which are highly collaborative tools. These allow a higher degree of asynchronous collaboration than was previously possible and the technologies can be implemented at low cost. Similarly, instant messaging and chats provide the ability for synchronous interaction that is very much a part of the lives of many college students. This familiarity can be leveraged for classroom use with appropriate, and often free and readily available, software tools.
- Be realistic about the stability of the technology. Over 90% of instructors report frequent problems (Navarro, 2000). You can't expect to use transparencies as a backup to an interactive lecture with dynamic linking. Especially with the vulnerability of the Internet and servers to virus and worm threats, there will be times when the Internet is down or so slow that interactivity isn't possible. Plan for technical problems and have a contingency plan that is communicated to students.
- Be realistic about the reward system for incorporating technology. If you are at an institution where research is valued more than teaching, then you may need to forego creating Web content. Navarro (2000) also notes that "cyberprofs" are reporting strong negative reactions from their colleagues. If you are sitting in your office answering student e-mail or creating course content, you don't appear to be teaching.
- Make sure intellectual property and royalty procedures are clearly spelled out. Many faculty do not consider the issue of copyright and intellectual property when course materials are developed (Rueter, 2001). Most faculty believe they own their own course materials. This is often not the case. The issue becomes even muddier when entire courses are delivered on the Web (levels 5 and 6). A course that you developed could be offered by the university with someone else teaching it, without your consent or knowledge. Earnings from distance learning are viewed quite differently by faculty and administration (Guernsey & Young, 2001).
- Make sure you and your administration agree what "quality" teaching is. Age-old tenets of quality teaching include meaningful discussion, question and answer discourse, and significant teacher-student interaction. If faculty develop a Web-enhanced course following the myth of preserving student interaction, they will be quickly mired in Web activities that consume the majority of their time with no observable educational payoff. The less subtle problems that stem from a lack of administrative understanding include difficulties in obtaining resources, especially released time for the initial development of a Web class, lack of understanding about how many hours are needed to run the course when you aren't standing in front of a classroom, e-mail overhead, managing list serves, problems in obtaining reasonable hardware and software to develop and maintain a Web course, and the number of students that should be placed in the section.

FUTURE TRENDS

As younger, more computer-literate faculty emerges, there will be a slow and steady move toward the incorporation of Internet components into university courses. Many educational pundits believe that we are moving into a new learning paradigm with the integration of technology into our schools (Von Holzen, 2000). This new educational model envisions a complete shift in course delivery from the traditional lecture classroom to on-demand, flexible learning through the use of telecommunications technology or "just-in-time" learning. In this paradigm, the faculty will become the designers of interactive course materials.

CONCLUSION

With this new paradigm, many of the issues discussed in this chapter may take care of themselves. In the meantime, faculty who are considering Web-enhanced or Web-delivered courses need to be aware of the issues. But, most of all, we believe that learning is more than just content delivery; we need to create learning environments whether they are in the classroom or in cyberspace.*

KEY TERMS

HTML (Hypertext Markup Language): This is the foundation protocol for the world wide Web (WWW) that allows text, images, links, and other materials to be combined together into a single presentation.

LMS (Learning Management Systems): Also known as *content management systems*, these systems combine a variety of collaborative features into a single user interface, making it easier to administer and design content (faculty) and access and use (students). There are a number of commercial and open-source systems available with the most well known being WebCT and Blackboard (commercial), and Moodle (open-source).

RSS (Really Simple Syndication or, alternatively, Rich Site Summary (the former is the preferred term and is in wider use): This technology is based upon XML and is designed to facilitate the syndication, aggregation, and consumption of Web-based content.

Web-Based Course: A course, which is delivered entirely by electronic methods such as the Internet.

Web-Enhanced Course: A traditional course with some electronic enhancements, such as Web pages for course syllabi, data files, and test reviews.

XML (Extensible Markup Language): This markup language, which is much more robust than html, is used for numerous different applications but is primarily known as a container for networked database information and the foundation of RSS.

Issues of E-Learning in Third World Countries

Shantha Fernando
University of Moratuwa, Sri Lanka

INTRODUCTION

Around the world, e-learning is becoming popular, especially among higher education institutes (universities). Many highly ranked universities have either already deployed an e-learning system and are fully operational, or they are in a process of deployment where e-learning-based and non e-learning-based educational environments co-exist. It is also possible to find a few virtual universities. The amount of money and effort that has to be spent on e-learning is high. In addition to the initial e-learning system installation costs, there are ongoing maintenance, management and content development costs. Due to the rapid growth in the field of e-learning and the role it plays in today's education systems, those working in the field have begun to introduce standards for different aspects of e-learning. The Open Knowledge Initiative (OKI) which is described as "a collaboration among leading universities and specification and standards organizations to support innovative learning technology in higher education" is an example (OKI, 2003).

Many highly ranked universities use commercial e-learning systems such as BlackBoard, WebCT, e-college, Netschool, etc. Several open source products are available though their usage is not wide spread, although it is expected that collaborative projects such as Sakai will enable large-scale open source products to be introduced to the market. This effort is described on the Sakai website as, "The University of Michigan, Indiana University, MIT, Stanford, the uPortal Consortium, and the Open Knowledge Initiative (OKI) are joining forces to integrate and synchronize their considerable educational software into a modular, pre-integrated collection of open source tools" (OKI, 2003).

BACKGROUND

Many third world countries have become "Transitional Countries". The term "transitional country" has been used in different ways in different times and different contexts. However, today's meaning of a "transitional country" is a country that lies between a developed and a developing country, and has an evolving market economy. Dung (2003) states:

Generally speaking, the expression 'transition' is used, mainly by political scientists, in the context of changes that have followed the fall of regimes, usually when dictatorial regimes have given way to more democratic ones, but this usage has been extended to contexts where previously rigid structures, such as those governing the economy, are giving way to more liberal, market-friendly structures and associated features of liberal democracy.

Third world or transitional countries require sustainable development. Sustainable development of a country is very much dependent on industry, higher education and research, hence university education is vital. The importance of the higher education is stressed in the United Nations Resolution on the Decade of Education For Sustainable Development January 2005 – December 2014 (UN Report, 2002). For a third world country, as De Rebello (2003) puts it, "The university system was seen as being uniquely equipped to lead the way by their special mission in teaching and training the leaders of tomorrow, their experience in transdisciplinary research and by their fundamental nature as engines of knowledge."

CURRENT TRENDS IN INFORMATION TECHNOLOGY IN THIRD WORLD COUNTRIES

IT is becoming a driving force of economy. Realizing its potential, many transitional countries have embarked on projects in collaboration with funding agencies to improve IT services, though their IT infrastructure facilities are not adequate. Many foreign investors start IT based companies in transitional countries. The products are aimed at the US or European market, where the parent companies are based. India, in particular, exemplifies this for the IT sector, and many major IT companies have branches in India. In Sri Lanka, due to the limited market, poor infrastructure and slightly higher labor costs, such foreign investments are limited. However, the level of IT expertise is at a competitive level. Many local IT companies carryout sub-contracts for foreign IT companies. A few companies directly interact with the global market. Realizing the potential, the Sri Lankan government embarked on "e-Sri Lanka move" project to introduce e-governance and to improve e-services within the country, and formed the ICT Agency using World Bank

funds (Development Gateway, 2003). Motivated by these initiatives and realizing the importance of e-learning for today's form of higher education, some Sri Lankan universities have deployed e-learning systems as pilot projects and a few others have started exploring the possibility of using e-learning for their university education.

Due to the employment opportunities offered for IT professionals of transitional countries by developed countries, many professional IT programs have been initiated in transitional countries. In Sri Lanka, income generated by foreign employment has now become considerable compared to its other income sources such as garment, tea, rubber, minerals, spices, etc. Though most employment opportunities are labor-oriented, many professional opportunities are in the IT sector. However, this causes "brain drain".

IMPORTANCE OF E-LEARNING FOR HIGHER EDUCATION IN THIRD WORLD COUNTRIES

In order to understand the importance of e-learning, it is important to consider what we mean by e-learning. According to the definition of NCSA's e-learning group (Wentling, T.L. et al., 2000):

E-learning is the acquisition and use of knowledge distributed and facilitated primarily by electronic means. This form of learning currently depends on networks and computers but will likely evolve into systems consisting of a variety of channels (e.g., wireless, satellite), and technologies (e.g., cellular phones, PDA's) as they are developed and adopted. E-learning can take the form of courses as well as modules and smaller learning objects. E-learning may incorporate synchronous or asynchronous access and may be distributed geographically with varied limits of time.

In an abstract form, I would define it as "electronically facilitated, enhanced and managed learning". It can consist of many components or elements of a learning environment of a university system if they can be electronically facilitated, enhanced and managed. Some aspects that could be integrated into an e-learning system to make an impact in a university system, especially in the context of a third world country, are given below.

- Curriculum related aspects – courses and course contents, discussions, library catalogues, etc.
- Academic administration related aspects – registrations, student information, grading, etc.
- Technology infrastructure related aspects – alternative technologies, lab facilities, home use, etc.
- Societal context related aspects – cultural events, forums, activities, etc.
- Industrial collaboration related aspects – industrial expertise and contents, know-how dissemination, guidance to/from industry, etc.

These aspects, when incorporated in an e-learning system, will improve the quality of the higher education, if implemented using strategies and technologies suitable for constrained environments in third world countries. However, deployment of a suitable e-learning system requires a particular educational, administrative and technological environment, and the university educational system will also need to undergo changes. This is where the issues are faced in third world countries. One should not think that the deployment of e-learning is an adaptation to the required educational change. Contrarily, an ability to adapt is a must for the deployment of e-learning.

Bates (2000) states that higher education institutes consider technology-based learning for the following reasons:

- the need to do more with less
- the changing learning needs of society
- the impact of new technologies on teaching and learning (Bates, 2000, p. 8).

Although we observe that mainly the universities in developed countries tend to consider the above reasons, they are applicable to any university. It is in this context that e-learning is becoming attractive. However, when universities in third world countries embark on e-learning-based educational transformations, they face many barriers. In many cases, e-learning cannot be implemented in the way it is done at US or European universities. The approach has to be tailored to the environment, if it is to be a success.

COMMON ISSUES TO BE ADDRESSED

Administrative Issues

Most of the universities in third world countries are traditional universities. Gunn (2000) in his keynote paper states the following:

Perhaps the most critical challenge to traditional universities is develop capacity to change. This calls for major restructuring, removal of unnecessary processes and streamlined administration procedures. Motivation to progress, change and develop is hard found in the current insecure climate. . . The challenge this raises is being able to exploit the resources of commercial interests while maintaining quality and standards of service as a priority area. Ability to achieve

the right balance between opposing forces of cost and quality without reducing education to the lowest common factor will be a powerful survival strategy.

In many third world countries university academic administration is stream-lined and rigid. Changes are usually not welcomed. Many fear loosing the value of their jobs if IT strategies are introduced. Many administrative officers have the mentality that the others should come to them to get the work done. While this shows an attitude problem or an inferiority complex, it affects many productive plans.

However, rigid administrative procedures are sometimes required to prevent exploitation and use of facilities for personal advantage.

Some administrative functions can be handled efficiently through e-learning. Typical examples would be student semester and exam registrations, yearly progress archiving, student information management, etc. However, administrative officers such as registrars, examination branch officers, etc, are not comfortable when it is handled entirely by the e-learning system. There is the fear they might loose their job. Another fear is whether they will have any value for the university. A valid concern that is raised is whether the e-learning system is secure enough to protect confidential data and prevent students tampering with data.

IT Infrastructure Issues

IT infrastructure facilities in third world countries are often primitive. While IT infrastructure needs improvement for better interconnectivity of academic institutes, a countryman's concern is food, water supply, clothing, roads and transportation, housing, primary schools, and other essential items for their living. Governments in these countries have to allocate the majority of their funds for the latter and a low priority is given for IT infrastructure. It is not justifiable to allocate huge funds for the improvement of IT infrastructure when the basic needs of the people are not met. The good news is that some form of infrastructure is already available. The solution we propose for the improvement of higher education using e-learning has to consider alternative techniques given this serious limitation. This is not to say that mobile communications and other new inventions are not penetrating the market.

Consider Sri Lanka as a case, every university is interconnected by a university network called LEARN (Lanka Academic and Research Network). Some universities have 2 Mbps E1 links, while the rest have only 128 or 64 kbps links. Very soon the latter will be upgraded, but the maximum would be 2 Mbps in the foreseeable future. The current international bandwidth allocated for the whole university network is below 2 Mbps. This will gradually increase on demand, but on-demand increase implies the presence of congestion. The universities also experience disruption of the telecom services, either due to faults or non-payment of bills. However, within these infrastructure constraints, the majority of universities are able to have an acceptable level of communication for the current IT operations within the country. Web servers are acceptably fast and e-mail is heavily used for communication and collaboration among academics. A few e-learning systems are also operational.

Any e-learning-based solution has to work within these IT infrastructure constraints. Within a university it will work acceptably since many universities have local area networks with either gigabit fibre optics, or fast Ethernet or at least 10 Mbps links. Between universities it will work as long as it does not have heavy content delivery, congesting the links. However, international collaborations through e-learning will not be at the levels required by many e-learning systems in the near future.

Limitation of Equipment

In third world countries, equipment such as servers, routers, cabling, laboratory computers, etc. are usually procured under special university budgets, or grants and loans from funding agencies. It is not possible to expect frequent upgrades to equipment. It is very unlikely that high-end servers with redundant power supplies and disk arrays will be always available for the deployment of an e-learning system and redundancy and backup systems are not a priority. Sometimes valuable information stored in the system may be at stake. However alternative approaches such as weekly or critical time-based backups may be carried out.

Thus, any approach to introducing e-learning has to start with a low-end solution. Once the importance is recognized by the authorities, some form of ongoing support is feasible. Strategic planning is required to get the funds for improving the performance and reliability of the systems gradually.

It is not possible to assume that students will always have access to computers. While a few have their own computers, the majority of the students in transitional countries use common lab facilities to access computers. Labs are open only during working hours and usually scheduled for different groups of students based on assignments and workloads. In most cases, e-learning-based learning activities also need to be planned accordingly. For an example, if an assignment is given with a deadline for the submission through the e-learning system, this deadline has to be flexible in situations such as insufficient computers, labs being not open on demand, workers' strikes which are frequent in many third world countries, long electricity power cuts, etc.

Cost Factors of E-Learning Systems

Most of the commercially developed e-learning systems such as BlackBoard, WebCT, etc, used by US and European

universities are extremely expensive for the third world countries to purchase. A monetary grant may be a possibility, but then the question would be maintenance costs, purchase of additional modules to suite the changes as time passes, costs of customizations, etc., if these costs have to be born by the university, which are very high given the limited budgets. Therefore, any grant must include these costs. Otherwise, it will be a waste of funds.

An alternative is to select an open source solution. However, currently it is difficult to find the exact match of an open source solution, or to customize it to a particular university's environment. Projects such as Sakai may help solve this situation in the future, but we have to wait until their collaborative environment is functional. However, there is the concern whether it also will assume state-of-the-art technology infrastructure.

Another alternative is in-house development, however, for this to be a success, continuous employment of developers and good software development approaches with research input from an e-learning perspective is required. Finding developers is not a difficulty in most transitional countries, and the costs for this will be far below the purchase of a commercial e-learning system. To succeed, however, a vision to continue the project, and institutionalized incentives to the people involved, should be in place. While the result of this approach may not be as sophisticated as, or as reliable as, available commercial systems, it is possible to come up with an acceptable solution at a very low cost. In the author's environment, it was possible to get a group of students to start on the development of an e-learning system using research findings. Later, an expert was used to further improve it to be used as a production system. It needs further development, but the advantage is, while the required institutional changes for an e-learning-based education are conveyed to the rest of the faculty, the changes can also be synchronized with the development cycle, as illustrated by Collis and Moonen (2001). Even if a fully fledged e-learning system had been purchased, it would have been a failure due to the faculty being not ready to adapt immediately.

Reliability Issues

Reliability issues have already been mentioned under IT infrastructure issues and limitation of equipment. The following summary is provided to emphasize the issue of reliability.

- Frequent electricity power failures.
- Data communication connectivity failures or disruptions due to non payment of bills.
- Congested links.
- Less emphasis on backup and redundant systems.

Socio-Cultural Issues

In most of the third world countries, especially in South Asian and African continents, socio-cultural setting is very prominent. It affects how people engage in learning activities. Verbal and physical interactions are important and hence total virtual learning environments may not produce good results. This situation may change in the years to come, especially among the urban population. However, socio-cultural aspects cannot be neglected when dealing with education, and it is true also for technology-based education, as described by Gunawardena (1998).

Most of the e-learning systems and available contents are based on popular languages. However, this is not to say that they do not support other languages, but it will require an additional effort to prepare contents in native languages. In many third world countries primary education is done in native languages, although at university level popular languages like English or Spanish may be the medium. This situation can create communication barriers in e-learning-based learning processes.

Many people in third world countries believe that developments in IT will cause many people to lose their jobs. This is a serious social issue. However, there are situations where it is thought to be the other way round. For an example, in e-Sri Lanka move, the government expects that there will be an increase in job opportunities if IT is promoted. For an example, to deploy e-learning in a university environment, additional support staff is required for facilitation, content creation, maintenance, etc.

FUTURE TRENDS AND CONCLUSION

E-learning can play a major role in higher education in third world and transitional countries. It will help improve the higher education, thereby contributing to sustainable development. Using e-learning it is possible to improve curriculum, academic administration, industry collaboration, etc.

Emerging related standards such as Sharable Content Object Reference Model (SCORM, 2003), IEEE Learning Technology Standards Committee (LTSC, 2002) and collaborative work currently being carried out such as OKI (OKI, 2003) will make e-learning more widespread.

However it may not be possible to deploy it in third world countries in the way it is done in the highly ranked universities in the US and European countries. First, the related issues have to be addressed and alternative solutions should be explored. Given suitable alternative solutions, or desirable approaches, e-learning can be a success in many third world and transitional countries.

KEY TERMS

Academic Administration: Administration procedures or formalities linked with university education, such as registrations for semesters or examinations, progress reviews and monitoring, eligibility formalities, student history records or progress archiving, promotions to levels or years, academic timetables, etc.

E-learning: Electronically facilitated, enhanced and managed learning.

IT Infrastructure: Technological infrastructure that enables the transfer of information.

Learning Environment: Overall university setting in which many educational and administrative processes interact.

Open Source E-learning Systems: E-learning systems developed by the Open Source Community and freely distributed with their own license or a GPL (General Purpose License) to use, modify and distribute together with the source code.

Third World Countries: Countries that are not yet developed.

Transitional Countries: A third world country that is in a transition process based on more liberal, market-friendly structures and associated features of liberal democracy.

Virtual Universities: All the learning and administration activities are done through e-learning and very minimum physical interactions, or no physical interactions at all.

INTRODUCTION

The advent of Web Services (WS) has signaled a true revolution in the way service-oriented computing and remote procedure invocation over the Web are conducted. Web Services comprise of a set of loosely coupled specifications to coordinate process execution from distance, based on common and widely accepted Web protocols such as HTTP, FTP, and XML, and therefore, providing increased development flexibility. Since the WS Framework was built on top of those protocols, Web Services have been widely acclaimed by the Web development community and paradoxically; they have marked one of the few examples in the history of computer protocols where a global consensus has been reached.

The Web Service framework consists of essentially three basic components:

1. The *Web Service Description Language* (WSDL), a language that allows formal functional characterization of the provided functionalities;
2. The *Simple Object Access Protocol* (simply SOAP from its version 1.2), a protocol that defines the format of the information interchange; and
3. The *UDDI* (Universal Description, Discovery and Integration) is a catalog of Web Service descriptions.

All three of these components are specified using XML markup. The elegance of the WS architecture lies in the fact that every WS transaction is taking place over established Web protocols such as HTTP and FTP. As remarked in Ballinger (2003, p. 5): "A Web Service is an application logic that is accessible using Internet standards." This very fact has accounted for the rapid and universal adoption of Web Services.

This work is organized as follows: First, a review of underlying technologies and tools is presented. Consequently, existing techniques for design methodologies are described. Next, an overview of storage and retrieval techniques for Web Services is given followed by real-world applications of Web Services. We conclude with open issues and discussion.

BACKGROUND

The need for executing process from remote computers seems to have emerged right after the first networking efforts. To put it simply, people need to share their data or access other peoples' data over the Internet, in the easiest possible way (Ballinger, 2003, p. 2). These needs are formally described under the term *Service Oriented Architecture* (SOA). Typically, SOAs are distributed system architectures focusing on network-centric, message-based and platform-independent communication (World-Wide Web Consortium [W3C], 2004a, 3.1).

Web Services constitute a brilliant example of an SOA implementation, albeit not the only one. Some of its precursors include: UNIX RPC, Microsoft's COM/DCOM, CORBA, and Java RMI. All of the latter have failed however due to their complex architecture.

REVIEW OF TECHNOLOGIES AND TOOLS

This section deals with the state-of-the-art in the technologies supporting the development of Web Services.

The Web Service Framework

The base protocols for the Web Services architecture are HTTP, XML, SOAP, WSDL, and UDDI. The role of HTTP and XML is more or less self-explanatory; they provide the wrapper protocols for every kind of data communication. In

the sequel, we shortly describe the remaining protocols.

- *SOAP (W3C, 2003) defines the format of message interchange. This interchange takes place when* discovering, binding, consuming a Web Service.
- WSDL (W3C, 2004c), is a language to describe the functionalities of a Web Service and provide additional details about the ways it can be accessed, the points it can be reached, and so forth.
- UDDI (UDDI) defines a separate entity (registry) that mediates in the development process by hosting descriptions of Web Services.

First of all, SOAP (W3C, 2003) is a protocol that requires the creation of XML-like documents defining the format of every communication taking place during a Web Service deployment. SOAP messages are created each time a computer seeks or runs a WS and each time it sends messages, that is, query results, to a remote computer. A typical SOAP message contains data format, required WSDL messages for the procedure and, if it calls a remote procedure, the WSDL-coded names of functions that will be called.

WSDL (W3C, 2004c) is another WS standard built around XML specifications. While SOAP defines the format of messages that will be exchanged, WSDL is the language that totally describes Web Services. First of all, a WSDL document contains descriptions of data types, XSD or custom, used in the procedure invocation. The messages that must be exchanged used during the execution, that is conveying I/O information, are also defined. Names of available remote procedures are also registered. Furthermore, apart from the names, *bindings* are also defined; bindings refer to the message protocol (most commonly, SOAP and HTTP) in use and that is, to a URL that provides access to the service. An important feature of WSDL is the possibility to insert in arbitrary elements inside a WSDL document, meta-information to be utilized for documentation purposes.

Once having joined the Web Service game, one needs to find out which function to call to carry out a specific task, by which parameter, which protocol to use, and so forth. It was agreed during the early days of WS architecture to use centralized registries for this purpose. These registries would gather all the information about available Web Services they host and they would provide technical details, WSDL descriptions, on how to use them. These registries were termed UDDIs. The globally available UDDIs are few, including Microsoft's[1] and IBM's[2], however UDDIs also exist inside large corporations. The UDDI protocol requires the registry to provide the corresponding APIs for service registration and querying.

Corporate records inside a UDDI registry are implemented via *businessEntities.* Each party that wishes to publish a set of Web Services registers a new *businessEntity.* A *businessEntity* area contains business related information about the entity, which publishes the Web Services, such as contact information, e-mail, business categorization, and textual descriptions. A further sub-entity inside each *businessEntity* is the *businessService.* Each *businessService* contains a record for a conceptually or otherwise related subset of the provided Web Services. Web Services in the same *businessService* can be, for example, geographically related or performing different functionalities of the same category, e.g. functions

Figure 1. The hierarchical structure in UDDI documents

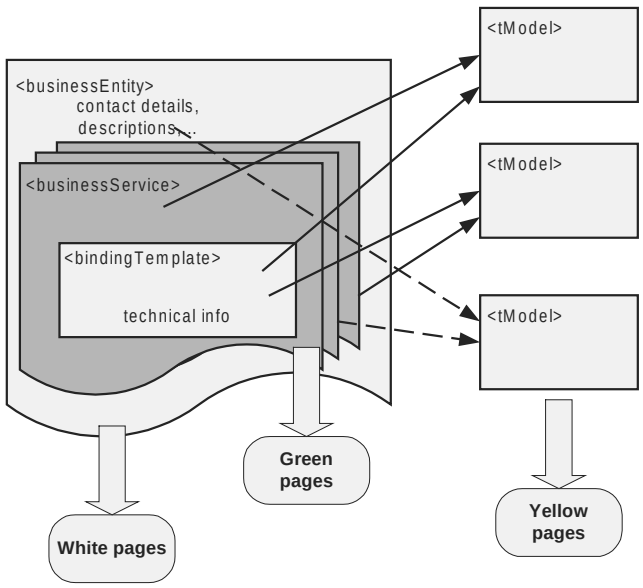

Figure 2. The Web Services Model (Arrows indicate communication with SOAP messages)

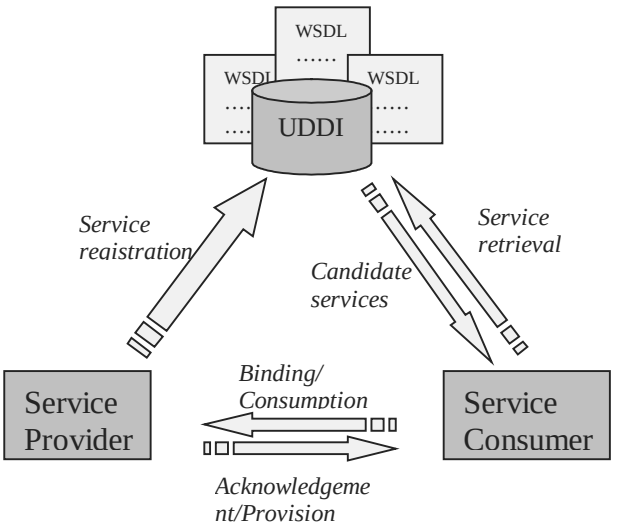

querying available rooms or booking a hotel room. Textual descriptions can also be part of the *businessService* structures. Each service in such a structure can contain one or more technical sections or *bindingTemplates.* A *businessService* may contain information on the service access point, but this information is not enough for the service consumption. The gap is filled by the *bindingTemplate*, which provides the required technical details, the service fingerprint, for service consumption.

Often Web Service fundamental functionalities are standardized. Many *bindingTemplates* provide pointers to external taxonomy elements that, in turn, specify the abstract functionalities of certain kinds of Web Services. Such an element is called a *tModel* and it is generally not part of the UDDI itself. A *tModel*, also provides URL references to the source of taxonomy and also textual descriptions.

According to this structuring of the UDDI entities, the contained structures can be informally characterized as follows (see also Figure 1):

- "white pages": information contained in *businessEntity*.
- "green pages": information required for the successful invocation of the Web Service, found in *businessService* and *bindingTemplate*.
- "yellow pages": general categorization of the provided functionality and conformance to prespecified industrial or commercial standards. This information is recorded in *tModel*.

Web Service Release and Consumption

Release and consumption is a three-step process:

1. The *provider* advertises its services in WSDL and registers in an available UDDI node.
2. The *consumer* searches the UDDI catalog, finds the required services, and retrieves the deployment details.
3. The consumer requests the service from the provider, and the provider responds with data.

All the necessary communication steps are conducted with SOAP messages. This process is best illustrated in Figure 2.

Development and Operation Platforms

One reason for the success of Web Services is the adoption of all leading providers of application development platforms with Java and .NET being the major delegates.

The .NET platform is supplemented by other products and services like Visual Studio .NET/.NET Framework for the development of applications, the .NET Passport service and .NET My Services. The .NET Framework is the programming model of the .NET platform for the development and operation of XML Web Services and applications. Visual Studio .NET is based on the previous editions of Visual Studio, so that it can offer flexibility and facilitate the development of integrated services. Finally, ASP.NET is a collection of objects

and classes, which allow the development of an application providing facile application development, since all the settings are kept in XML files while the components and their changes are automatically updated by the system.

Another possibility for WS development is to use Java-based APIs. The UDDI specifications do not directly define a Java-based API for accessing a UDDI registry. The Programmer's API specification only defines a series of SOAP messages that a UDDI registry can accept. Thus, a Java developer who wishes to access a UDDI registry can do so in a number of ways:

1. Using Java-based SOAP API;
2. Using a custom Java-based UDDI client API; or
3. Using JAXR.

Business Workflows

The demand expressing and orchestrating business workflows with the aid of Web Services was recognized early by the WS community. Therefore, languages to control business processes have been developed including *Business Process Execution Language for WS* (BPEL4WS) (Curbera et al., 2002) and *WS-Business Process Execution Language* version 2.0 (WS-BPEL)(OASIS, 2004). A very important recent development in the choreography field is the announcement of the *Web Services Choreography Description Language* Version 1.0 (W3C, 2004b). This initiative aims to serve as an additional layer on top of the corporate workflows in order to orchestrate their interactions.

Drawbacks of the Core Specification

The WS Architecture is not free of drawbacks and limitations. We briefly outline the most significant of them without going into much detail since this goes beyond the scope of this article.

- **Not flexible WS Discovery:** Discovery is based on matching keywords against functional descriptions. This will not adequately cover most of the service invocations needs
- **Quality of Service (QoS):** No method to deliver WSs under certain quality considerations is provided by the core specification.
- **Centralized Registries:** UDDIs may suffer from single point failure and bottlenecks.

RETRIEVAL OF WEB SERVICES

The UDDI data structures do not allow for advanced retrieval but only for strict matching of prespecified technical descriptions. We shortly present in this section some recent efforts to provide WS Information Retrieval.

Information Retrieval Based Methods

The simplest method is the *Keyword Based*. This model is followed by the legacy UDDI Standard and the discovery mechanism it supports. The retrieval corpus is based on textual descriptions found inside UDDI tModels. Queries are formed by keywords and are subsequently matched against keyword descriptions. This approach is similar to the Boolean IR model (Baeza-Yates & Ribeiro-Neto, 1999, Chap. 2).

A more elaborate approach (Sajjanhar, Hou, & Zhang, 2004) is to model WS descriptions as term vectors spanning a corpus vector space. WS vectors are collectively represented in a term-document matrix. Latent Semantic Analysis is used in the sequel to reduce the dimensionality of the vector space and map query vectors more closely to WS-vectors.

Distributed Retrieval

In the system of Schmidt and Parashar (2004), a unique ID was generated for each Web Service through the Hilbert curve mapping. The IDs are then stored in a Chord (Stoica, Morris, Karger, Kaashoek, & Balakrishnan, 2003) of Web-Service-storing peers. Thus, the storage and retrieval of WS inherits the load balancing capability and the dynamic nature of Chord.

A peer-to-peer solution (P2P) is also proposed in Li, Zou, Wu, and Ma, (2004). Their approach is to aggregate WS descriptions, hash them, and distribute them over a P2P overlay. Agent based solutions include Montebello and Abella (2003). This approach aims to describe an environment called DASD (DAML Agents for Service Discovery) where WS requesters and providers can discover each other with the intermediary action of a Matchmaking service.

On the other hand, a novel approach adopting main-memory dynamic interpolation searching to P2P overlays is NIPPERS (Makris, Sakkopoulos, Sioutas, Triantafillou, Tsakalidis, & Vassiliadis, 2005). NIPPERS is proved to display improved performance in searching and managing WS in overlay networks and performs asymptotically better than the popular current DHT-based overlay network, Chord.

APPLICATIONS

The WS development paradigm has been adopted in quite a few application domains, inside and outside IT. In the next paragraphs, we mention some representative examples.

IT-Related Applications

One of the standard WS applications would be incorporation to a help desk application. In this sort of application, the operator needs to retrieve and modify customer data from the central (and remote) company database. Even small Web-based tasks inside a corporation can be built with WSs; logging-in and out of an intranet, Web-based registrations are two more examples.

E-business is another field where WSs have met wide acceptance. Garofalakis, Sakkopoulos, Sirmakessis, and Tsakalidis (2003) give an insight on methods to use Web Services for a hypermedia environment offering various e-services for both customers and company employees in the context of a telecommunication carrier. Medjahed, Rezgui, Bouguettaya, and Ouzzani (2003), have built an integrated e-government system for welfare services, which is based on Web Services. Their system uses the WS framework not only for simple Web-based tasks but also to allow composition of government-to-citizen provisions. Notably, the WS framework seems to be ideal for implementing e-government applications, since it enables e-government applications to outsource from existing e-government services and handles privacy issues uniformly (Medjahed et al., 2003). Sakkopoulos, Kanellopoulos, and Tsakalidis (in press) build a Web-based vocational monograph system. Their work leverages the WS framework, which is enriched with semantics of a specialized ontology and with Web mining techniques.

Other Applications

Hu (2002) presents a methodology to combine Web services with an ontology in order to unify the underlying data subcomponents of an industrial control system. Liopa-Tsakalidis, Sakkopoulos, Savvas, Sideridis, and Tzimas (2005) have described HydroWeb, a system to facilitate hydroponic cultivation via Web-based training, communication with experts and online monitoring. Web Services were chosen as a platform to unify communication and application development from various sources of information.

FUTURE TRENDS

Web Services have been an active research area during the last years. Nevertheless, several steps have to be taken to elaborate on certain aspects of Web Service framework. We see as important further steps the provision of: semantic WS matching, efficient methods to deliver Quality of WS (QoWS), online QoWS-aware selections, and effective methods for approximate WS matching. Furthermore, it seems quite intriguing to use data mining and clustering techniques to improve retrieval of Web Service data. All the previously mentioned directions are especially challenging in the presence of orchestrated Web Services and Web Service-based workflows.

CONCLUSION

This article has only scratched the surface of a vast emerging architecture, the *Web Services framework*. We have presented up-to-date descriptions of the basic underlying concepts, the WS proponents, and we have given an essence of the potential applications of WS. Due to their simplicity, their flexibility, and the platform independency, Web Services have become the leading development paradigm in the most major IT projects. For the purposes of this article, we have presented some of these applications ranging from e-business, e-government to industrial applications. As the WS penetration becomes larger, some of the weaknesses of the initial specifications have been taken into serious consideration, including flexible service discovery (Garofalakis, Panagis, Sakkopoulos, & Tsakalidis, 2004), security, assurance of QoS characteristics, workflow support, orchestration, and so forth. Still, there is a large margin for improvement in QoS support and efficient discovery. All in all, everything points out that we are in front of a software development methodology that will mark the years to come.

KEY TERMS

Distributed Application Development: A programming paradigm focusing on designing distributed, open, transparent, scalable, fault tolerant systems. This paradigm is a natural result of computer internetworking.

Information Retrieval: Information Retrieval (IR) deals with the representation, storage, organization of, and access to information items. The representation and organization of the information items should provide the user with easy access to the information in which he is interested.

Information Technology: Information technology (IT) or information and communication technology (ICT) is the technology required for information processing. In particular the use of electronic computers and computer software to convert, store, protect, process, transmit, and retrieve information from anywhere, anytime.

Web Engineering: A branch of software engineering, addressing the specific issues relating to design and development of large-scale Web applications. It focuses on the methodologies, techniques, and tools that are the foundation

of complex Web application development and which support their design, development, evolution, and evaluation.

Web Services: A family of standards promoted by the W3C for working with other businesses, developers, and programs, through open protocols, languages, and APIs, including XML, SOAP, WSDL, and UDDI.

World Wide Web: Computer network consisting of a collection of Internet sites that offer text and sound and animation resources through the hypertext transfer protocol.

XML: Short for Extensible Markup Language, a specification developed by the W3C. XML is a pared-down version of SGML, designed especially for Web documents. It allows designers to create their own customized tags, enabling the definition, transmission, validation, and interpretation of data between applications and between organizations.

IT Evaluation Practices in Electronic Customer Relationship Management (eCRM)

Chad Lin
Curtin University of Technology, Australia

INTRODUCTION

Organizations are becoming increasingly aware of the need to scrutinize their bottom-line financial returns of business automation initiatives. To achieve this, organizations have to become more customer-centric. According to Karakostas, Karadaras and Papathanassiou (2005), a 5% increase in customer retention can result in an 18% reduction in operating costs. Therefore, the need to build and maintain customer relationship has become a priority for organizations. However, according to a KPMG survey, only a small percentage of companies were able to obtain even basic customer information despite the fact that 89% of companies consider customer information to be extremely important to the success of their business (McKeen and Smith, 2003). As a result, many organizations are adopting electronic customer relationship management (eCRM) applications in order to gather, organize, understand, anticipate, and respond to the constant evolution of customers' requirements and demands.

Indeed, eCRM is forecasted to become increasingly important as businesses seek to deliver their services and information as well as to provide transactional facilities via online and wireless platforms, in additional to the more traditional means of communication channels (e.g., call centers and customer service) (Tan, Yen and Fang, 2002). The market worldwide for eCRM applications is predicted to grow from US $3.4 billion in 2000 to US $10.5 billion in 2005 (EPS, 2001).

Yet, despite the huge investment and widespread agreement that eCRM has direct and indirect impact on customer satisfaction, loyalty, sales, and profit, it has been found that 70% of eCRM solutions that have been implemented by businesses fail (Feinberg, Kadam, Hokama and Kim, 2002). Moreover, studies carried out by Gartner, Forrester, AMR Research, and the Yankee Group claim that most of CRM implementations did not return the expected ROI (Foley, 2002). This is because management tends to be myopic when considering their IT (information technology) decisions, primarily because they are unable to evaluate (specifically the indirect benefits and costs) eCRM applications (Ernst and Young, 1999).

To address this issue, this paper sets out to investigate the current evaluation practices by Australian organizations implementing eCRM. The other objective is to identify the key issues faced by managers to justify and measure their eCRM. Hopefully, the finding can help business organizations to better manage their eCRM investment and its contribution to improving their long term profitability.

BACKGROUND

eCRM Characteristics and Elements

Advances in IT have provided businesses with an opportunity to deliver CRM functions more effectively. The use of IT to deliver CRM has lead to the emergence of electronic customer relationship management (eCRM) and specialist software vendors in the marketplace. This new generation of customer relationship management products is called eCRM because it supports the multiple electronic channels that are now available to customers (Bernett and Kuhn, 2002). The "e" is usually dropped when speaking about eCRM when it refers to CRM that has technology-facilitated interfaces with customers in a broad electronic commerce context which goes beyond the web (Chen and Chen, 2004). The followings are some of the definitions of eCRM found in the literature (Table 1).

Many researchers consider eCRM to be a subset of CRM, meaning that eCRM is one more channel through which an organization can deploy its customer relationship management strategy. eCRM differs from CRM is three important ways (EPS, 2001):

- It includes email, wireless channels, and Web;
- It is enterprise-ready rather than focused on departments or call centers; and
- It extends to cover partner channels such as extranets.

eCRM falls into three main types: operational, analytical, and collaborative (Fjermestad and Romano, 2003). Operational eCRM is concerned with the customer touch points such as automating sales force while the analytical eCRM utilizes technology to process and analyze large amounts of customer data (Sigala, 2004). Collaborative eCRM, on the other hand, focuses on creating a real-time eCRM infra-

Table 1. Various definitions of eCRM

Citations	eCRM Definitions
Steinmueller (2002)	eCRM is the collection of techniques that is employed, or that might be employed, to capture, retain, analyze, and productively utilize information about customers (or potential customers) for the purposes of pre-sales support, making sales and arranging delivery, and providing post-sales support.
Fjermestad and Romano (2003)	It is a combination of hardware, software, processes, applications, and management commitment.
Karakostas et al. (2005)	eCRM means that the sources of customer-related data are collected from the customer interactions with the Web and Internet-based systems.

structure for enterprise sales, service, marketing, and product development to better support customer requirements.

Evaluation of eCRM

As mentioned earlier, organizations invested substantial financial and organizational resources in eCRM annually, but had encountered extremely high failure rates, unhappy customers, and wasted money. While most eCRM vendors promised lots of benefits and dramatic return on investment results, it is difficult to substantiate their claims without undergoing proper evaluation and benefits realization processes (Lin, Pervan, McDermid, 2005; Love, Irani, Standing, Lin, and Burn, 2005). For example, a research conducted by Capgemini indicated that 52% of organizations surveyed could not measure their eCRM investments (Capgemini, 2004). Although there is now a well established field of research concerned with IT evaluation, there has been limited academic and practice based work undertaken on in the domain of eCRM applications (Kim, Suh and Hwang, 2003). The difficulties associated with determining the benefits and costs of IT are the major constraint to investment justification for eCRM. Consequently, many service organizations are faced with a dilemma, that is, how to manage the performance of an enterprise system that has both an internal and external focus and, thus, adds value for stakeholders (Dibb, 2001).

The difficulty in evaluation centers on the fact that both benefits and costs are difficult to quantify (Sugumaran and Arogyaswamy, 2004). In particular, the less precisely bounded environment of electronic commerce technology such as eCRM adds more complexity to the measurement problem as this type of investment is physically distributed between suppliers and customers, making the evaluation process even more difficult (Straub, Hoffman, Weber and Steinfield 2002). Indeed, many organizations have found that these IT project costs and benefits can be difficult to estimate and control. Some new and old measures need to be differentially applied for evaluating phenomena such as electronic commerce and the Internet (Straub, et al., 2002).

RESEARCH METHODOLOGY

As mentioned earlier, the benefits and added value that can be obtained from implementing eCRM have not materialized for many businesses (Ernst and Young, 1999). This is because there is currently a lack of clearly defined and measurable benefits as well as systematic approach to evaluate the eCRM systems (Auer and Petrovic, 2003). Effective evaluation of IT investments is critical to its successful implementation (Lin and Pervan, 2003; Tsao, Lin and Lin, 2004; Ward and Daniel, 2006). To address this issue, specific objectives of the research are to:

1. identify the key factors and issues faced by organizations to justify the implementation of eCRM projects; and
2. determine the current evaluation practices by Australian organizations implementing eCRM projects.

Case study utilizing semi-structured interviews (tape-recorded), observation, and document review were employed for this research, since the need for using multiple sources of data arises from the ethical need to increase the reliability and validity of the research processes (Mingers, 2001). According to Remenyi and Williams (1996), case study is one of the most frequently used research methods in information systems research.

A series of exploratory in-depth formal and informal interviews were conducted in Australia with senior managers and key personnel from several organizations to gain an overview of the business processes and the evaluation practices of their eCRM investments. Interviews were

carried out within 16 organizations in Australia that were involved in eCRM projects. The industries represented in the following cases: hospitality industry (8 organizations), education (1 organization), service industry (2 organizations), IT/Computer industry (2 organizations), and housing industry (3 organizations). Some of these organizations' customers were also contacted. At least two interviews were conducted for each organization. More than 35 interviews were conducted.

In addition to the use of the semi-structured interviews and observation data collection techniques, the researcher examined more than 1000 pages of relevant documents (e.g., annual reports, project reports) that were collected from the participating organizations. These documents provided some useful means of corroborating data from the other sources (e.g., observation and interview data) and expanded on details in order to eliminate or minimize the weakness of human memory when dealing with history.

DISCUSSION

A number of interesting and important issues have come from the analysis of the data gathered and some key issues are presented below in some detail.

1. Lack of proper assessment of business needs - Pre-project planning and justification processes were not properly carried out to assess the needs and feasibility of the eCRM system. These systems were implemented largely based on the "gut feeling" or intuition of the senior executives, the adoption of similar systems by their competitors, or persuasion by the eCRM vendors. Almost all organizations interviewed admitted that no proper pre-project planning, assessment, and justification was carried out before the implementation of eCRM. They were mostly done either through intuition or they believed in the eCRM vendors' words. For example, one project manager who was responsible for implementing an eCRM project said: *"This is the company we trust. This is the company that has just implemented a huge project for us ... this company has operated in couple of other companies in Australia."* This is consistent with research findings where the difficulties and uncertainties associated with IT investment evaluation forced senior executives to rely on gut feeling or intuition when making IT investment decisions (Lin and Pervan, 2003).
2. Different industry requires different implementation and use of eCRM systems - The extent to which the eCRM system was used was largely depending on the type of the industry (Rigby, Reicheld, and Schefter, 2002). Chen and Chen (2004) identified industries such as retail management, office supplies and equipment, hospitality, computer hardware/software, and entertainment as some of the industries that were mostly likely to employ eCRM. From the interview transcripts and other data collected, those industries which provided mainly face-to-face (personalized) services and where the employees were in competition for commissions (e.g., housing industry) tended to use either a standalone eCRM system or less sophisticated version of eCRM system. For example, it was difficult to have a centralized eCRM system within the housing industry as all sales representatives and consultants were in competition with each other in attracting new customers and retaining existing customers. When asked about the eCRM usage within his organization, a real estate agency managing director said: *"I am the only sales representative who is using it. The other sales representative use their own systems and they have to use other means of keeping in contact with their customers."* This is consistent with finding by Melville, Kraemer and Gurbaxani (2004) in which industry characteristics moderate the ability of firms to apply IT (such as eCRM) for improved organizational performance and to capture the resulting benefits. There was simply little incentive for them to share their customers' information via eCRM.
3. Lack of formal IT investment evaluation methodology – According to the interview data, less than one-third of the organizations interviewed had evaluation process. Only five out of 16 organizations interviewed had carried out some sort of evaluation processes (i.e., Scorecard, KPI analysis, benefits/costs and quantitative analysis). The rest were simply relied on their senior management's impressions or gut feeling/intuition. When asked about the evaluation process, one participant said: *"I have said to myself how much time it takes and what is the efficiency? If it can give me nil gain or plus gain that's good. If it gives me negative gain then I am not interested."* Most organizations indicated that they did not have the capability and resources to do so, or they did not know they had no evaluation process. One project manager even did not know about the evaluation process and suggested the executive director might be responsible for doing the evaluation. While almost all of them thought it would be worthwhile to do it, most of them simply did not do it, or relied on their intuition. This is consistent with finding by Karakostas, et al., (2005) where most of the respondents did not have a universal acceptance of metrics and failed to evaluate the performance of their eCRM.

Some of the other issues arising from this interpretive analysis are listed below but are not discussed due to space limitations. Details are available from the author.

4. Lack of user involvement.
5. Lack of benefits realization process.
6. Lack of integration with other systems.
7. Difficulties in identifying indirect costs (or intangible costs).
8. A gap in theory and practice in risk assessment by most organizations.
9. Lack of obvious linkage between the expected outcomes of the eCRM implementation and organizational objectives.
10. Lack of proper change management by many organizations.
11. Lack of incentives to use the eCRM systems.
12. Business processes versus software driven.

CONCLUSION

The results show that most organizations interviewed appeared to fail in some ways to conduct a proper assessment of business needs before implementing eCRM. Pre-project planning and justification processes were not properly carried out to assess the needs and feasibility of the eCRM projects.

In addition, the extent to which the eCRM system was used was largely depending on the type of the industry, size of the organizations, and type of job responsibilities. Large organizations and organizations in certain industries such as hospitality, and computer hardware and software were most likely to adopt eCRM. Not only did they have higher usage of eCRM, but also they were more likely to implement more sophisticated eCRM systems. eCRM usage had also something to do with the type of job responsibilities. The top management, for example, were more likely to use eCRM more often than their subordinates who did not always perceive eCRM systems as useful and necessary.

Most organizations did not carry out pre-project justification processes. Only half of the organizations interviewed had some sort of justification process. Those which did carry out the processes had very basic form of justification processes such as assessment of the vendor's demo or simple cost/benefit analysis. Furthermore, most organizations claimed to use a variety of criteria to evaluate their IT investments. However, only less than one-third of the organizations interviewed had carried out some sort of evaluation processes (i.e., Scorecard, KPI analysis, qualitative and quantitative analysis).

Finally, no formal IT benefits realization methodology (such as the Cranfield Process Model of Benefit Management (Ward and Daniel, 2006)) or process was specified by any of the participants. This is really a cause for concern as successful eCRM requires that organizations allocate sufficient resources for building customer relationships and continuously evaluating eCRM initiatives. The evaluation and benefits realization mechanisms can expedite the organizational learning process and help make eCRM work to the benefits of all customers and external partners.

FUTURE TRENDS

An article titled "IT Doesn't Matter" has argued that IT has become a commodity because it has become widespread, as happened to other innovations such as engines and telephones (Carr, 2003). However, Carr's (2003) views on IT are not shared by many IT practitioners and academics who argue that IT still has a lot to offer in the future and can deliver competitive advantages to organizations.

In addition, more recent evidence suggests that many organizations simply got carried away with IT and spent money unwisely in late 1990s and early 2000s. It is inevitable that more successful organizations will analyze their economics carefully, spend on only those IT applications that would deliver productivity gains, and evaluate their investments carefully through a disciplined approach with innovative management practices.

KEY TERMS

Analytical eCRM: It is concerned with the technology to process and analyze large amounts of customer data.

Benefits Realization: It is a managed and controlled process of making sure that expected business changes and benefits have been clearly defined, are measurable, and ultimately to ensure that the changes and benefits are actually achieved.

Collaborative eCRM: It is a business model that focuses on creating a real-time eCRM infrastructure to better support customer requirements.

CRM: Any initiative or process designed to assist an organization in optimizing interactions with customers via one or more touch points.

eCRM: It is the element of CRM that uses the Web to create a holistic approach to internal and external communication.

IT Investment Evaluation: This is the weighing up process to rationally assess the value of any acquisition of software or hardware which is expected to improve business value of an organization's information systems.

Operational eCRM: It is concerned with the customer touch points such as automating sales force.

Productivity Paradox: Despite large investments in IT over many years, there has been conflicting reports as to whether or not the IT benefits have actually occurred.

IT Outsourcing Practices in Australia and Taiwan

Chad Lin
Curtin University of Technology, Australia

Koong Lin
National University of Tainan, Taiwan

INTRODUCTION

Globally, information technology (IT) outsourcing has spread quickly in many countries and spending by organizations in IT outsourcing is increasing rapidly each year. According to Gartner (Blackmore, De Souza, Young, Goodness, and Silliman, 2005), total spending on IT outsourcing worldwide is likely to rise from US $184 billion in 2003 to US $256 billion in 2008. However, defining IT outsourcing is not an easy task as it can mean different things to different organizations. Hirschheim and Lacity (2000) define IT outsourcing as the "practice of transferring IT assets, leases, staff, and management responsibility for delivery of services from internal IT functions to third-party vendors." Willcocks and Lester (1997) define outsourcing as the "commissioning of third-party management of IT assets or activities to deliver required results." The scope and range of outsourcing services have also increased as well, as evidenced by the promotion of BPO (business process outsourcing), ASP (applications service providers), global outsourcing, R&D (research and development) outsourcing, and web and e-business outsourcing (Gonzales Gascon and Llopis, 2005; Huang, Lin, and Lin, 2005).

While there is already much research on the economics of IT outsourcing, critical success factors for IT outsourcing decision-making and for outsourcing vendor management (Barthelemy and Geyer, 2004; Hirschheim and Lacity, 2000), there is very little literature on the actual linkage between IT outsourcing and the use of evaluation methodologies in organizations, especially in how these organizations evaluate their IT outsourcing contracts and ensure that the benefits expected from these contracts are delivered eventually.

The aim of this paper is to examine issues surrounding the evaluation and benefits realization processes in Australian and Taiwanese organizations undertaking IT outsourcing. The paper first reviews relevant literature with respect to IT outsourcing, the evaluation of IT outsourcing, and IT benefits realization. Key findings from a survey of the top 2000 Australian organizations, as well as a survey to top 3000 Taiwanese organizations, will then be presented. The paper examines these findings and issues in light of these large organizations' evaluation practices.

BACKGROUND

IT Outsourcing

Whatever the objective, the possibility of IT outsourcing tends to generate strong emotions among the senior executives and external contractors. There are many reasons contributing to the growth of the outsourcing. A review of relevant IT outsourcing literature reveals the following organizational goals for their IT outsourcing projects: lower costs, access to world class expertise, economies of scale, risk sharing, increased efficiency/service level, elimination of internal irritants, higher quality of goods and services, greater focus on core functions, increased flexibility, and reduction in technological obsolescence risk (Aubert, Rivard, and Patry, 2003; Barthelemy, 2003; Kakabadse and Kakabadse, 2001).

There are several important factors that govern successful and less successful outsourcing decisions. These include: differentiation of the business from the competitors, strategic direction of the business, degree of uncertainty of the business environment, scope of outsourcing services, quality of outsourcing contract, technology maturity, level of IT integration, in-house capabilities, and trust (Barthelemy, 2003; Hormozi, Hostetler, and Middleton, 2003). In addition, there are other factors that are more critical for offshore outsourcing than for domestic outsourcing. According to Adelakun (2004), the following critical success factors are very important for offshore outsourcing: people factors (e.g., language skill and project management skill), technical factors (e.g., workers technical skill), business infrastructure factors (e.g., service level agreement details), regulatory factors (e.g., travel and visa restrictions), and client interface factors (e.g., security and trusting relationship). In particular, the traditional approaches to security are failing as we move to open networks and business models due to IT outsourcing (Grimshaw, Vincent, and Willmott, 2002; Wright, 2001). In

addition, IT outsourcing also forces organizations to extend the boundaries of trust outside of their former closed spheres (Wright, 2001). According to Khalfan (2004), these two issues are the most prominent risk factors that would affect the attitudes of organizations to IT outsourcing.

Furthermore, despite the promised savings from the IT outsourcing contracts, there have been problems. These include constant budget blowouts, dubious savings claims, deep dissatisfaction, and non-delivery of service levels (Aubert, et al., 2003; Sullivan and Ngwenyama, 2005). Reasons for this include failing to properly monitor and evaluate IT outsourcing contracts and projects, especially the performance of contractors (Lin, Pervan, and McDermid, 2005; Perrin and Pervan, 2004).

IT Investment Evaluation in IT Outsourcing

Complexity and scope are often the major constraints and difficulties in IT investment evaluation and benefits realization processes (Tallon, Kraemer, and Gurbaxani, 2000; Ward and Daniel, 2006). Many IT projects fail to deliver what is expected of them because organizations focus on implementing the technology rather than tracking and measuring the performance of IT projects (Lin and Pervan, 2003). One reason for this is that most organizations fail to properly monitor and evaluate their IT outsourcing projects (Perrin and Pervan, 2004; Willcocks and Lester, 1997). According to Kakabadse and Kakabadse (2001), the development of suitable methodologies for IT outsourcing has been very slow. For example, McIvor (2000) found that most organizations had no formal process to evaluate their IT outsourcing decision and, instead, relied on limited cost analysis associated with the outsourcing decision. Beaumont and Costa (2002) found that evaluating all costs relevant to outsourcing was a very difficult task. According to Hsu, Wu, and Hsu (2005), most large organizations (52.4%) in Taiwan do not perform evaluation on a regular basis and those organizations which do evaluate tend to do so irregularly. In fact, 15.1% of organizations surveyed did not evaluate at all (Hsu, et al., 2005).

Organizations that make extensive use of IT evaluation methodologies or measures have higher perceived payoffs from IT (Tallon, et al., 2000). Misra (2004) found that outsourcing organizations need to choose the evaluation methodologies which: (a) lead to the desired behavior by both outsourcers and outsourcing contractors; (b) are within the outsourcing contractors' control; (c) can be easily measured by both the outsourcers and outsourcing contractors; (d) can be evaluated by objective criteria rather than subjective criteria; and (e) can be aligned with business objectives.

IT Benefits Realization

While IT investment evaluation is important, it does not guarantee that the benefits identified and expected by organizations are realized (Lin, et al., 2005). This is because IT is just one enabler of process change and it only enables or creates a capability to derive benefits. The essence of benefits realization is to organize and manage so that the potential benefits arising from the use of IT can actually be realized (Changchit, Joshi, and Lederer, 1998).

The identification of expected benefits of a proposed IT outsourcing project is a challenging task. According to Lin and Pervan (2003), very few organizations have a benefits realization approach. Ironically, much attention is paid to ways of justifying investments with little effort being expended in ensuring that the benefits expected are realized. As benefits are frequently long term, uncertain and intangible future benefits are too wide-ranging to be estimated with any accuracy. After all, the critical role of benefits realization depends on external IT outsourcing contractors' ability to not just deliver excellent service, but also to turn this service into organizational consequences such as control of costs, meeting organizational goals, flexibility, and focusing on core functions (Rouse, Corbitt and Aubert, 2001).

While there is a clear indication in the literature of a greater reliance on IT outsourcing by organizations, the importance of outsourcing evaluation and benefits processes has received limited attention, as has the linkage between IT outsourcing and the use of IT investment evaluation and benefits realization methodologies.

RESEARCH METHODOLOGY AND FINDINGS

Research Objectives and Methodology

Corporate spending on IT outsourcing is increasing at a rapid rate. In Australia, there is an increasing push by businesses for offshore IT outsourcing (to India, in particular), although many industry executives believe that Australia can also become an offshore destination as it is at least 25% cheaper to run a commercial undertaking in Australia than in the US or Western Europe (Hollands, 2004). In Taiwan, foreign companies spent a total of US $66 billion on IT outsourcing to Taiwan in 2005 and over 70% of Taiwan's IT output was actually outsourced to China (Burns, 2006). However, no research has been carried out to obtain an overview of IT investments and benefits management processes and practices in these two economies. The research aims to provide new empirical evidence comparing Australia (a developed

economy) and Taiwan (a newly industrialized economy) on their IT outsourcing investment evaluation and benefits realization practices.

The survey approach was chosen as it has the advantage of being able to focus on problem solving and pursue a step-by-step logical, organized, and rigorous method to identify problems, gather data, analyze the data, and draw valid conclusions (Sekaran, 1984).

Specifically, the survey sought to:

1. establish current practices and norms in managing IT outsourcing benefits and evaluation by organizations in Australia and Taiwan; and
2. investigate the usage of the IT outsourcing investment evaluation and benefits realization methodologies or approaches by organizations in Australia and Taiwan.

The sample for the Australian study was obtained by mailing questionnaires in 2005 to the IT managers and CIOs of 900 Australian organizations randomly selected from the top 2000 Australian organizations (Dun and Bradstreet mailing list). Prior to determining the sample size for the survey, a pilot survey of IT managers/CIOs of ten companies in Australia and Taiwan was conducted. Comments about the pilot questionnaire were all positive and so no significant changes were made to the questionnaire. The survey elicited a total of 176 responses and a response rate of 19.6%.

The sample in Taiwan was selected from a list published by a semi-governmental organization, the Institute for Information Industry (III, 2005). Questionnaires were sent to top 3000 organizations in Taiwan in 2005 and 889 questionnaires were returned (a response rate of 29.6%). In the absence of objective data on the organizations' evaluation practices, the IT executives' perceptions were used. Although there has been some debate regarding the legitimacy of perceptual measures as a proxy for objective measures, research has succeeded in alleviating some of the concerns by showing that perceptual measures of organizational performance has a strong positive relationship with more traditional objective measures (Tallon, et al., 2000). For example, a study by Venkatraman and Ramanujam (1987) showed that there was a high degree of correlation between perceptual and objective performance measures in the process of measuring performance of several competing organizations.

Chi-squared Goodness of Fit tests, on industry sector, net revenue, and total number of employees, showed that the sample respondents were statistically similar (at the 1% significance level) to the target population. Late returns were compared with other response received earlier in order to check for non-response bias. No significant differences were detected between two samples (Armstrong and Overton, 1977). Therefore, the respondents can be considered representative of the population as a whole.

Most of the information presented below is based on descriptive statistics (i.e., frequencies) but some comparisons between groups were made using crosstabs, ANOVA, and correlation statistics. In the following discussion of results the percentages referred to normally represented the proportion of valid (answered) cases only and did not indicate missing values. A statistical software package, SPSS (v11.05), was deployed to analyze the quantitative data collected through the survey.

Survey Findings and Discussion

In the following discussion of results the percentages referred to normally represented the proportion of valid (answered) cases only and did not indicate missing values. Additionally, most of the information presented below was based on descriptive statistics.

Overall, the responding Australian organizations were large in revenue and number of employees, typical of the large corporate sector with large numbers from wholesale and retail (18.2%), government and utilities (15.3%), construction, mining, and engineering (11.9%), and health and pharmaceutical services (11.4%) (Table 1).

On the other hand, most Taiwanese organizations were from manufacturing (31.7%), wholesale and retail (25.3%), and information technology and communication industries (Table 1). More than half of the responding organizations had more than US $50 million in total revenue and 250 employees (Table 2).

IT Investment Evaluation and Benefits Realization for IT Outsourcing

Respondents were asked about adoption, usage and success with formal methodologies or processes for various IT outsourcing activities. The Australian results revealed a reasonably high adoption of methodology for IT investment evaluation (67.6%), but less for IT benefits realization (41.5%). However, the results also showed that 15.3% had failed to adopt an IT investment evaluation methodology while 32.4% of responding organizations failed to adopt an IT benefits realization methodology. Therefore, overall, their use was found to be commonplace, but by no means universal. In particular, a significant majority had a formal methodology or process for their IT investment appraisal. On the other hand, the survey results in Taiwan also revealed lower adoption rates for IT investment evaluation (43.9%) and IT benefits realization (42.1%). The ANOVA revealed that both Australian and Taiwanese organizations tend to adopt either both methodologies or none at all.

Table 1. Background information of the respondent organizations – industries & IT budget

	Australia	Taiwan
Range	**Percent (%)**	**Percent (%)**
(a) Industries

250-500	6.8	26.0
501-1000	21.6	6.6
1001-5000	46.0	16.3
5000 and above	10.8	23.1
Total	**100**	**100**

In addition, Australian respondents indicated that IT investment evaluation methodology was widely used in 50.6% of cases. However, only 29.0% of the respondents had pointed out that an IT benefits realization methodology was widely used in their organizations. On the other hand, the Taiwanese respondents reported that both methodologies were widely used in only 38.9% and 39.9% of cases, respectively.

In terms of *effectiveness* of those methodologies in ensuring successful IT outsourcing, 46.1% and 32.4%, respectively, of the Australian organizations pointed out that they were effective. Overall, the IT investment evaluation methodology was not effective in ensuring successful IT outsourcing. Furthermore, IT benefits realization methodology was neither widely used nor effective in ensuring successful IT outsourcing. The figures for the effective utilization of these methodologies by the Taiwanese organizations were 40.6%, and 38.7%, respectively.

Motivation for IT Outsourcing

Almost all organizations surveyed had outsourced at least part of their IT functions. Cost reduction (70.0%) due to lower salaries was considered an important factor for IT outsourcing by Australian organizations. However, this was given a very low priority by the Taiwanese organizations. Instead, time saving (68.7%) and ability to focus on core activities (68.4%) were the most often mentioned benefits for IT outsourcing in Taiwan. Furthermore, most Australian and Taiwanese organizations preferred those external IT outsourcing contractors which had a good track record and extensively skills and experience in outsourcing. The size of external IT outsourcing firms was not an important selection factor for both Australian and Taiwanese organizations.

FUTURE TRENDS

IT outsourcing spending will continue to rise in the future. The rising price of oil will put increasing pressure on organizations to both utilize technology and outsource to remain competitive. Despite the recent debates in the US and other western countries about outsourcing of skilled IT jobs to other low-cost countries such as India and China, and about organizations' obligations to the broader stakeholder community, offshore IT outsourcing has often been employed by most large organizations to reduce the cost of future IT investments and to improve the cash flow of the organizations (Burns, 2006; Hollands, 2004; Rottman and Lacity, 2004).

CONCLUSION

This paper seeks to provide new empirical evidence of IT investment evaluation and benefits realization practices in large Australian and Taiwanese organizations undertaking IT outsourcing projects. The results indicate that while the usage of IT investment evaluation methodologies by Taiwanese organizations is lower than organizations in Australia, the usage of IT benefits realization methodologies is about the same for both groups of organizations. In addition, large Australian organizations are more able to conduct IT investment evaluation methodologies more widely and effectively, whereas large Taiwanese organizations are more likely to deploy IT benefits realization methodologies widely and effectively.

The surveys also show that the extent of outsourcing is quite high in large Australian and Taiwanese organizations. Furthermore, Australian and Taiwanese organizations differ on their motivation for IT outsourcing. Cost reduction is the number one reason for IT outsourcing for large Australian organizations while time saving and ability to concentrate on core activities are the most often mentioned IT outsourcing reasons for Taiwanese organizations.

A key contribution of this exploratory comparative study is to provide new empirical evidence on IT outsourcing practices as well as IT investment evaluation and benefits realization processes in large Australian and Taiwanese organizations. The findings here can assist senior executives in making their IT outsourcing decisions. Finally, our study took place at a particular point in time. This research has relied on the information provided at a particular point in time. Further research could take a longitudinal approach as the perception and evaluation of benefits are likely to change over time. Alternatively, our study could be replicated in a few years time in other countries.

KEY TERMS

Benefits Realization: It is a managed and controlled process of checking, implementing, and adjusting expected results and continuous adjusting the path leading from investments to expected business benefits.

IT Benefits Realization Methodologies: Approaches that are used to ensure that benefits expected in the IT investments by organizations are eventually delivered.

IT Investment Evaluation: This is the weighing up process to rationally assess the value of any in-house IT assets and acquisition of software or hardware which are expected to improve business value of an organization's information systems.

IT Investment Evaluation Methodologies: Approaches that are used to evaluate and monitor organizations' IT investments.

IT Outsourcing: The practice of transferring IT assets, leases, staff, and management responsibility for delivery of services from internal IT functions to external contractors.

SPSS: It is a statistical and data management software package for analyzing collected questionnaire data.

Survey Research: It is a research method using questionnaires to obtain the required information.

IT Supporting Strategy Formulation

Jan Achterbergh
Radboud University of Nijmegen, The Netherlands

INTRODUCTION

This overview approaches information and communication technology (ICT) for competitive intelligence from the perspective of strategy formulation. It provides an ICT architecture for supporting the knowledge processes producing relevant knowledge for strategy formulation.

To determine what this architecture looks like, we first examine the process of strategy formulation and determine the knowledge required in the process of strategy formulation. To this purpose, we use Beer's viable system model (VSM). Second, we model the knowledge processes in which the intelligence relevant for the process of strategy formulation is produced and processed. Given these two elements, we describe an ICT architecture supporting the knowledge processes producing the knowledge needed for the strategic process.

BACKGROUND: STRATEGY FORMULATION, A VIABLE SYSTEM PERSPECTIVE

Strategy formulation aims at developing and selecting goals and plans securing the adaptation of the organization to its environment. These goals and plans may refer to specific product-market-technology combinations (PMCs) for which the organization hypothesizes that they ensure a stable relation with its environment. The process of strategy formulation needs to generate such goals and plans, needs to reflect upon their appropriateness, and needs to select certain goals and plans to guide the behavior of the organization. This is a continuous process. Goals and plans can be seen as hypotheses about what will work as a means to adapt and survive. Therefore, they should be monitored constantly and revised if necessary. In short, strategy formulation is a continuous contribution to maintaining organizational viability.

Although many authors deal with the process of strategy formulation, we choose the viable system model of Beer (1979, 1981, 1985) to define this process more closely. We select the VSM because Beer explicitly unfolds the functions required for the viable realization and adaptation of an organization's strategy.

To explain what these functions entail, it is useful to divide them into two groups: functions contributing to the *realization* of the organization's strategy and functions contributing to its *adaptation*.

The first group deals with the realization of the organization's strategy. It consists of three functions. Function 1 comprises the organization's primary activities constituting its "raison d'être" (Espejo, Schumann, Schwaninger, & Billello, 1996, p. 110). Function 2 (coordination) coordinates interdependencies between these primary activities. The third function is called the control function. It ensures the synergy of and cohesion between the primary activities by specifying their goals and controlling their performance.

To illustrate these functions, consider Energeco, a company servicing its environment with eco-energy. Function 1 of Energeco consists of three primary activities: supplying solar, tidal, and wind energy. To give an example of the coordination function, suppose that specialists in high-voltage energy are a shared resource between Energeco's business units. Also suppose that there is no coordination between these business units. In this case, the allocation of high-voltage specialists to a project in the business unit Solar Energy may require a revision of the allocation of these same specialists to a project in the business unit Wind Energy. Without a function supporting the coordination of these interdependencies, the business units Solar Energy and Wind Energy may become entangled in a process that oscillates between allocating and revising the allocation of these specialists to projects. It is the task of Function 2 to coordinate these interdependencies. The control function's task is to translate the identity and mission of the viable system (for Energeco, supplying eco-energy) into goals for the primary activities (in this example, supplying wind, solar, and tidal energy) and to control the realization of these goals.

The second group deals with the adaptation of the organization's strategy. It consists of control (Function 3), intelligence (Function 4), and policy (Function 5). Intelligence scans the organization's relevant environment and generates and proposes plans for adaptation. In the example of Energeco, developments in production technology may introduce the possibility of cost-effective, large-scale production of eco-energy from biomass. Intelligence should pick up these developments, assess them, and if relevant, translate them into proposals for innovation. Because of its knowledge of the potentials for change of the primary activities, control (Function 3) reviews the feasibility of the plans proposed by intelligence. For instance, it may object to the plans proposed

by intelligence because they require a change posing a risk to the performance of the primary activities.

Discussion about the relevance and feasibility of the proposals for adaptation between intelligence and control should produce finalized plans for adaptation. It is the task of the policy function to balance the discussion between intelligence and control and to consolidate the finalized proposal in the organization's strategy. For instance, in the discussion between intelligence and control about the feasibility of the adoption of large-scale production of eco-energy from biomass, the policy function should ensure that control and intelligence are equally represented in the discussion. By opting for the production of energy from biomass, the policy function consolidates producing eco-energy from biomass as a new goal for Energeco. Figure 1 depicts the process of strategy formulation in terms of the VSM functions and activities.

To contribute to the strategy-formulation process, control, intelligence, and policy require knowledge about particular domains. Table 1 provides an overview of the knowledge required by each function to contribute to the process of strategy formulation.

Given the overview of functions involved in the strategy-formulation process, their relations, and the knowledge required by these functions to contribute to the process of strategy formulation, it is now possible to look into the knowledge processes needed to produce this knowledge and the ICT architecture supporting these knowledge processes.

KNOWLEDGE PROCESSES CONTRIBUTING TO STRATEGY FORMULATION

The question for this section is by means of what processes knowledge in the knowledge domains should be produced and processed so that the process of strategy formulation can take place. To answer this question, we first need to specify what these knowledge processes are. Then we need to link these processes to the knowledge required by control, intelligence, and policy to contribute to the strategy-formulation process.

We distinguish four relevant processes for producing and processing knowledge: generating (G), sharing (S), retaining (R), and applying (A) knowledge (cf. Achterbergh & Vriens, 2002; Bukowitz & Williams, 1999; Davenport & Prusak, 1998).

These four knowledge processes can now be linked to the process of strategy formulation, as formulated according to the VSM. According to the VSM, the functions intelligence, control, and policy contribute to strategy formulation. This contribution involves the *application* of knowledge in the knowledge domains to arrive at the four core products of strategy formulation: proposals for innovation, their reviews, the finalized plans for innovation, and their consolidation. The knowledge applied by each function is *generated* either by that function or by one of the other functions of the VSM. In the latter case, knowledge must be *shared* between functions. Applying, generating, and sharing knowledge requires the *retention* or *storage* of knowledge.

Figure 1. The process of strategy formulation according to the VSM

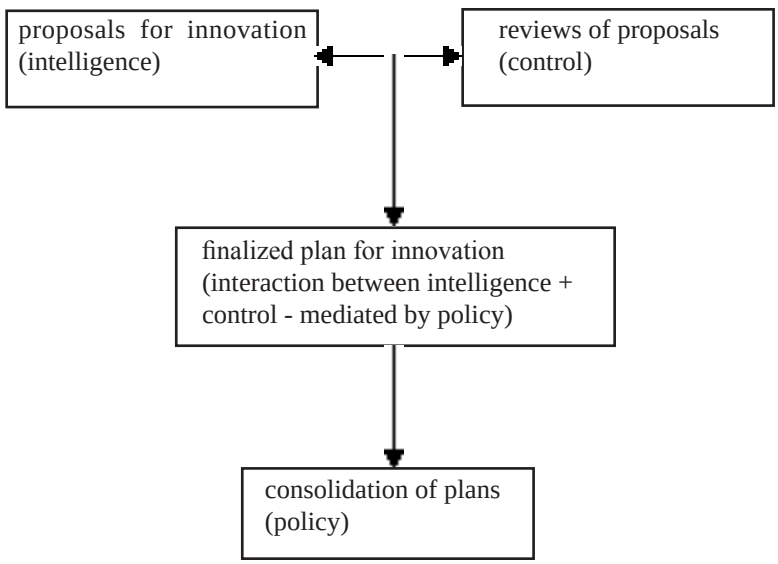

Table 1. Knowledge required by each function to contribute to the strategy formulation process

Function	Related domains of knowledge
F3: Function 3 (control)	For reviewing F4 proposals Organizational goals Proposals for innovation made by F4 Desired goals for F1 based on proposals for innovation Expected performance of the primary activities (goals for F1 activities) Gap between desired and current goals for F1 Required capacity for reorganization of F1 activities Modus operandi of F1 activities Actual capacity for reorganization of F1 activities Gap between required and actual capacity for reorganization Review of proposals for innovation Finalized plans for adaptation of organizational goals (a joint F3 and F4 product) Regulatory measures to counter the imbalance between F3 and F4 (see Function 5)
F4: Function 4 (intelligence)	Organizational goals Goals set by performance and modus operandi of F1 activities Developments in the relevant environment of the organization Reviews by F3 of proposals for innovation Regulatory measures to counter the imbalance between F3 and F4 (see Function 5) Finalized plans for adaptation of organizational goals (a joint F3 and F4 product)
F5: Function 5 (policy)	For balancing purposes Norms for balance between F3 and F4 Proposals by F4 and their reviews by F3 (relative contribution of F3 and F4 to the discussion on adaptation) Actual (im)balance between F3 and F4 Causes of imbalance between F3 and F4 Experiences with regulatory measures to counter the imbalance between F3 and F4 Regulatory measures to counter the imbalance between F3 and F4 For consolidation purposes Finalized plans for adaptation of organizational goals (a joint F3 and F4 product) Organizational goals

Table 2 provides an overview of the relation between the five functions in the VSM, the knowledge domains, and the application and generation of knowledge in these domains. Based on this table, it is possible to draw conclusions about sharing and retaining knowledge. In the table we only included the relevant knowledge for strategy formulation. However, some of this knowledge is generated by Function 1; this is the reason of its inclusion in the table.

The first column of Table 2 summarizes the knowledge domains listed in Table 1. In this column, we eliminated all redundant entries. Columns 2 to 5 indicate whether knowledge in a specific knowledge domain is generated and/or applied by a specific function.

Given the link between the knowledge processes, the functions contributing to the strategy-formulation process, and the knowledge required by them, it is now possible to outline an ICT architecture that can support the generating, retaining, sharing, and applying of this knowledge by these functions.

AN ICT ARCHITECTURE SUPPORTING KNOWLEDGE PROCESSES NEEDED FOR STRATEGY FORMULATION

Knowledge from several knowledge domains specified in Table 2 should be generated, stored, shared, and applied to take the steps in the process of strategy formulation: formulating proposals for innovation, reviewing them, making finalized plans for innovation, and consolidating them. We use these steps in the process of strategy formulation as a point of departure for outlining an ICT architecture (cf. Laudon & Laudon, 1997; Tan, 2003; Turban, McLean, & Wetherbe, 2002) for an information system supporting this process. In the literature, ICT architectures are presented as conceptual models, specifying (at a general level) the parts of an ICT infrastructure (applications, databases, technological ICT elements) and their relations. In this chapter we focus on the application and databases parts. An outline of the architecture is presented in Figure 2.

This architecture consists, ideally, of five modules and knowledge and/or databases. The modules (at the right in

Table 2. Functions, knowledge domains, and knowledge processes for strategy formulation

Knowledge domains	F1	F3	F4	F5
Goals set by performance and modus operandi of the primary activities in F1	G,A	A	A	
Organizational goals	A	A	A	G,A
Proposals for innovation made by F4		A	G,A	A
Desired goals for F1 based on proposals for innovation		G,A		
Gap between desired and current goals of F1		G,A		
Required capacity for reorganization of F1 activities		G,A		
Actual capacity for reorganization of F1 activities		G,A		
Gap between required and actual capacity for reorganization of F1 activities		G,A		
Reviews by F3 of proposals for innovation		G,A	A	A
Finalized plans for adaptation of organizational goals (a joint F3 and F4 product)		G,A	G,A	A
Regulatory measures to counter the imbalance between F3 and F4		A	A	G,A

Norms for balance between F3 and F4				G,A
Actual imbalance between F3 and F4				G,A
Causes of imbalance between F3 and F4				G,A
Experiences with regulatory measures to counter the imbalance between F3 and F4				G,A

Figure 2. Outline of an architecture of an information system supporting strategy formulation

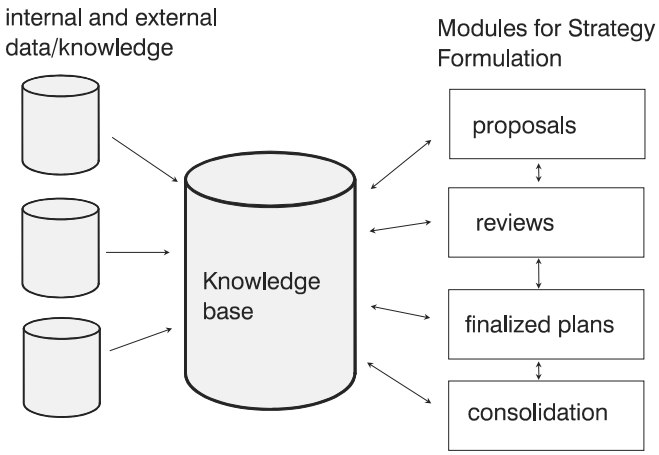

Figure 2) are applications helping to generate the products of the process of strategy formulation. With the help of these modules, the knowledge from the knowledge domains is applied to produce the proposals, reviews, and (consolidated) plans. The architecture further consists of a central knowledge base in which the knowledge in the knowledge domains necessary for strategy formulation (see Table 2) is stored. This central knowledge base in turn may receive knowledge from other internal and external knowledge and/or databases. Below, we discuss the modules and knowledge bases and their relation to relevant knowledge processes in the course of strategy formulation in more detail.

1. The proposal module
The main product of this module is a list of innovation proposals and their justification. To produce this list, one should have access to the knowledge in the relevant knowledge domains. To generate this knowledge, the module should have access to external and internal information. For instance, it may have access to a data warehouse by means of a front-end tool, or it may have access to external online databases. Furthermore, the module may have access to a database consisting of previously rejected or accepted proposals. The proposals for innovation produced with this module are stored in the central knowledge base.

2. The review module
   The input for this module consists of the proposals for innovation. The output is a list of accepted and rejected proposals and the reasons for their acceptance or rejection. To make this list, the module should apply the knowledge in the central knowledge base. This knowledge may be available or may have to be generated. To generate the knowledge, access to several internal and external databases may be required. Also, (external) data on the results of the current PMCs may be input for rejecting or accepting innovations. The review module may benefit from a database with (a classification of) reasons for acceptance or rejection.

3. The finalized-plans module
   This module is mainly a means for sharing proposals for innovation (and their reviews) in order to arrive at a finalized plan. It overarches the proposal and review module. By means of this module, results of the review module are shared and applied to revise the proposals (with the aid of the proposal module). The revised proposals are, in turn, used to produce new reviews (with the aid of the review module) and so forth. This module should (a) facilitate sharing proposals and (b) ensure the finalization of an innovation plan. To these ends, this module should support sharing knowledge about

   • the rules for interaction (such as discussion format and deadlines),
   • criteria for imbalance in the discussion,
   • a monitoring function regarding the imbalance,
   • rules and incentives for countering this imbalance, and
   • an overview of the history of the discussion (as well as an overview of previous discussion).

   Implementation could be by means of intranet applications (e.g., an internal discussion site).

4. The consolidation module
   This module has as its output the consolidation of (a specific selection of) the innovations on the finalized list of innovations. To make this selection, the arguments used in the previous modules should be scanned and valued. Its main goal is to share the results of the strategy-formulation process with relevant parties in the organization. It should enable sharing knowledge about (a) the selected innovations, (b) the reasons for their selection, and (c) their consequences for the current way of doing business. The process of sharing may benefit from a database with (previously successful) communication formats that can be a part of the consolidation module.

5. The central knowledge base
   The central knowledge base consists of all the knowledge in the knowledge domains relevant for strategy formulation. The knowledge base stores the knowledge produced in the modules and supports these modules by servicing them with knowledge relevant to their processes.

Above, an ICT architecture is outlined for an information system supporting strategy formulation. It shows how support should be focused on the products of strategy formulation. Moreover, the focus of the support is on the four knowledge processes involved in the production of proposals, reviews, plans, and consolidations. That is, the application of knowledge leads to proposals for innovation, reviews of these proposals, finalized plans, and consolidation of selected finalized plans. For these products, knowledge from the knowledge domains should be generated, stored, and/or shared. This knowledge is (partly) stored in the knowledge base. The knowledge may be generated by using the four modules and/or by using internal or external databases. Furthermore, knowledge from the knowledge domains may be shared by using connections between the modules.

The description of the architecture specifies the functionality of the different modules in it and how they should be connected. These specifications can be used to select or build the ICT tools to realize the architecture and the knowledge processes it supports.

FUTURE TRENDS

Given the particular outline of the proposed ICT architecture supporting the strategy formulation process, it is possible to link up with current trends that may enhance its performance.

- Developments in the technology for integrating databases (e.g., data warehouse technology) may support the intelligence function in the proposal phase by facilitating the integration and analysis of internal and external knowledge required for strategy formulation.
- Currently, data warehouses are often organized to fit the format of the Balanced Business Scorecard (Kaplan & Norton, 2001). This scorecard is primarily geared to strategy implementation. The format of the VSM, its related knowledge domains, and steps for formulating strategy may be used to organize data warehouses to fit the requirements for strategy adaptation (Achterbergh, Beeres, & Vriens, 2003).

- Proposing and reviewing proposals for adaptation may be enhanced by the application of computer-aided techniques such as gaming, system dynamics, scenario analysis, and group model building.
- By systematically linking strategy formulation to knowledge management, it becomes possible to enhance the quality of the knowledge processes related to strategy formulation by using acquired insights on improving infrastructures for knowledge management.

CONCLUSION

In this overview, we design an ICT architecture supporting strategy formulation on the basis of the viable system model. By applying the viable system model to the strategy-formulation process, it becomes possible to identify the functions required for strategy formulation, the relations between these functions, and the knowledge required by them.

By identifying the knowledge processes producing and processing this knowledge, and by linking these processes to the functions and the knowledge they require to contribute to the strategy-formulation process, it becomes possible to outline an ICT architecture supporting the processes of generating, retaining, sharing, and applying the knowledge needed for strategy formulation. This architecture consists of five modules dedicated to proposing, reviewing, finalizing, and consolidating strategy changes and related knowledge databases containing knowledge in the knowledge domains required for strategy formulation.

KEY TERMS

ICT: Information and communication technology. ICT can be used to indicate the organization's technological infrastructure (comprising of all hardware, software, and telecommunications technology) and to indicate one or more specific collections of hardware, software, and telecommunications technology (i.e., one or more ICT applications).

ICT Architecture: The ICT architecture provides a conceptual model, specifying (at a general level) the parts of an ICT infrastructure (applications, databases, technological ICT elements) and their relations. In this chapter we concentrate on the application and databases parts.

Knowledge Domain: the knowledge related to defining, recognizing, and solving a specific problem.

Knowledge Processes: In the literature, one often finds four knowledge processes: (a) generating knowledge, (b) sharing knowledge, (c) storing knowledge, and (d) applying knowledge.

Strategy: In the literature, many definitions are given. A possible definition is the desired portfolio of product-market-technology combinations of an organization.

Strategy Formulation: The process by means of which the desired portfolio of product-market-technology combinations is defined and updated. This process can be modeled using the viable system model consisting of four steps: defining proposals for innovation, reviewing these proposals, finalizing proposals, and consolidating finalized proposals.

Viable System Model: This model is developed by Beer (1979, 1981) and specifies the necessary and sufficient functions organizations should possess to maintain a separate existence in their environment.

Viability: Viability is the ability of a system "to maintain a separate existence." Most organizations are continuously trying to maintain their viability.

Key Factors and Implications for E-Government Diffusion in Developed Economies

Mahesh S. Raisinghani
TWU School of Management, USA

INTRODUCTION

E-government has grown in significance with the growth of the digital age and the global economy; however, at a slower pace. Its impact is pervasive and is evident in the availability and distribution of products and services within agencies, to business, and to citizens in western countries. There are many aspects of e-government; researchers have written extensively on the subject and have reached conclusions that will continue to evolve as new discoveries are made.

The business community, and society at-large, have been challenged by the complexities of e-government in meeting the needs in developing countries as well. The relationship between developed and underdeveloped countries is interdependent due to natural resources that may be available in underdeveloped countries and products that may be modified in their packaging and price for sale to the people in underdeveloped countries (e.g., toothpaste packaged in small, disposable packets, or shampoo in small vials, or second/third generation mobile phones to keep it affordable for the people in the underdeveloped countries). The polarization between e-government and society is due to conflicting financial, geopolitical/ethical and societal goals (Webber, 2006); this issue is evident in the adoption rates and usage of government Web sites. Although progress has been made in identifying e-government opportunities, the juxtaposition of government infrastructure, technology, and societal needs often conflict and, as a result, have adversely impacted the products and services offered by e-governments throughout the western world and ultimately, the adoption rates.

BACKGROUND

A recent visit to some state and local government Web sites, including New York City (http://www.nyc.gov/portal/site/nycgov/) and North Carolina (http://www.ncgov.com/), revealed that some local and state government Web sites in the United States offer static information. Unfortunately, governments have failed to take advantage of the full functionality of the Internet; moreover, they have ignored the upsurge in Internet usage in the commercial sector. Webber (2006) notes that while Canada outpaces the United States in nearly all Internet activities, both countries fail to capitalize on its potential to increase citizen interaction and to reduce costs associated with providing goods, services and information (Webber, 2006, 1). Most sites are based on a brochure-ware format; citizens can download forms, complete them and return the information by traditional postal mail; Webber notes that form downloading is one of the most common activities on US and Canadian sites. Further, he notes the growth and adoption of e-government may be hampered by an antiquated form-based approach to requesting and providing services (Webber, 2006, 1).

E-GOVERNMENT USAGE

An examination of e-government adoption must begin with an examination of Web site usage and an identification or profile of the typical Internet user. Figure 1 compares the profiles of the typical Australian, Canadian, and US online citizens. For those who do go online, many do not take advantage of general portal information.

Australian E-Government User Profile

In March 2006, the results of a recent government prospectus on Australia's e-government, which was, for the first time, endorsed by the prime minister and cabinet were announced,. The prospectus highlighted the government's flawed approach of layering Internet functionality over antiquated policies as opposed to first determining who is using the Internet, that is, user profile, and the purposes for which they use it. Today, only one in three online consumers uses the Internet to access government services. The profile of the typical online Australian government Web site users mirrors that of its American and Canadian counterparts (i.e., government Web site users) in many ways, however, there are some noteworthy differences; these differences are summarized as follows.

- The typical Australian user is a baby boomer in her mid-40s; it should be noted that females dominate online government site use in Australia with 62%. This contrasts with the US and Canada, where usage

Figure 1. Comparison of Australian, US, and Canadian Online Citizen Profiles (Webber, 2006, p. 3)

	Australia	US	Canada
Age	44	46	43
Average household income	A$50,303	US$65,942	C$53,096
Female	62%	52%	51%
Married or living with a partner	57%	70%	69%
Has a college degree	35%	37%	28%
Has broadband at home	40%	42%	57%
Technology optimist	46%	58%	56%
Owns one or two computers	69%	77%	81%
Uses the Internet more than 3 hours per week	79%	70%	61%
Goes online daily	69%	62%	56%

Base: Australian and North American online consumers

Source: Forrester's Consumer Technographics Q1® 2005 North American Retail, Automotive, A Online Study and Forrester's APCTAS Q1 2006 Survey

is equally spread between men and women. Fifty seven percent are married, however, 68% have no children. The average income of the e-government Web site user is 8% higher than their nonuser counterparts (Webber, 2006, p. 3).

- Online activities vary by federal, state, and local Web sites. Activities on a federal Web site include downloading or printing out a government form, filling in tax details or completing tax returns online; accessing information regarding benefit eligibility; accessing employment information; accessing tourism information, and applying online for benefits (Webber, 2006, p. 4). Activities on a state Web site include downloading or printing out government forms, accessing tourism information, license renewal or vehicle registration, accessing employment information and accessing motor vehicle related information (Webber, 2006, p. 5). On the local level, activities include accessing tourism information, accessing employment information, accessing real-estate information, downloading or printing out a government form, and ordering consumer publications (Webber, 2006, p. 5).

Canadian E-Government User Profile

Taken as a whole, Canadians prefer to use other channels to communicate with the government; these include the phone channel, mail, or in-person contact (Cardin, 2006, p. 1). The driver for this behavior is based on the type of inquiry, which, in turn, determines the type of interaction with the government (Cardin, 2006, p. 3). Citizens use the Internet to perform general research, for example, government statistics, laws and regulations, and possible employment opportunities within the government; in contrast, they prefer phones for personal research, including eligibility for health and government services, checking the status of tax returns, or applying for health benefits (Cardin, 2006, p. 2). In-person contact is the channel of choice for passport transactions, social security numbers, and government benefits; mail remains the channel of choice for filing taxes (Cardin, 2006, p. 3).

United States E-Government User Profile

While more than 38 million US citizens applied for Medicare benefits, only 5% applied online. This gap is evident in the security arena as well; although there has been a marked increase in attention to security and safety since 9/11, less than 10% of North American citizens visited government Web sites for information on security, health or safety issues, including the Avian flu, terrorism, or natural disasters (Webber, 2006). The most prolific e-government users are baby boomers; Young boomers range from age 41–50 and older boomers range from age 51-61. The most popular activity is downloading forms and research. Seventeen percent visit state government sites while 15% and 14% visit federal and local sites, respectively (Webber, Holmes, & Hanson, 2006, p. 1). One common thread among US e-government users is they are technology enthusiasts. Not surprisingly, Gen X and Gen Y are the most optimistic about technology, however, older boomers outpace younger boomers (65% to 61%); seniors are the most reticent at 58% (Webber et al., 2006, p. 3).

Although discussion, to this point, has been limited to Australia, Canada, and the US, an examination of the EU is warranted as well. The United Kingdom readily recognizes that numerous benefits could be achieved from increased Internet usage by its citizenry. These include wider participation/reduced social exclusion; improvements in information sharing between services and agencies; greater variety and choice and convenience for access; and improved speed and efficiency (Phippen & Lacohee, 2006). Unfortunately, citizen engagement is poor and lags significantly behind the US and Canada; only 1 in 10 citizens use online government services; this fact is particularly alarming, based on recent expenditures, and begs the question – Do they know their audience and what they want (Phippen & Lacohee, 2006, p. 205)?

Causes of Citizen Apathy Toward E-Government

The causes of apathy or reluctance to use e-government services are both qualitative and quantitative. Qualitative causes include appearance and performance, while quantitative causes include public safety, fraud services, and the digital divide (Webber, 2006).

Appearance and performance includes site responsiveness and readability; factors include speed, functionality, security, and reliable performance. Site trust is critical to older boomers and seniors; appearance and fun factor are less important to all except for Gen Yers. Public safety and fraud services include consumer and safety information leads. E-government users want information on public safety, including emergency services, courts, and health advisories; fraud warnings (scams), product recalls, and general consumer protection information.

Main Management Concerns/Issues in Regard to E-Government

The primary management concerns and issues with regard to e-government are listed as follows; they, too, are exacerbated by security, privacy issues, and financial/cost constraints. These same issues, when viewed from the perspective of

Figure 2. Citizens Look for an Increase in Online Government Services across a Spectrum of Topics (Webber, 2006)

"In which government service and/or department areas would you like to see an increase in eGovernment initiatives (i.e., an increase in information, transactions, and communication methods)?"

	Gen Yers (18 to 26)	Gen Xers (27 to 40)	Younger Boomers (41 to 50)	Older Boomers (51 to 61)	Seniors (62+)
Employment opportunities in government	62%	68%	67%	72%	58%
Worker benefits (e.g., unemployment and disability)	60%	64%	69%	72%	59%
ID cards (e.g., licenses, passports, and green cards)	54%	56%	51%	52%	42%
Parks and recreation opportunities	56%	61%	60%	61%	53%
Human rights, health, and welfare benefits	59%	60%	62%	59%	50%
Consumer information (e.g., fraud services)	59%	71%	75%	76%	68%
Environment and natural resources	55%	61%	63%	61%	54%
Public safety (e.g., emergency services, courts, and health advisories)	63%	68%	72%	74%	63%
Grants available from the government	72%	69%	74%	69%	58%
Housing, planning, and zoning	58%	66%	64%	61%	52%

the citizen, provide additional context on their concerns and issues.

- *Client definition* –. Agencies are set up to work in silos, however, consumers may be daunted by Web sites that are agency-focused when the information need is problem oriented, that is, "I know what I need I just don't know where to get assistance." Having to know the specific address of a government agency in order get services is not a "delighter" and may ultimately drive consumers either to more expensive channels such as phone or in-person or if like services are available, the private sector (Pavlichev & Garson, 2004).
- *Political implications* - The issue of using state Web portals for political purposes is an ethical issue. Sites with political messages should be segregated from sites focused on providing services (Pavlichev & Garson, 2004).
- *Centralization vs. decentralization* – From the consumer's perspective, information should be centralized to ease consumer access; however, decentralization may allow the agency to act as an entrepreneur in integrating horizontally, vertically, and externally to provide the best environment for the consumer (Weber, 2005).
- *Commercialization* – standardization of Web site naming conventions in an ongoing discussion and would provide ease of use for the consumer. Additionally, using the site for advertising space may set expectations for the consumer that the state is endorsing the product (Pavlichev & Garson, 2004).
- *Outsourcing* - While in-house expertise may be a consideration, the public may take a dim view of this practice, as there are issues of public information access and privacy. Additionally, fees may be assessed to access government information would have negative impact on usage (Pavlichev & Garson, 2004).

Figure 2 consolidates responses of survey participants to the question, "In which government Service and/or department areas would you like to see an increase of e-government initiatives?"

THE DIGITAL DIVIDE

The digital divide is defined as patterns of unequal access to information and communications technologies (ICTs); the divide was originally identified in the 1990s, and specifically referenced computers and the Internet (Khosrow-Pour, 2006). It is an accepted fact in academia and in political circles that the lack of computer and Internet access has created a divide between people of color, specifically, African-Americans and Latinos, and whites (Pavlichev & Garson, 2004). In a study conducted in September, 2000, researchers found that 50% of whites had Internet access; conversely, only 36% of African-Americans and 44% of Hispanics have Internet access (Pew Internet & American Life Project, 2000). The study also showed that the divisions were influenced by economic factors; of families with incomes greater than $75,000, 78% of whites, 79% of Hispanics, and 69% of African-Americans were online. The contrast was stark for those with income of less than $30,000; 68% of whites, 75% of African-Americans, and 74% of Hispanics were not online. By 2005, the number of people online line had increased,

Table 1. Digital divide demographics

CATEGORY	STATISTICS
Age – Online access increased as the age of the population decreased	18 – 19: 83%; 20 – 24: 81%; 25 – 29: 78%; 30 – 34: 76%; 35 – 39: 73%; 40 – 44: 69%; 45 – 49: 65%; 50 – 54: 61%; 55 – 59: 55% 60 – 64: 41%; 65 – 69: 27%; 70 – 74: 15%
Employment Status – Online access increased with employment or college attendance	Full time student: 94%; part-time student: 84%; employed: 76%; not employed: 51%; retired: 33%
Household Income – Online access increased in direct correlation to income	=> $75k: 89%; $50k - $75k: 81%; $30k – 50k: 69%; < $30k: 44%
Education attainment – Online access increased in direct correlation to education level	College degree +: 88%; some college: 75%; HS grad: 52%; less than HS: 32%
Race and ethnicity (English-speaking) – Online access varied by ethnic population	Asian-American: 82%; White: 67%; Hispanic: 59%; 43% African American
Community type - Online access varied by community	Suburban: 68%; Urban: 62%; Rural: 56%
Disability: Online access varied by disability	Not disabled: 67%; disabled: 38%

however, ethnic disparity still existed. When viewed by race, 70% of whites go online as opposed to 57% of African-Americans. Additionally, Americans age 65 and older, as well as those with less education, were less connected (Pew Internet & American Life Project, 2005).

Analysis of US Digital Divide Demographics

Table 1 summarizes the findings from the 2005 study on data gathered for the Congressional Internet Caucus (Pew Internet American Life Project 2005):

The digital divide determines which citizen can or will avail themselves of government services. Table 2 documents the number of citizens who used government online services. While these numbers may seem significant, they pale in comparison to the total US 2005 population of more than 296 million. Simply put, more than half of the American population is not participating in e-government. Those citizens who cannot or choose not to participate in government activities are at a disadvantage. One major area of concern is e-democracy, which is defined as all forms of electronic communications between government and its citizens (Pavlichev & Garson, 2004).

Many governments are taking steps to leverage the benefits of ICTs to increase accountability, transparency, and the quality of services to its citizens (Khosrow-Pour, 2006). E-democracy is based on five principals: access, convenience, awareness, communications, and involvement in the political process; the goal is to encourage active rather than passive participation (Pavlichev & Garson, 2004). E-democracy efforts are the focus of governments throughout the world; many governments are creating programs with the sole purpose of engaging citizens in the political and governmental process. While those efforts are admirable and are part of the equation necessary to close the digital divide, the issue of access is paramount and must be addressed.

Recent data shows that progress is being made in the African-American and Hispanic communities. As a result of significant reduction in laptop costs, more computers in public community sites, such as schools and libraries, and availability of mobile devices, such as cellphones, more minorities have online access (Marriott, 2006). A 2006 Pew study noted that 74% of whites go online compared to 61% of African-Americans and 80% of English-speaking Hispanics; these figures represent a significant increase from the 2005 statistics (Marriott, 2006).

One untapped market, from the perspective of government usage, is the mobile market. While the private sector has numerous efforts underway to use the tool for marketing and as an access point for the Internet, the government has yet to follow. In a recent Pew study, the benefits of cellphone usage were documented, and are indicative of strong user engagement. Additionally, they also indicate that users are willing to reallocate their personal and business time, and to intersperse both with mobile activity; moreover, they provide 24x7 availability. Governments should consider these benefits and develop plans to make information available via mobile access, thereby, bringing e-democracy into the 21st century.

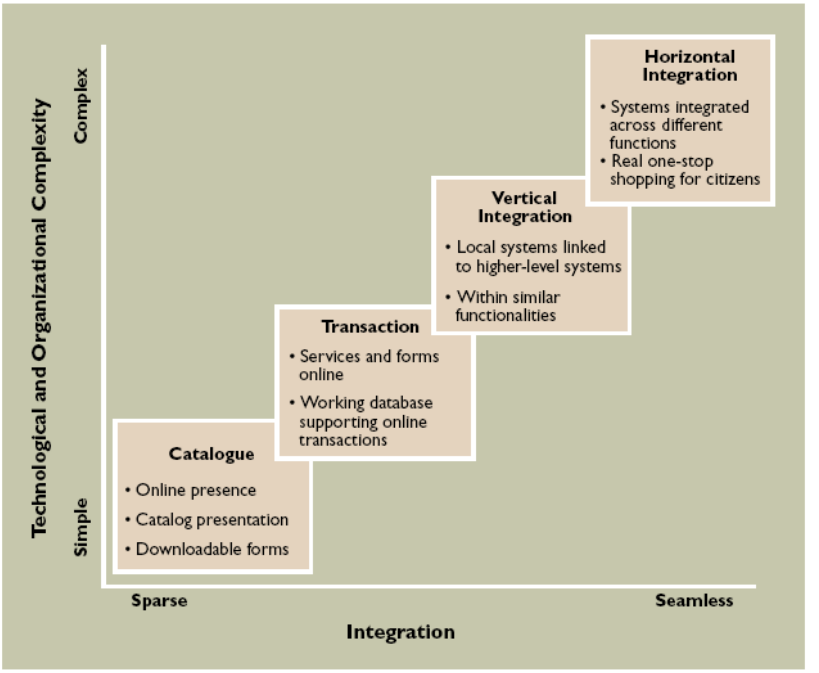
INTERNATIONAL DIGITAL DIVIDE

Efforts are underway to address issues in South American countries, specifically Brazil, Argentina, and Peru. The One Laptop per Child Program (OLPC) is a UN-sanctioned effort to close the digital gap on an international level. Libya, Liberia, Rwanda, and Thailand are included. The program distributes low-cost PCs with simple hardware and software configurations to children in these countries, thus, providing the tools needed for self-directed education. OLPC is not specifically an e-government initiative, but has the goal of giving children in these countries the tools needed to teach

Table 2. eCitizen activities

Activity	**Number of Users Millions)**
Government Web sites	83
2004 political campaign	63
Research on policy issues	52
E-mails regarding 2004 campaign	43
E-mails to government officials to affect changes in policy	38
Access to health and safety information	36
Research/application for government benefits	29
Participation in organized lobbying campaigns	24
Participation in 2004 campaign through donations and/or volunteer activities	11

Figure 3. Evolutionary progression of e-government



themselves (OLPC, 2007). The potential benefits of this effort are many; in addition to the immediate benefit of teaching children in these countries, the greater benefit is that the UN, in conjunction with its partners, Intel, and OLPC, is preparing a generation of computer literate citizens. Moreover, adoption rates may be higher, since the computers and associated Internet access may be the only means of accessing information. This effort may have positive implication for western countries, and should be considered, and potentially included in, future e-government strategies.

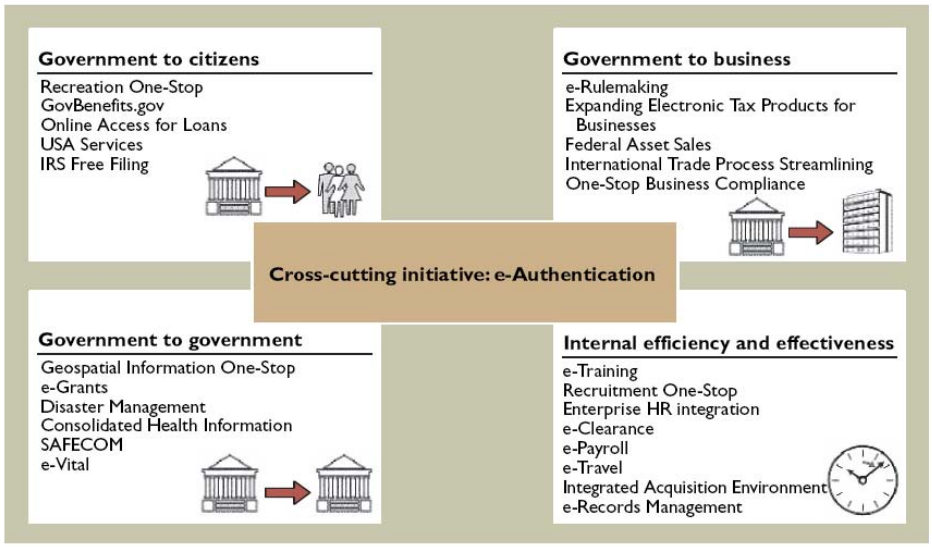
FUTURE TRENDS

The evolution of e-government can be charted as a comparison of technological and organizational complexity vs. the degree of integration. The progression is depicted as a linear relationship, however, government may choose to skip stages or combine them. Figure 3 depicts the dimension and stages of e-government development (Lee, Tan, & Trimi, 2005, p. 100).

Although the US, Canada, and the European Union each recognizes that improvements can be made to increase citizen engagement, each country is recognized as a leader in e-government development. The US effort includes the Office of Management and Budget's e-government strategy, an action plan with 25 initiatives (Lee et al., 2005, p. 100). The strategy, depicted in Figure 3, addresses government to business, government to citizen, government to government, and internal efficiencies and effectiveness.

Efforts in the European Union have been noteworthy as well. In April 2006, the European Commission issued the e-government action plan that provides specific actions needed to support e-government. These include horizontal government integration policies, funding, and coordination activities. The plan outlines high-level goals that will be addressed between 2006 and 2010. The goals include leaving no citizen behind, making efficiency and effectiveness a reality, providing high-impact key services for citizens and businesses, putting enablers in place, and strengthening participation and democratic decision making (Di Maio, 2006). Under this approach, e-government will be available to all citizens, regardless of socioeconomic status, and is expected to increase participation in e-democracy. Additionally, citizen's concerns regarding privacy and security are expected to be addressed as well through the deployment of identity management and document authentication (Di Maio, 2006).

Figure 4. U.S. Office of Management and Budget 25 e-government initiatives



CONCLUSION

E-government has had a pervasive impact on society (e.g., Government to Business (G2B), Government to Consumer (G2C), Government to Government (G2G) e-commerce). Millions of citizens around the world access government Web sites daily; unfortunately, this number is only a fraction of the total population. User profiles of citizens in the United States, Canada, and Australia are similar, and reflect similar usage patterns. Citizen apathy can be categorized as both qualitative, for example, appearance and performance, and quantitative, for example, public safety and fraud services. Within the government itself, issues have been identified that impact the adoption rate as well; these include client definition, political usage, centralization vs. decentralization of information, out-sourcing, and standardization of site naming conventions. One of the most highly publicized reasons identified as an impact to e-government adoption has been the digital divide. Citizens, specifically those of color and of lower socioeconomic status, have had less access to technology and as such, have not been able to avail themselves of the products and services offered via e-government sites. Recent studies show that while the gap is lessening, it still exists. The United Nations has efforts underway in developing countries, such as the One Laptop per Child program in South America and Africa; this program should be adopted in western countries as well.

Governments in western countries continue to look for ways to improve citizen adoption rates; both the United States and the European Union have developed strategic plans that target the issues listed here. In order to continue to improve adoption rates, governments must keep abreast of the technological advances that the Internet and associated technology offers; however, more importantly, they must listen to their customers and build a mousetrap that they want and need.

KEY TERMS

Electronic Government (E-Government): The use of digital technologies to transform government operations in order to improve efficiency, effectiveness, and service delivery.

Government to Business (G2B) E-Commerce: When a government entity sells products and services to businesses.

Government to Consumer (G2C) E-Commerce: The electronic commerce activities performed between the government and its citizens or consumers, including paying taxes, registering vehicles, and providing information and services.

Government to Government (G2G) E-Commerce: Either (1) the electronic commerce activities performed within a single nation's government or (2) the electronic commerce activities performed between two or more nations' governments including providing foreign aid.

Horizontal Government Integration: The electronic integration of agencies, activities, and processes across a special level of government.

Identity Theft: The forging of someone's identity for the purpose of fraud.

Internet: A vast network of computers that connects millions of people all over the world.

World Wide Web (Web): A multimedia-based collection of information, services, and Web sites supported by the Internet.

Keystroke Dynamics and Graphical Authentication Systems

INTRODUCTION

In information systems, authentication involves, traditionally, sharing a secret with the authenticating entity and presenting it whenever a confirmation of the user's identity is needed. In the digital era, that secret is commonly a user name and password pair and/or, sometimes, a biometric feature. Both present difficulties of different kinds once the traditional user name and password are no longer enough to protect these infrastructures, the privacy of those who use it, and the confidentiality of the information, having known vulnerabilities, and the second has many issues related to ethical and social implications of its use (Magalhães & Santos, 2005).

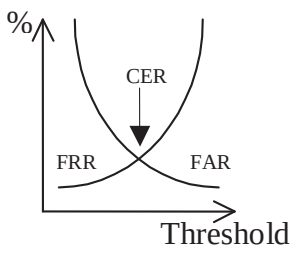
Password vulnerabilities come from their misuse that, in turn, results from the fact that they need to be both easy to remember, therefore simple, and secure, therefore complex. Consequently, it is virtually impossible to come up with a good password (Wiedenbeck, Waters, Birget, Brodskiy, & Memon, 2005). On the other hand, once users realize the need for securing their authentication secrets, even fairly good passwords become a threat when the security policies (if at all existing) fail to be implemented. The results of an inquiry made by the authors in 2004 to 60 IT professionals show that, even among those that have technical knowledge, the need for password security is underestimated (Magalhães, Revett, & Santos, 2006). This is probably one of the reasons why the governments increased their investment in biometric technologies after the terrorist attack of 9/11 (International Biometric Group [IBG], 2003).

The use of biometric technologies to increase the security of a system has become a widely discussed subject, but while governments and corporations are pressing for a wider integration of these technologies with common security systems (like passports or identity cards), human rights associations are concerned with the ethical and social implications of their use. This situation creates a challenge to find biometric algorithms that are less intrusive, easier to use, and more accurate.

The precision of a biometric technology is measured by its false-acceptance rate (FAR), which measures the permeability of the algorithm to attacks; its false-rejection rate (FRR), which measures the resistance of the algorithm to accept a legitimate user; and its crossover error rate (CER), the point of intersection of the FAR curve with the FRR curve that indicates the level of usability of the technology (Figure 1). For a biometric technology to be usable on a stand-alone base, its CER must be under 1%. As an algorithm becomes more demanding, its FAR is lower and its FRR is higher. Usually the administrator of the system can define a threshold and decide what the average FAR and FRR of the applied algorithm will be according to the need for security, which depends on the risk evaluation and the value of what is protected; also, the threshold can be, in theory, defined by an intrusion detection system (software designed to identify situations of attack to the system).

Establishing the error rates of a biometric technology is a complex problem. Studies have been made to normalize

Figure 1. Crossover error rate



their evaluation, but the fact is that the results are strongly dependent on the number of individuals involved in the process and, what is worst, on who is chosen. This means that, even with a large amount of data collected, the results can be very different if we change the evaluated group. The lack of trust in the precision evaluation methodologies and values is one of the reasons why the human rights associations are opposing the generalization of use of biometric technologies and their acceptance as standards for authentication procedures (Privacy International, Statewatch, & European Digital Rights, 2004). Even so, in an inquiry made by Epaynews (http://www.epaynews.com), 36% of users stated that they would prefer to use biometric authentication when using credit cards, a value only comparable to the use of personal identification numbers (PINs) and much higher than the 9% of authentication obtained by signature.

Considering all the advantages and disadvantages of biometric procedures, it seems that the only way is to allow the user a choice. Being so, the traditional password systems must be enhanced both in the biometrical way and in another completely different way. On the biometric component we propose keystroke dynamics, a biometrical authentication algorithm that tries do define a user's typing pattern and then verifies in each log-in attempt if the pattern existing in the way the password was typed matches the user's known pattern; it is the only biometric technology that can be used with the existing log-in and password systems without requiring any extra hardware. On the nonbiometric component, we propose the use of a graphical authentication system, a log-in system that verifies the user's knowledge of specific images or parts of images to grant or deny successful log-in, because it has been proven that it provides a wider key space and because it can be used to generate complex secret strings from simple passgraphs (the user's secret code to access a system protected by a graphical authentication system, constituted by a sequence of points where the user must click in order to obtain a successful log-in).

BACKGROUND

Keystroke Dynamics

As in many other problems, there have been two different approaches to the challenge of finding an algorithm for keystroke dynamics that minimizes the CER: machine learning and deterministic algorithms.

Among the solutions based on machine learning, we can find the work presented by Ord and Furnell (2000) that tested this technology with a 14-person group to study the viability of applying it to the simple use of PINs typed on a numeric pad. Unfortunately, the results suggest that, for large-scale use, the technology is not feasible. Deterministic algorithms have been applied to keystroke dynamics since the late '70s. In 1980, Gaines et al. (1980) presented a report on the study of the typing patterns of seven professional typists. The small number of volunteers and the fact that the algorithm is deducted from their data and not tested for other people later results in lower confidence in the FAR and FRR values presented. However, the method used to establish a pattern was a breakthrough: the study of the time spent to type the same two letters (digraph) when together in the text. Since then, many algorithms based on algebra and on probability and statistics have been presented. Joyce and Gupta presented in 1990 an algorithm to calculate a value that represents the distance between acquired keystroke latency times and correspondent times previously stored. In 1997, Monrose and Rubin used the Euclidean distance and probabilistic calculations based on the assumption that the latency times for one digraph exhibits a normal distribution. Later in 2000, they also presented an algorithm for identification based on the similarity models of Bayes, and in 2001 they presented an algorithm that uses polynomials and vector spaces to generate complex passwords from a simple one using the keystroke pattern (Monrose et al., 2001).

In 2005, Magalhães, Revett, and Santos presented an improvement of the Joyce and Gupta algorithm and tested it with 170.391 attacks to 143 patterns, obtaining a 0% FAR with an FRR of 26%, and an estimated CER below 5%.

Graphical Authentication Systems

A graphical authentication system is a log-in system that verifies the user's knowledge of specific images or parts of images to grant or deny successful log-in. Greg Blonder (1996) was the first to describe graphical passwords, presenting in a United States patent a system that would allow users to choose a picture, the number of regions to be clicked, and their sizes and positions. Since then, many variations of this system were presented and images have gained their way into the authentication processes.

Among the most popular graphical authentication systems, we find Passfaces™ from the Passfaces Corporation (2005), a commercial system where the user chooses a previously selected face from a set of faces and repeats this process for different faces in different sets for a defined number of times. However, being popular does not imply being secure, and a study of the users' choices demonstrated that they are, in some cases, similar for all users. For instance, 10% of the passwords of males could have been guessed with only two attempts (Davies, Monrose, & Reiter, 2004).

The déjà vu scheme involves a matrix of *m* images in a set, where *n* images are part of the user's portfolio, previously chosen from a set of proposed images. The user must identify those *n* images to log in.

The draw-a-secret (DAS) scheme is a graphical authentication system with an approach completely different. In DAS, the user draws something over a grid that becomes the

authentication secret. This system has been implemented with success on PDAs (personal digital assistants) and further studies will be made to analyse the users' choices and acceptance (Jermyn, Mayer, Monrose, Reiter, & Rubin, 1999).

In the visual identification protocol (VIP) several possibilities were created. From a set of 10 predefined images the user chooses 4 placed on the same position and typed in the same order (VIP1), or placed in random positions (VIP2). VIP3 is a process where four of the eight images existing in the user's portfolio are displayed along with 12 distractors, and the user must identify them in no particular order. The studies showed that the most common errors associated with VIP1 and VIP2 were related to bad sequences, where the identified images are correct but selected in the wrong order, and in VIP3 most of the errors were due to the wrong identification of the images, for instance, any flower being considered as the chosen flower (de Angeli, Coventry, Johnson, & Coutts, 2003).

In 2006, Magalhães et al. presented a graphical authentication system that included letters and numbers in images with the objective of allowing PDA users to click their user names in an easy way. From that system they discovered that the selection of the image and the rules that control the choice of passgraphs are critical factors in the success of the implementation of this kind of system. In particular, they found that users have a common tendency to choose the first available images, and that the use of images with corners and the existence of letters placed in a row create serious vulnerabilities to the system. Eyes are also a common choice and should be avoided. Therefore, the results suggest the use of images without corners, like nature images, cut in a round form. If the choice of keeping the letters is made, they must be placed in a random way throughout the images. Another dangerous tendency is the use of passgraphs constituted by regions placed in the same row or in the same column, therefore the system must reject the choice of passgraphs that meet this criteria, forcing the users to navigate inside the image by demanding the use of at least two different rows and two different columns.

ENHANCEMENT OF LOG-IN AND PASSWORD SYSTEMS

Since most of the existing systems trust passwords to provide access control and considering that passwords are not enough, we propose the enhancement of this process by adding a new module to the authentication system. This module gives two options to the user: a password with biometric control (keystroke dynamics) or a passgraph. If the user chooses the password system, he or she will be prompted (Figure 2) to enter the password several times in order to establish a pattern (this is called the enrollment process), and the everyday authentication process is, from the user's point of view, exactly the same as it was before the introduction of our module.

Each time that a user enters a password for authentication, the window captures both the characters stroked and the times between successive actions (pressing a key, releasing the key, pressing another key, and so on). The module verifies if the sequence of times matches the stored pattern (locally or in a portable device, like a smart card) and if (and only if) it does, the sequence of characters is sent to the original password authentication system that will verify correctness and allow or deny access to the user. Therefore, we have introduced another layer of security (biometrics) without any extra effort or equipment.

If the user chooses to use a passgraph, avoiding the biometrics component, he or she will have to choose several positions in an image. These positions, clicked in the same sequence, will be the secret access code of that user. Figure 3 shows a possible authentication window with a place to choose one of several possible images (in this case, the choice Mozart is the one that is active) and a place to enter the user name (in this case, the student's identification number). Nevertheless, this image would not be a good choice since it is not compliant with the best procedures in image selection for authentication, as described before.

Each time a user enters a passgraph, the sequence of clicks is transformed by a unidirectional function into a complex string that is passed into the original password field of the hosting system. In this way, we have obtained a simple and easy-to-memorize way of having extremely complex passwords.

As a last remark, one should notice that passgraph-area technology is very vulnerable to eavesdropping and, therefore, are more suitable for access made in private environ-

Figure 2. Keystroke-dynamics enrollment window

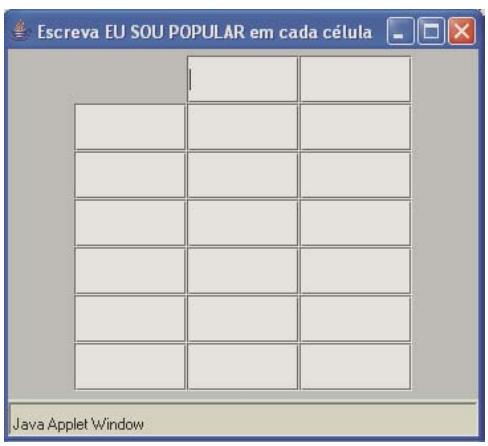


Figure 3. Passgraph authentication window

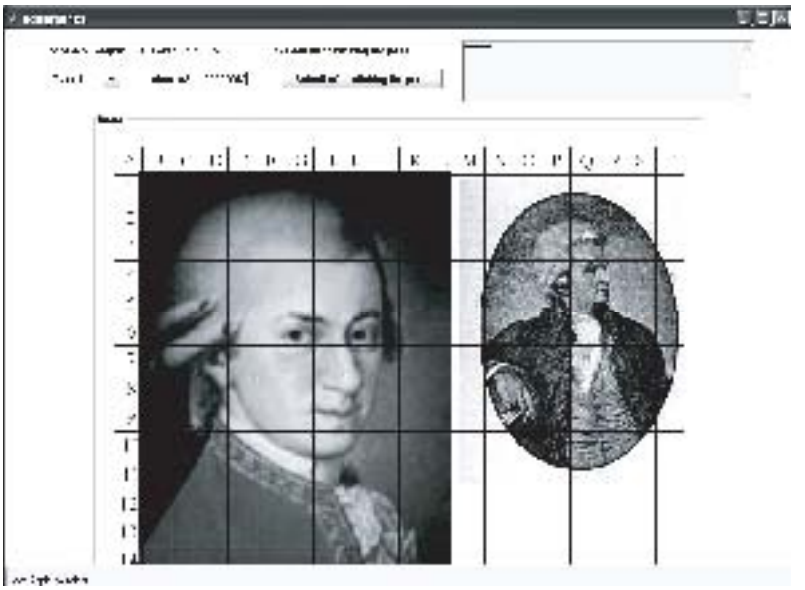

ments or on small portable devices, like smart phones or PDAs.

FUTURE TRENDS

Future work in this field will focus on improving the algorithms for keystroke dynamics, namely by combining the recent results provided by the artificial intelligence systems with the existing statistical algorithms.

Concerning passgraphs, studies are needed to improve the algorithms that convert the sequence of clicks into a sequence of characters and to improve the quality of the guidelines for image selection. This technology can also be integrated with other information security technologies in order to maximize their potential. On the other hand, artificial intelligence techniques can also be used to understand further more the use of secret codes in order to improve the quality of the proposed systems.

CONCLUSION

In conclusion, we can say that the technology has achieved a way to overcome, at least to a certain point, the entropy generated by users that continues to proceed in a way that is not the most efficient concerning security. Assuming human behaviour as a fact, ways were found to achieve best practices in security (like complex passwords) from the normal and traditional practices of users.

We have verified that keystroke dynamics and graphical authentication systems can, when used together, improve the security of the traditional log-in and password systems without adding significant complexity to their use and avoiding the ethical problems generated by biometrics when they are presented not as a choice but as an imposition. In fact, not only do these systems not present any ethical problems (when used together and leaving to the user the choice of which one to use), they can even provide a good use of the digital authentication processes by allowing those that cannot read or write (and therefore cannot use a password) to use the system, a matter especially relevant in the third-world countries that are now embracing new technologies, for instance, in electoral processes.

KEY TERMS

Authentication: It is the process of verifying the identity alleged by a user who tries to gain access to a system.

Collaborative Biometric Technology: It is a biometric authentication technology that requires the user's voluntary and intended participation in the process. It opposes the stealth biometric technologies that can be used without the user's consent.

Crossover Error Rate (CER): Authentication algorithms need to simultaneously minimize permeability to intruders and maximize the comfort level, therefore they have to be both demanding and permissive. This contradiction is the base for the optimisation problem in authentication algorithms, and the measure of success for the overall precision of an algorithm and its usability is the CER, the value obtained at the threshold that provides the same false-acceptance rate and false-rejection rate.

False-Acceptance Rate (FAR): This rate is a measure of the permeability of an authentication algorithm. It is calculated by dividing the number of the intruder's successful log-in attempts by the total number of the intruder's log-in attempts.

False-Rejection Rate (FRR): This rate is a measure of the comfort level of an authentication algorithm. It is calculated by dividing the number of unsuccessful attempts made by legitimate users by the total number of legitimate log-in attempts.

Graphical Authentication System: It is a log-in system that verifies the user's knowledge of specific images or parts of images to grant or deny successful log-in.

Identification: It is the process of discovering the identity of a user who tries to gain access to a system. It differs from authentication because in the identification process, no identity is proposed to the system, while in authentication, an identity is proposed and the system will only verify if that identity is plausible.

Keystroke Dynamics: It is a biometrical authentication algorithm that tries do define a user's typing pattern and then verifies in each log-in attempt if the pattern existing in the way the password was typed matches the user's known pattern. Another application of keystroke dynamics, at least in theory, is the permanent monitoring of the user's typing pattern in order to permanently verify if the user that is typing is the legitimate owner of the system's account being used.

Passgraph: It is the user's secret code to access a system protected by a graphical authentication system. It is constituted by a sequence of points the user must click in order to obtain a successful log-in.

Stealth Biometric Technology: It is a biometric authentication technology that can be used without the user's consent. It opposes the collaborative biometric technologies that require the user's voluntary and intended participation in the process.

Threshold: It is the variable that defines the level of tolerance of an algorithm. It can be set to a more demanding value, raising the false-rejection rate and lowering the false-acceptance rate, or it can be set to a less demanding value, lowering the false-rejection rate and raising the false-acceptance rate.

Knowledge Architecture and Knowledge Flows

INTRODUCTION

Modern society is increasingly seen as a knowledge economy; institutions, firms and individuals progressively rely on knowledge as a key component for individual and collective growth. This calls for a clear understanding of knowledge and its sharing patterns. This article has a two-fold aim: on the one hand, it aims at reviewing some of the most common *definitions of knowledge* provided in the economic and science and technology literature; on the other hand, it aims at providing a taxonomy of *knowledge flows* which should help scholars in distinguishing among various forms of knowledge sharing. Subsequently, we shall present a description of future trends and put forward some possible extensions of knowledge literature. Finally, our concluding remarks will be presented in the last section of the article.

BACKGROUND

The growing information flow which characterises the so-called "information society" has made organisations increasingly concerned with the problem of selecting and organising information in a cost-efficient manner. However, it would be incorrect to refer to the learning activity simply as the accumulation of information. In fact, firms are increasingly concerned with the acquisition of knowledge which, as recognised by many scholars (see among many others: Foray, 2004; Steinmueller, 2002), differs substantially from information.

Knowledge and Information

This leads us to the core distinction between information and knowledge. Ancori, Bureth, and Chohendet observed how the classical approach of economics adopts a vision that "allows the reduction of knowledge to information, or more precisely allows knowledge to be considered a stock accumulated from interaction with an information flux" (2000, p. 259). However, this view has recently come under criticism as knowledge and information should be considered as two distinct concepts: the latter taking the form of structured data which can be easily transferred through physical supports, and the former involving cognition (see e.g., Tsoukas, 2005; Steinmueller, 2002). To clarify this distinction, we could analyse the differences between the reproduction processes of knowledge and information: While cost of reproducing information amounts solely to the physical cost of making a copy (e.g., the cost of a photocopy, the cost of duplicating an electronic file), the cost of reproducing knowledge is much higher as it involves a cognitive process required to disarticulate knowledge, transfer it to someone else, and rearticulate it for further use (Foray, 2004). Hence, reproducing knowledge involves an intellectual activity, whereas reproducing information simply involves duplication.

Tacit and Codified Knowledge

After having assessed the existence of a clear distinction between information and knowledge, we shall now turn our attention to the definition of knowledge itself. As mentioned above, knowledge has to be articulated in order to be transferred. This is because knowledge is, in its original form, completely embedded in the mind of the person who first developed it. In other words, we could say that knowledge is originally created as tacit and subsequently codified by means of a cognitive process which involves its articulation.

Before reasoning on the codification process, we need to better clarify what is tacit knowledge. The tacit dimension of knowledge corresponds, in the view of Polanyi (1967), to the form or component of human knowledge distinct from, but complementary to, the knowledge explicit in conscious cognitive processes. In the Hungarian polymath view, we know more than we can tell, where the portion of knowledge possessed and not communicable is the essence of tacitness.

In different moments in time and across different individuals, a different proportion of knowledge will be tacit and a different proportion will be codified. Hence, tacitness is a contextual rather than an absolute situation, this depending explicitly on the process of codification, which should be seen as a convergence process of tacit to codified knowledge. Cowan and Foray noted how "as the new knowledge ages, it goes through a process whereby it becomes more codified. As it is explored, used and better understood […] more of it is transformed into some systematic form that can be communicated at low cost" (1997, p. 595).

The relevance of codification for economic purposes has been largely debated. The core argument put forward is that codified knowledge, when compared to tacit, can be transferred more easily, more quickly, and at lower costs. Cowan, David, and Foray (2000) argued in favour of codification stating that an uncodifiable (unarticulable) knowledge is not very interesting for social science. This stance is criticised by Johnson, Lundvall, and Lorenz (2002) who contest the view that codification always represents progress. According to these authors, tacit knowledge is a relevant component in human training, including the kind of training provided in institutions such as schools, universities and research institutes.

Knowledge Flows: Tacit vs. Codified

This argument (Johnson et al., 2002) introduces a key point for us in the debate: Tacit and codified knowledge flow in very different ways. Specifically, once codified, knowledge can be stored in a mechanical or technological way, like in manuals, textbooks or digital supports; it can be transferred from one person to another relatively easily, incurring the effort of getting access to the source of codified knowledge and decoding it for further use. In this respect, as observed by Steinmueller (2000), the context and intended recipient of the decodified knowledge makes a great deal of difference to the costs and feasibility of the initial codification. However, if appropriately codified (i.e., codified keeping in mind the intended recipient), knowledge can be easily transferred, taking also great advantage of modern information and communication technologies.

On the contrary, "[d]ifferent methods like apprenticeship, direct interaction, networking and action learning that include face-to-face social interaction and practical experiences are more suitable for supporting the sharing of tacit knowledge" (Haldin-Herrgard, 2000). Haldin-Herrgard identifies five main difficulties associated with tacit knowledge flows, related to perception, language, time, value, and distance. Perception refers to the characteristic of unconsciousness which entails a problem of people not being aware of the full range of their knowledge; difficulties with language lie in the fact that tacit knowledge is held in a nonverbal form and hence involves extra efforts to be shared; the time issue refers to the fact that the internalization of tacit knowledge takes a long time as it involves direct experience and reflection on these experiences; value is a problem as many forms of tacit knowledge, like intuition and rule-of-thumb, have not been considered valuable, lacking the status of "indisputable methods;" finally, the issue of distance relates to the need for face-to-face interaction for the diffusion of tacit knowledge.

This last point brings us back to the tacit/codified distinction: As already observed, modern information technology can play a major role in diffusing codified knowledge, but tacitness is hard to diffuse technologically. Perhaps, as observed by Haldin-Herrgard (2000), today and in the future high technology will facilitate this diffusion in artificial face-to-face interaction, through different forms of meetings in real-time, using, for instance, audio and video conferences. This perspective is shared by other scholars; in a recent paper Brökel and Binder stated, for instance, that "[n]ew information technologies, for example, video conferences, cast doubt on the advantages of face-to-face contacts" (2007, p. 154).

PROPOSING A TAXONOMY OF KNOWLEDGE FLOWS

The discussed distinction between tacit and codified knowledge is at the heart of the problem of understanding knowledge flows. However, in our view, the existing literature has neglected to classify the different ways in which knowledge can flow among agents. This has created some confusion and has generated a misuse of specific concepts. In this section, we propose a taxonomy of knowledge flows which should help in clarifying the different forms of flow patterns.

Knowledge Gain vs. Knowledge Diffusion

We start our analysis distinguishing between the two broad concepts of *knowledge gain* and *knowledge diffusion*. The first relates, in our view, solely to those processes of knowledge flows which deliberately involve a barter among subjects: A portion of subject's A knowledge flows to subject B, who pays subject A back either with a portion of his or her knowledge or with a different coin.

We shall refer to the first of these two options (i.e., knowledge is paid back with other knowledge) as *knowledge exchange*, and to the second option (i.e., knowledge is paid back with a different coin) as *knowledge trade*. An example of knowledge exchange has been used by Cowan and Jonard who define a model in which knowledge flows "through barter exchange among pairs of agents" (2004, p. 1558). Patterns of knowledge trade, on the other hand, relate, for instance, to those cases where disembodied knowledge flows through technology and patent trade (Arora, Fosfuri, & Gambardella, 2002).

Note that knowledge gain relates to both tacit and codified knowledge. Codified knowledge can flow among distant agents, whereas tacit knowledge gains require always a direct interaction (i.e., face-to-face) among agents.

Substantially different is the concept of knowledge diffusion. Here, knowledge is no longer traded on a voluntary basis (*quid pro quo*), but freely flows while agents interact. Several scholars have referred to this process as knowledge

spillover (Jaffe, 1986), or knowledge percolation (Antonelli, 1996). The common idea behind these definitions is that knowledge flows freely, within a specific space, and can be economically exploited by the recipient agent. The kind of knowledge being spilled-over is tacit in nature, and requires some "absorptive capacity" to be effectively recombined in the cognitive framework of the recipient agent.

Decomposing Knowledge Diffusion

We shall now look more carefully into knowledge diffusion, decomposing it into knowledge spillover, knowledge transfer and knowledge integration. The latter of these three concepts refers to a process which combines dispersed bits of knowledge held by individuals to be applied in a coordinated way, and only on a temporary base. On the contrary, knowledge spillover and knowledge transfer denote two similar processes in which bits of knowledge convey from one agent to another such that the recipient can absorb it into her/his already existent personal knowledge (i.e., some previously acquired related knowledge is required); the only difference between these two processes being that spillover are unintended processes of knowledge diffusion (e.g., while chatting with colleagues), whereas knowledge transfer requires a defined will (e.g., while jointly working on a project).

Knowledge transfers and knowledge spillovers are the most cited typologies of knowledge diffusion patterns (see, for instance, Cabrera & Cabrera, 2002; Morone & Taylor, 2004; van der Bij, Song, & Weggeman, 2003). However, these mechanisms present some disadvantages: They are expensive and often time-consuming and they off-set the specialisation of employees needed for innovation, as it assumes that individuals absorb diverse specialised knowledge by means of face-to-face encounters. In fact, here we are posing a question of depth of knowledge vs. breadth of knowledge. As suggested by Grant, "[d]ue to cognitive limits of human brain, [tacit] knowledge is acquired in a highly specialised form […]. However, production […] requires a wide array of knowledge, usually through combining the specialised knowledge of a number of individuals" (1996, p. 377). The possibility to integrate knowledge without having to acquire it might provide a solution to these drawbacks. In light of these arguments, Grant (1996) asserts that integration of specialist knowledge is at the heart of production in a knowledge-based society.

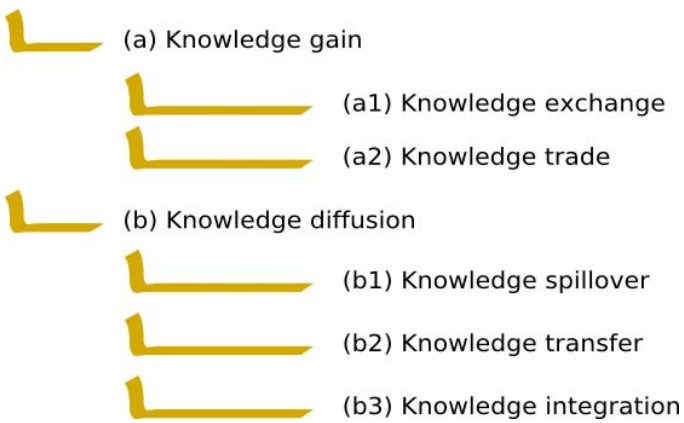
But how does integration occur? In a recent paper Berends, Debackere, Garud, and Weggeman (2004) examined knowledge integration in an industrial context. They defined knowledge integration as dominated by *thinking along*, that is, a mechanism through which an agent applies knowledge temporarily to a problem of somebody else and communicates the generated ideas to that other person. Hence, it involves temporary cognitive work with regard to a problem of someone else.

Interestingly, the concept of knowledge integration does not involve any permanent flow of knowledge from subject A to subject B in the conventional sense. We consider it as an "atypical" form of knowledge diffusion.

Now, recombining the analysis developed in this section, we shall propose a taxonomy of knowledge flows.

Figure 1 shows a taxonomy of concepts emerging from analysis of the knowledge flows literature. At the top level in the hierarchy are knowledge gain and knowledge diffusion, which we classify as distinct phenomena of flows. Knowledge exchange and trade are subclasses of knowledge gain, whereas knowledge spillover, transfer and integration are derived from a decomposition of knowledge diffusion.

Figure 1. A proposed taxonomy of knowledge flows



Assessing Knowledge Flows Taxonomy

It is important to assess the goodness and limitations of the proposed scheme. The following figure introduces a check-list evaluation of the taxonomy as a general framework for understanding knowledge flows.

The first four points should be evident from earlier sections of this article: it is grounded in previous studies and tries to integrate them; it can be used for comparing previous studies on knowledge flows and, specifically, for understanding knowledge flows in information systems. The model has been developed in a flexible (open) way and further insights could always be included. Our analysis also highlights different assumptions about governance and control of knowledge. In the case of knowledge gain, one assumes the functionality, as well as the ability, of locking flows in a rigidly controlled domain of knowledge. The strategy is to maximise the payoff of current knowledge assets and obtain a fair value in exchange. The drawback of this approach is that over the long term it tends to stifle creativity and diminish diversity in production of new knowledge and recombination of existent knowledge. The opposite strategy is the promotion of largely uncontrolled diffusion, where value is often derived from the outcomes on a larger scale: the generation and exploitation of whole new economic areas, and the impact this has on the opportunities and constraints for the organisation.

In spite of the discussion of such stylised facts, the taxonomy does not fully consider the implications of knowledge flows either for economic or innovation systems (points 7 and 8). With respect to empirical validation of the taxonomy, this point is addressed in the following section concerning measurement of knowledge flows.

FUTURE TRENDS

A Challenge for Future Research: Modeling Knowledge Flows

In the area of knowledge flows several different types of modeling have been used. Conceptual modeling ranging from organisational models to taxonomic models (such as the one presented above) are found. Mathematical modeling can be used to determine solution states and optimization behaviours. On the other hand, simulations are promising tools with which to investigate knowledge flows because they can express the dynamics in a model.

The role of formal modeling and simulation is to allow exploration of the hypotheses embodied in the program over a range of different conditions. Models can be, to a greater or lesser degree, based on empirical data on knowledge flows. Although measurement is often problematic (see the next section), efforts to improve the empirical basis of modeling are key to the increasing sophistication of recent knowledge diffusion models, to improving the clarity of conceptual models and to helping the modeler to arrive at a more rigorous conceptualisation.

Figure 2. A check-list for assessing the taxonomy

CHECK-LIST	"CASTING OUT NINES"	Yes	No
	1. integrates different models or studies	✓	
	2. allows to compare and contrast different models or studies	✓	
	3. has a clear structure	✓	
	4. is suitable for understanding knowledge flows in information systems	✓	
	5. could be modified or extended as new information emerges	✓	
	6. is suitable for evaluating knowledge governance and control	✓	
	7. fully covers the implications for innovation systems		✓
	8. fully covers the economics of knowledge		✓
	9. is empirically valid		✓

Measuring Knowledge Flows and Validating the Proposed Taxonomy

In order to validate and develop the proposed taxonomy, it is necessary to select suitable methods to observe and measure knowledge flows. Measurement is a key issue in assessing theoretical models, and in doing so we are concerned with distinguishing between measures of knowledge gains and measures of knowledge diffusion.

Measurement can be categorised according to the context in which an investigation is carried out. We shall define three possible investigation contexts within which data on knowledge flows can be gathered: (a) literature-based, (b) field-based, and (c) laboratory-based.

Since the seminal contribution of Jaffe (1986), many economists attempted to measure knowledge flows tracing the citation flows across patents (see, among others, Alcácer & Gittelman, 2006). Specifically, this strand of empirical literature aims at measuring "the benefits that one inventor receives from the innovations of others" (Fung & Chow, 2002, p. 353). Other researchers have investigated international flows of knowledge as measured through papers' citation (on bibliometric studies see, for instance, Sivadas & Johnson, 2005) or as measured in scientific meetings, using proceedings citations (see, for instance, Godin, 1998). These are all measures of knowledge diffusion; specifically, the first two refer to knowledge transfer (in fact, scientific papers and patents reflect the intention of transferring knowledge), whereas the last measure could incorporate pure knowledge spillovers as well.

The common ground of these studies is that they concentrate their attention on citations as a key empirical indicator of knowledge flows. However, not all knowledge flows through citations. For instance, citations refer solely to codified knowledge, hence dismissing all sources of tacit knowledge flows. A possible solution to this problem is offered by field-based research which, through field work and case studies, could better capture other sources of flows and would allow to clearly distinguish among knowledge gain, knowledge diffusion and their subcategories (see, for instance, Morone, Sisto, & Taylor, 2006).

A further step in this direction was made by Berends et al. (2004). The authors chose an ethnographic research strategy which combines interviews with community members with close observation of their work practices in their natural context. Hence, by means of such studies, researchers can analyse knowledge processes, in their natural context, as they are actively realised. Note that it was exactly through this empirical investigation that it was possible to define the abovementioned concept of knowledge integration.

The third approach involves laboratory experiments which might provide further insight on the actual processes of knowledge flows. This is a rather new research strategy, based on the analysis of agents' behaviour in a laboratory artificial environment. The main advantage of this approach is that it allows to track exactly who is interacting with whom and how knowledge flows from one agent to another (see Morone, Morone, & Taylor, 2007). One shortcoming of this methodology relates to the fact that knowledge structure is *ex-ante* determined and remains static through the experiment; moreover, knowledge flows fall in a predefined category (e.g., knowledge transfer or knowledge integration) which is imposed upon players. This results in a predetermined space of knowledge which bounds possible flows and does not allow classifying different categories of flows.

CONCLUSION

This article presented a review of recent studies of knowledge flows with relevance to economic and science and technology literature, arriving at some definitions of terms in the knowledge economy field. The main finding was that much of this discussion was based on the distinction between knowledge gain and knowledge diffusion, resulting from different assumptions about governance and control of knowledge.

This finding leads directly to the main contribution of the article presented in section three: A new taxonomy of knowledge flows, in which we expand on the concept of knowledge diffusion and highlight a further decomposition which, we hope, should help in distinguishing among various forms of knowledge sharing.

KEY TERMS

Codified Knowledge: Knowledge that has converged upon common concepts and usages such that it can be transferred more easily.

Knowledge Diffusion: A situation where knowledge flows freely, within a specific space, and can be economically exploited by the recipient agent.

Knowledge Gain: A process of knowledge flow which involves deliberate barter among subjects.

Knowledge Integration: A process which combines dispersed bits of knowledge held by individuals to be applied in a coordinated way.

Tacit Knowledge: Knowledge that is embedded in the mind of the person who has acquired it.

Taxonomy of Knowledge Flows: A conceptual model which attempts to distinguish among various forms of knowledge sharing.

Knowledge Combination vs. Meta-Learning

Ivan Bruha
McMaster University, Canada

INTRODUCTION

Research in intelligent information systems investigates the possibilities of enhancing their over-all performance, particularly their prediction accuracy and time complexity. One such discipline, data mining (DM), processes usually very large databases in a profound and robust way (Fayyad et al., 1996). DM points to the overall process of determining a useful knowledge from databases, that is, extracting high-level knowledge from low-level data in the context of large databases. This article discusses two newer directions in this field, namely knowledge combination and meta-learning (Vilalta & Drissi, 2002).

There exist approaches to combine various paradigms into one robust (hybrid, multistrategy) system which utilizes the advantages of each subsystem and tries to eliminate their drawbacks. There is a general belief that integrating results obtained from multiple lower-level decision-making systems, each usually (but not required) based on a different paradigm, produce better performance. Such multi-level knowledge-based systems are usually referred to as *knowledge integration* systems. One subset of these systems is called *knowledge combination* (Fan et al., 1996). We focus on a common topology of the knowledge combination strategy with base learners and base classifiers (Bruha, 2004).

Meta-learning investigates how learning systems may improve their performance through experience in order to become flexible. Its goal is to search dynamically for the best learning strategy. We define the fundamental characteristics of the meta-learning such as bias, and hypothesis space.

Section 2 surveys the various directions in algorithms and topologies utilized in knowledge combination and meta-learning. Section 3 represents the main focus of this article: description of knowledge combination techniques, meta-learning, and a particular application including the corresponding flow charts. The last section presents the future trends in these topics.

BACKGROUND

So far, commonly utilized decision-making systems have been exploiting a single technique, strategy, or topology. Consequently, their accuracy and overall performance have not been so high (Pratt & Thrun, 1997). New data mining (DM) systems utilize results obtained from several lower-level systems, each usually (but not required) based on different paradigm, or combine or refine them within a dynamic process. Thus, such a multi-strategy (hybrid) system consists of two or more individual 'agents' that interchange information and cooperate together.

It should be noted that there are in fact two fundamental approaches for combining the information from multi-data tasks:

1. In *data combination*, the data sets are merged into a single set before the actual knowledge acquisition.
2. In *knowledge* (*theory*) *combination*, or *sensor fusion*, several agents (base classifiers, sensors) process each input data set separately, and the induced models (knowledge bases) are then combined at the higher-level.

When we look at the issue of the multi-strategy systems from the other side, we come to the *meta-learning*. Generally speaking, meta-learning investigates the way the learning systems can increase their performance and efficiency over experience.

The base learners, the ones with a simple inductive paradigm, such as algorithms inducing decision trees or decision sets of rules, or neural nets, generate a hypothesis (concept description) by applying a fixed bias that is implanted in the knowledge base of the learner. The performance usually increases by larger training sets and losing the restrictions on the hypotheses (concept descriptions).

Using other words, a meta-learner searches dynamically for the best learning strategy and consequently, its performance is flexible. There are a few strategies of the meta-learning, however, various researches recognize it in various ways so that one cannot specify exactly which strategy belongs to meta-learning and which not (Vilalta & Drissi, 2002). Also, there is no sharp boundary between knowledge combination and meta-learning; some researches on machine learning (ML) and DM claim that the first is the subset of the latter, some not. Therefore, this article introduces the most common sights to this issue.

Another taxonomy of these systems distinguishes the way of arrangement of datasets and learning paradigms. We thus differentiate:

1. **Different subsets of training data with a single learning paradigm:** Different subsets are either generated when they are collected, or a single (usually larger) database is split to several subsets, following a certain criterion. Each base learner (with the same learning technique) processes different training subset. Typical examples of such a technique is bagging (Breiman, 1996) and boosting (Freund & Schapire, 1997).
2. **Different training parameters with a single learning paradigm:** Each learning algorithm is accompanied by various parameters that have to be setup. We can thus generate several base learners by changing these parameters, and use then the entire dataset for all the base learners, see for example Bruha (2004).
3. **Different learning paradigms:** The entire multi-strategy system consists of several base learners, each with different learning paradigm (learning system inducing decision trees, that inducing set of decision sets, artificial neural net, genetic algorithm, etc.). These base learners then can process the same database (Kotsiantis & Pintelas, 2004; LiMin et al., 2004).

It should be also noted that there is no uniform terminology in the knowledge-intensive systems (including DM, machine learning, and meta-learning); therefore, we use here usually not a single but several most common terms that can be found in literature.

KNOWLEDGE COMBINATION AND META-LEARNING

Knowledge Combination

A large research in ML focuses on improving topology of classifiers by combining various paradigms into one multi-strategy (hybrid) system which utilizes the advantages of each subsystem and tries to eliminate their drawbacks. There is a general belief that integrating results obtained from multiple lower-lever classifiers produce better performance. We can consider the boosting and bagging algorithms (Bauer & Kohavi, 1999) as already traditional topologies of this approach.

Generally speaking, the main advantages of such hybrid systems are: better performance than that of individual lower-level agents included, the ability to process multivariate data from different information sources, and better understanding of internal data processing when a complex task is solved.

Multi-level knowledge based techniques (called *knowledge integration* systems) can be divided into the following three 'subtechniques:'

1. **Knowledge combination/selection:** The input to such a system is usually formed by several knowledge bases (models) that are generated by various DM algorithms (learners). Each model (knowledge base) independently produces its decision about prediction. These results are then combined into a final decision (knowledge *combination*) or the best decision is selected according to a given statistical criterion (knowledge *selection*).
2. **Knowledge merging:** Several models (knowledge bases) are merged into one robust, usually redundant, model by utilizing statistics that accompany these models.
3. **Knowledge modification (also called revision, refining):** The input is an existing 'old' knowledge base and a 'new' database. A DM algorithm revises (modifies, refines) the current knowledge base according to the knowledge which is 'hidden' in the 'new' database. The new knowledge base thus gets over the 'old' knowledge by being updated by knowledge extracted from the 'new' database.

The first project in this field is evidently (Brazdil & Torgo, 1990); their system merges several decision trees generated by ID3 into a robust one. The already mentioned bagging and boosting algorithms can be viewed as representatives of multi-models. Another direction is formed by the system XCS that is a mixture of genetic algorithms and neural nets (Wilson, 1999). There are several extensions of this system, for example, NXCS (Armano et al., 2002). Another hybrid multisystem combines genetic algorithms with decision trees (Carvalho & Freitas, 2000). All these research projects have revealed that knowledge combination improves the performance of the base classifiers. Knowledge modification is quite often utilized in Inductive logic programming (ILP); they usually use the term 'theory refinement' (Haddawy et al., 2003).

(Fan et al., 1996) introduce the methodology of stacked generalizers and meta-combiners. It can be viewed as learning from information generated by a set of base learners, or using other words, as learning of meta-knowledge on the learned information. The base learners (each usually utilizing a different inductive strategy) induce base classifiers; the base classifiers applied to a training set of examples form so-called meta-database; it is then used by the meta-learner to derive a meta-classifier. The two-level structure of classifiers is then used for making decisions about the input objects.

There are many interesting issues in this field, for example, combining statistical/fuzzy data (probability distribution of classes, quality of decision/performance, reliability of each base classifier), cascade classifiers (Gama & Brazdil, 2000).

Application: Meta-Combiner

Here we present one particular topology and fundamental configuration of a knowledge combination system, a *meta-combiner*. It consists of a few different *base learners*, each utilizing a different inductive strategy. Each base learner generates a *base classifier* by processing a subset of training data. Afterwards, the base classifiers classify another subset of training objects, and their decisions (outputs) form a *meta-database*, a set of training meta-objects (examples). Afterwards, it is then processed by a *meta-learner* that then generates a *meta-classifier*.

It should be noted that the meta-classifier does not exploit the traditional 'select best' strategy (i.e., by selecting the best base classifier), nor by 'by vote' strategy (i.e., by selecting the class the majority of base classifiers predict). It rather combines the decisions (predictions, classes) of all the base classifiers.

Consequently, in the classification phase, the base classifiers first derive their predictions (classes, decisions); then a meta-object is derived from these predictions, which is then classified by the meta-classifier. The entire scheme of the meta-learner and the meta-classifier is called *meta-combiner*.

A training set is split for the meta-learning purposes into two subsets: the *genuine-training* and *examining* ones. The genuine-training subset is applied for inducing the base classifiers; the examining one for generating a meta-database.

We now specify the format of a meta-database. Let BCl_q be the q-th base classifier, q=1...,Q (where Q is the number of the base classifiers). Each examining example **x** of the examining subset generates corresponding meta-object **z** for the meta-database as follows. Let z_q be the decision (class) of the q-th base classifier for the examining object **x** (we call z_q a *meta*-attribute to distinguish them from *input* attributes A_n). Then the corresponding meta-object of the meta-database looks as follows:

$$\mathbf{z} = [z_1, \ldots , z_Q , Z]$$

where z_q , q=1...,Q is the decision the of q-th base classifier BCl_q , Z is the desired class of the examining object **x** .

Let T be a training set of K training examples, S be an integer in the range <2; K> . Let us have Q different base learners BL_q , q=1,...,Q, and a meta-learner ML. The flow chart of the meta-learning phase looks as follows:

procedure META-LEARNING-PHASE(T, S)

1. Partition the training set T randomly into S disjoint subsets of equal size (as equal as possible). Let T_s be the s-th such subset, s=1,...,S, card(T_s) the number of its objects (examples)
2. Form S pairs [T_s , $T \setminus T_s$] , s=1...,S ; for each s, $T \setminus T_s$ is the genuine-training subset and T_s the examining one, generated from the training set T .
3. Let *MetaDatabase* be empty
4. **For** s=1,...,S **do**
   - 4.1 Train all base learners BL_q using the genuine-training subset $T \setminus T_s$; the result is Q base classifiers BCl_q , q=1,...,Q
   - 4.2 Classify the examining objects from T_s by these base classifiers
   - 4.3 Generate card(T_s) meta-objects using the above class-combiner rule and add them to *MetaDatabase*

   enddo
5. Train the meta-learner ML using *MetaDatabase*; the result is a meta-classifier *MCl**
6. Generate the base classifiers BCl_q* , q=1,...,Q again but use the entire training set T (these classifiers are marked by star and will be used in the meta-classification)

Step 4.1 is depicted by Figure 1. The entire meta-learning phase (i.e., steps 4.2, 4.3, and 5) is portrayed on Figure 2.

Similar scenario is applied for the classifying an unseen object **x** :

procedure META-CLASSIFYING-PHASE(**x**)

1. Classify the unseen object **x** by all Q base classifiers BCl_q* ; let the output of the q-th base classifier BCl_q* be z_q , q=1,...,Q
2. Generate the corresponding meta-object **z** = [z_1, ..., z_Q]
3. Classify the meta-object by the meta-classifier *MCl**; its result (decision) is the class to which the given input object **x** is classified

We can now observe that the base classifiers BCl_q* and the meta-classifier *MCl** form the overall product that can be immediately used by an end-user for classifying unseen objects, see Figure 3.

The number S of split subsets is crucial for this system. Therefore, we use the term *S-fold meta-combiner*. (Fan et al., 1996) introduces two architectures: combiner and stacked generalizer. Their combiner corresponds to the two-fold and stacked generalized to the K-fold meta-combiner. The 'foldness' S of the meta-combiner is a decisive parameter of the entire system. We empirically observed that the value S=4 gives good results (Bruha, 2004).

Bruha (2004) also deals with inconsistency of the meta-databases; it can happen quite often there exists more identical meta-objects having different desired classes. The project uses

Figure 1. Base learners using the genuine-training subset $T \setminus T_s$ induce Q base classifiers

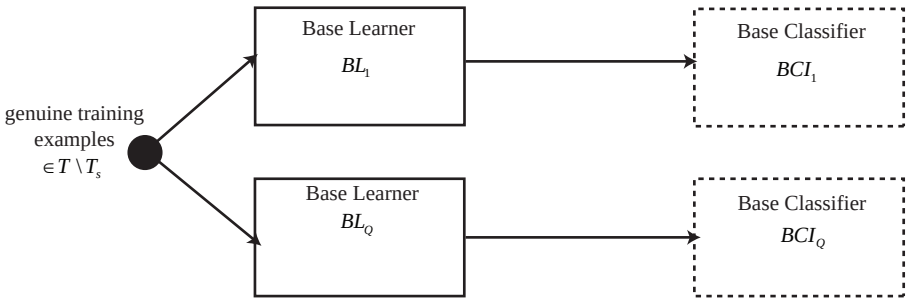

Figure 2. The entire meta-learning phase

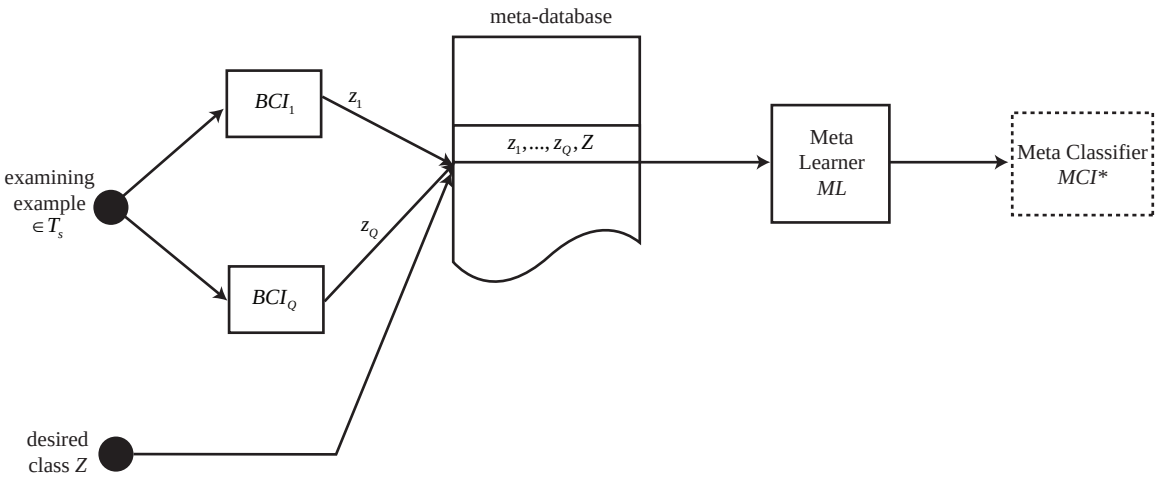

Figure 3. Meta-classifying phase

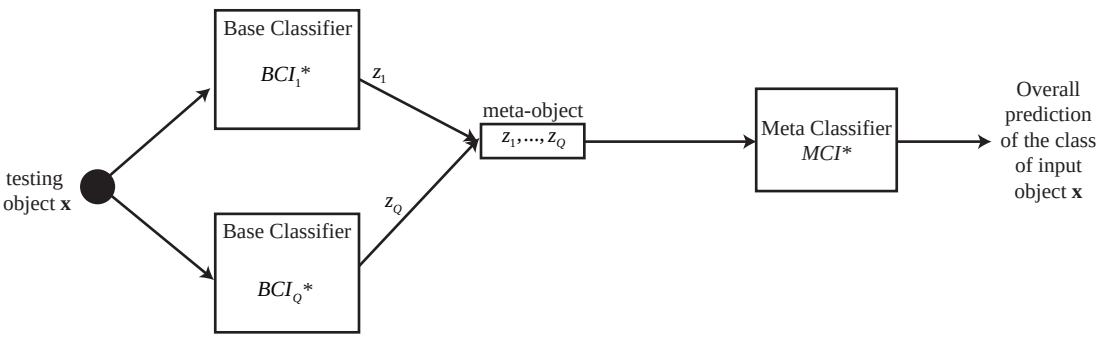

'purification' procedure that adds as many informative input attributes until the meta-database becomes consistent.

Meta-Learning

First, we introduce some definitions. A learning algorithm (learner) is learned by a training set of pre-classified examples [**x**, *Z*] where **x** is a training object (example) and *Z* its desired class (specified by a Designer of the entire learning task). The mapping DAC(**x**) = *Z* is an unknown designer-assigned classification. Since a training set is always finite and need not be consistent, the learning algorithm (learner) will not be able to induce a genuine form of the mapping DAC, but only its approximation. It conducts a search through a *hypothesis space* until it finds a hypothesis that approximates (according to a given criterion) the unknown DAC . A learning algorithm exhibits a set of assumptions (*bias*) that restrict the inductive process. First, it restricts the size of the hypothesis space, and second, it orders (ranks) the hypotheses in the hypothesis space.

A traditional (base) learner exhibits a fixed hypothesis space. Thus, it can learn efficiently only a limited number of learning tasks. Therefore, the previous meta-combiner is not recognized by many ML researches as a meta-learning system because it exhibits a fixed form of bias.

Vilalta and Drissi (2002) claim that the goal of the meta-learning is to choose the right learning algorithm for a particular learning task. A meta-learning system should indicate how to match learning algorithms with the properties of a learning task, that is, it should dynamically select a learning algorithm. Furthermore, a meta-learning system should be able to solve the problems of the learning tasks placed outside the scope of available learning algorithms.

One profound feature of meta-learning is to specify the ways of how to associate a learning algorithm with those learning tasks in which the learner works in an optimal fashion. Usually, a designer defines a set of learning tasks' characteristics (*meta-features*) that are essential to the learner's behavior. By utilizing these meta-features we can induce the conditions under which a learning algorithm works better than the others. For instance, the meta-features are the distribution of training examples among concepts (classes), number of examples, number of attributes, number of classes, and other statistics above a training set.

We can observe even further steps of exploiting these techniques: instead of selecting a learning algorithm for a particular domain of learning tasks, we can select a learning algorithm for each testing object; we assume that a learning algorithm exhibits a reasonably prestigious behavior around the neighborhood of the given testing object. Brazdil and Soares (2000) discuss the system in which learning algorithms utilizing the k-nearest neighbor strategy are ordered by the accuracy and the time complexity.

Meta-learning systems can also utilize the dynamic selection of bias for shifting a learner's applicability along a set of the learning tasks. The goal is to modify the hypothesis space to have better coverage of the given learning task. One possibility is to modify the size of the hypothesis space. Another possibility is to change the hypothesis space by adding or deleting the input attributes that represent the objects (examples). Adding new attributes increases the size of the hypothesis space and, thus, weakens the bias; and vice versa. Bruha (2000) utilizes the quality of decision rules for the actual classification; it updates the rule qualities within the testing.

Humans learn for the entire life by experience. This idea could be utilized also in machine learning. If a learning system wants to improve its performance, it should gather the knowledge about learning (*meta-knowledge*). Thrun (1998) and others discuss the idea of *learning-to-learn*. This strategy studies how to improve learner's behavior by detecting the characteristics among various learning tasks. Baum (1998) presents the idea of learning agents; learning agents collaborate and generate new learning agents.

Many other enhancements and applications of meta-learning can be found in Brazdil, Soares and Da Costa, (2003) and Todorovski and Dzeroski (2003).

FUTURE TRENDS

There are several ways of further research in these new disciplines of ML and DM. Let us survey the most promising trends:

- Knowledge combination can be extended to *higher-level* combining methods. For instance, (Fan et al., 2002) investigate classifier ensembles and multilevel tree structured combining methods. Bruha (2006) explores three-level combiners; the first two are formed by the meta-combiner discussed above, and the third level utilizes the decision of this meta-combiner and other classification systems, such as averaging, regression, best decision scenario, voting scenario, dynamic selective voting, naive Bayesian combination.
- *Meta features* that specify the way how a learner could be associated with a learning task is another direction in future work. They could be selected by a decision-making system that would choose the most optimal ones. Thus, we come to a strategy with two different levels of decision-making algorithms.
- *Learning-to-learn* is another direction of future work. Still, there is no general strategy how to improve learner's behavior by detecting the characteristics among various learning tasks. It will require to study

the characteristics of meta-knowledge, that is, collecting knowledge about learning.

- The idea of *learning agents* is also a promising trend. They can independently learn how a given learning algorithm processes a certain task and make up a decision for future which algorithms would be utilized for a new task.
- Vilalta and Drissi (2002) present a promising trend for meta-learning. It proposes the idea of *self-adaptive learning* algorithms. They are supposed to change their internal topology (bias) according to characteristics of a given learning task. Such a learner would accomplish it by continuous accumulation of meta-knowledge that would consist of suitable forms of bias for each learning tasks. At the beginning, possessing no meta-knowledge, a self-adaptive learner would use fixed bias, and as more learning tasks were analyzed and processed, the learner would accumulate and utilize the meta-knowledge. Consequently, it looks like a life-long learning process.
- Embedding *genetic algorithms* and similar optimization tools for generating more robust decision-making and knowledge-combining systems is another direction in this field. Particularly, genetic algorithms seem to be a very powerful and robust technique for inducing reliable and consistent knowledge bases (models). They can serve at both basic level and meta level as we discussed.
- So far, there was only a limited invention of the quality of base learners (or more general, low-level decision-making systems) that generate their decisions to a higher-level system. *Redundancy* of the base learners seems to be one of the solutions, as it complies with the human life. (We also have our knowledge stored in several 'pockets').
- Gama and Brazdil (2000) introduce their cascade algorithm. To our opinion, it is another direction of knowledge combination techniques. It combines statistical and logical techniques together in order to reach a better performance of the entire system.

CONCLUSION

This article discusses two relatively new directions in ML and DM research: knowledge combination and meta-learning. We have also presented one particular learner (meta-combiner) in details as an application in order to exhibit the complexity and topology of such learners.

We have also mentioned that different researchers in ML have different view about knowledge combination and meta-learning. There exists a common opinion that meta-learning algorithms exhibit flexible bias and dynamic search in hypothesis space, however, there is no sharp boundary between the above ML directions (Vilalta & Drissi, 2002). The article surveys several known topologies of meta-learners, too. A large source of papers on meta-learning and knowledge combination can be found on the internet.

KEY TERMS

Classifier: A decision-supporting system that given an unseen (to-be-classified) input object yields a prediction, for instance, it classifies the given object to a certain class.

Knowledge Combination: Its input is usually formed by several knowledge bases (models) that are generated by various Data Mining algorithms (learners). Each model (knowledge base) independently produces its decision about prediction; these results are then combined into a final decision—or the best decision is selected according to a given criterion.

Learner: Given a training set of (representative) examples (accompanied usually by their desired classes/concepts), a Learner induces concept description (model, knowledge base) for a given task.

Meta-Combiner: Its common topology involves base learners and classifiers at the first level, and meta-learner and meta-classifier at the second level. The meta-classifier combines the decisions of all the base classifiers.

Meta-Knowledge: Generally speaking, it is a knowledge about knowledge bases. In case of the meta-learning, it is a knowledge about the learning process(es) that is accumulated by a meta-learning algorithm within analyzing and processing various learning tasks.

Meta-Learning: It investigates how learning systems may improve their performance through experience in order to become flexible. Its goal is to search dynamically for the best learning strategy.

Model (knowledge base): Formally described concept of a certain problem; usually represented by a set of production rules, decision trees, semantic nets, frames.

Knowledge Discovery from Genomics Microarrays

Lei Yu
Binghamton University, USA

INTRODUCTION

The advent of genomic microarray technology enables simultaneously measuring the expressions of thousands of genes in massive experiments, and hence provides scientists, for the first time, the opportunity of observing complex relationships between various genes in a genome. In order to extract biologically meaningful insights from a plethora of data generated from microarray experiments, knowledge discovery techniques, which discover patterns, statistical or predictive models, and relationships among massive data, have been widely applied in microarray data analysis. For example, clustering can be applied to identify groups of genes that are regulated in a similar manner under a number of experimental conditions or groups of samples that show similar expression patterns across a number of genes (Jiang, Tang, & Zhang, 2004). Classification can be performed to characterize the cellular difference between different samples, such as between normal and cancer cells or between cancer cells with different responses to treatment, and can potentially be used to predict the classes of samples based on their gene expression patterns (Statnikov, Aliferis, Tsamardinos, Hardin, & Levy, 2005). Feature selection or gene selection can help identify among thousands of genes a small fraction of genes that are relevant for discriminating between different sample types, and may potentially lead to the identification of a few biologically relevant "marker" genes for subsequent biological validation (Saeys, Inza, & Larranaga, 2007).

This article provides a brief introduction to the field of knowledge discovery and its applications in discovering useful knowledge from genomic microarray data. It describes common knowledge discovery tasks for genomic microarray data, presents representative methods for each task, and identifies emerging challenges and trends in knowledge discovery from genomic microarray data.

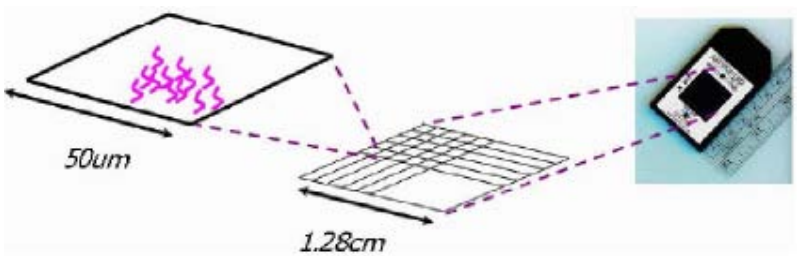
BACKGROUND

Knowledge discovery from data refers to the overall process of converting raw data into useful information, which consists of data preprocessing, data mining, and postprocessing of data mining results (Tan, Steinbach, & Kumar, 2005). The purpose of data preprocessing is to transform the raw input data into an appropriate format for subsequent data mining process. The tasks involved in data preprocessing include cleaning data to remove noise, duplicate, inconsistent, or missing information, integrating data from multiple sources, transforming data values into the right scale and format, and selecting instances and features that are relevant to the data mining task at hand. Data mining is the automatic process of extracting interesting patterns or knowledge from data. Data mining tasks can be generally divided into two major categories: predictive tasks and descriptive tasks. The objective of predictive tasks is to predict the values of a particular feature, based on the values of other features. The objective of descriptive tasks is to derive patterns that summarize the underlying relationships in data. These tasks are often exploratory in nature and frequently require postprocessing techniques which validate and explain the results. For example, visualizing the patterns allows analysts to explore the result from multiple viewpoints. Statistical tests can be used to validate the significance of the results and eliminate patterns that are generated by chance. For a comprehensive discussion on various knowledge discovery tasks, please refer to widely adopted text books on data mining (Han & Kamber, 2005; Tan et al., 2005). This article focuses on knowledge discovery tasks that are commonly performed on genomic microarray data introduced next.

Gene expression microarrays are silicon chips that simultaneously measure the mRNA expression levels of thousands of genes. Different types of microarrays use different technologies for constructing these chips and measuring gene expression levels. Detailed description of these technologies is beyond the scope of this article. Interested readers can refer to Draghici's book (Draghici, 2003) for an introduction. Here we briefly describe microarray technologies using Affymetrix arrays (shown in Figure 1) as an example, which are currently one of the most popular commercial arrays. However, the methodology for constructing other types of arrays would be similar, but would use different technology-specific data preparation and cleaning steps (Piatetsky-Shapiro & Tamayo, 2003).

Each Affymetrix array (GeneChip) contains probes for different genes tiled in a grid-like fashion. The simultaneous measure of expression levels of thousands of genes is done by hybridizing a complex mixture of mRNAs (derived from tissue or cells) to the probes. Hybridization events

Figure 1. An example of microarray: Affymetrix GeneChip (right), its grid (center), and a cell in the grip (left). Image courtesy of Affymetrix



are detected using a fluorescent dye and a scanner that can detect fluorescence intensities. The scanner and associated software perform various forms of image analysis to measure and report raw gene expression values. This allows for a quantitative readout of gene expression on a gene-by-gene basis (Piatetsky-Shapiro & Tamayo, 2003). To date, one microarray chip is capable of measuring expression levels for over 40,000 genes in the entire human genome.

The expression level of a specific gene among thousands of genes measured in an experiment is eventually recorded as a numerical value. Expression levels of the same set of genes under study are normally accumulated through multiple experiments on different samples (or the same sample under different conditions) and recorded in a data matrix. In data mining, data is often stored in the form of a matrix, of which each column is described by a feature or attribute and, each row consists of feature-values and forms an instance, also named as a record or data point, in a multidimensional space defined by the features. Figure 2 illustrates two ways of representing microarray data in a matrix form. In Figure 2 (a), each feature is a sample (*S)* and each instance is a gene (*G*). For each gene, its expression levels are measured across all the samples (or conditions), so f_{ij} is the measurement of the expression level of the i^{th} gene for the j^{th} sample where $i = 1,..., n$ and $j = 1,..., m$. In Figure 2 (b), the data matrix is the transpose of the one in Figure 2 (a), in which features are genes and instances are samples. Sometimes, data in Figure 2 (b) may have class labels c_i for each instance, represented in the last column. The class labels can be different cellular conditions of the underlying samples. A typical microarray data set may contain thousands of genes but only a small number of samples (often less than a hundred). The number of samples is likely to remain small at least for the near future due to the expense of collecting microarray samples.

Different data mining tasks can be performed on the two different forms of data shown in Figure 2. When genes are treated as instances (as in Figure 2 (a)), *gene clustering* can be performed to find similarly expressed genes across many samples. When samples are treated as instances (as in Figure 2 (b)), three different tasks can be performed: *sample clustering* which aims to group similar samples together and discover classes or subclasses of samples, *sample classification* which aims to classify diseases or phenotypes of novel samples based on patterns learned from training

$$\begin{array}{cccccc} & S_1 & S_2 & \cdots & S_m \\ G_1 & f_{11} & f_{12} & \cdots & f_{1m} \\ G_2 & f_{21} & f_{22} & \cdots & f_{2m} \\ \vdots & & & & \vdots \\ G_n & f_{n1} & f_{n2} & \cdots & f_{nm} \end{array} \qquad \begin{array}{ccccccc} & G_1 & G_2 & \cdots & G_n & \\ S_1 & f_{11} & f_{21} & \cdots & f_{n1} & c_1 \\ S_2 & f_{12} & f_{22} & \cdots & f_{n2} & c_2 \\ \vdots & & & & \vdots & \vdots \\ S_m & f_{1m} & f_{2m} & \cdots & f_{nm} & c_m \end{array}$$

samples with known class labels, and *gene selection* which aims to select a small number of discriminative genes from thousands of genes.

KNOWLEDGE DISCOVERY FROM MICROARRAY DATA: TASKS AND METHODS

In this part, we present common knowledge discovery tasks from microarray data and representative methods for each task. These tasks include two descriptive data mining tasks: gene clustering and sample clustering, one predictive task, sample classification, and one preprocess task, feature selection.

Clustering

Clustering is a process of grouping similar samples, objects, or instances into clusters under some similarity measure (Tan et al., 2005). Clustering has proven to be helpful to understand gene function, gene regulation, cellular processes, and subtypes of cells. On one hand, identifying groups of genes with similar expression patterns across different samples (also called co-expressed genes) may help understand the functions of many genes for which information has not been previously available and give rise to hypotheses regarding the mechanism of the transcriptional regulatory network (Jiang et al., 2004). On the other hand, identifying groups of samples with similar expression patterns across a number of genes may reveal subcell types which are hard to identify by traditional morphology-based approaches (Jiang et al., 2004). We present three groups of frequently used clustering methods which can be applied for both gene clustering and sample clustering on microarray data.

Hierarchical clustering Each instance forms a cluster in the beginning, and the two most similar clusters are merged until all instances are in one single cluster. The clustering result is in the form of a tree structure, called dendrogram, which can be broken at different levels using domain knowledge. Tree structures are easy to understand and can reveal close relationships among resulting clusters, but they do not provide a unique partition among all the instances because different ways to determine a basic level in the dendrogram can result in different clustering results.

Partition-based clustering Unlike hierarchical clustering methods, partition-based methods divide the whole data into a fixed number of clusters. Examples are *K*-means, self-organizing maps, and graph-based partitioning (Jiang et al., 2004). The methods of *K*-means often require specification of the number of clusters *K* and the selection of *K* instances as the initial clusters. All instances are then partitioned into the *K* clusters, optimizing some objective function (e.g., inner-cluster similarity) by assigning each instance to the most similar cluster determined by the distance between the instance and the mean of each cluster in the current iteration. Self-organizing maps (SOMs) are variations of *K*-means methods and require specification of the initial topology of *K* nodes to construct the map. In graph-based partitioning methods, a Minimum Spanning Tree (MST) is often constructed and the clusters are generated by deleting the MST edges with the largest lengths. Graph-based partitioning methods do not heavily depend on the regularity of the geometric shape of cluster boundaries as *K*-means and SOMs do.

Fuzzy clustering Traditional clustering methods introduced before require that each instance belong to a single cluster, even though some instances may only be slightly relevant for the biological significance of their assigned clusters. Fuzzy *C*-means (Dembele & Kastner, 2003) applies a fuzzy partitioning method that assigns cluster membership values to instances. It links each instance to all clusters via a real-valued vector of indexes. The value of each index lies between 0 and 1, where a value close to 1 indicates a strong association to the corresponding cluster while a value close to 0 indicates no association. The vector of indexes thus defines the membership of an instance with respect to the various clusters.

Classification

Apart from clustering methods which do not require *a priori* knowledge about the classes of available instances, a classification method requires training instances with labeled classes, leans patterns that discriminate between various classes, and, ideally, correctly predict the classes of unseen instances. Many classification methods can be applied to predict diseases or phenotypes of novel samples from microarray data. We present four commonly used methods (Statnikov et al., 2005; Tan et al., 2005).

Linear discriminative analysis (LDA) For an m x n gene expression matrix $\boldsymbol{X}$ (m is the number of samples and n is the number of genes), it seeks linear combinations xa of sample vectors $x_i = (x_{i1},\ldots,x_{in})$ with large ratios of between-class to within-class sum of squares. In other words, it tries to maximize the ratio a^TBa/a^TWa, where B and W denote respectively the n x n matrices of between-class and within-class sum of squares.

Nearest neighbor (NN) usually does not learn during the training phase. Only when it is required to classify a new sample does NN search the data to find the nearest neighbor for the new sample and use the class label of the nearest neighbor to predict the class label of the new sample. *K*-NN makes the prediction for a new sample based on the most common class label among the *K* training samples most similar to the new sample.

Decision trees classify samples by building a tree-like structure. Specifically, they recursively split samples into two child branches based on the values of a selected feature, starting with all the samples. Each leaf node of the tree is pure in terms of classes, and the resulting partition corresponds to a classifier. By limiting the number of consecutive branches, they can produce more generalized classifiers.

Support vector machines (SVMs) try to separate a set of training samples of two different classes with a hyperplane in an *n*-dimensional space defined by *n* features (genes). If no separating hyperplane exists in the original space, a kernel function is used to map the samples into a higher-dimensional space where a separating hyperplane exists. Complex kernel functions that provide nonlinear mappings result in nonlinear classifiers. SVMs avoid overfitting by selecting a hyperplane that is maximally distant from the training samples of two different classes, called maximum margin separating hyperplane, from among many hyperplanes that can separate the two classes.

Gene Selection

Traditional classification and clustering methods are often designed for data where the number of instances is greatly larger than the number of features. In microarray data, however, the number of features (genes) is very huge and the number of instances (samples) is relatively small for sample classification and sample clustering tasks. The characteristic of high dimensionality (thousands of features) in microrray data presents a great challenge to the efficiency of many classification and clustering methods. Moreover, the shortage of instances in the context of high dimensionality often causes many classification methods to generate models that overly fit the known training data or causes many clustering methods to produce clusters purely by chance. Therefore, selecting a small number of genes from thousands of genes is essential for successful sample classification and clustering. Feature selection, the process of choosing an optimal subset of features from original ones according to a certain criterion, is a frequently used data preprocessing technique in knowledge discovery from data with high dimensionality. Liu and Yu (2005) provide a good introduction to the problem of feature selection and various feature selection methods for classification and clustering. Some of these methods have been applied on microarray data as an effective tool for gene selection task (Saeys et al., 2007).

Among various methods, ranking-based methods often evaluate genes in isolation without considering gene-to-gene correlation. They rank genes according to their individual relevance or discriminative power to the targeted class and select top-ranked genes. Some methods based on statistical tests or information gain have been employed (Li, Zhang, & Ogihara, 2004). However, simply combining a highly ranked gene with another highly ranked gene often does not form a good gene set because some highly correlated genes could be redundant to each other. Removing redundant genes among selected ones can achieve a better representation of the characteristics of the targeted class and lead to improved classification accuracy. Representative methods that handle gene redundancy can be found in Peng and Ding (2005) and Yu (2008).

FUTURE TRENDS

Traditional clustering methods introduced previously perform clustering along only one direction, either grouping genes using the set of samples as features or grouping samples using the set of genes as features. For a given data set to be clustered, along either direction, the feature space is globally determined and is shared by all resulting clusters. However, it is well known in molecular biology that only a small subset of the genes participates in any cellular process of interest and that any cellular process takes place only in a subset of the samples (Jiang et al., 2004). Recently, a number of bi-clustering or co-clustering methods have been proposed to capture coherent expression patterns exhibited in "blocks" within gene expression matrices, where a "block" is a submatrix defined by a subset of genes on a subset of samples. These methods aim to simultaneously cluster genes and samples under certain heuristic objective functions. Madeira and Oliveira (2004) provide a review of some recent work in this area.

Various classification methods coupled with feature selection methods have been applied to microarray sample classification and show promising accuracy in predicting the classes (diseases or phenotypes) of novel samples. However, existing classification and feature selection methods are not adequate for identifying leads for potentially useful biomarkers. The primary goal of biologists in conducting microarray experiments is sometimes not to build models for sample classification, but to detect a few biomarkers from many potential candidates for subsequent costly biological and clinical validation. The increasingly known gap between necessary genes for accurate classification models and biologically relevant genes for biomarker identification requires novel knowledge discovery tasks which can generate knowledge of both statistical significance and biological relevance and incorporate domain knowledge of experts (Berens, Liu, Parsons, Yu, & Zhao, 2005).

CONCLUSION

Gene expression microarrays are a revolutionary technology with great potential to provide accurate medical diagnostic, develop cures for diseases, and produce a detailed genome-wide molecular portrait of cellular states (Piatetsky-Shapiro

& Tamayo, 2003). Knowledge discovery methods are effective tools to turn massive raw data from microarray experiments into biologically important insights. In this article, we provide a brief introduction to knowledge discovery and genomic microarray data analysis and a concise review of various knowledge discovery methods for genomic microarray data.

KEY TERMS

Classification: A process of predicting the classes of unseen instances based on patterns learned from available instances with predefined classes.

Clustering: A process of grouping instances into clusters so that instances are similar to one another within a cluster but dissimilar to instances in other clusters.

Data Mining: the automatic process of extracting interesting patterns or knowledge from data.

Feature Selection: A process of choosing an optimal subset of features from original features according to a certain criterion.

Gene: A hereditary unit consisting of a sequence of DNA that contains all information necessary to produce a molecule that performs some biological function.

Gene Expression Microarrays: Silicon chips that simultaneously measure the expression levels of thousands of genes.

Genome: All of the genetic information or hereditary material possessed by an organism.

Knowledge Discovery: The overall process of converting raw data into useful information, consisting of data preprocessing, data mining, and postprocessing of data mining results.

Knowledge Flow Identification

INTRODUCTION

Knowledge management (KM) is an important factor in organizational competitive advantage (Ichijo & Nonaka, 2007). Unfortunately, traditional KM initiatives frequently fail when they are included in the work processes of organizations (Stewart, 2002). One of the factors responsible for this is that these initiatives are not well aligned to the real knowledge needs of the organization's knowledge workers. Thus, it is important to seek approaches to help to align KM initiatives to the real work processes of organizations (Maier & Remus, 2002), considering what is important for their knowledge workers (Dalkir, 2005; Wiig, 2004).

In this chapter, we describe the knowledge flow identification methodology (KoFI), a methodology, based on process engineering techniques, that has been developed to aid in the study of organizational processes from a knowledge flow perspective. The methodology proposes a set of steps and tasks that can be carried out to analyze knowledge flows in business processes; thus, helping to identify issues such as the knowledge workers' needs, the knowledge (and its sources) that is principally involved in the processes, the working tools that may (positively or negatively) affect the flow of knowledge in the process, or the problems that may be restricting the good flow of knowledge in the process. To exemplify the usefulness of the KoFI methodology, we provide a brief description of some of the results obtained from the application of the methodology, in real settings, in which it was helpful for various purposes, including: the design of a multiagent-based KM system, the development of a knowledge map for a process, the identification of the manner in which to integrate a tool currently used in an organization as a basis for a KM strategy, and for the development of an organizational knowledge portal.

BACKGROUND

The integration of KM into organizational processes has been considered one of the most important research approaches for the present and future of KM (Scholl, König, Meyer, & Heisig, 2004). It can be found in literature, some works addressing the integration of KM in organizational processes. Maier and Remus (2002), for instance, have studied different approaches for process-orientated KM strategies, and have developed a framework that is useful for characterizing them. Some other authors have proposed process-modeling approaches for studying the knowledge involved in organizational processes, most of which have been designed to aid in the development of KM systems (e.g., Bera, Nevo, & Wand, 2005; Kim, Hwang, & Suh, 2003; Nissen & Levitt, 2004; Papavassiliou & Mentzas, 2003; Smith & McKeen, 2004; Strohmaier & Tochtermann, 2005; Woitsch & Karagiannis, 2002). Most of the approaches we have found in literature are orientated towards developing specific KM systems, or they require special tools for using them. We have not found work focused on understanding the knowledge requirements of a process rather than on proposing specific solutions. Before proposing a specific approach for managing knowledge in an organization, it is important to analyze the organizations' work processes from a knowledge flow perspective (Nissen, 2002), since supporting knowledge flow should be the main focus of KM (Borghoff & Pareaschi, 1998).

The KoFI methodology, presented in this chapter, uses process-engineering techniques to analyze organizational processes from a knowledge flow perspective. The main differences, between our proposal and others, that we have found in literature, is that our approach focuses mainly upon understanding the flow of knowledge and the problems that affect it, and not upon developing specific types of KM

systems. However, more importantly, our approach takes a special interest in the current technologies that might be involved in the flow of knowledge within an organization, to consider them as a part, and perhaps as the basis, of the KM strategies. This is relevant since, as Davenport (2007) states, the most promising way to integrate KM into organizational processes is to embed KM into the systems that people use to do their jobs. Even in organizations that do not have explicit KM initiatives, employees frequently tend to apply certain KM activities implicitly, and the information systems that they use in their daily work may serve to partially support such activities. We argue that if we base KM strategies upon the work being done by the members of an organization, and use their current tools to do so, then we will be in a better shape to design KM systems that are really useful for organizations.

THE KOFI METHODOLOGY

The KoFI methodology was designed to aid in the analysis of software processes from a knowledge flow perspective (Rodríguez, Martinez-Garcia, Vizcaino, Favela, & Piattini, 2005; Rodríguez-Elias, Martinez-Garcia, Favela, Vizcaino, & Soto, 2007). It was defined to assist in three main areas: 1) to identify, structure, and classify the knowledge that exists in the process studied, 2) to identify the technological infrastructure that supports the process and affects the knowledge flow, and 3) to identify forms with which to improve the knowledge flow in the process.

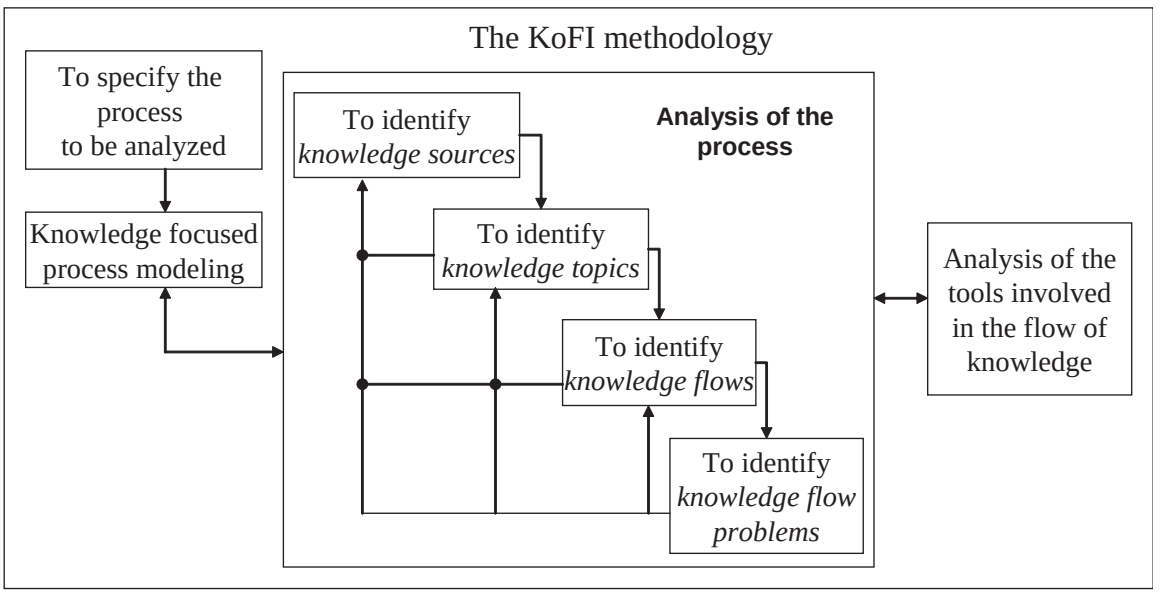
KoFI is orientated towards helping to analyze specific work processes. Therefore, it is necessary to define the specific process and model it. The process models are later analyzed following a four-stage process (see Figure 1) to finally identify and describe the tools that, positively or negatively, affect the flow of knowledge.

The process followed to apply the methodology is iterative, since each stage may provide information useful for the preceding stages. The process models are also capable of evolving while they are being analyzed in the different stages of KoFI. We shall now provide some directions about how each stage can be carried out.

The Knowledge-focused Process Modeling Phase

Traditional process modeling languages (PMLs) can be used to identify issues related to implicit knowledge flows, such as the information sources that are required, generated, or modified by an activity (Abdullah, Bennest, Evans, & Kimble, 2002). However, it is important that a PML used to analyze knowledge flow provides explicit representa-

Figure 1. General view of the KoFI methodology. KoFI has three main phases: knowledge-focused process modeling, analysis of the process (which include identification of knowledge sources, topics, and flows, and knowledge flow problems), and analysis of the tools affecting the knowledge flow.



tion of the knowledge consumed or generated in activities, the knowledge required by the roles participating in those activities, the sources of that knowledge, or knowledge dependencies. Unfortunately, there is a lack of PMLs that focus on the identification of knowledge involved in the processes (Bera et al., 2005). One way to address this situation is to adapt existing PMLs to integrate the representation of knowledge.

Modelling the process at different levels of abstraction is recommended. First, a general view of the process can be defined with a general and flexible process modeling technique. To perform a detailed analysis, a more formally constrained language should be used. It may also be helpful to use a PML that has been designed for the type of process that is being analyzed, since this language should provide primitives to represent specific elements involved in that type of processes, and the explicit representation of those elements will facilitate their analysis. In our case, we have used rich picture (Monk & Howard, 1998) to develop general models of the processes, and the software process engineering metamodel (SPEM) (Object Management Group, 2002) to develop the detailed models. The latter has been chosen due to the fact that our main domain area is software processes. Owing to space limitations, and since the focus of this chapter is not on the modeling languages, further details of this aspect are not presented; detailed examples can be found in Rodríguez-Elias et al. (2007). In this section, we shall limit ourselves to simply presenting the main activities that are carried out in each stage of KoFI.

The Process Analysis Phase

The analysis of the process is carried out in four stages, described in the following paragraphs.

Identifying Knowledge Sources

After modeling the process, the first step is to identify the main documents and people involved in that process. It is important that the sources identified be organized and classified. To this end, a taxonomy can be defined, which is one of the first steps in the development of KMSs (Rao, 2005). An ontology can be also developed to help define the relationships between the sources and the other elements of the process. This ontology can later be used to structure the knowledge base of the process.

Identifying Knowledge Topics

The topics of knowledge that can be obtained from the sources found in the previous stage are defined, together with the knowledge that the people involved in the process may have or require. In this stage, a taxonomy and an ontology can also help to classify the types of knowledge and define their relationships with other elements of the process. The ontology must define means to relate the knowledge sources with the knowledge areas or topics that can be found in them.

Identifying Knowledge Flows

In this stage, the process model is used to identify the way in which the knowledge and sources are involved in the activities performed in the process. The main activities in the processes must be identified, along with the decisions that the people performing those activities have to make. The process models are used to analyze the way the knowledge flows through the process while the people involved perform their activities; for example, the sources that could be being used as knowledge transfer mechanisms between activities or people. It is important to identify either flows of knowledge between activities or between sources, for example, the transfer of knowledge from a person to a document.

Identifying Knowledge Flow Problems

The knowledge flows, identified in the previous stage, are analyzed to discover the problems that may be affecting them. For example, whether the information generated from an activity is not captured, or whether there are sources that might be able to assist in the performance of certain activities, but that are not consulted by the people in charge of them. To do this, we propose using *problem scenarios*, which are stories describing a problem that is taking place in the process being analyzed (Rodríguez-Elias, Martínez-García, Vizcaíno, Favela, & Piattini, 2005). This story must show how the problems detected are affecting the knowledge flow. Then, one or more alternative scenarios must be defined to illustrate possible solutions and the manner in which those alternative solutions may improve the flow of knowledge. These possible solutions are then used as the basis for proposing the KM strategy or system.

The Tool Analysis Phase

The final phase of the methodology focuses on analyzing the manner in which the tools used to support the activities of the process affect the flow of knowledge. To this end, we have used the Rodriguez-Elias, Martínez-García, Vizcaino, Favela, and Piattini framework (2008). This framework proposes four main steps that can be used to analyze information systems as knowledge flow enablers. First, the application domain of the system is defined. This includes identifying the use, scope, and domain of the knowledge managed. The second step consists of identifying the structure of such knowledge. Later, the third step focuses on defining the KM activities being supported by the tool. Finally, the fourth step consists

of the definition of the main technical aspects considered important for the tools. For instance, the level of autonomy of the tool or the distribution of the knowledge managed.

After the application of the methodology, information should have been obtained that is useful, for example, in defining the knowledge base of the process, discovering the problems affecting the flow of knowledge and the mechanisms through which knowledge is flowing, and making proposals to improve the knowledge flow.

APPLYING KOFI

The KoFI methodology has been successfully applied in three case studies. The following paragraphs describe how it provided support in each case.

Designing a multiagent-based KM system. The first use of KoFI was in the analysis of a software maintenance process in which it was helpful in creating a knowledge map of the process that was later used to develop an agent-based KM system to automatically identify knowledge needs and search for knowledge sources that would be useful for solving specific change requests (Rodríguez et al., 2004).

Using a current system as a base for a KM strategy. The second case was focused on identifying the tools being used as knowledge flow enablers, also in a software maintenance process. From this study, the main tool identified was the one used to manage the maintenance requests sent by the clients of the organization studied (Rodríguez-Elias *et al.*, 2008). Some proposals were made for using this tool as basis for a KM strategy. The methodology helped us to identify the relationships between the different sources and the activities of the process, to define the manner in which to link the tool to the other sources of knowledge related to the maintenance requests.

Designing a knowledge portal. The third use of the methodology was to design a knowledge portal for an industrial company. In this case, the methodology was used by one of the members of the company to guide the identification of the main activities carried out in each of the departments of the company, the knowledge required in such activities, and the sources from which that knowledge could be obtained. With this information, a knowledge map was structured, which is now being used as the basis of a knowledge portal being developed by the company.

FUTURE TRENDS

One of the challenges of KM systems is to evaluate their possible benefits before investing heavily in their implementation. Unfortunately, the benefits of KM initiatives emerge in the long run, and are influenced by many factors that are difficult to control and measure. We state that one way to minimize the risk of investing in KM initiatives that are useless for the knowledge workers is to base such initiatives on the real work being done by the people who we expect to benefit from them, and to integrate the KM approaches within the tools in daily use. However, this does not ensure a successful KM approach. Therefore, it is still necessary to develop frameworks to help evaluate the possible usefulness and usability of KM approaches before investing in them. Because of the large set of different types of KM approaches, creating such a framework is a challenge. We consider that integrating such a framework into the KoFI methodology could make a great contribution to the usefulness of our approach. This is just one of the open issues that we should address in our future work.

CONCLUSIONS

Integrating knowledge into every day work is of ever-increasing interest to present-day KM experts. However, accomplishing this for specific organizations is not an easy task. In this chapter, we have presented a methodology that has been successfully used to improve knowledge flows in organizational processes. By taking the knowledge needs of employees into account, we expect to benefit process knowledge management. Moreover, we propose to include the tools used to support daily work as part of the KM strategies. In this chapter, we have summarized three case studies that show examples of how the methodology has been useful. However, it is necessary to perform more studies in different settings if we are to continue evaluating its benefits and limitations.

KEY TERMS

Knowledge Flow: The transfer of knowledge from the place it is created or stored to the place it needs to be applied.

Knowledge Flow Facilitators: All those mechanisms or entities that interfere in the transfer of knowledge within an organization's processes.

Knowledge Management: A discipline focused on providing technologies or techniques to help organizations to store, process, disseminate, and reuse their knowledge in order to take advantage of it.

Knowledge Source: A source from which knowledge, with practical applications can be obtained, such as know how, know what, know where, and so forth.

Knowledge Topic: A definition of a particular area of knowledge that is useful for the members of an organization.

KoFI: Knowledge flow identification methodology

Ontologies: Conceptual models for specifying meanings of, or knowledge about, a common domain.

Problem Scenarios: Textual descriptions of problems observed in a specific situation. They are presented in the form of a story that illustrates the problem and offers possible alternative solutions.

Process Modeling: An activity in which a process is represented through a formalism called the process modeling language, which facilitates its analysis and abstracts the important aspects for the process analyzer.

Knowledge Management as Organizational Strategy

Cheryl D. Edwards-Buckingham
Capella University, USA

INTRODUCTION

"More than ever before, the effectiveness of organizations depends on their ability to address issues such as knowledge management, change management, and capability building, all of which could fall into the domain of the HR function" (Lawler & Mohrman 2003, p. 7). In its leadership role, Human Resources (HR) has many tasks and responsibilities. According to Lawler and Mohrman (2003), there are several key organizational challenges faced by HR departments. These challenges include improving productivity, increasing quality, facilitating mergers and acquisitions, improving new product possibilities, and knowledge management. Knowledge management (KM) is defined as the tools, techniques, and processes for the most effective and efficient management of an organization's intellectual assets (Davies, Studer, Sure, & Warren, 2005). Knowledge management consists of the combination of data and information processing capacity (i.e., information technologies), as well as the creative and innovative capacity of human resources. Knowledge management entails an organization viewing its processes as knowledge processes, in which these processes involve application of knowledge within the organization. Knowledge management focuses on the generation and application of knowledge, leveraging and sharing knowledge to increase the derived value, importing knowledge in the form of skilled employees, connecting knowledge workers, and motivating knowledge workers (Mohrman & Finegold, 2000). According to Robbins (2003) the process of knowledge management entails organizing and distributing an organization's collective wisdom so that the right information gets to the right people at the right time. As knowledge management becomes increasingly important, organizations must strive to understand the dynamics of knowledge management. This article will discuss the elements of knowledge management, in addition to presenting a case on how organizations can use knowledge management as strategy, where knowledge management is valued more than funding as a strategic resource.

BACKGROUND

According to Metaxiotis, Ergazakis, and Psarras (2005), knowledge management has its origins in several business improvement areas including Total Quality Management, Business Process Reengineering, Information Systems, and Human Resource Management. Historically knowledge management can be distinguished within three timeframe generations (Metaxiotis et al., 2005). The first generation encompasses the period between 1990-1995. Within this generation knowledge management initiatives focused on defining knowledge management, exploring its benefits, and designing KM-specific projects (Metaxiotis et al., 2005). In addition, artificial intelligence (AI) has been essential in the evolution of knowledge management, where AI is represented and defined as computer intelligence. AI has influenced knowledge management research pertaining to knowledge representation and knowledge storage. Knowledge storage (also referred to as knowledge repository) is based on the storage of knowledge and information for later use, both intellectually and physically (i.e., documents). The main goal of storage is . The second generation of knowledge management emerged around 1996, in which organizations began to establish jobs for KM specialists and knowledge workers. Within this generation, knowledge management research focused on knowledge definitional issues, business philosophies, systems, frameworks, operations and practices, and advanced technologies. The second generation of knowledge management emphasized knowledge management as a systematic organizational change, where management practices, measurement systems, tools, and content management needed co-development (Metaxiotis et al., 2005). The third generation of knowledge management encompasses present-day philosophies. According to Wiig (as cited by Metaxiotis et al., 2005), the difference in the third generation is the degree to which the third generation is integrated with the enterprise's philosophy, strategy, goals, practices, systems, procedures, and how it becomes part of each employee's work-life. The third generation of knowledge management plays on the link between knowing and action, where all knowledge is considered inherently social and cultural, and organizational knowledge can only be realized through change in organizational activity and practice (Metaxiotis et al., 2005).

The underpinnings of knowledge management encompass knowledge workers. Knowledge workers are considered experts in some abstract knowledge base, in which they identify with their profession and not a particular organization (Griffin & Ebert, 2002). This knowledge base can

consist of both educational and work experiences that add to the knowledge workers repository. Knowledge workers utilize acquired knowledge as raw materials and often rely on technology to design new products and business systems. In today's workforce the need for knowledge workers increases as the importance of information-driven professions increases. For knowledge workers, re-training and training updates are crucial in maintaining their skill set. Deficiencies in training and training updates can result in a loss of competitive advantage for the organization. As knowledge workers maintain their skills, they seek knowledge-based pay, also referred to as skilled pay. According to Griffin and Ebert (2002), knowledge-based pay is a performance pay plan based on rewarding employees for acquiring new skills or knowledge. This pay plan is based on the premise that as the knowledge worker acquires more knowledge and skill, he or she becomes more valuable to the company. Once knowledge workers are sustained, organizations can then engage in utilizing various classes of knowledge.

As organizations engage in knowledge management, it is beneficial to be aware of knowledge classes. Small and Sage (2005) state that there are two main classes of knowledge, tacit and explicit. Explicit knowledge is knowledge that can be codified. It is formal and systematic and can be found in books, enterprise repositories, databases, and computer programs. Zack (1999b) notes that explicit knowledge is more precise and formally articulated. Tacit knowledge is difficult to articulate and more personal, rooted in contextual experiences. "Tacit knowledge is subconsciously understood and applied, difficult to articulate, developed from direct experience and action, and usually shared through highly interactive conversation, storytelling, and shared experience" (Zack, 1999b, p. 2). Once organizations are familiar with the classes of knowledge, they can then evaluate their present knowledge base in an effort to use knowledge management as a tool for organizational strategy.

KNOWLEDGE MANAGEMENT AND ORGANIZATIONAL STRATEGY

Knowledge management entails how an organization can generate and communicate knowledge, where knowledge is defined as usable ideas (Behery, 2008). Knowledge management involves the process of managing knowledge to meet existing needs, identifying and exploiting existing and acquired knowledge assets, and developing new opportunities (Metaxiotis et al., 2005). From an organizational viewpoint, knowledge management focuses on exploiting and developing knowledge assets to further the company's goals and objectives. The objective of knowledge management is to identify and leverage collective knowledge in an effort to aid organizations in achieving a competitive advantage through utilization of organizational strategy. Strategy within an organization encompasses an organization's plans or actions for attaining a specific goal. Knowledge management can be used within an organization's strategy as a tactic for achieve its goals and objectives. As organizations seek competitive advantage, utilization of knowledge management can be beneficial. The benefits of organizations incorporating knowledge management into their organizational strategy include innovation, increased organizational learning, improved intellectual asset management, increased operational efficiency, time-to-market improvement, and continuous improvement (Demarest, 1997). Holsapple and Joshi (2000) list several factors that can influence an organization's inclusion of knowledge management in its strategy. These factors include culture, leadership, technology, organizational adjustments, employee motivation, and external aspects. These factors can be further organized into three categories, which include managerial influences, resource influences, and environmental influences. Once organizations have an understanding of the origins of knowledge and knowledge management, the organization can then create knowledge management projects as a strategy component to attain their organizational goals.

Davenport, DeLong, and Beers (1998) categorized four types of knowledge management projects based on organizational objectives. These categorizations, organized by objectives, include the following:

1. To create knowledge repositories, which store both knowledge and information, often in documentary form. Repositories can fall into three categories: those that include external knowledge, such as competitive intelligence; those that include structured internal knowledge, such as research reports and product-oriented marketing material as techniques and methods; and those that embrace informal, internal, or tacit knowledge, such as discussion databases.
2. To improve knowledge access, to provide access to knowledge, or to facilitate its transfer among individuals; here the emphasis is on connectivity, access, transfer, technologies (i.e., videoconferencing systems), sharing tools, and telecommunications networks.
3. To enhance the knowledge environment, so that the environment is conducive to more effective knowledge creation, knowledge transfer, and knowledge use. This involves tackling organizational norms and values as they relate to knowledge.
4. To manage knowledge as an asset, as well as recognize the value of knowledge to an organization. An organization's intangible assets, to which value can be assigned, can include assets (i.e., technologies that are sold under license or have potential value), customer databases, and detailed parts catalogs.

Organizations can then utilize these categorizations to develop teams and engage in the knowledge management process via knowledge sharing.

Organizations can utilize knowledge sharing in its stratagem. Knowledge sharing can be regarded as a catalyst for knowledge management. According to Dixon (2000) organizations are addressing the issue of knowledge sharing because knowledge sharing is more feasible as technology evolves, as well as due to the organization's growing awareness of the importance of knowledge to organizational success. Dixon (2000) posits that there are three myths to knowledge sharing which include: (1) build it and they will come (referencing knowledge sharing as a warehoused entity), (2) technology can replace face-to-face contact, and (3) first you have to create a learning culture to share knowledge. If organizations seek to engage in knowledge management, they must dispel these myths and engage in knowledge activities. There are two main types of knowledge activities which include finding effective ways to translate their ongoing experiences into knowledge (creating common knowledge) and transferring knowledge across space and time (leveraging common knowledge). Creating common knowledge entails the team performing a task, achieving the outcome, exploring the relationship between the action and outcome, and gaining common knowledge. Leveraging knowledge entails the team performing a task, achieving the outcome, exploring the relationship between the action and outcome, gaining common knowledge, selecting a knowledge transfer system, translating knowledge into a form usable by others, and lastly, adapting knowledge for its own use by the receiving teams. Once knowledge is created or exploited, leveraging (transferring) the knowledge is key in achieving organizational success.

In addition to knowledge sharing, exploiting existing knowledge and knowledge transferring can be used in the organization's stratagem. Exploiting existing knowledge and transferring knowledge within the organization can result in cost savings for an organization (Dixon, 2000). Cost savings can be a key component in an organization's strategy as it seeks to minimize costs and maximize profits. To achieve these results the organization must look at methods of knowledge transfer. There are several methods to transfer knowledge. Knowledge is transferred effectively when the transfer process fits the knowledge being transferred. According to Dixon (2000), there are five main methods to transfer knowledge as follows:

1. *Serial Transfer:* The knowledge a team has gained from doing its task in one setting is transferred to the next time that the team does the task in a different setting. Tacit and explicit knowledge are utilized.
2. *Near Transfer:* Explicit knowledge a team has gained from doing a frequent and repeated task is revised by the other teams doing similar work.
3. *Far Transfer:* Tacit knowledge a team has gained form doing a non-routine task is made available to other teams doing similar work in another part of the organization.
4. *Strategic Transfer:* The collective knowledge of the organization is needed to accomplish a strategic task that occurs infrequently but is critical to the whole organization. Utilizes tacit and explicit knowledge.
5. *Expert Transfer:* A team facing a technical question beyond the scope of its own knowledge seeks the expertise of others in the organization. Utilizes explicit knowledge.

Once an organization identifies the type of knowledge that will be exploited, the type of knowledge transfer that will yield the best results can be chosen. According to Dixon (2000), transferring and leveraging knowledge is critical for an organization's current and future viability.

According to Zack (1999a), organizations are viewing knowledge as their most valuable and strategic resource. To maintain a competitive edge, organizations must manage their intellectual resources and capabilities strategically. An organization's strategy can aid in guiding knowledge management. Its strategic framework can act to identify knowledge management initiatives that support the organization's mission, strengthen its competitive positions, and create shareholder wealth. For this reason, Zack (1999a) asserts that knowledge management can be considered the most important strategic resource, and the ability to acquire, integrate, store, shape, and apply it becomes the most important capability for building and sustaining a competitive advantage. As knowledge management takes the forefront, it appears that organizations are valuing knowledge, not funding, as the most strategically important resource. As a result, learning is viewed as the most strategically important capability for business success. Halawi, McCarthy, and Aronson (2006) posit that knowledge management is utilized as a strategy to improve organizational competitiveness. Strategy is vital to organizational success. According to Griffin and Ebert (2002), organizational strategy entails setting strategic goals (long-term goals derived from the organization's mission), analyzing the organization, analyzing the environment, matching the organization and its environment, and formulating strategy. Therefore, within the scope of knowledge management, strategy formulation should be considered.

Porter (1979) posits that the essence of strategy formulation is coping with competition. The state of competition in an industry depends on the five basic forces. These forces as depicted by Porter (1979) include threat of entry, bargaining power of suppliers, bargaining power of customers, threat of substitute products or services, and jockeying for position. Once organizations have assessed the forces that can affect competition, they can use this knowledge in strategy formulation and implementation. Porter (1998) asserts

that having knowledge of sources of competition provides groundwork for a strategic agenda of action. These actions include highlighting strengths and weaknesses, animating positioning of the company in its industry, and clarifying areas where strategic changes may yield the greatest payoff. Utilizing knowledge management in strategizing can ultimately result in operational effectiveness, in which an organization outperforms rivals in performing similar activities.

FUTURE TRENDS

According to Delmonte (2003), we have entered into an information age where the use of information technology could become the source of competitive advantage. Davies et al. (2005) affirm that knowledge is currently the key battleground for competition. In addition, knowledge is viewed as the result of requirements for highly skilled labor, new computing, telecommunications technologies, faster innovation, and shorter product cycles. To capitalize on this trend, organizations must consider their human resource capabilities and engage in knowledge management. Weatherly (2005) states that there has been a shift toward integrated human resource information technology and self-service functionality. This integration affects employees and HR personnel. The shift has been a direct response to the competitive challenges of today's economy. Advances in computer technology and Web-based technology have been attributed to advances in the economy. Weatherly (2005) posits the following:

"A critical success factor influencing an organization's ability to lead, simply languish or ultimately falter in the marketplace will eventually come to rest on the positive synergy the organization is capable of generating between the human capital assets in its employ and the judicious investments in technology that it makes in its efforts to remain abreast of competition." (p. 32)

In relation to knowledge management, HR has the task of utilizing informational assets within the organization. The organization's business processes and support systems must be parallel to continue to utilize and expand essential assets. As information technology is used in managing knowledge, support systems like automation become beneficial.

HR automation can also be referred to as self-service, where employees can essentially service themselves with mechanized processes. Automation comprises HR tasks that utilize technologies and computerization to replace the labor intensity of various tasks. The benefits of HR automation include reduced turnaround time per transaction, reduced cost per transaction, and reduced number of inquires to HR. Ultimately, automated service promotes greater efficiency and cost effectiveness for the organization. Examples of self-service include Web-based technologies used to automate and computerize administrative transactions. Administrative transactions include payroll, benefits, and training. The traditional approach to HR administration including costly processes, redundant data management, and paper-based processes can be replaced with automated processes. Utilizing automation allows organizations flexibility in allocating resources to functions that promote accomplishment of the company's mission and objectives. In today's business world the change from traditional approaches to encompassing the acquisition and management of information has become a competitive force (Raeside & Walker, 2001). Knowledge management systems, pooled with effective knowledge management strategy, can maximize the potential for an information system to contribute to sustained competitive advantage (Delmonte, 2003). As organizations engage in establishing a competitive advantage, the necessity for changes and evolution involving information technology are becoming apparent.

CONCLUSION

Knowledge management seeks to effectively and efficiently manage an organization's intellectual assets through the utilization of organizational tools, technology, and processes (Davies et al., 2005). Knowledge management has origins that encompass a gamut of business improvement areas including Total Quality Management, Business Process Reengineering, Information Systems, and Human Resource Management. The knowledge management process can include: (1) utilizing knowledge workers, (2) managing knowledge to meet existing organizational needs, (3) identifying and exploiting existing and acquired knowledge assets, and (4) developing new opportunities (Metaxiotis et al., 2005). Within the scope of knowledge management, organizations can share knowledge, exploit existing knowledge, and transfer knowledge as a part of their organizational strategy. As knowledge management becomes fundamental, organizations are valuing knowledge more than funding, making knowledge management strategically important for organizational success. As trends like the use and dependence upon information technology within the knowledge management process become ubiquitous, organizations must seek to engage in continuous improvement to maximize resources as they seek to remain competitive. Utilization and continued development of knowledge management within organizations will yield organizational benefits, including increases in productivity and profit generation, as well as establish competitive advantage.

KEY TERMS

Automation: The process and transformation of manual labor into automated and/or computerized processes.

Explicit Knowledge: Formal, systematic knowledge that can be codified (Zack, 1999b).

Knowledge: The collection of what has been learned or perceived.

Knowledge Creation: Translating ongoing experiences into knowledge (Dixon, 2000).

Knowledge Leverage: Transferring knowledge across space and time (Dixon, 2000).

Knowledge Management: Utilizing tools, techniques, and processes to regulate intellectual assets (Davies et al., 2005).

Knowledge Process: Application of creating and leveraging knowledge.

Organizational Strategy: An organization's tactics and actions to achieve the company's mission and objectives.

Tacit Knowledge: Knowledge rooted in contextual experiences that is subconsciously understood (Zack, 1999b).

Knowledge Management Challenges in the Non-Profit Sector

INTRODUCTION

The concept of knowledge management is rooted in cognitive psychology and organizational theory. Knowledge management is concerned with the creation, storage, and distribution of knowledge by groups, organizations, and communities. Two theoretical frameworks are instrumental in shaping the knowledge management discourse: organizational knowledge creation (Nonaka, 1994) and organizational knowledge (Spender, 1996).

Widely cited in the literature is Ikujiro Nonaka's (1994) explication of the epistemological and ontological dimensions of organizational knowledge creation. Michael Polanyi (1966), makes a distinction between tacit and explicit (codified) knowledge in the epistemological dimension, whereas social interaction is the foundation of the ontological dimension. Over the years, the term knowledge management has been conflated with organizational learning and memory. Realizing that knowledge, memory, and learning are all interrelated, John-Christopher Spender (1996) proposed a knowledge-based theory of the firm. The knowledge-based theory of the firm is primarily concerned with the collective capabilities of generating, combining, and applying knowledge.

Given the advances in computing and telecommunications technologies, scholars have considered how information technologies can be used strategically to facilitate knowledge management (Alavi & Leidner, 2001). For example, wikis, blogs, content management systems, and the like provide dynamic infrastructures that support the creation, transfer, and application of knowledge. More importantly, these tools enhance organizational memory that can subsequently be shared across time and space. However, a knowledge friendly culture (Davenport & Prusak, 1998) precedes an effective knowledge management program.

The purpose of this article is to explore the challenges that arise in nonprofit settings, particularly the ways in which knowledge is stored and transmitted through an organization's culture. We propose two key challenges that influence organizational culture: acceptance of change and leaders' ability to develop a knowledge friendly culture. We conclude with a discussion on the role that these factors played in constraining a knowledge friendly culture in two case studies.

BACKGROUND

While the historical definition outlines knowledge management traditionally in firms where knowledge workers possess and share knowledge that is critical for the firm to capture, nonprofit organizations, in principle, benefit from some of the same goals. The goals of knowledge management in for-profit firms include competitive advantage, greater innovation, better customer experiences, consistency in good practices, and facilitating organizational learning. Although competitive advantage may not be a worthy goal for a nonprofit organization (NPO), consistency in good practices and facilitation of organizational learning are. Addressing the key knowledge management goals and challenges in a nonprofit setting has its own set of unique challenges.

Nonprofit organizations range from small, diverse community-based organizations that address local issues and rely primarily on volunteer labor, to large, nationally-based organizations such as the Red Cross. Nonprofit organizations consist of such groups as arts and culture, education and research, health services, social and legal services, religion, fraternities and sororities, civic and social services, and foundations. As such "their knowledge capital is heterogeneous, widespread, rarely formalized, and unstable" (Lettieri, Borga, & Safoldelli, 2004). These groups depend on temporary volunteers to help them work on specific projects (Boris, 1998). Yet some NPOs use paid labor. These workers can be classified as part- or full-time employees or consultants. Employees usually occupy a leadership position such as executive director and consultants and lead specific projects

based on their expertise such as technology infrastructure. Because nonprofits do not offer high salaries and are more strongly linked to a cause, they may not attract people with strong leadership skills. The lack of strong leadership and permanency pose a problem for knowledge management.

The above goals and challenges of nonprofit knowledge management are rooted in organizational culture. Organizational culture can be thought of as patterns of problem solving and ways of thinking that must be taught to new members (Schein, 1988). We argue that the culture of nonprofit organizations poses challenges for knowledge management. Challenges such as acceptance to change and leadership compromise consistency in good practices and facilitation of organizational learning. Knowledge management, therefore, must first be integrated into a nonprofit organization's culture.

CHALLENGES WITH KM IN NONPROFIT ORGANIZATIONS

In this section, we outline two cultural factors within nonprofit organizations that lead to challenges in knowledge management. One of these two factors also serves as a point for analysis in one of the two case studies examined in the next section.

Acceptance of Change

Two perspectives dominate the literature on organizational change: episodic and continuous (Weick & Quinn, 1999). Changes in personnel or technology trigger episodic change, whereas improvisation, learning, and adaptation trigger continuous change. The leader's role shifts from a change agent, creating change in the episodic view, to redirecting change in the continuous view. Each perspective illustrates a role for leadership and the subsequent importance of first modeling change in order to facilitate changes in the culture of the organization. Accepting change is a challenge in nonprofit organizations because values and norms do not support social structures and relationships that enhance knowledge management. Social structures that enhance knowledge management include heterarchy (instead of hierarchy) (Hedlund, 1994; Schutt, 2003) and knowledge sharing among the dynamic relationships of groups and individuals (Alavi & Leidner, 2001; Gilbert, 2002; Hurley & Green, 2005; Sahay & Robey, 1996; Schutt, 2003; Snowden, 2002).

In addition, volunteer culture complicates nonprofit social structure. Reliance on volunteers makes knowledge management a key challenge because new volunteers entering a nonprofit organization need to know just enough to get a job done. However, recurring volunteers may come in once or twice a month and need to know if anything has affected their task since the last time they volunteered. Volunteer turnover is also a problem for knowledge management. Volunteers working in a nonprofit setting may last only a few months, and without a knowledge management program, the knowledge they gain leaves with them. This constant change of incoming and outgoing volunteers poses challenges for managing volunteer knowledge.

Furthermore, for both volunteers and staff, organizational learning and socialization can enhance acceptance and sustainability of change (Farooq et al., 2005; March, 1991; Sahay & Robey, 1996; Schein, 1986, 1988). This socialization occurs as a result of organizational learning where mutual learning can be used for the development of knowledge in organizations. Organizational learning must be sustained (Farooq et al., 2005; Merkel et al., 2005) as part of routines that support the dynamic relationships of groups and individuals. Knowledge management can enhance sustainability, but NPOs must recognize the need for change as part of the organizational culture. As part of accepting change and supporting knowledge management, nonprofit organizations can explore knowledge management technologies.

Knowledge management technologies that are more likely to fit into the culture of NPOs are knowledge sharing technologies rather than knowledge application technologies because knowledge application technologies are domain specific and take more resources than most nonprofits have to dedicate to technology. Knowledge application technologies include expert systems and case-based reasoning systems. Expert systems capture knowledge and apply that knowledge to problems in a domain, resulting in a solution. On the other hand, case-based reasoning systems use knowledge from past experiences or cases to solve new problems. Because these systems take an enormous number of resources to design, develop, and maintain, such systems are beyond the financial scope of many nonprofit organizations. Yet, the scope of problems, for example, expert knowledge applied to fundraising problems, that nonprofit organizations face might be addressed using a knowledge application technology.

Knowledge sharing technologies, however, are already used by nonprofit organizations. Technologies such as the e-mail, search engines, document management systems, and databases store and allow users to share knowledge. Both knowledge application and knowledge sharing technologies must support the dynamic flow of knowledge and fit into the complex ecology of knowledge in organizations (Snowden, 2002). Technology acceptance occurs in the context of organizational culture that supports knowledge management initiatives through socialization and organizational learning. Accepting and sustaining a knowledge management culture remain key challenges for nonprofit organizations.

The goal of a business organization is to earn a profit, whereas the goal of a nonprofit is to provide a service. Structure and survival motivate change in for-profits. Competition

drives learning and change, whereas nonprofits struggle with learning and change because volunteer help is valuable. Pressuring volunteers too much to learn and accept change could result in them leaving. Nonprofits cannot leverage their volunteers as much as for-profits can leverage their workers because volunteers are not paid. This is a challenge for nonprofits because they have to learn how to provide efficient and effective services, but the volunteer culture can introduce inefficiencies. Strong leadership supports learning and change.

Leadership

Leadership is a key factor in creating and sustaining a knowledge management culture. In the nonprofit sector, a leader must bring the community together for a cause. Knowledge holders in an NPO include volunteers, employees, and board members (Lettieri et al., 2004). An NPO leader must understand the difference between the knowledge and skills required by, and the knowledge and skills available to, the organization (Lettieri et al., 2004) in order to create and sustain a knowledge management culture. Bringing knowledge management changes to an organization is challenging. As such leaders need to serve as change agents and understand that supporting an entire knowledge management socio-technical system requires a collective buy-in from many stakeholders (Young, 2001). Change to a knowledge management culture can result in anxiety and leaders must be able to support the psychological barriers to change such as the required change in assumptions (Schein, 1986, 1988) that include embracing the paradoxical nature of knowledge as both thing and flow (Snowden, 2002). In order to develop a knowledge friendly culture, leaders need to be aware of and model knowledge management values including support and nurturing of knowledge workers in the nonprofit socio-technical system: process, organizational culture, and information technology (Powell & Swart, 2005; Schutt, 2003).

CIVIC NEXUS AS THE NONPROFIT ORGANIZATION CONTEXT

We explore further the challenges that organizational culture poses for knowledge management in nonprofit organizations in the context of two case studies. The case studies were part of a larger research project called Civic Nexus. Civic Nexus was a participatory action research study in which we partnered with nonprofit organizations to understand and enhance their information technology practices. We worked with groups for 1 year. We began with fieldwork to understand how nonprofits use technology and how it fits with their work practices and values. This early fieldwork helped us to understand the socio-technical expertise and decision-making structure that a group already had in place. We leveraged this early understanding to help the groups choose a project on which we worked together.

Technology projects could include technical developments (e.g., hardware, software or Web site), transformations in procedures or practices (e.g., knowledge management), or organizing technical training sessions. Implementing projects provided a meaningful context from which nonprofits could learn to plan and execute technology-related activities. Because learning and sustainability were goals of the project, we embedded ourselves in the organization's structure and played the role of facilitator, became a member of a committee, or worked one-on-one with key staff members. After the year, we gradually "faded," staying in contact to check learning and sustainability by monitoring their ability to continue with the accomplishments we produced together over the year. The two groups, a local symphony and a grassroots historical initiative that we worked with, both have had specific problems with knowledge management. Although problems with leadership and change existed in both groups, the symphony mainly experienced problems with leadership and the historical group mainly experienced problems with change. Specific knowledge management technologies were related to the leadership and change challenges resulting in problems with technology use. Both organizations had access to knowledge sharing technologies. Whereas the historical group had problems with e-mail and a document management system, the symphony had problems with a database.

Case Study 1: The Nittany Valley Symphony

The symphony recently celebrated its fortieth anniversary and is the only classical music group local to central Pennsylvania. Over the course of the year we worked on a project to improve office flow and database access for the Executive Director (ED). A board of directors oversees the executive director, who was the only paid office staff member. Volunteers helped out in the office when special regular tasks needed to be accomplished, for example, preparing envelopes and letters to mail to past concert attendees or managing a poinsettia sale during the winter holiday season. One regular office volunteer works in the office two to four times a week to manage accounts received and another once a week to enter data. A committee, called management of information systems (MIS), consisting of a board member as chair and other volunteers, manages the information technology in the office. This committee designed and implemented a database, purchased computers and software, and ensures that the information systems are maintained.

Civic Nexus researchers worked closely with the MIS committee, executive director, and volunteers to research

and analyze a problem situation and devise a solution. The MIS committee decided to work on a project that assessed the information needs of the organization and whether the database was currently meeting those needs. The executive director was unable to track donations and send thank-you letters, among other tasks, using the database. The database, however, functionally could serve these tasks, but its usability was a major barrier for the executive director.

After working together with the Civic Nexus researchers, the MIS committee decided that part-time help, a technical office manager, might relieve some of the database problems. After a reworking of the budget and approval by the board, another staff member was hired to manage the database and other technical office issues that the ED was unable to address. The key knowledge management challenge, leadership, in the NVS is related to this office flow and suitability of IT project.

Leadership

The new ED was hired because of her 20 years of fundraising experience. Despite her experience as a fundraiser, she was unable to use the main knowledge management tool: the Access database. In an interview, the new ED shows her resistance to learning about the database.

Interviewer: And the database,

ED: The Access

Interviewer: Yea, Access, you are learning, what did you say?

ED: I don't want to, I know nothing about Access

Interviewer: I know the one day you were using tables [in Access]

ED: That's what I say and that's what I am going to stick to

Interviewer: Okay

ED: I do not want. But you know, the more you know, the more they [the board of directors] are going to expect you to do.

The current ED resists engaging in the sociotechnical structure of the organization, and this results in a disruption in the knowledge management practices, even if they were not optimal. The resistance indicates that the ED may not be equipped to lead the organization's knowledge management practices.

While the recent initiatives by the MIS committee showed some progress toward overcoming knowledge management challenges, no clear leadership role existed in the NVS. Little communication and knowledge sharing occurred between the office and the board. This disconnection in management caused some tension between the ED and the board and does not model leadership support for knowledge management.

Turnover with the ED also posed a challenge for knowledge management, and the recent turnover was particularly problematic. Although the former and new executive directors were able to work together for 2 weeks to help with knowledge transfer, the former ED was a young graduate of business school with database skills. Had this pairing of these two executive directors, a younger one with technical skills and an older one with fundraising knowledge, been longer, the skill transfer might have had more impact (Convertino, Farooq, Rosson, & Carroll, 2005) on the new ED's ability to lead knowledge management initiatives. In addition, the board did not recognize the value of pulling information out of the database to make decisions until recently when the MIS committee brought it up. Therefore, no change agent exists. Yet, the MIS committee seemed to be playing the role of change agent in the move toward better knowledge management.

Although the new awareness brought forth by the Civic Nexus involvement brought a positive impact on knowledge management within the NVS, the organization continues to have challenges with knowledge management related to contextual factors. For example, the strength of leadership depends on who occupies the president and executive director positions. Knowledge management opportunities and challenges depend on the current awareness of KM and the current resource pool. Furthermore, because "enormous 'gold mines' of knowledge are buried in databases" (Becerra-Fernandez, Gonzalez, & Sabherwal, 2004), importance lies in the symphony's ability to harvest this knowledge effectively. The MIS committee is making strides toward organizing office flow and IT practices, but their strides are slow. Although it is unlikely that the NVS will have a stable knowledge management culture, the MIS committee is working to extract knowledge from its database, and from our experience with other groups involved with the Civic Nexus project, the NVS has more sophisticated knowledge management practices than other groups we have worked with.

Case Study 2: The Underground Railroad

The Underground Railroad (UGGR) is a small, loosely connected, grass-roots group of volunteer historians in a small rural town in the Commonwealth of Pennsylvania. The group's goals are to identify and document sites that were involved in historic Underground Railroad activity and seek federal verification of the sites. No paid positions exist in

this group. In fact, the leader's book sales and independent fundraising efforts provide financial resources. We engaged in a mutual partnership to design and develop an online collaborative environment to support the goals of the group and to facilitate knowledge management. In this section, we highlight several factors that have inhibited adoption and productive use of the technology during the first 6 months of our partnership.

Acceptance of Change

Data from participant observation and interviews revealed that the group values timely responses to requests for information. Even though an IT infrastructure is now in place, adoption of the technology has undermined the productive use for knowledge management activities. In one case, use of the software is rather limited on two fronts. First, the group leader does not have Internet access at home and does not see any real value in having Internet access at home when she has access to the Internet at work. Second, another central actor in the local group is prohibited from accessing the Internet while at work. Therefore, no overlap occurs when accessing the online collaborative environment between two key members. As a result, members bypass the online system and continue to use e-mail and telephone as their primary modes of communication.

In a similar case, one of the actors involved lacks computer literacy and the motivation to learn to use computer technology. For instance, this subject matter expert has been a prominent figure in the local historical community for decades. During a training workshop, this individual demonstrated that he held quite a fount of tacit knowledge with respect to the UGRR history and knowledge of where documentation could likely be found. In addition, he knows which sites would be most attractive in terms of nominating them to the federal agency. However, this individual refused to use technology. In fact, he indicated that "he has gotten this far in life without using technology, so why start now." In order to capture some of his tacit knowledge, an undergraduate student was assigned to type his comments and selections into the discussion forum.

The second major challenge concerns the group leader's change in behaviors. In order to facilitate a knowledge friendly culture and bring the group together for a cause, the leader must serve as a change agent. Understanding this role presents a challenge for leaders in nonprofits. The leader must first undergo deep change in order to lead by example and model knowledge management values. As mentioned above, the group leader does not have Internet access at home and has continued to favor e-mail and verbal communication as opposed to using the online collaborative environment. When asked why, she responded, "That's just the way that we are used to doing things." For example, we held a workshop in order to train the users on the collaborative tools and give them an opportunity to use the tools. However, the group leader and other members favored verbal communication instead of computer-mediated communication. One member interrupted the flow and asked, "Aren't we supposed to be typing our comments into the system?" The room went silent for a moment and then the verbal dialogue between the group leader and two other participants continued.

Currently, this organization's culture is somewhat frozen. As a result, the organization is presently unaware of the need to change its culture in order to adopt technology and alter its values, norms, and routines. In the next action research cycle, we will intervene in order to assist the leader in understanding her role in facilitating a community of practice in order to develop a knowledge structure capable of stewarding knowledge for the organization.

FUTURE TRENDS

To support knowledge management within nonprofit organizations, future research on KM in nonprofit settings should focus on social-technical interventions that emphasize planned change in the organization's culture in the context of communities of practice. Future research on support networks and community information technology conferences where communities of practice emerge can elicit support for knowledge management among nonprofit organizations. In addition, we suggest that participatory action research is a malleable tool to facilitate and manage the trajectory and change in organizational culture. Finally, while the case studies showed that two small nonprofit organizations continue to face challenges with knowledge sharing technologies such as e-mail, a document management system, and a database, we caution larger, more resource rich nonprofit organizations to establish knowledge management practices before they implement a more sophisticated knowledge application technology.

CONCLUSION

We conclude that the two nonprofit organizations in this study are capable of neither episodic nor continuous change without outside intervention. Indeed, these case studies illustrate that changes in organizational culture may be more pronounced in nonprofit settings. Facilitating change in the culture of the organization requires a shift in culture and changes in leadership behavior. The leader must create conditions that are conducive to a knowledge friendly culture by first altering their underlying norms, values, and assumptions. Only then will change be effective.

KEY TERMS

Communities of Practice: Knowledge-based structures that facilitate knowledge sharing and development, and support learning.

Knowledge Management: The creation, storage, and distribution of knowledge by groups, organizations, and communities.

Knowledge Management Systems: Information systems that are designed to support the creation, capture, storage, and distribution of expertise and knowledge.

Organizational Culture: The values, norms, and assumptions that are widely held by members of the organization that subsequently shape their behavior.

Organizational Knowledge: Tacit and explicit knowledge that is part of the organization's culture and identity, routines, standard operating procedures, and is expressed in documents.

Organizational Knowledge Creation: Knowledge that is created through a continuous dialogue between tacit and explicit knowledge through the processes of socialization, combination, internalization, and externalization.

Organizational Learning: A social process in which individuals in organizations enhance decision making and problem solving by improving knowledge and understanding.

Nonprofit Organization: An organization in the social sector whose main purpose is to either provide a service or support a cause.

Participatory Action Research: An interventionist method that involves close collaboration between the researcher and practitioners.

Knowledge Management for Production

INTRODUCTION

Knowledge is one of the key drivers of innovation and success in the modern, information-based society. Consequently, knowledge has to be "operated" and "managed," which causes particular challenges due to the intangible nature of knowledge: "… it is fluid as well as formally structured; it is intuitive and therefore hard to capture in words or understand completely in logical terms. Knowledge exists within people, part and parcel of human complexity and unpredictability. " (Davenport & Prusak, 1998, p. 5) Being held in minds, knowledge is not easily accessible and hence, not manageable in the usual sense. Nevertheless, knowledge management (KM) tries to establish appropriate processes of externalizing, internalizing, and applying the knowledge of people involved in a given environment. Within that context, the notion of *knowledge* has undergone various definition attempts and interpretations.

From an economic and corporate perspective, knowledge was viewed as a commodity, like other products, to be packaged, archived, retrieved as needed, and sent across networks. An example of this approach is the "Wissenstreppe" (knowledge staircase), proposed by Klaus North (2002). This model proposes eight steps, each of which is linked to an instruction on how to reach the next step. The lowest level [1] consists of symbols. Combining these with rule-based syntax creates *data* [2], and the addition of semantics produces *information* [3]; information enriched by connectivity leads to *knowledge* [4]. Knowledge combined with applicability results in *ability* [5], which in combination with *willing* can be converted to *behaviour* [6]. Effective behaviour leads to *competence* [7]. Competences leading to a unique selling proposition (USP) create *competitive advantage* [8].

Knowledge became increasingly a decisive factor in competitive gain (e.g., Bryant, 2006), leading to an expanding demand for KM. However, manifold problems caused the failure of several KM initiatives, and led to the rediscovery of earlier approaches, such as that of Michael Polanyi (1973, 1985). Casselman and Samson (2005) extended the two types of knowledge, *explicit knowledge* and *tacit knowing*. Explicit knowledge can be represented by signs (symbols, text, and images), and thus stored electronically. As such, it is quite similar, or even might be seen as synonymous, to "information." Tacit knowing is always tied to a subject, that is, to a mind, and therefore, cannot be stored in a technical system. Nonetheless, it is possible to initiate processes that lead to the generation, externalisation, internalisation, and thus, to the sharing of tacit knowing.

Information technology (IT) is the natural enabler of managing *explicit knowledge* since it supports to store and handle signs: electronic content of any kind is easy to extend, rework, comment, structure, and complemented by metadata. These basic features of any document-based information management are strengthened in combination with standard or tailor-made KM Systems (KMS), like the one described in this chapter to support knowledge processes.

BACKGROUND

Tacit knowing can be understood as knowledge that is required to perform a behaviour, such as riding a bicycle, for which explicit knowledge is not mandatory (Dreyfus, Dreyfus, & Athanasiou, 1988): Even a child can learn to ride a bike without explicitly knowing specific rules or being able to articulate rules or formulas for balance calculations underlying bicycle riding. Knowledge that can be transformed into a skill is strongly embedded in experience, for example, gained from practising or sensing. Something can be understood comprehensively; reasons and connections can be recognised. Nevertheless, tacit knowing comprises aspects that are difficult to codify, such as personal convictions, perspectives, and values (Nonaka & Takeuchi, 1995).

The difficulty, and often even incapability, of articulating knowledge is one challenge of KM. Another one comes from the fact that even if *explicit knowledge* is available, it does not necessarily translate to action. In contrast to tacit knowing, explicit knowledge can be acquired via rote learning, which, however, can fail in its application or in conversion to intelligent behaviour. Learning facts without

relevant experience, understanding, or insight, results in the opposite of *tacit knowing*: lazy knowing, that is, knowledge that lacks capability.

The core concern of organisational KM, however, is the concrete use derived from (transforming or applying) knowledge, and not only to collecting and storing facts in databases, which would promote lazy knowing primarily. Therefore, KM, in the manufacturing industry, should focus on supporting and improving production processes. There are four categories of software-systems that can be used within that context (in sequence of increasing appropriateness):

Content management systems (CMS) and enterprise content management (ECM) transform structurally and semantically predefined (forms) information (content) into a desired uniform appearance (corporate identity). They are easy to handle, and establish tree structures of knowledge items, potentially complemented by metainformation.

Document management systems (DMS) store all kind of documents in a well-structured or extendable fashion. The documents have attached metadata, and they are indexed for rapid finding by full-text search. DMS have features like check in, check out, authorisation concept, workflow, user roles, history, and versions.

Learning management systems (LMS) are designed for knowledge transfer, but mostly concentrate on *internalisation* (learning). Content is created and arranged by experts.

Groupware (GW) systems focus on supporting the communication and collaboration of people having a common task or goal. They feature common workplaces for storing, exchanging, and processing documents, writing comments, and managing tasks.

When dealing with the introduction of knowledge management into an established organization, various social, technical, and organisational challenges arise that have to be considered for success:

1. ***Social challenges*** generally arise from changes inevitably coming up with the introduction of KM and KM-systems within an organisation. Change always requires energy in order to adapt to new circumstances, and also raises fear of failing to cope with the change. Specific KM-related social challenges are the willingness to share knowledge, knowledge externalization (how to articulate?), knowledge input, and retrieval.
2. ***Technical challenges*** refer to the functionality needed, and to the integration of KM mechanisms into the existing system landscape (platforms) that, in our case, required a tailor made solution. The KM user interface should behave (look and feel) similarly to the existing systems in order to be easily handled and used. In particular, the corporate design has to be conserved. Even in the case of a tailor-made solution, however, it should be flexible, w.r.t., both the user interface and the database interfaces. Another challenge comes from the key function of KM support, namely the search, if it is to be supported semantically and ontologically.
3. ***Organisational challenges*** primarily address individual learning: learning and knowledge processes mostly run self-organised; learners are stamped with personal conviction, perspectives, and values, forming a complex cognitive structure (Maturana & Varela, 1988; von Foerster, 1985/1999). Thus, structural changes can be achieved by controlling measures, but not instrumented or determined, and, knowledge processes cannot be completely planned.

Another organisational challenge is **search,** which can only be as good as the data to be searched. Consequently, all employees should use the same words ("language") for describing problems or solutions so that at least a wording-directive is needed. Another point is to train the users how to search.

Enhancing the level of education and further training of employees needs **time**, **freedom,** and "**knowledge rooms**": knowledge processes cannot be controlled by the parameters of economic efficiency. People need not only time to *internalize information*, they need also time for unconscious processes of internal assimilation and its linking, for understanding new and unplanned experiences, and for unexpected knowledge processes coming up with different types of acting.

Users have to be "won" without destroying their *intrinsic motivation*. Brain scientists, like Spitzer (2005), think that we have a natural predisposition to learn with fun, which is often distressed by education in school (Quinn, 2007). This could be pushed back if external rewards raise the knowledge sharing, retrieving, and transmission to something special. Thus, KM should offer to integrate knowledge processes in a natural way into the working day, where working and learning melts together.

Users easily can be stressed by huge systems coming with a big bang. Therefore, it is necessary to introduce a critical solution in small and easy-to-handle parts and steps: from function to function, and from department to department. The best way is to start in the area with the highest psychological strain, and with lead users, possibly supporting them by rapid prototyping and workshops.

Last, but not least, all the efforts put into motivating and training people, establishing, filling, and maintaining a knowledge base, must have a sustainable effect: this requires continuous attention of users and feedback, and appropriate activities in case of necessary modifications. A KM system, for example, should always exhibit something new to the user in order to attract his/her attention and motivation.

KNOWLEDGE FOR PRODUCTION (KFP)

Supporting knowledge management in the production industry is an important concern. We now focus on an exemplary approach for that domain, that is, a KM methodology and tools for a global operating craft paper production company having a three shift and 24/7 work process. Product quality here strongly depends on the knowledge each employee has about his/her workplace's share of the production process. Typically, this is *tacit knowing*, "stored" in the heads of the employees. Often, it cannot be explained or even will not by these people, because they are afraid of loosing competitive advantage, honour, identity, or power. In addition to that, the given setting mostly does not allow for the most effective way of sharing knowledge, namely face-to-face, think, for example, of distributed working areas, asynchronous attendance times due to shifts, and so forth.

INITIAL POSITION

Knowledge transfer from shift to shift is done using a "shiftbook" listing important events, using post-it notes for other information, and a few minutes talk (e.g., about observed or induced changes in chemical pulp composition). This is a source of information loss.

There are rules on how to enter data in the shiftbook; however, these are not consciously observed, and problem solutions are rarely added. Finding entries in the shiftbook reveals well-known problems associated with handwritten information, such as sequential search, illegible handwriting, no structure, paper quality, and so on.

If a problem occurs that cannot be solved by a certain employee, the practice is to ask for peer or expert help. Implicit knowledge about who might be asked in such a case may exist, but does not so in any case. Even when it is known whom to ask, this particular person might not be present: on annual leave, illness, retirement, or absence from work for other reasons.

The greatest psychological stressor, however, relates to knowing how to handle errors and production breakdowns. Check lists with procedures for standard production or for error handling do exist, but they cover only the top layer of guidelines and cannot meet all potential events. Moreover, the interpretation of rules may differ among employees who might proceed in different ways, depending on comprehension and level of education. It is known what skills are needed for a specific task; however, the competence level of the person to fulfil that task is not. Think of car driving, which is feasible for people having a driving license. This licence certificates a set of defined skills but gives no indication of the driver's quality in driving.

SOLUTION: SYSTEM ARCHITECTURE AND SYSTEM INFRASTRUCTURE

Based on the considerations presented in the Introduction and Background sections, at the eBusiness Institute of the Alpen-Adria-Universität, we developed a system family called "Knowledge for Production" (KFP), as shown in Figure 1.

ESP, the electronic shift protocol, was implemented first in 2002, and it aimed at providing an electronic shiftbook in order to resolve the afore-mentioned handover problems between shifts: ESP replaced the former handwritten shiftbook that was unstructured, mostly unreadable, and therefore very unclear.

Secondly, the module "Learning for Production" (LFP) was developed, which is to systematically collect, control, and manage the "Best Practice" knowledge about all production processes. The integration into the enterprise was supported by procedures and incentives agreed upon by the worker's council and the company's management.

The module E-Search supports a comprehensive search that makes it possible to find and combine information from all ESP and LFP knowledge bases.

During the realization phase, it turned out to be favourable to divide LFP into two subsystems with interlinked knowledge bases: the learning management system (LMS) and the knowledge management system (KMS). LMS provides a user tracking system, allowing him/her to control his/her level of education, needed courses, and important documents which he/she should or must read. In contrast to that, KMS supports a flexible unguided rummaging in any documents organized in a tree-structured knowledge base.

Figure 2 shows the user interface of the KMS application. The left-hand side features the navigational structure that maps the plant's production architecture. Documents linked to the nodes (machines/components) are shown in the middle right area. The KMS has a special access rights concept for the plant structure, that is, each user has different rights (read, write, and lock) on each subnode of the navigation tree. These rights will be inherited by the subnodes and may only be extended in the order specified. Further KMS features are the attributes of the respective document

Figure 1. KFP-architecture

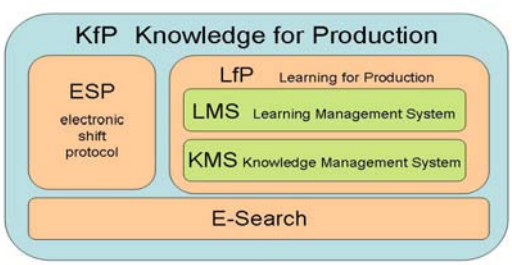

Figure 2. KMS-template

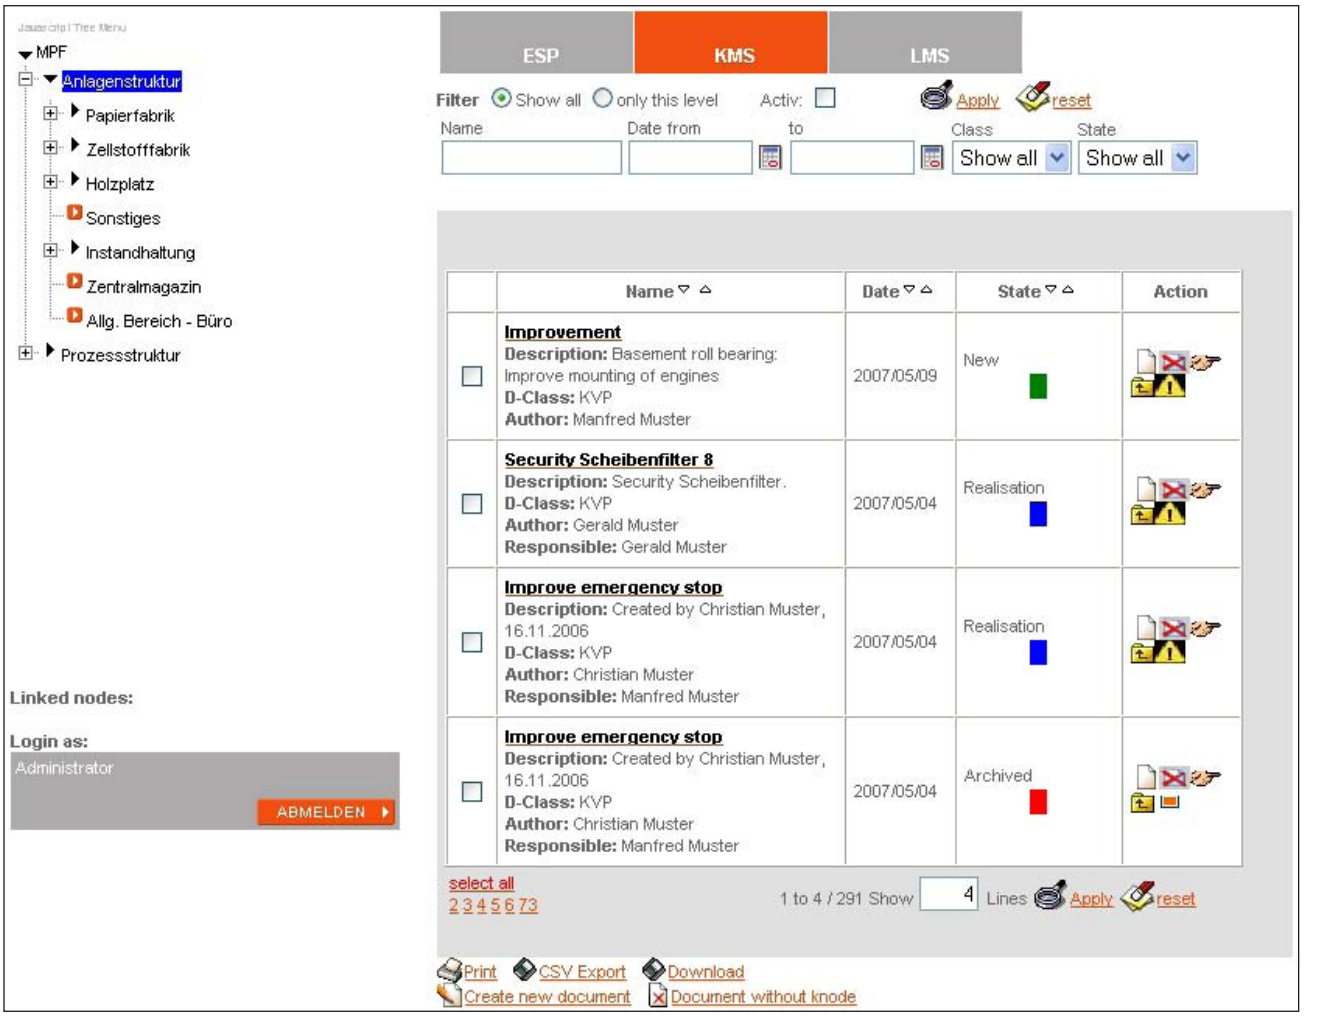

classes, which may be classified as mandatory, or optional. These fields are controlled, on the one hand, by the defined user roles and, on the other hand, by authorizations on the navigation tree. In addition, there are specific rights for the document owner, and for the particular role of the document class responsible person. There is also a freely configurable workflow for each document class. This workflow defines the order of the possible conditions of the document status as well as the visibility for the user. The workflow controls the possibility of editing metadata for documents.

FUTURE TRENDS

KM, in the production industry, mainly deals with knowledge close to the machines, production processes, and products. Mostly, this knowledge is not directly available at the shop flow workplace. Mobile, handheld, and embedded devices will help here. Potentials and limits of so-called "micro content," and the related "micro learning," are currently discussed (Hug, Lindner, & Bruck, 2006). Pervasive computing devices, combined with mechanisms for self organization, will be integrated to support pull and push strategies, and generally, will open new dimensions in KM.

The functioning of machines and processes is often hard to understand for the workers, in particular, if the relevant parts are hidden, due to casing or inaccessibility. This raises the safety for the workers but handicaps learning. In such cases, animated simulation, which also might visualize failure situations, can support knowledge acquisition. This becomes more and more good practise due to decreasing licence costs for simulation software.

Insufficient search algorithms are a bottleneck that could be overcome by the use of ontologies (Benjamins, Fensel, & Perez, 1998), which, however, require high initial development efforts and support by experts.

Another important aspect of future KM is the social collaboration: Shop floor workers usually are not trained in using communication tools like discussion boards, forums, blogs, wikis, and so on. They prefer face-to-face communication instead of fighting with problems in formulating texts. Thus, a new communication culture and speech/language processing mechanisms will have to be introduced.

CONCLUSION

Supporting and introducing KM into an organization is a sensitive issue that can hardly be standardized. Therefore, it seems to be the better way to adapt a KM system to the existing (proved) processes (best practises) instead of creating troubles by using the opposite way. People like and cultivate their habits. Changes consume energy and create fear or displeasure. Therefore, an important goal is to find the area with the highest psychological strain, and to start here by establishing the intended system step by step and department by department (always looking for the best moment to do so). The users should be within the main focus, and the system should support the user in the best way. Technical know-how of users differs, and there may be a huge gap in the ability of using KM systems. This can be balanced either by keeping the handling of the system as intuitive as possible, by training the users, and other by offering helping tools, for example, spell check or auto completion of data input, and so on.

There is no perfect strategy for KM system use and its initiation. Guidelines might help, enabling the user to intensify his/her work as he/she increases in competence and abilities.

The KFP tools we developed are now productive in practice, and the experience and expertise gained from the development are transferable to other knowledge management initiatives, especially to those in the manufacturing industry. For example, companies generally encounter knowledge-transfer-related problems in the event of annual or sick leave and retirement. Problems may also arise from limited opportunities for communication among employees because shift work reduces or even eliminates direct contact.

During content creation for KFP, experts and trainees were motivated to work together and thereby, took the advantage of collaborative processes and learning: The experts learned about the specific skills, limitations, and knowledge of the trainees thus, learning how to externalise, represent, and *transfer* ("teach") their *knowledge*. The trainees learned to ask the right questions in order to elicit the expert's knowledge.

KEY TERMS

Explicit Knowledge: Knowledge that can be represented in signs (symbols, tests, and images). Thus, explicit knowledge can be stored in technical systems, and can be managed. As such, some see it as synonymous to **information**.

Information: Refers to quantitative, arranged, perceivable, and distinguishable (mental) units that have representations (signs). Long ago, Shannon defined information as the "reduction of uncertainty," Wiener made a disctinction from matter and energy.

Knowledge: Refers to quality and potential. It is related to understanding, experience, and expertise, and is gained from practising or sensing. Knowledge "can be seen as a culturally recognized set of performances called "knowing" that suggest that a person "has" the potential for further performances […] and, thus, is said to have "knowledge" of a certain form (Day, 2005, p. 631). For Siemens (2006) all knowledge is information, but NOT all information is knowledge.

Knowledge Management: Means the organization of explicit knowledge in technical systems and the enhancing of tacit knowing by supporting organizational knowledge processing.

Knowledge Management Systems (KMS): Software systems that provide features to collect, store, organize, distribute, and retrieve explicit knowledge in the form of information. KMSs are intended to support knowledge processing.

Lazy Knowledge: Simply based on facts. It lacks understanding, insight, and experience and therefore, lacks capability.

Tacit Knowing: The process of creating *knowing how*, of creating general understandings, insights, experience, and/or expertise from particular entities. *Knowing* is one psychological category of intentionality. (Day, 2005; Polanyi 1973, 1985)

Knowledge Management in E-Government

INTRODUCTION

Over the past decade, government has created innovative and complex systems connecting people to information by focusing on Knowledge Management (KM) practices. KM, described as the comprehensive management of an organization's expertise through collecting, categorizing and disseminating knowledge, leads to knowledge discovery through techniques such as data mining. These developments have transformed traditional access to public services into e-government. Ever increasing demand to access and information has also brought about e-government policy development challenges for integrative KM practices in public services (Riege & Lindsay, 2006). In particular, the size and complexity of governmental structures and the vast data stores have become problematic (Koh, Ryan, & Prybutok, 2005). Because government uses, collects, processes, and disseminates sensitive information containing personal, financial and medical data, it is very easy for organizations to reprocess the information and disseminate it (Hewett & Whitaker, 2002). Ebrahim and Irani (2005) state that the benefits gained by data mining and KM practices are erased when information is not viewed as confidential but instead as a commodity to be bought and sold. Therefore, e-government must uphold a higher standard of ethics in KM practices through continued development of codes of conduct and governance policies for data that build citizen trust and ensure success of e-government services and transactions (Verschoor, 2000). An excellent framework to effectively preserve this trust is a balanced scorecard (BSC), which was first introduced by Kaplan and Norton (1992, 1996a, 1996b). The framework serves to continuously improve the KM process when modified for e-government. Therefore, this chapter describes technological and organizational challenges faced by e-government in KM and retrieval and presents the BSC framework to overcome these challenges.

BACKGROUND

Government information systems have proved to be an efficient way to facilitate communication, provide information and deliver services to citizens. While database management systems lead to better data capture, storage, processing and sharing capabilities, extracting useful information from the data presents adversities for government (Robertson & Powell, 1999).

Electronic data capture and storage for later retrieval are major expenses associated with successful data mining applications (Robertson & Powell, 1999). Knowledge capture results from the use of data sources to find intelligent patterns in the data. The increase in the number existing government e-commerce sites that have the means to capture citizen data greatly reduces the cost of starting a data mining application (Tan, Steinbach, & Kumar, 2006).

Data mining software applies complex algorithms to massive data stores important for discovering relationships (Turban, Leidner, McLean, & Wetherbe, 2006). Within the public sector, data mining methods yield powerful information about the interrelationships between data elements (Robb & Coronel, 2006). Likewise, rich opportunities exist for uncovering "new" intelligence in government information.

While data mining technology advances, the potential impacts of mining citizens' private data present legal, social and ethical questions (Taipale, 2007). In addition to privacy, inherent risks of accuracy and integrity can result when data is merged from multiple sources. Safeguards for addressing privacy and integrity risks include formal codes of ethics, written ethics policies mandated employee training, and even audits that flag unauthorized access to data (von der Embse, Desai, & Desai, 2004). More specifically, legislators have enacted laws and regulations to protect citizen data (Glover & Owen, 2004). These include the Gramm-Leach-Bliley Act for financial data, Children's Online Privacy Protection Act for use/collection of child data online, the Electronic Communications Privacy Act, Privacy Act, Cable Communications Policy Act, and HIPAA regulations regarding medical information.

From a risk perspective, numerous technologies utilized in the e-government environment, as well as process/user interactions and system compatibility issues must be evaluated as potential areas of misuse or impediments. Technologically, the maze of perspective subcategories such as m-government (mobile government), u-government (ubiquitous government), and g-government (government GIS/GPS applications) provide complexities that are not much different from public sector information portals (Riley, 2007). However, the highly private nature of the data, ethical questions about its ownership, and IT infrastructure makes the stakes higher in an e-government configuration (Taipale, 2003).

From a process interaction perspective, risks can arise from the following types of systems: Government-to-Citizen (G2C), Government-to-Business (G2B), Government-to-Government (G2G) or Government-to-Employees (G2E) (Turban et al., 2006). For example, G2C systems support the majority of citizen data captured, including online systems for driver license renewal, vehicle tag renewal, voter registration, social benefits management, court records, and state property appraisal information. Despite the highly personal and private nature of G2C Web site exchanges, the G2B systems, which interface with business information systems, open even a more complex Pandora's Box of data security and data access solutions (Sagheb-Tehrani, 2007). G2G systems linking governments face problems with inconsistent policies/laws, intergovernment or interagency politics, language barriers, and customs (Jing & Pengzhu, 2007). Finally, G2E systems face privacy and safety issues of providing employees with access to employee benefit information and communication portals with human resources departments (Pardhasaradhi & Ahmed, 2007).

Besides technical and structural risks, the historic development of many e-government information systems in a "vacuum" rather than through coordinated efforts have led to incompatibilities with other systems and data redundancy (i.e., the same data is stored in more than one place). These incompatibilities result in citizen and legislative outrage, as well as increased costs, poor performance, and a lack of sharable components and data (Park & Ram, 2004).

KNOWLEDGE MANAGEMENT AND RETRIEVAL IN E-GOVERNMENT

Now that a discussion of technological and organizational challenges with government information systems faced by e-government in KM and retrieval has been presented, this section will discuss how the BSC can be used to ensure trusted e-government services and transactions.

Because uses within e-government environments vary widely (including even debt or courtroom trial management and litigation support), it is important to consider the skill-set and priority diversity of users, as well as organizational core capabilities. Integrated e-government systems must be able to manage data/document capture, convert data to digital format, allow for Internet/intranet document publishing, track correspondence and electronic information distribution, and complete action tracking functions (such as suspenses and corrections) in a systematic manner.

The balanced scorecard, first introduced by Kaplan and Norton (1992, 1996a, 1996b), can be modified for e-government use to provide one of the best frameworks to enhance the integrated retrieval functions of KM systems. One of the key advantages of this approach is that it provides order to the unstructured nature of electronic data or text mining through a systematic process of extracting knowledge. Secondly, the BSC modification continues to support, improve, and add value to the productivity of data warehouse retrieval capabilities. Using four perspectives (finance, customers, internal processes and training growth), the BSC promotes continuous improvement at each phase of the KM process for e-government. As Figure 1 shows, each step of the KM strategy addresses these perspectives and continually transforms the review and audit function to evaluate knowledge created.

Basically, the finance perspective addresses timely and accurate funding data, as well as issues of risk assessment and cost-benefit data associated with the KM system (Arveson, 1998). The kinds of customers, processes used to service these groups, value-added service delivery, and satisfaction metrics are all part of the customer perspective (Davison, Wagner, & Ma, 2005). The internal business process perspective focuses on how well the organization is performing its mission mission-oriented processes (i.e., specific and unique functions of the e-government environment) and support processes (i.e., more repetitive functions benchmarked using generic metrics) (Patton, 2007). Finally, the training growth perspective highlights employee training and attitudes toward the organizational culture can lead to strengthened user communications for problem solving (Wu, 2007).

The knowledge audit is both the beginning and ending point that closes the loop when establishing effective e-government KM strategies. At a minimum, the knowledge audit should: (1) determine what target areas of knowledge should be audited and what limitations exist; (2) identify benchmarks and how results will be measured and tracked against this reference; and (3) evaluate existing/missing knowledge in target areas (Daghfous & Al-Nahas, 2006). After identifying the parameters of the knowledge audit, the strategic steps will of KM will examine perspectives of reducing costs (financial), enhancing customer value (customer), leveraging advantageous organizational processes (internal processes), and promoting change in the KM system through continuous learning cultures (training growth). Figure 2 displays examples of each perspective that could be incorporated when developing the organization's

KM strategy. Realizing the advantages of this framework requires constant reinforcement of a "knowledge pull" position rather than a top-down "knowledge push" position. In the more successful "knowledge pull" model, e-government can tap into its intellectual resource strengths by rewarding its users for sharing, seeking and creating knowledge rather than creating frustrating experiences of pushing information where it is needed (Hauschild, Licht, & Stein, 2001).

FUTURE TRENDS

With the capabilities of computer hardware doubling every 18 months since the first computer (UNIVAC) was delivered to the U.S. Census Bureau in 1951, data mining in e-government without a doubt will continue to grow (Gray, Liu, Nieto-Santisteban, DeWitt, & Heber, 2005). Data mining algorithms that were once thought to be intractable can now easily be run on today's hardware. University and industry researchers continue to find new ways to automatically merge data from disparate sources while preserving data integrity and new algorithms to provide meaning within data patterns.

Unfortunately, these logistical and technical improvements do not address the legal, moral and ethical concerns. When data mining tools are able to discover sensitive e-government intelligence that is dangerous or hurtful, then citizens, legislators and the legal profession may choose to exercise more controls or pass legislative safeguards (Taipale, 2007). One safeguard is the newly revised Federal Rules of Civil Procedures (FRCP), which went into effect on December 1, 2006, that address which data is the relevant, discoverable, and deemed preservable in a court of law (U.S. Judicial Conference, 2005). While much of the data captured by e-government systems is not only of interest to the public but is also valuable to other government agencies and businesses (Pollach, 2007), rules on how to control access to this "private" data vary from state-to-state and country-to-country. For example, many state agencies provide free and easy access to information about traffic and

Figure 1. Knowledge management process for e-government

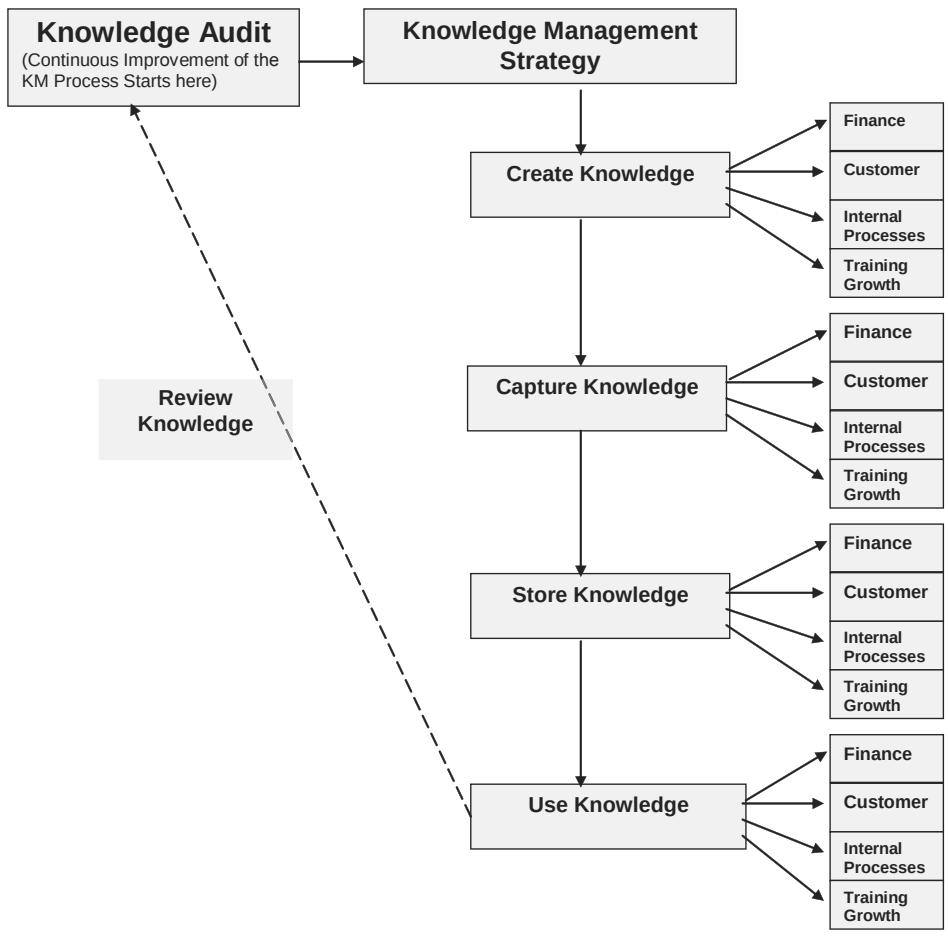

Figure 2. Creation, capture, store and use knowledge perspective in organization's KM strategy

CREATION OF KNOWLEDGE	
Finance	*Are there sufficient financial resources to support the information technology for the entire KM system?*
Customer	*What information could be presented to customers as value-added knowledge, by converting data currently gathered?*
Internal Processes	*Who are the people who play knowledge roles within the organization? Are they knowledge facilitators, curators, or engineers? Is an analysis of the interplay among interorganizational technology, social networks and competitive dynamics important for the organization?*
Training Growth	*How is knowledge created within the organization?*

CAPTURE KNOWLEDGE	
Finance	*How does unnecessary information capture affect service costs?*
Customer	*What knowledge hierarchy exists for serving customers in terms of the complexity, depth, security needs, etc. of captured data?*
Internal Processes	*Would experimental investigation of alternative navigation structures yield benefits? What repositories contain explicit knowledge (i.e., formal codified knowledge documented in reports, papers, rules, laws, patents, formulas, or books)?*
Training Growth	*Are there opportunities through training to advance tacit knowledge capture (i.e., informal uncodified knowledge that resides in people's heads over years of experience)?*

STORE KNOWLEDGE	
Finance	*What is the cost/benefit of storing certain data?*
Customer	*Which knowledge assets, if lost, would threaten users or the organization's existence?*
Internal Processes	*Who has access to the internal and external information sources?*
Training Growth	*By instituting certain employee policies (enhanced by training), can the organization eliminate valuable storage regarding electronic information?*

USE KNOWLEDGE	
Finance	*From a financial standpoint, what is the value of KM in productivity, agility, innovation and reputation for the organization?*
Customer	*Do the organizational structures and incentives foster knowledge sharing within and outside the organization?*
Internal Processes	*What processes/tool support is required to acquire, refine, index, store, retrieve, disseminate, and present knowledge? Are scheduled reviews or controls used to promote development and validation of the knowledge chain model in the organization?*
Training Growth	*What mechanisms exist for cooperative sharing among knowledge workers? What learning effects would benefit multiparticipant collaborative systems for the organization?*

criminal violations, vehicle registration information, and property data. While citizens may find it useful to review the accuracy of their own traffic, court, or property ownership information, there are risks of commercial exploitation of e-government data which can be used to identify lucrative customer relationships. Likewise, criminals may enjoy access to citizens' addresses, phone numbers, automobile data, arrest records, distance from schools and playgrounds, credit reports, and more.

One of the largest data-selling companies is Choice Point. When the Homeland Security Administration wanted to test the value of data mining in identifying post-9/11 terrorists, the FBI turned to Choice Point for help (Harris, 2005). Using data from e-government sources plus private databases owned by Choice Point, the company used propriety data mining methods in search of terrorists. After legislators and citizens expressed ethical concerns about citizen privacy and for-profit company involvement in the war on terrorism, the project was quickly terminated. While it is unclear if efforts were abandoned due to ethical concerns or unsuccessful results in terrorist identification, the point is that data-mining's value for e-government will continue to grow, be tested, and targeted for more applications of rich mine-able data (Strohm, 2005; Taipale, 2003, 2007).

CONCLUSION

Social, ethical and legal challenges in connection with information transformations are causing organizations, including e-governments, to examine privacy, piracy, safety, data security, data integrity, competence, honestly, loyalty and fairness (Chow, 2001; Himma, 2007). Legislators and the legal profession have stepped in to control the dissemination of information in light of social and ethical voids associated with limited or deficient knowledge policy development (Hewett & Whitaker, 2002). Organizations need to carefully review existing legislation as well as understand the legal implications of it and may benefit from seeking legal advice. Performing internal audits and updating organization's policies and procedures are recommended as new legislation evolves. For example, new information privacy legislation should alert an organization to ensure that their policies, procedures, controls, and systems are in compliance and receive continuous scrutiny. To assist with KM in e-government, a modified BSC provides a first step toward establishing a effective KM strategies (Kaplan & Norton, 1992, 1996a, 1996b). Using the BSC, continual improvement of the knowledge management process for e-government can be accomplished using four key perspectives. By transforming strategies into objectives, overcoming the barriers to knowledge management and retrieval in e-government can reduce costs (financial), enhance customer value (customer), leverage advantageous organizational processes (internal processes), and promote KM system change through continuous learning (training growth).

KEY TERMS

Balanced Scorecard: The Balanced Scorecard (BSC) was developed by Kaplan and Norton in 1992 to examine how an organization is using the activities and processes to meet its strategies, using the four key perspectives of finance, customers, internal processes, and training growth.

Data Mining: The use of algorithms to automatically search through massive data stores from different sources in order to find unknown patterns and interrelationships that ascribe meaning to the data.

Data Redundancy: The same data is stored in more than one place.

Knowledge Audit: An examination of KM systems for purposes of evaluating knowledge components against targeted benchmarks.

Knowledge Management: The comprehensive management of an organization's expertise that consists of collecting, categorizing and disseminating knowledge.

Knowledge Management (KM) Strategy: A knowledge management strategy identifies the key needs, issues, and components within an organization and provides a framework for addressing these. Specifically, knowledge management strategy components include how an organization creates, captures, stores and uses knowledge.

Knowledge Pull: Knowledge pull taps into the intellectual strengths of its users, who share, seek, and create knowledge efficiently and effectively at the optimal cost.

Knowledge Push: Knowledge push is typically associated with a traditional top-down approach to managing knowledge. In other words, the knowledge delivery is not initiated by the receiver and lacks collaborative potential of knowledge pull.

Knowledge Management Systems Acceptance

INTRODUCTION

Knowledge management is a set of systematic actions that organizations can take to obtain the greatest value from the knowledge available to it (Davenport & Prusak, 1998). Systematic means that knowledge management is made up of intentional actions in an organizational context. Value means that knowledge management is measured according to how knowledge management projects contribute to increased organizational ability (see for example Prieto & Gutiérrez, 2001; see Goldkuhl & Braf, 2002, on the subject of organizational ability). The motivation for knowledge management is that the key to competitive advantage for organizations in today's business world is organizations' ability to manage knowledge (Nonaka & Takeuchi, 1995; Davenport & Prusak, 1998). Knowledge management as an intentional and value-adding action is not easy to accomplish in practice (Scarbrough & Swan, 1999). Scarbrough and Swan (1999) present several case studies in knowledge management, successful and unsuccessful in their respective knowledge management projects. A major point and lessons learned from the case studies is that prevalent approaches in knowledge management overstate technology and understate how technology is implemented and applied.

To succeed with knowledge management, encompassing development of information technology-based information system, some requirements have to be fulfilled. An important aspect in the development process is system acceptance. Implementation is at large a process of acceptance. Implementation is the process where the system becomes an integrated part of the users' or workers' work practice. Therefore implementation is essential to make a knowledge management project successful in order attain an increased organizational ability and to succeed with knowledge management.

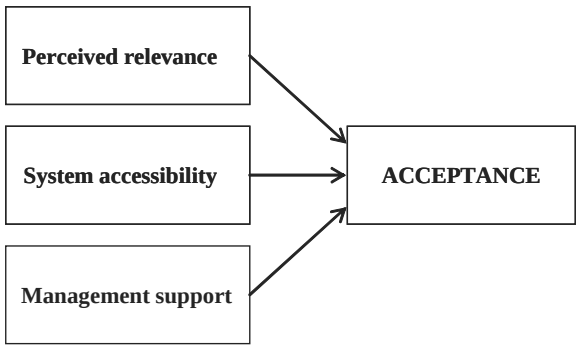
ISSUES OF KNOWLEDGE MANAGEMENT: SYSTEMS AND ACCEPTANCE

In this section we provide broad definitions and discussion of the topics to support our positions on the topics of knowledge management and systems acceptance.

MANAGING KNOWLEDGE

Work in knowledge management has a tendency to omit social or technological aspects by taking on one of two perspectives on knowledge management, the anthropocentric or the technocratic view (Sveiby, 2001; Swan, 1999). The anthropocentric and the technocratic views represent two contradictory views on knowledge management and can be summarized as technology can or technology cannot. The gap between the anthropocentric and technocratic view depends on a difference of opinions concerning the notion of knowledge. The technocratic view conceives knowledge to be some organized collection of data and information, and the anthropocentric view conceives knowledge to reside in humans, not in the collection (Churchman, 1971; Meredith & Burstein, 2000). Our conception of knowledge is that of the anthropocentric view. Taking on an anthropocentric view on knowledge management does not mean that we discard knowledge management technologies; we rather take on a balanced view on the subject. Information technology can support knowledge management in an organization through a number of different technological components, for example intranets, extranets, data warehouses, and database management systems (Borghoff & Pareschi, 1998; Tiwana, 2000; Ericsson & Avdic, 2002). The point in taking on an anthropocentric view of knowledge management is not to lose sight of the knower who gives meaning to the information and data found in IT-based knowledge management systems.

Figure 1. Requirements of Acceptance Model (Ericsson & Avdic, 2003)



KNOWLEDGE MANAGEMENT SYSTEMS

Information systems can include either operative or directive and decision support information (Langefors, 1966; Yourdon, 1989). Operative systems provide system users with information necessary in workers' daily work, while directive and decision support systems provide system users with information that improves the quality of decisions workers make in daily work. Knowledge managements systems are systems developed to manage knowledge directly or indirectly to give support for an improved quality of a decision made in workers daily work, and as an extension, an increased organizational ability. A knowledge management system typically includes directive information, for example in guiding a user's choice in a specific work situation. Such systems are often optional in the sense that users can deliberately refrain from using the system and/or refrain from taking the directed action. Accordingly, user acceptance is crucial for the degree of usage of knowledge management systems.

ACCEPTANCE OF TECHNOLOGICAL SYSTEMS

Technology acceptance has been subject of research by, for example, Davis, Bagozzi, and Warshav (1989), who developed the well-known Technology Acceptance Model (TAM) and later a revised version of the original model, TAM2 (Venkatesh & Davis, 2000). TAM is an explanative model explaining user behavior of computer technologies by focusing on perceived ease of use, perceived usefulness, attitude towards use, and behavioral intentions as determinants of user behavior. TAM2 is an extension of the original model including external factors related to perceived usefulness.

The framework for system acceptance, Requirements of Acceptance Model (RAM) have some resemblances with TAM and the later TAM2. RAM is in comparison with TAM descriptive in nature. Workers' work practice is treated as an integrated element of RAM, compared with not being treated as a determinant of system use in the original TAM and as an external factor in TAM2. Further, RAM covers acceptance of knowledge management systems, and TAM/TAM2 cover a broad range of computer technologies. RAM systematically acknowledges factors important in implementation of knowledge management systems to gain acceptance of such systems.

REQUIREMENTS OF THE ACCEPTANCE MODEL

We perceive acceptance to be a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. In this section we present the requirements of acceptance in RAM. The Requirements of Acceptance Model is illustrated in Figure 1.

PERCEIVED RELEVANCE

The workers, who are to use the system, must perceive the knowledge management system as relevant. Since it is possible for workers to work without using the system, it has to be obvious that usage of the system implies adding value to the work result. An additional aspect of relevance related to perceived relevance is how the system should be integrated in running work, that is, to make the system an integrated part of the workers' work practice.

In summary, perceived relevance is about workers, who are to use the system, perceiving the system as (Ericsson & Avdic, 2003)

- adding value to the work results; and
- being integrated in running work.

ACCESSIBILITY

To obtain acceptance of knowledge management systems, accessibility has to be satisfactory. It must be accessible to the workers who are to use the system. Accessibility is a question of who is to be the user (type of workers concerning organizational position), what action and work the system is to support (daily work, product development, innovation, etc.), where users get access to the system (the physical access), when the system is ready to use, and how the system's interface fulfills the goal of the system.

In summary, systems accessibility is about (Ericsson & Avdic, 2003):

- knowing who the user is;
- systematizing the actions workers perform in the work practice the system is to support;
- deciding the system's physical access;
- securing a certain degree of usage before the system is put into operation; and
- ensuring the system's design meets the goals of the system.

MANAGEMENT SUPPORT

Management support is vital according to many models on information systems development, especially when the system is a directive/decision support system (Yourdon, 1989). Knowledge management systems are typically directive systems, and workers have a choice in deciding whether to use the system or not. Management support is important to stress the value for workers to use the system and to make conditions for workers to do so.

DEVELOPMENT IS A PROCESS OF ACCEPTANCE

There must be a fit between workers' work practice and technology to get acceptance of knowledge management systems. The technology used to create a knowledge management system must fit the actions workers perform in their work practice. On an overall level there must be a fit between technology and actions performed by individual workers, and between individual workers and the organization as a whole, thus forming a coherent whole. It is in the development of knowledge management systems that the requirements of acceptance are fulfilled. A common conception concerning information systems development is that it constitutes analysis, design, construction, and implementation of information systems (Hirschheim, Klein & Lyytinen, 1996).

The groundwork for acceptance is made during the design, but foremost when implementing the system. Workers who are to use the system should be engaged at an early stage of the development process. The point of including workers at an early stage is to acquaint users with the system and the purpose of the system. Further, this is an opportunity for workers to influence the system's design and content. The most prominent aspect addressed when involving workers at an early stage is that of choosing and determining the meaning of crucial concepts managed by the system. Crucial concepts managed by the system are the knowledge represented in the system, and by determining concepts, knowledge represented

Table 1. Summary of RAM (Ericsson & Avdic, 2003)

Perceived relevance—Workers, who are to use the system, have to perceive the system as:
- Adding value to work results
- Being integrated in running work

Systems accessibility—System accessibility is about:
- Knowing who the user is
- Systematizing actions workers perform in the work practice the system is to support
- Deciding the physical location where users get physical access to the system
- Securing usage of the system before it is put into operation
- The systems' design must meet up to the goals of the system

Management support—Fundamental because management authorizes development of systems

in the system takes on a systematized character. Further, by involving the workers in the process of choosing and determining the meaning of crucial concepts managed by the system, the knowledge represented in the system does not lose its origin or meaning. The point is to keep the knowledge represented in the system within a frame of understanding or meaning, as perceived by workers. A knowledge management systems should be seen as a tool developed to support workers in learning and acquiring knowledge about actions taking place at work. This requires closeness between how concepts are perceived by workers and how such concepts are represented in a system.

FUTURE TRENDS

Research on technology acceptance (i.e., Davis et al., 1989; Venkatesh & Davis, 2000) has focused on user behavior of computer technologies. RAM is developed for and is used to assess acceptance of knowledge management systems. Acceptance has not been a crucial issue within the knowledge management area. A problem with knowledge management systems is that they work in theory, but seldom in practice (Wickramasinghe, 2003). A contributing factor to that picture may very well be that of having overlooked usage-related problems connected to knowledge management systems. In that sense, knowledge management systems acceptance can be expected to be an area for further research in the future.

CONCLUSION

Acceptance of knowledge management systems is a function of perceived relevance, systems accessibility, and management support. Together these elements constitute our framework RAM. RAM is summarized in Table 1.

The Requirements of Acceptance Model point towards several important aspects concerning relevance, accessibility, and support. The groundwork for system acceptance is the development process. Development is very much a process of acceptance as a process of developing the system itself. Through requirements of acceptance, knowledge management systems can remain and continue to be a contributing factor for the organization's ability to do business.

KEY TERMS

Anthropocentric View of Knowledge: Knowledge resides in humans.

Information Systems Development: Constitutes analysis, design, construction, and implementation of information systems.

Knowledge: Knowledge is personal and talked about and may thus be public and shared among a group of people who have a common frame of reference, providing means for people to make sense of and apply knowledge in practice.

Knowledge Management: The name given to the set of systematic actions that an organization can take to obtain the greatest value from the knowledge available to it.

Knowledge Management Systems: Typically, directive systems developed to manage knowledge directly or indirectly to give support for an improved quality of a decision made in workers' daily work, and as an extension, an increased organizational ability.

Perceived Relevance: Workers who are to use the system perceive the system as adding value to the work results and being integrated in running work.

Systems Acceptance: A function of perceived relevance, systems accessibility, and management support.

Systems Accessibility/Development: Knowing who the user is, systematizing the actions workers perform in their work practice the system is to support, deciding the system's physical location, securing a certain degree of usage before the system is put into operation, and ensuring the system's design meets the goals of the system.

Technocratic View of Knowledge: Knowledge is an organized collection of data and information.

Knowledge Management Technology in Local Government

Meliha Handzic
Sarajevo School of Science and Technology, Sarajevo

Amila Lagumdzija
Sarajevo School of Science and Technology, Sarajevo

Amer Celjo
Sarajevo School of Science and Technology, Sarajevo

INTRODUCTION

Increased interaction, interdependency and volatility on a global scale are rapidly changing local governments' external environment, their community characteristics, and their organisational orientation. In circumstances of high uncertainty and ambiguity, the success of local governments depends to a greater extent on how well they utilise knowledge resources in adjusting to contextual changes. This requires special attention to knowledge management (KM). The major challenge for KM in local government is to foster the development of an enriched knowledge base that will enable local actors to better deal with adjustment and development issues of importance to their communities (Anttiroico, 2006). The purpose of this article is to address technical issues in organisational KM.

Referring to the theoretical work by Handzic (2004), the article considers the role of various information and communication technologies (ICT) in facilitating the processes in which knowledge is created, transferred and utilised in local governments. Findings reported in the article are part of an ongoing research project into the adoption of KM principles and practices in public sector organisations in Bosnia and Herzegovina (BiH). The role of ICT in local government KM solutions addressed in this article is only one of several aspects covered by the research project. Further project details can be obtained elsewhere (Handzic, Lagumdzija, & Celjo, 2007).

BACKGROUND

The spectrum of views on the role of ICT in KM ranges from those that see knowledge as a uniquely human concept and consider that KM has little to do with technology, to those that see knowledge as an object and therefore KM as being mostly about technology (Swan, 2003). The integrated approach advocated by Handzic (2004) bridges the artificial divide between two extreme perspectives by considering KM as a socio-technical phenomenon with both technology and people playing an important role.

Within the integrated framework, technology is placed among major influencing factors on knowledge processes. The functionalities of ICT are perceived as significant in shaping organisational efforts for knowledge creation, transfer and utilisation, and thus for organisational learning, improvement and innovation. In order to better understand and appreciate the importance of technology in KM, this section surveys some ICT-based KM initiatives deployed in firms and their roles in supporting knowledge processes.

The KM literature offers a number of useful classifications of ICT tools for KM based on their functions and techniques (Binney, 2001; Tsui, 2003). Most recently, Handzic and Zhou (2005) developed a typology of KM technologies that includes seven categories based on the distinction of KM processes they support. They include: knowledge storage, access, search/retrieval, sharing/delivery, discovery/visualisation, utilisation and platform technologies. These categories are used to frame the discussion about the applications of ICT in KM in this article.

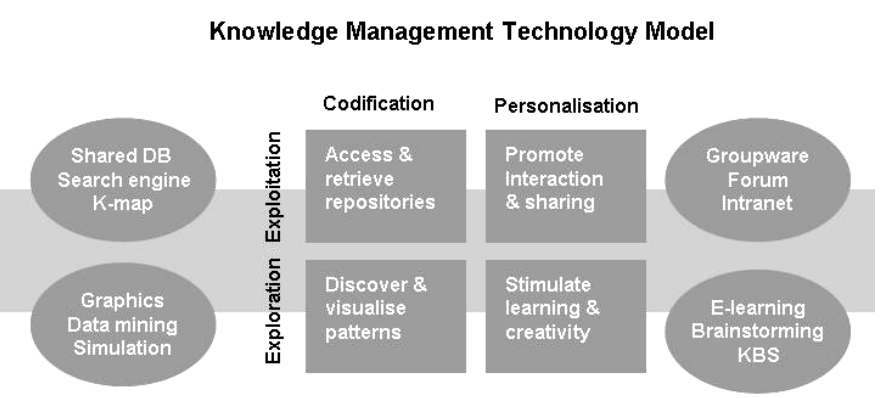
- *Knowledge storage technologies* cover databases, textbases, data warehouse, data marts and various multimedia systems used to capture and store organisational knowledge with the objective to enhance organisational memory and to provide broader access to knowledge resources (Alavi & Leidner, 2001). These technologies organise and make available knowledge in a variety of representational formats, and store current and retain historical and cross-functional aspects of knowledge.
- *Knowledge access technologies* such as knowledge maps, knowledge directories and yellow pages are tools used to improve access to knowledge stored in

knowledge repositories or facilitate knowledge transfer among individuals. These systems act as navigation aids that help knowledge seekers to quickly locate important explicit and tacit knowledge sources (Wexler, 2001).

- *Knowledge search/retrieval technologies* including search engines and intelligent agents are tools used to locate internal knowledge on intranets or external knowledge on the Internet, with the objective of increasing the speed and accuracy of knowledge search. These software programs enable access to unstructured information and can carry out search tasks with some degree of independence and autonomy (Tsui, 2003).
- *Knowledge sharing/delivery technologies* represent various applications that use ICT to facilitate peer-to-peer communication and knowledge sharing (Hansen, Nohria, & Tierney, 1999). E-mail systems, electronic bulletin boards, whiteboards, electronic forums, videoconferencing, voice mail, and groupware are some examples of such tools used to provide the right knowledge to the right person at the right time. Specialised groupware applications also offer support for collaborative processes.
- *Platform technologies* comprise net-based tools such as internet, intranets, extranets and portals that are used to provide connectivity and support knowledge sharing inside and outside the organisation. They are also commonly used by organisations to construct a single point of access to multiple sources of internal and external knowledge (Awad & Ghaziri, 2004). In general, they provide network platforms for knowledge collection, communication and analysis.
- *Knowledge discovery/visualisation technologies* describe applications that look for hidden patterns in data in order to discover and make visible previously unknown patterns (Fayyad, Piatetsky-Shapiro, & Smyth, 1996). Data mining, statistical tools, graphical representation and simulation technologies are technologies that use complex and sophisticated algorithms to extract and visualise new knowledge with a goal of supporting improvements and changes to the way knowledge is used, shared and transferred.
- *Knowledge utilisation technologies* such as knowledge-based systems, workflow systems, expert systems, rule induction and decision trees are tools used to enable knowledge workers to apply the best decision-making expertise and improve performance (Becerra-Fernandez, Gonzales, & Sabherwal, 2004). These systems harness technology by imbedding knowledge into work processes, with the objective of facilitating knowledge integration and application. They can also enable people to learn more easily through experience.

The classes of technologies illustrated above are not mutually exclusive. They can serve multiple purposes and can be combined in many ways to achieve synergic effects and tackle particular problems or support particular KM motives. The priority areas where technology can help organisations to deliver KM are summarised in Figure 1. These include support for "codification" (i.e., strategy focusing on explicit knowledge forms) or "personalisation" (i.e., strategy focusing on tacit knowledge forms) in processes of "exploitation" (i.e., knowledge use and sharing of the existing knowledge) or improving "exploration" (i.e., people's ability to discover and create new knowledge).

Figure 1. Theoretical KMT model



EMPIRICAL STUDY

Four inner-city and five outer-city municipal councils of Sarajevo were examined in this study as part of ongoing research into the current KM trends in local government in BiH. Inner-city municipalities have strong developmental orientation toward banking, finance, trade and consulting; boast pro-active universities and leading business partners; and have in common with other European cities a forward looking attitude and a high level of social capital (Anttiroico, 2006). In comparison, the outer-city areas suffer from having no university and being too dependent on domestically-oriented and labour-intensive industries. They are also sparsely populated areas with poorly resourced local administration. The initial study by Handzic et al. (2007) revealed differences in technical KM solutions among local councils. The intention of this study was to explore these differences more deeply. Results are presented in the following sections.

Types of ICT Used in KM

The results of the analysis presented in Table 1 indicate the extent of organisational usage of seven types of ICT in KM for nine local councils. The first four ICT types listed in the table are usually considered to have a more generic function, while the last three are seen as being more specific to knowledge management (Edwards & Shaw, 2004).

With respect to results by technology types, the form of ICT most widely used for knowledge management was storage technology, such as databases. This was identified as being in current extensive use (H) by all nine local councils. The second most common was sharing/delivery technology, such as e-mail systems mentioned as currently in extensive use by six local councils. Platform technologies were the other type of ICT mentioned as being in considerable use (H or M) for knowledge management in six councils. The other type of ICT being used considerably was search/retrieval technology, indicated by five councils. Three other classes of ICT were mentioned less frequently as being used significantly (H or M) for knowledge management. Access technologies received only four mentions and discovery/visualisation and utilisation technologies both received even fewer, with three mentions. These technologies were little (L) or not in current use at all (N).

The analysis of results by councils reveals that, at one end of the scale are two councils (4, 9) who already make considerable use of all seven types of ICT in their knowledge management solutions. At the other end of the scale are three councils (5, 6, 8) where technology was seen as only of marginal relevance to knowledge management. In these councils, only storage technologies were in significant use and all other technologies only marginally or not at all, as in council 8. In between these two extreme groups are four councils (1, 2, 3, 7) who make very significant use of four generic ICT (sharing and platform, in addition to storage and retrieval), but make use of only some or none of three KM specific ICT (access, discovery and utilisation). The one exception is council 3, where several generic ICT systems were in use, but not search/retrieval. Overall, the results indicate that the majority of councils foster the use

Table 1. Usage of ICT for KM

Local council	Storage technology	Sharing technology	Platform technology	Retrieval technology	Access technology	Discovery technology	Utilisation technology
C4	H	H	H	H	H	H	H
C9	H	H	H	H	H	H	H
C1	H	H	H	M	H	H	L
C7	H	H	H	H	H	L	L
C2	H	H	M	H	L	L	H
C3	H	H	H	L	L	L	L
C5	H	L	L	L	L	L	L
C6	H	L	L	L	L	L	L
C8	H	L	L	N	N	N	N

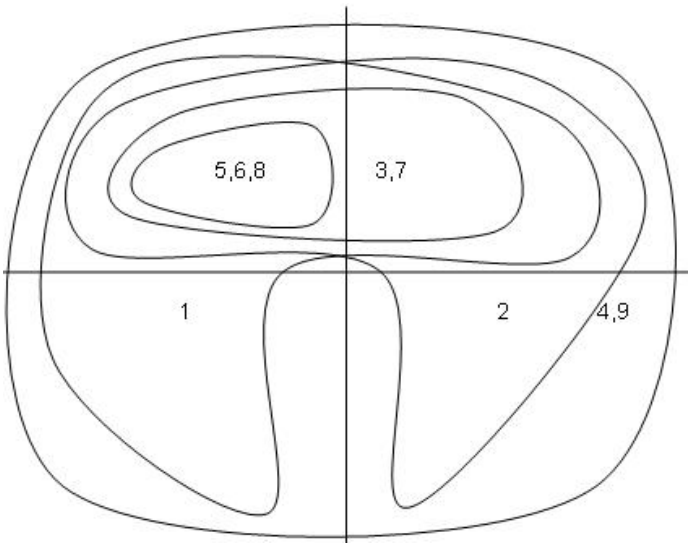
Figure 2. Empirical KMT model



of technologies that are generic rather than specific to KM (72% vs. 37% significant mentions).

Roles of ICT in KM

The results reported here focus on the roles played by ICT in supporting KM strategies of knowledge exploitation or exploration, codification or personalisation. For analysis purposes, the empirical KM technology model presented in Figure 2 was built from local councils' ICT usage data.

Looking at the nature of ICT support for councils' KM strategies, there is a clear emphasis on facilitating exploitation of existing knowledge. All nine councils (1-9) demonstrate extensive use of technology to make available institutional knowledge repositories and to link organisational members to share personal knowledge. With respect to exploration, only two councils (4, 9) appear to use full technology potential to support creation of new knowledge, one council (1) makes some use of technology to support knowledge discovery and one (2) to facilitate experiential learning through knowledge application.

Further comparison of different ICT usage roles in local councils' KM as reflected in Figure 2 reveals a slightly greater emphasis placed on supporting codification than personalisation KM strategies. All nine councils (1-9) show extensive use of generic storage ICT in creating and disseminating knowledge artefacts and documents. However, only six councils (1-4, 7, 9) show considerable use of generic sharing and platform technologies to link people for communication and collaboration purposes. KM specific technologies appear to play a much lesser role in supporting either KM strategy, with only four councils (1, 4, 7, 9) using technology to facilitate knowledge access, three (1, 4, 9) to support knowledge discovery from data, and three (2, 4, 9) for learning by doing through knowledge application to the task.

Stages of KM Development

Further analysis of findings presented in Figure 2 reveals that local councils examined are currently in different stages of KM development. Three councils (5, 6, 8) appear to be in the first stage, concentrating mainly on capture and storage of codified knowledge. Such KM approach is consistent with the goal of minimising risk of losing valuable knowledge. Four councils (1, 2, 3, 7) appear to be in the second stage of KM development. They focus on sharing of the existing knowledge in people (not just in stores) through interaction. This approach is consistent with the goal of improving performance efficiency and effectiveness. The remaining two councils (4, 9) focus on creating knowledge environment conducive to innovation by balancing exploitation and exploration, and employing both codification and personalisation strategies. This approach suggests that they are in the third and final stage of KM development.

In general, inner-city councils are at higher stages of KM development than outer-city councils. Three out of four inner-city councils are in stage 2 and one in stage 3. In comparison, three out of five outer-city councils are in stage 1, one in stage 2 and one in stage 3. These findings are largely consistent with their contextual circumstances. It is clear that the majority of local councils in this sample have some way to go in developing and implementing effective KM strategies. From the follow-up interviews with two

innovative councils' officials, it is evident that these inner and outer city councils recognise new opportunities for local development (media-city and eco-tourism, respectively) and transform themselves to respond to new challenges.

FUTURE TRENDS

The findings on ICT usage in KM show clear emphasis on basic storage and sharing technologies that include files/databases and e-mail/net systems. These findings match earlier findings by Zhou and Fink (2003) and Edwards and Shaw (2004), reporting general preference for commonly known generic IT systems over those specifically labeled as being for KM. Possible reasons for this focus on simple generic systems may be found in familiarity, convenience and obvious benefits of these systems. In contrast, sophisticated and complex intelligent systems might have been rejected due to their "black-box" effect. This suggests an interesting line of inquiry for future research.

In terms of order of preference, storage technology was mentioned most often as being extensively used followed by sharing/delivery and platform technologies. This order is different from the Zhou and Fink (2003) Australian survey where e-mail, intranet and the Internet were rated as most effective ICT for KM. The fact that KM specific technologies often recommended elsewhere (Zyngier, Burstein, & Rodriguez, 2003) were rarely mentioned in this study suggests that people might have been unaware of such technologies or lacking skills to implement them. Indeed, the frequent comment received by participants in this research project concerns obstacles to effective KM in terms of inadequate ICT literacy of public sector employees. Future research should look deeper into these obstacles.

The study also considered how various ICT systems favoured by different local councils supported their organisational KM strategies. The findings indicate a clear emphasis on exploiting existing knowledge through shared repositories and personal interaction. Such strategic orientation is consistent with the currently stated business goal for BiH government administration of improving efficiency and effectiveness of its public services (Handzic et al., 2007). It is also consistent with empirical evidence from Australia showing its local government concerns with the loss of knowledge and the deployment of mechanisms for the sharing and reuse of knowledge (Martin, 2000). The challenge is to move toward innovation.

Furthermore, the findings indicate that ICT played a relatively greater role in supporting codification than personalisation KM strategy. This is not surprising, as codification approaches rely heavily on ICT to provide high-quality, reliable and fast systems to enable preservation and reuse of explicit knowledge (Hansen et al., 1999). In comparison, personalisation approaches rely more on people and invest moderately in ICT to facilitate conversations and the exchange of their tacit knowledge. Despite this, Edwards and Shaw (2004) found that personalisation and sharing of knowledge were prominent in the UK organisations. In this sample, physical proximity may have contributed to the lesser need for computer-mediated communication among employees. The role of contextual factors in KM needs to be further investigated.

Finally, the current state of ICT use in local councils is indicative of different stages in the evolutionary KM development. The majority of councils are in the early development stages, stressing reuse economics and explicit knowledge forms. These can ensure survival but not advancement, as suggested by Von Krogh, Ichijo, and Nonaka (2000). In addition, it is important to note that ICT deployment cannot resolve all KM problems and warrant effective performance. There is also need for leadership support, learning culture and continued measurement and adjustment.

CONCLUSION

This study identified current trends in usage of ICT in KM initiatives in the local government of Sarajevo. From the survey responses received, it is apparent that there was a marked preference for the use of technologies that are generic rather than specific to KM; this finding reinforces earlier ones from the UK and Australia. However, there was greater emphasis on information than on communication elements of ICT, which is contrary to UK and Australian studies and deserves further investigation.

Looking at the nature of ICT support for KM, it is obvious that technology was used more to facilitate exploitation of existing than exploration of new knowledge. This is one area for potential action by practice to move toward creation and innovation. It is also true that technology was more valuable and convenient in supporting codification than personalisation. In addition, using the KM development model, the study found that local councils in this study fitted into the categories of risk minimisers, efficiency-seekers and innovators. This leaves a significant scope for further improvement in KM among the first two groups.

Finally, it is obvious that the findings of this study are limited by choice of BiH context, local government organisations, and by the participants' self-reporting their opinions. Therefore, further research is necessary to address current limitations and ensure that these findings have broad applicability.

ACKNOWLEDGMENT

Finally, please note that the submitted article/research was funded by the Ministry of Science and Education, Canton

Sarajevo and was completed by three co-authors while working for SSST during 2007. The principal investigator/project leader was Meliha Handzic and research assistants Amila Lagumdzija and Amer Celjo. A modified/extended version of the article has been accepted for publication by IJKM (IGI journal).

KEY TERMS

KM Development Model: a sequential evolutionary model of development in KM that includes three stages: retain knowledge to minimise risk, share knowledge to improve efficiency, and generate knowledge for innovation.

KM Strategies: codification (focuses on explicit knowledge) and personalisation (focuses on tacit knowledge).

KM Technology: any information or communication technology (ICT) used for the purpose of managing knowledge.

KM Technology Roles: support codification or personalisation strategies in processes of knowledge exploitation or exploration.

KM Technology Model: two-by-two matrix relating different types and roles of ICT in KM.

KM Technology Types: seven classes of ICT in KM based on the different knowledge processes they support (knowledge storage, access, search/retrieval, sharing/delivery, platform, discovery/visualisation, utilisation technologies).

Knowledge Management (KM): set of socio-technical initiatives and processes that move or modify knowledge stocks.

Knowledge Sharing Tools for IT Project Management

INTRODUCTION

Information technology (IT) project disasters make worldwide headlines, and billions of dollars have been lost due to poor project implementations. The Standish Group, a research advisory firm, reports that only one-third of the over 13,500 IT projects evaluated in 2003 were successful, and half of the reported IT projects were classified as challenged, meaning they experienced cost and budget overruns (Larkowski, 2003). While the state of IT project management is improving, organizations must explore ways to reduce unnecessary spending that occurs because of failures, cost and schedule overruns on IT projects. One possibility is to improve knowledge sharing to avoid repeating mistakes and to build on successes from the past.

BACKGROUND

IT project management is demanding because of time pressure, restricted capital, and high degrees of uncertainty during projects and is comprised of complicated and ill-structured problems (Grupe, Urwiler, Ramarapu, & Owrang, 1998). However, valuable knowledge gained before, during, and after the completion of projects is rarely captured, shared, and utilized in future projects. As a result, projects suffer from reinvention of solutions, repetition of mistakes, and loss of process knowledge after project completion. These problems are further exacerbated by the turnover of project managers and the lack of technologies that effectively integrate relevant knowledge with existing project management software (Tiwana & Ramesh, 2001).

Knowledge is a combination of experience, values, contextual information, and insight used to create, absorb, and evaluate new experiences and information (Davenport & Prusak, 2000). Project managers rely on past experiences to make decisions that keep the project within schedule, budget, functionality, and quality targets; however, these experiences are rarely shared among project managers (Schindler & Eppler, 2003). Furthermore, a problem faced by many IT project managers is their own lack of experience as an IT project manager. Individuals are often promoted to an IT project manager position because of their superior programming skills. However, these experiences alone are not enough to guarantee success as an IT project manager (Standish Group, 2001). Fortunately, a variety of knowledge sharing tools can help inexperienced project managers acquire relevant knowledge. Even for IT project managers with extensive knowledge, such tools provide good opportunities to learn from others when confronted with a unique problem (Newell, 2004).

TOOLS FOR SHARING KNOWLEDGE

Many tools have been developed to assist IT project managers in avoiding project failures, including post-mortem analysis, knowledge management systems, and networking. Rather than focusing on specific tools for sharing knowledge, this section describes generic classes of knowledge sharing tools available to IT project managers. Each tool is described in terms of *what* type of knowledge is shared (i.e., available in documented form or emergent through interaction), *who* is the primary user of the tool (i.e., project manager or entire project team), *where* knowledge is shared within the organization (i.e., between individuals or organization-wide), and *why* the tool is used for sharing knowledge (i.e., exploitation of existing knowledge or a basis for exploration of new knowledge).

Post-Mortem Analysis

Post-mortem analysis is supported by a process and a series of documents to identify successes and failures for a given project (Sinofsky & Thomke, 1999). Good post-mortem analyses not only record the history of the project itself,

but also provide information on what went wrong during specific phases of the project's life cycle (Thomke & Fujimoto, 2000). Often, organizations only conduct post-mortem analyses on projects that have been abandoned or have failed (Esusi-Mensah & Przasnyski, 1995); however, there are benefits to conducting post-mortem analyses on successful IT projects. Organizations that perform post-mortems state that the knowledge gained is useful in avoiding repetition of past mistakes, improving processes on future projects, providing historical accounts of what went wrong, and enhancing performance on future projects (Esusi-Mensah & Przasnyski, 1995).

The output of a post-mortem analysis is a series of documents. These documents can be shared across the entire project team as they articulate the aspects of a project that were successful and the areas needing further improvement. Although the results of post-mortems can benefit the entire project team, a survey of post-mortem analyses found that IS managers, system developers, and new IT project managers were more likely to consult these documents than other groups such as programmers, senior management, and other functional managers (Esusi-Mensah & Przasnyski, 1995). Post-mortem analyses are shared across the organization, frequently through the use of new processes or management practices. The knowledge gained through post-mortem analyses is exploited throughout the organization to minimize the repetition of problems, better plan or manage new projects, and guide the development of new management procedures (Esusi-Mensah & Przasnyski, 1995).

KNOWLEDGE MANAGEMENT SYSTEMS

Within the knowledge management literature, there are three types of systems to create and share knowledge: codified, personalized, and collaborative systems. While codified knowledge systems transform knowledge into documented form, a personalized system helps people interact to create and communicate knowledge (Hansen, Nohria, & Tierney, 1999). Codified knowledge systems are basically shared databases; personalized knowledge systems encourage interaction. Collaboration systems combine personalized and codified knowledge and focus both on supporting interaction among colleagues and providing a repository to share knowledge that emerges through the collaboration.

Codified knowledge systems store knowledge in databases where it can be accessed and used easily by anyone in the organization, making knowledge available to all members of a project team and across project teams (Hansen et al., 1999). As a result, all project team members, from developer to project manager, can benefit from the codified knowledge. The purpose of developing and maintaining a codified knowledge system and populating it with knowledge is to disseminate knowledge throughout the organization (Hansen et al., 1999). By investing in codified knowledge and a tool to effectively share the stored knowledge, organizations can exploit knowledge obtained and captured during prior IT projects on future projects.

Organizations use codified knowledge systems in an effort to prevent knowledge from leaving the company by relying on technology for the storage of knowledge. Because IT projects are vulnerable to personnel changes, codified knowledge systems are created to exploit knowledge from past projects. Because knowledge is documented and stored within a shared system, temporal and geographical differences between the knowledge-seeker and knowledge-holder are irrelevant. The primary problem with these knowledge sharing systems is that the knowledge captured and stored often goes unused. The reason is that IT project managers must acknowledge that there is a need to seek out additional knowledge and this knowledge must be clearly communicated across project teams (Newell, 2004). Successful utilization of codified knowledge systems requires individuals and teams to seek out available knowledge as part of their project management activities.

Personalized knowledge systems help those seeking knowledge find people who have the needed knowledge or who can help create that knowledge (Davenport & Prusak, 2000). These systems are useful when the necessary knowledge is not easily documented; therefore, brainstorming sessions or conversations between an expert and the knowledge seeker are needed to provide the necessary knowledge (Hansen et al., 1999). The complex nature of IT project management suggests that some problems are better suited to this interactive method of knowledge sharing. A key limitation to this approach is that knowledge does not remain behind to benefit others when experts leave the company (Hansen et al., 1999).

Personalized knowledge systems provide a map or listing of individuals in the organization who possess different types of knowledge (Davenport & Prusak, 2000). Knowledge sharing is based on personal interaction rather than on explication of the knowledge to be shared (Hansen et al., 1999). All members of a project team, including the IT project manager, developers, and others, are able to solicit advice from those with expertise in a given subject matter. The purpose of developing and maintaining a personalized knowledge system, or knowledge map, is to communicate expertise across the organization. Personalized knowledge systems are often used for brainstorming and addressing unique problems that arise during a project (Hansen et al., 1999), and the reason for adopting these systems is to create new knowledge through the combination of existing personal insights.

Collaboration systems enable groups of people to share information, communicate, coordinate, and work together as a team (Lamont, 2004). These systems enable team members that may be geographically dispersed to work and share knowledge within the team. Incorporating collaboration sys-

tems into standard project management practices has helped organizations to better organize and manage projects (Stevens, 2001). Collaboration systems also enable version control for project plans, provide access to relevant information to project team members, and create awareness of issues that could affect the execution of a project (Stevens, 2001). Collaboration systems focus on creating and sharing knowledge electronically rather than paper-based documentation. The primary benefits of collaboration systems are the ability to bring people together within a team to solve problems and make decisions quickly and effectively and to provide them with repositories through which they can effectively share the knowledge that emerges through the collaboration. The purpose of these systems is to create, make available, and explore new knowledge to solve a unique problem. Collaboration systems are capable of supporting all members and stakeholders of the IT project team by allowing team members to communicate and brainstorm with colleagues that have knowledge relevant to the project.

Networking

A more informal method of knowledge sharing is working with others. Because projects have a finite duration, team members are disbanded at the end of a project and often placed on new teams with different members. This swapping of team members either within or across projects can enable knowledge sharing (Newell, 2004). People can learn from one another through the sharing of experiences (Davenport & Prusak, 2000). In addition, the informal relationships built from expanding one's social network can be used to share knowledge among IT project managers more effectively than extensive knowledge repositories (Newell, 2004). Effective networking can be enabled through systematic assignment of individuals to specific projects and through mentoring and apprenticeship arrangements.

Networking is often informal as one person seeks out another for knowledge, insight, and advice. Knowledge is emergent as individuals share stories and discuss experiences through conversation. Networking can be useful to any member of a project team, including IT project managers and developers. While organizations may arrange mentor relationships, the resulting knowledge sharing is occurring among colleagues. In a project environment, which often contains team members with diverse backgrounds, organizations have an opportunity to develop novel and creative ideas (Bresnen, Edelman, Newell, Scarbrough, & Swan, 2003). Formal methods, such as mentoring and apprenticeship, provide structured learning opportunities for the protégé to reuse knowledge (Swap, Leonard, Shields, & Abrams, 2001). Informal networking methods, such as communities of practice, promote knowledge creation as an integral part of project practices.

Templates

Templates can be used in projects to facilitate repeatability and consistency (Dvorak, 2003). Because specific processes are often similar across projects, templates are effective means to ensure that details are not overlooked and deliverables are complete and consistent (Dvorak, 2003). Templates can be collected and stored in a repository together with selected examples of how the template has been used. A significant portion of time is spent on documenting a project through development plans, quality plans, test plans, requirements specifications, and design specifications. Using shared templates can make such knowledge readily available to new projects and improve process productivity and product reliability (Ben-Menachem & Gelbard, 2002).

With this method of knowledge sharing, knowledge is documented as a template for easy reuse. Templates can be used by project managers to standardize their processes and documentation (Method123, 2003) or by software developers and team members for specifying requirements, writing code, or documenting the system (Ben-Menachem & Gelbard, 2002). Templates help individuals, teams, and organizations move forward quickly while maintaining consistency across projects (Dvorak, 2003). Templates are typically created for organizational level usage and are promoted as company standards; however, in other cases, templates serve as suggested practices. Eventually the success of templates relies on individuals who adopt them to avoid creating documentation from scratch. Exemplar project plans or requirements documents can often be reused and adapted to meet the needs of current projects quite similar to how generic, standardized letters can be used to quickly generate a personal response to a customer.

Best Practices

There are several sources available to assist project managers in managing IT projects. The Project Management Institute has developed the *Project Management Body of Knowledge* (PMBOK), which is a book of standards that describes the sum of knowledge within the profession of project management (Project Management Institute, 2000). The purpose of these standards is to provide project managers with a series of best practices applicable to a variety of projects. A second popular project management source is PRINCE (PRojects IN Controlled Environments), originally developed in 1989 by the Central Computer and Telecommunications Agency in the United Kingdom. PRINCE is used to "guide the project through a controlled, well-managed, visible set of activities to achieve the desired result" (PRINCE2, 2004). Both the *Project Management Body of Knowledge* and PRINCE2 contain best practices to guide project managers through a successful project. These sources are based on lessons learned through successful and failed projects. While PMBOK is a

generic set of standard best practices applicable to any type of project, the original PRINCE methodology was created specifically for IT projects. The updated version, PRINCE2, is a more generic set of best practices that can be applied to any type of project.

Best practices, as presented in sources like PRINCE2 and PMBOK, represent documented knowledge that is available via training materials, books, and Web sites for distribution to those interested in leveraging the knowledge. Standard best practices are specifically designed to enable project managers to better execute projects (PRINCE2, 2004; Project Management Institute, 2000) and are typically promoted and shared within the entire profession and across each organization. Organizations may have their own best practices or methodologies that are used for all projects within the enterprise. Developing these can often be done successfully through a combination of standard best practices and local traditions for project management.

FUTURE TRENDS

While not all knowledge sharing tools discussed here require the use of IT to accomplish their objective, the evolving nature of technology can change how these systems will be used in the future. Many software vendors for project management systems and knowledge management systems are incorporating collaboration technology into the software (Stevens, 2001). This enables team members to work together to solve problems regardless of geographic location. This integration of collaboration capabilities into standard tools enable a more seamless sharing of ideas. Another emerging trend is that as organizations find more benefits from knowledge sharing across IT projects, new roles are created to facilitate the documentation of knowledge gained during a project and the sharing of knowledge across other projects within the organization (Schindler & Eppler, 2003). Furthermore, as organizations learn about the benefits of networking to share knowledge, there will be a need to create more opportunities for IT project managers within the organization to interact and build relationships with one another (Newell, 2004). This can be accomplished via knowledge fairs, talk rooms, or conferences (Davenport & Prusak, 2000) and such initiatives can help IT project members appreciate the knowledge available among their colleagues as well as identify tools to capture and share this knowledge (Newell, 2004).

CONCLUSION

Knowledge sharing tools, such as the ones described in this article, provide organizations with the ability to share valuable lessons learned across IT projects (Schindler & Eppler, 2003). Care must be taken, however, to remember that simply instituting a knowledge sharing tool does not in and of itself lead to increased project success (Davenport & Prusak, 2000). Organizations should consider *what* type of knowledge to be shared, *who* the users of the knowledge are, *where* in the organization sharing is expected to take place, and *why* the organization is adopting specific tools for enhanced sharing of knowledge. Organizations can use one or more of these tools to enable knowledge sharing across software projects. Doing so creates an opportunity to capitalize on past successes and avoid prior mistakes in IT project management.

KEY TERMS

Best Practices: Set of standards developed for specific activities to guide project managers in managing a successful project.

Codified Knowledge Systems: Documented and stored knowledge residing in a centralized database which serves as a repository of knowledge within the organization.

Collaboration Systems: Information systems used to enable colleagues to virtually meet to discuss, brainstorm ideas, and share the knowledge that emerge from their collaboration.

Knowledge: Combination of experience, values, contextual information, and insight used to create a framework to evaluate and absorb new experiences and information.

Knowledge Sharing: Knowledge that is communicated among people with similar job functions and backgrounds.

Networking: Social relationships that facilitate knowledge sharing through intense interaction, discussion, and sharing of practices and values.

Personalized Knowledge Systems: Knowledge map that enables people seeking knowledge to find people within the organization with the necessary knowledge and skills.

Project Management: Use of knowledge, skills, tools, and techniques to perform activities related to a temporary venture to develop a unique product or service according to stakeholder specifications.

Post-Mortem Analysis: Process to identify and document successes and failures for a given project.

Templates: Documents—such as project plans, budgets, or documentation—used on prior projects that are continually reused to maintain consistency across projects.

A Language/Action Based Approach to Information Modelling

Paul Johannesson
Stockholm University/Royal Institute of Technology, Sweden

INTRODUCTION

There are several different views of the role of information systems. Two of the most important are the data view and the communicative view. According to the data view, the primary purpose of an information system is to provide a model of a domain, thereby enabling people to obtain information about reality by studying the model. In this respect, an information system works as a repository of data that reflects the structure and behaviour of an enterprise, and the system provides data that can be used for decisions about the enterprise. In contrast, the communicative view states that the major role of an information system is to support communication within and between organisations by structuring and coordinating the actions performed by organisational agents. The system is seen as a medium through which people can perform social actions, such as stating facts, making promises, and giving orders.

The data and communicative views of information systems are mirrored by two different views of organisations: the functional view and the constructional view (Dietz, 2003a). The functional view focuses on the functions of an organisation with respect to its environment, in particular, the resources that the organisation consumes and produces. A model of an organisation from a functional perspective is a black-box model, as it shows the interactions with the environment but not the internal mechanisms. The constructional view, on the other hand, focuses on how behaviour and function are brought about by the operations and structure of an organisation. A model of an organisation from a constructional perspective is a white-box model as it shows the inner workings of the organisation.

In information systems design, the starting point has often been based on the data view and the functional view, though frequently augmented by concepts like reasoning and monitoring. However, these views easily lead to a computer- and technology-biased management of the communication taking place in an organisation, and they benefit from being complemented by the communicative and constructional views. A promising theoretical foundation for these views is the language/action approach, which is based on theories from linguistics and the philosophy of language. In the language/action approach, business actions are modelled on the notions of speech acts and discourses, which provide a basis for distinguishing between different communication phases, such as preparation, negotiation, and acceptance. The purpose of this chapter is to outline how the language/action approach can be used as a basis for the information modelling of communicative aspects in organisations.

BACKGROUND

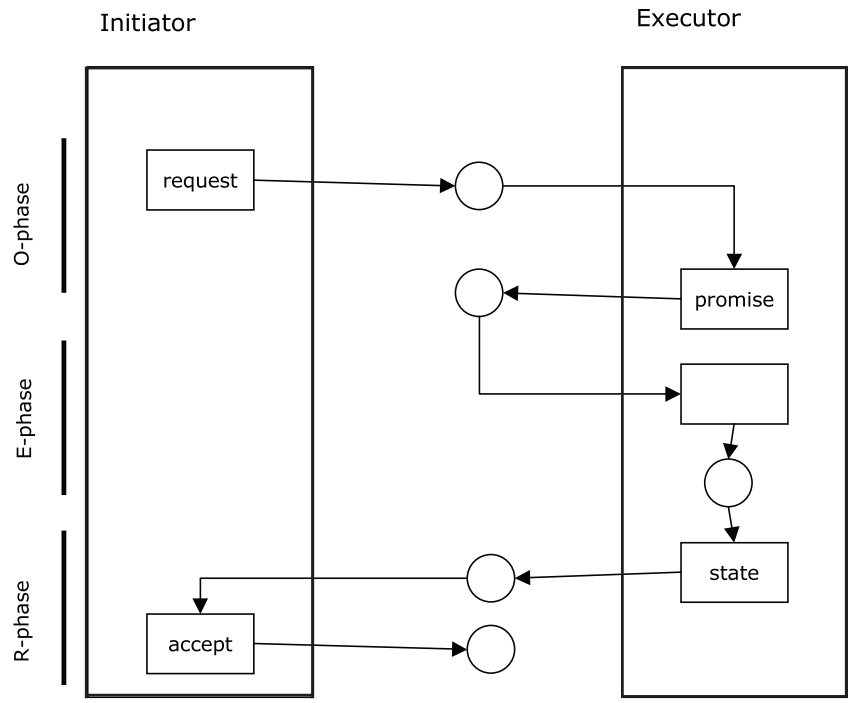
One important foundation of the language/action approach is speech act theory (Austin, 1962; Searle, 1969). The basic insight of speech act theory is that language can serve purposes other than that of representing the states of affairs of the world. Certain statements are equivalent to actions. For example, when someone says "I apologise," "I promise…," or "I name this ship…," the utterance changes the psychological or social reality. Statements such as these are called *speech acts*, and they enable people to use language as a means for acting as well as coordinating action.

In Searle (1969), a classification of speech acts is proposed based upon the way in which a speech act affects the social world. Searle identified five classes: assertive, commissive, directive, declarative, and expressive. An *assertive* is a speech act, the purpose of which is to convey information from a speaker to a hearer, e.g., "the cat is on the mat." A *commissive* is a speech act, the purpose of which is to commit the speaker to carry out some action or bring about some state of affairs, e.g., "I promise to bring it back." A *directive* is a speech act, where the speaker requests that the hearer carry out some action or bring about some state of affairs, e.g., "Please bring me the salt." A *declarative* is a speech act, where the speaker brings about some state of affairs by the mere performance of the speech act, e.g., "I hereby baptise you Samuel." An *expressive* is a speech act, the purpose of which is to express the speaker's attitude, e.g., "I like coffee."

In order to understand the role of speech acts, it is helpful to view human communication as taking place in three different worlds:

- The physical world—In this world, people carry out message actions. They utter sounds, wave their hands, send electronic messages, etc. Furthermore, other in-

Figure 1. OER pattern



strumental acts may take place in the physical world, such as repairing equipment.

- The communicative world—In this world, people express their intentions and feelings. They tell other people what they know and try to influence the behaviour of others through communication, i.e., they perform speech acts. These speech acts are brought about by means of message actions in the physical world. Note that a message action does not need to be verbal, as it can also be expressed by body language.
- The social world—In this world, people change the social and institutional relationships among them. For example, people become married or acquire possession of property. People perform such social actions by performing speech acts in the communicative world.

LANGUAGE/ACTION FOR BUSINESS PROCESS MANAGEMENT

The most important applications of the language/action approach have been made in the area of business process management (Lehtinen, 1986; Weigand, 2003). A language/action perspective provides a clear and well-founded basis for identifying and modelling recurring patterns in business processes. One such pattern is the order–execution–result (OER) pattern (Dietz, 2003b), which models a basic form of interaction that occurs in every business process (Figure 1). The interaction takes place between two parties—the initiator and the executor—and governs how they coordinate their actions. The interaction starts in the order phase by the initiator making a directive speech act, namely, a request to carry out some action (shown by a rectangle), which results in a state (shown by a circle in Figure 1), where there is an order from the initiator to the executor. The executor accepts the order by performing a commissive speech act (a rectangle labelled "promise" in Figure 1), resulting in a state where there is a commitment for the executor to carry out the action. This concludes the order phase, which is followed by the execution phase, where the executor actually performs the action (shown by an unlabelled rectangle in Figure 1) he or she is committed to. This action may be an instrumental action, e.g., delivering a package, or a declarative speech act, e.g., grading an exam. However, the execution phase is always concluded by a declarative speech act, where the executor states that he or she has carried out the committed action. The final phase is the result phase, where the initiator performs a declarative speech act and acknowledges that the executor has carried out the requested action in a satisfactory way.

The pattern introduced above shows the success path, where the initiator and executor agree to each other's actions. However, the pattern needs to be extended to handle cases where the parties do not agree, e.g., when the initiator does not accept the result of the execution phase. Larger business processes are typically built up by combinations of the OER pattern, e.g., when three or more parties are involved in a process or when reciprocal commitments are created in the process. The latter case occurs, for example, in e-commerce, as discussed in Lind (1997, 2003). Several variants of the OER pattern have been proposed in the literature, e.g., the conversation for basic action in Winograd (1986).

FUTURE TRENDS

The language action approach influenced another recent trend in the information systems community, agent-oriented information systems (AOIS Workshops, 2004). The language/action approach can be seen as one of the most active traditions within agent-oriented information systems. Agent concepts offer high-level abstractions addressing issues such as knowledge representation, communication, coordination, and cooperation among heterogeneous and autonomous parties. One precursor of agent-oriented information systems was the REA framework (McCarthy, 1982), which was designed for representing and reasoning about economic exchanges. The basic REA pattern models an exchange by three components: the *events* of the exchange, the *resources* that are exchanged, and the participating *agents*. In order to obtain a resource, an agent must give up some other resource. Therefore, an economic exchange always consists of two corresponding events, e.g., a purchase and a payment. Extended versions of the REA pattern also include commitments that are established, where a commitment is an obligation to perform a resource transfer some time in the future. These commitments are created through applications of the OER patterns.

One of the most comprehensive approaches to agent-oriented information systems is agent-object-relationship (AOR; Wagner, 2003), which is based on the notions of agents, events, actions, claims, and commitments. These notions form the basis for a general meta-model that can be used as a foundation for any information system. Another related work is that by Weigand et al. (1998), which proposes a layered architecture for information systems. At the lowest layer, we find the elementary acts—speech acts as well as instrumental acts. The next layer contains the business transactions. A business transaction is the smallest sequence of speech acts that results in a new deontic state, i.e., a state in which an obligation to carry out some action has been created, or a state where an authorisation for certain actions has been established, or a state where some action has been accomplished so that a previous obligation has become fulfilled. A single speech act is, in most cases, not sufficient to achieve a deontic effect. In general, at least two messages are required. For example, a customer requests that a supplier deliver a product, and the supplier promises to do so. These speech acts will result in two obligations: one for the supplier to deliver and one for the customer to pay upon delivery. The top layer is the workflow level, where a workflow is a set of linked business transactions that realise a business objective within an organisational structure.

CONCLUSION

The language/action approach to information modelling and systems provides a solid theoretical framework for analysing and designing communicative action in organisations. One foundation of the language/action approach is speech act theory, which investigates how language can be used to perform actions. The main application of the language/action approach has been in the area of business process design and management, where the approach can assist in creating complete and well-functioning processes. A recent trend is to apply the language/action approach for agent-oriented information systems, including applications to e-commerce and e-business (Bergholtz, 2003).

KEY TERMS

Business Process: This is comprised of business transactions that realise a business objective.

Business Transaction: This consists of speech acts that result in a deontic effect.

Deontic Effect: This is the establishment of an obligation or the fulfilment of an obligation.

Information System: This is a system for supporting communication within and between organisations.

Instrumental Act: This is an act performed in order to change the physical world.

OER Pattern: This is a basic pattern for business interaction based on order–execution–result phases.

Speech Act: This is a linguistic act performed with the intention of changing the social relationships between agents, in particular, creating deontic effects.

Leader–Facilitated Relationship Building in Virtual Teams

David J. Pauleen
Victoria University of Wellington, New Zealand

INTRODUCTION

How do virtual team leaders assess and respond to boundary crossing issues when building relationships with virtual team members? Virtual teams are a new phenomenon, defined as groups of people working on a common task or project from distributed locations using information and communications technology (ICT). With rapid advances in ICT allowing alternatives to face-to-face communication, virtual teams are playing an increasingly important role in organizations. Due to their global coverage, virtual teams are often assigned critical organizational tasks such as multinational product launches, negotiating global mergers and acquisitions, and managing strategic alliances (Maznevski & Chudoba, 2000). Their use, however, has outpaced the understanding of their unique dynamics and characteristics (Cramton & Webber, 2000).

Virtual team leadership remains one of the least understood and most poorly supported elements in virtual teams. Virtual team leaders are often the nexus of a virtual team, facilitating communications, establishing team processes, and taking responsibility for task completion (Duarte & Tennant-Snyder, 1999), and doing so across multiple boundaries. Recent research (Kayworth & Leidner, 2001-2002) has begun to look at virtual leadership issues and suggests that the trend toward virtual work groups necessitates further inquiry into the role and nature of virtual team leadership.

This article begins by briefly looking at the key concepts of virtual team leadership, relationship building and boundary crossing. Then, drawing upon the author's research, it examines the complexity inherent in building relationship across boundaries, and concludes with suggestions on how virtual team leaders can mediate this complexity.

BACKGROUND

Virtual Team Leadership

There has been extensive research on leadership in collocated teams and groups. Typically, leadership can be viewed in a number of ways, from a structured authoritative role to the ability of individuals to intrinsically or extrinsically motivate followers. It is generally agreed that leadership involves social influence and the use of communication activities in motivating teams to achieve goals. Barge proposes leadership as mediation in order to overcome the variety of task and relational problems that may be encountered by a group and explains that leadership "entails devising a system of helping the group get its work done, that is simultaneously stable and flexible and assists in managing the information shared among members and between the group and its external audience" (Barge, 1996, p. 319).

A key leadership skill in Barge's concept of leadership as mediation is that of relational management, which refers to the ability of leaders to "coordinate and construct interpersonal relations that allow an appropriate balance of cohesion, unity, and task motivation with a group" (Barge, 1996, p. 325). Cohesive teams tend to perform better and are more motivated to complete tasks. Of concern here is how team leaders can coordinate and construct interpersonal relations in a virtual environment to overcome the difficulty of multiple boundaries that do not exist in traditional collocated teams.

The Importance of Relationship Building in Virtual Teams

The link between team effectiveness and team member relationships is an important but underdeveloped area of study in virtual teams. Usually defined implicitly rather than explicitly, relationships develop over time through a negotiation process between those involved (Catell, 1948). While face-to-face meetings are the preferred way to build relationships and to deal with sensitive and complex situations, it is possible with the skillful and thoughtful application of virtual communication channels to effectively lead a completely virtual team. Research has found that computer-mediated teams do share relational information and are likely to develop relational links over time (Chidambaram, 1966; Warkentin, Sayeed & Hightower, 1997).

The role of the team leader is to move the team towards its objectives by encouraging collaboration. This is done through a sustained process of relationship building, idea generation, prioritisation and selection. The particular challenge to virtual team leaders is to manage this process through ICT. In virtual team research stronger relational links have been associated with higher task performance, more effective information exchange, enhanced creativity and motivation, increased

morale, and better decisions (Warkentin & Beranek, 1999; Warkentin et al., 1997). The building of relationships with virtual team members has been shown to be a fundamental concern of virtual team leaders (Pauleen, 2003-04).

Boundary Crossing in Virtual Teams

Boundary crossing is a defining characteristic of virtual teams. Contemporary organizations have highly permeable boundaries allowing substantial communication across boundaries (Manev & Sorenson, 2001). Boundary crossing is an important organizational activity that enhances the flow of information from the external environment. The role and activities of virtual teams leaders make them natural and strategic boundary crossers.

While traditional co-located teams may have members from different functions and cultures, sophisticated new synchronous and asynchronous ICT make it ever easier to form teams consisting of members from different functions, offices, organizations, countries and cultures. Furthermore, virtual teams must function across time and distance, often with team members having never met. These conditions present significant challenges to team leaders and members, team processes and ultimately team outcomes. Because virtual teams are still relatively new, outdated organizational HR and IT policies, which do not support virtual team performance, may be compounding the challenges (Jackson, 1999; Vickery, Clark & Carlson, 1999).

Boundary crossing in virtual teams can affect relationship-building efforts. Maznevski and Chudoba (2000) showed that deliberately addressing relationship building to develop shared views and trust across all types of boundaries could help virtual team performance. The more boundaries between leaders and team members at the start of a virtual team, the more likely higher levels of relationship with team members as well as more intensive relationship-building strategies will be needed.

MAIN THRUST OF THE CHAPTER

The Effects of Boundary Crossing on Relationship Building

The practical effect of working across distance means that teams can and do comprise members from different departments, head and branch offices, and organizations, as well as different countries and cultures. Indeed, access to different organizational, functional and cultural perspectives is a key reason for using virtual teams. These differences represent important conditions that team leaders will probably need to assess and accommodate before commencing a virtual team. According to team leaders, the development of personal relationships between themselves and team members is an important prerequisite in establishing and maintaining virtual working relationships across three conceptual boundary-crossing categories: (1) Organizational Boundary Crossing, (2) Cultural/Language Boundary Crossing and (3) Time/Distance Boundary Crossing (Pauleen, 2003-04). While organizational and cultural/language barriers exist in co-located teams, they are more likely to be found in virtual teams and to a have a more significant impact. Time and distance boundaries are unique to virtual teams.

Organizational Boundary Crossing

Organizational boundary crossing includes intra- and inter-organizational boundaries. Different functions, departments, and organizations may have diverse work cultures as manifested by deeply held core beliefs and assumptions (Kayworth & Leidner, 2000). Wiesenfeld, Raghuram and Garud (1998) suggested that organizational identification would be the psychological tie that binds virtual workers together into an organization, preventing workers from thinking of themselves as independent contractors, operating autonomously.

A strong organizational culture might influence the level of relationship building necessary in a team composed of members from within the same organization, even if they are located in different countries. Strong organizational cultures are exemplified by institution-based trust relationships (Nandhakumar, 1999; van der Smagt, 2000) and an anticipation of future association (Pauleen, 2003-04). The degree of relationship building necessary and the strategy for going about it are likely to be quite different when a team starts with a strong intra-organizational culture. Conversely, virtual teams with members from different organizations will need to be aware of and navigate the different organizational cultures.

Another aspect of organizational boundary crossing is the particular preferences of certain organizations for certain technologies, for example, communication channels such as e-mail or voice mail when leaving messages. Team leaders may experience difficulties trying to agree on common communication platforms with team members outside of the organization.

Cultural/Language Boundary Crossing

Cultural/language boundary crossing is another critical area. Cultural/language boundary crossing will most likely take place in global virtual teams, though it may also be a factor in national or even local virtual teams (Pauleen, 2003-04). The key point is whether a team leader is working with a team member from another nationality or ethnic culture. The effects of culture in team settings can be profound, and include, among other important issues, how individuals relate

to each other (Kayworth & Leidner, 2000). Misinterpretations or distortions may occur as team members and team leaders interpret communications through their own cultural programming (Lewis, 1996), a challenge that is greatly complicated when attempted through ICT. In all cases, team leaders need to assess the impact of cultural differences.

In some cases, there may be a strong cultural preference for the use of face-to-face communication to build relationships. Only after a certain level of comfort is attained can ICT be used with any effectiveness. This strategy supports Hall's (1976) theory of high and low context cultures, which states that for some cultures communication is more about context then the actual verbal message. In high-context cultures, messages have little meaning without an understanding of the surrounding context, which may include the backgrounds of the people involved, previous decisions, and the history of the relationship. People from low-context cultures prefer more objective and fact-based information. The message itself is sufficient.

Team leaders will need to consider the degree of personal relationship necessary to get the working relationship underway, as well as the use of appropriate communication channels along with appropriate messages delivered in an appropriate manner (Pauleen, 2003-04).

Time and Distance Boundary Crossing

Time and distance boundaries most obviously distinguish virtual teams from co-located teams. The effect of distance on relationship building strategies is proportional to how far the team leader and team members are from each other. The further away, the more difficult the use of face-to-face communication, which could be problematic in situations where face-to-face communication is the best or maybe only option.

The effect of time on relationship building strategies concerns the challenge of working across time zones. This may have little impact on the degree of relationship building that may be necessary, but a large effect on creating strategies to build relationships, as the time differences can restrict the kinds of ICT, particularly synchronous channels such as telephone and videoconferencing, available to the team leader. Probably not an issue that will make or break a virtual team of professionals, it is one of the conditions that must be carefully and fairly assessed by the team leader before creating relationship-building strategies.

If asynchronous communication channels are used, such as e-mail, the problem of pacing communication exchanges can become a serious consideration. Response times between team leaders and team members may differ, constraining communications, causing uncertainty and negatively impacting trust (Jarvenpaa & Leidner, 1999;Warkentin & Beranek, 1999). Time lags due to technical infrastructure and technological breakdowns, if not understood by the people involved, can cause the team leader or team member to attribute non-communication to lack of manners or conscientiousness, which can then seriously affect relationships (Cramton & Webber, 2000).

Problems associated with crossing time and distance have the potential to greatly disrupt relationship building in a virtual team, particularly with inexperienced team members. It is necessary for the team leader to carefully assess these potential obstacles before creating relationship-building strategies, as well as anticipate the problems that may be caused by time and distance.

Challenges and Solutions for Team Leaders and Organizations

This discussion points to significant differences in co-located and virtual teams in leadership-led relationship building across boundaries. The greater number and variety of boundaries and their deeper impact pose special challenges that virtual team leaders will need to mediate. Table 1 summarizes the key communication challenges faced by virtual team leaders. Two of these challenges are discussed. First the need for virtual team leaders to expand and hone their repertoire of skills in handling virtual communication channels and second, what organizations can do to improve their teams' virtual communication skills.

The strategic use of communication channels is one critical skill that virtual team leaders will need to hone. Table 2 illustrates ways in which virtual teams leaders need to mediate cultural/language boundaries by consciously selecting the most appropriate communication channels. Higher context cultures will tend to require media rich channels such as phone and video conferencing to build relationships, at least until the development of a sufficient level of trust. In contrast, lower context cultures, which are more task-oriented, will tend to be more tolerant of a wider range of communication channels. Indeed, being task-oriented, building relationships might be secondary to getting started on the task. Knowing the cultural composition of the team and team members' prior experiences working virtually and across boundaries in general are part of the complex web of factors that leaders need to determine and then mediate if they are to successfully build relationships with team members and ultimately complete team tasks.

The second challenge concerns organizational support structures to improve both virtual team leader and member skills. Organizations need to be willing to provide training and support to develop effective boundary crossing behaviors among virtual team members. Virtual team processes and dynamics are different from those of co-located teams and require special skills focusing on networking and establishing links across boundaries (Duarte & Tennant-Snyder, 1999). Team members, and particularly team leaders, will often need to play multiple roles as negotiators (with customers),

Table 1. Mediating complexity - Communication challenges when building relationships with virtual team members across boundaries (Pauleen & Rajasingham, 2004)

	Types of Boundaries Crossed		
	Organizational	**Cultural/Language**	**Time & Space**
Co-located Teams	Shared organizational culture supports relationship building, although functional culture can pose challenges.	Nonverbal cues can be understood by experienced leaders. Non-native speakers	The ability to regularly meet face-to-face supports relationship building across cultures of all types.
Virtual Teams	Differing organizational policies inhibit communication, as do organizational preferences for the use of different communication channels and ICT infrastructure. Lack of situational knowledge of team members can cause misunderstandings and mis-attribution, leading to potential difficulties.	Lack of nonverbal cues is difficult to overcome with most available communication channels. Cultural preferences for certain communication channels, often face-to-face (see Table 2 for more detailed analysis of the use of channels across cultures)	Building relationships across time and space requires concerted efforts and more time than in co-located contexts. Arranging synchronous meetings or even phone calls across time zones is often problematic. Asynchronous channels face the problem of pacing communications. Dealing with "silence" is a particularly difficult challenge.

Table 2. Mediating complexity - Guidelines for using communication channels to build relationships in virtual teams across cultural/language barriers (Pauleen & Rajasingham, 2004)

Preferred Communication Channels			
		Native Speakers	Non-native Speakers
High Context Cultures (relationship-oriented) (tend toward formality)	Media rich, Synchronous, Face-to-face, phone, video/audio	Media rich, Synchronous, asynchronous	Face-to-face with interpreter, Asynchronous written with editor
Low Context Cultures (task-oriented) (Tend toward informality with notable exceptions, e.g., Germans)	Flexible, as above, plus e-mail, fax, computer conferencing (online synchronous written chat, asynchronous discussion boards)	All channels – synchronous and asynchronous	All channels with translator, interpreter or editor as required

network and coalition builders (with other teams), lobbyists (with top management), and motivators (of team members). To be effective, team leaders will need training in boundary crossing, networking and relationship building skills (Yan & Louis, 1999).

FUTURE TRENDS

There has been a pressing need for rigorous conceptual and empirical work to examine factors that influence virtual teams (Pare & Dube, 1999), and it is only in the most recent literature that there have been systematic attempts to look at how virtual team leadership can support virtual team suc-

cess. This article has briefly looked at issues related to team leader-facilitated relationship building across boundaries. Its results suggest directions for future research and practice, including the development of virtual leadership mediation and communication skills.

Realizing effective leadership in group, team and multicultural interorganizational communications across diverse perspectives and global virtual environments presents new, real and compelling challenges to team leaders, but these challenges also present unparalleled opportunities for teams to explore new perspectives, approaches and ideas (Adler, 2002). Understanding these challenges and developing effective leadership and organizational processes to meet them presents opportunities for both practitioners and researchers.

CONCLUSION

Crossing organizational, cultural and time and distance boundaries requires training, experience and organizational support. These can help team leaders determine how to work across boundaries that may be present in their team. In addition to its effects on building relationships, boundary-crossing differences can affect team processes and performance in many ways. Ignoring them is an invitation to team failure. Leaders must learn to mediate the increased complexity inherent in virtual teams. A starting point for leaders is to approach the complexity introduced by boundary crossing by asking these two questions:

1) What are the boundary crossing influences of this situation?
2) How can they be understood and worked with so that a good people-oriented environment of assurance and trust can be maintained and productivity enhanced?

Perhaps the ultimate challenge for team leaders, particularly in long-term or on-going virtual teams, is to work to merge the individual cultures – functional, organizational, national, and so forth - of the team members into a team culture.

KEY TERMS

Asynchronous Communication Channels: Communication channels that support communication that usually requires a period of time to pass between communicative transactions. These channels include e-mail, discussion boards, fax, and so forth.

Boundary Crossing: Virtual teams are often characterized by their boundary spanning attributes; that is, they usually cross time and distance, and often include different national (ethnic), organizational and functional cultures.

Personal Relationships: The kind of relationship between people exemplified by shared understanding, mutual trust and social bonding. Communication in personal relationships is initially directed toward the exchange of personal information and later toward the sharing of mutual experiences.

Synchronous Communication Channels: Communication channels that allow real-time interaction. These include telephone, video conferencing, chat, and of course, face-to-face communication.

Virtual Team: A given number of people at distributed locations communicating and working to some degree via information and communication technologies on a set project or task, which may be of a limited or unlimited duration. Face-to-face meetings at the start-up of the team or at regular intervals are possible in a virtual team.

Virtual Team Leader: This is the person who functions as the hub of the team, holding it together. In the literature, this person may be termed a team facilitator, (virtual) project manager, coordinator or coach depending on the nuances of the role, the perspective of the researcher and organizational terminology. The team leader responsibilities may include all or some of the following: selecting team members; setting team tasks and team member roles; ensuring project or task completion; liaising with stakeholders and clients; establishing communication and team protocols, facilitating interpersonal and team communication, handling conflict, and managing technology and in general ensuring effective participation of all the team members.

Working Relationships: The kind of relationship exemplified by people who work together toward the completion of work-based tasks. It involves communication related to sharing information, coordinating tasks, meeting timelines, and so forth.

Leapfrogging an IT Sector

Eileen M. Trauth
The Pennsylvania State University, USA

INTRODUCTION

Accompanying the global spread of the post-industrial society (Bell, 1973) are nations who see economic opportunity deriving from the development of an information economy to support it (Porat, 1977). But while advanced industrialized nations moved gradually from industrial to post-industrial work over a period of decades, newly industrializing countries are "leapfrogging" directly from agrarian to information-intensive work in a matter of years. Given this rapid labor force transformation, a critical consideration in the development of a global information sector is the development and management of information technology (IT) workers.

Ireland is an appropriate country for examination of this leapfrog phenomenon because it was one of the earliest examples of this phenomenon, having developed its information sector rapidly and successfully through inward investment by multinational firms during the 1970s to the 1990s. Thus, this case offers the point of view of both an advanced industrialized or "first wave" country and of a "second wave" country that is taking an alternate path into the information economy by rapidly moving directly from an agrarian or partially-developed industrial economy into an information economy. Since Ireland was one of the earliest examples of "leapfrogging", the Irish case has lessons applicable to other contexts (Trauth, 2000).

BACKGROUND

Ireland's rapid transformation from a poor, agrarian society to a robust information society fueled by its information economy was the result of policy initiatives, cultural compatibility with IT work and adaptive responses to opportunities and crises. Ireland's policy of economic development through inward investment was a direct reversal of the preceding policy of cultural and political sovereignty achieved largely through economic isolationism. But a combination of high emigration and high unemployment signaled the need for change (Trauth, 2001).

The multinational firms brought direct benefits through the jobs that kept people in Ireland and away from unemployment, and indirect benefit through the foreign investment that would provide both jobs and a new business climate. These outside influences were expected to help Ireland more quickly develop an indigenous entrepreneurial capacity. The long-term benefits would be the spillover effects from the development of technical and business expertise.

Ireland provided attractive economic incentives in the forms of tax relief and grants for equipping their factories, and training the work forces. These were the necessary conditions for establishing the multinational IT sector in Ireland. But the sufficient conditions were a societal infrastructure supportive of IT work and a qualified labor force to do it. Today, Ireland's software industry has emerged as a strong contender for multinational sites, along with Israel, India (Heeks, 1996) and Eastern Europe (Heavin, Fitzgerald, & Trauth, 2003). Ireland's software sector employs 30,000 people in both indigenous and multinational operations and creates revenues in excess of Euro 10 billion (Flood et al., 2002).

The Irish case offers two important sets of human resource issues. The first set relates to ensuring a supply of appropriately qualified IT workers. The second set relates to managing IT workers in a cross-cultural environment. To the extent that Ireland's experiences are typical of other second wave countries, the lessons learned apply to indigenous and multinational managers as well as government policy makers in other counties.

ENSURING A SUPPLY OF QUALIFIED IT WORKERS

(Re)Designing Societal Structures to Support IT Work

Among the societal infrastructures that were adapted to support the emerging IT sector, the most important was the educational infrastructure (Clancy, 1988). Irish policy makers recognized that the well-educated Irish population was a powerful resource that could be leveraged to support the emerging information sector. But there were two serious issues to overcome. The first was establishing equality of access to education. This was accomplished in 1968 when secondary education became state-funded. The other issue was enabling potential IT workers to acquire the specialized skills and knowledge for work in this sector. In the 1960's, the traditional university was not oriented toward vocational education much less vocational education of a technical nature. Consequently, in the 1970's and 1980's, two new

universities were established and the existing universities were adapted to incorporate business and IT skills into their curricula. Technical colleges were also established. Evening, adult-oriented programs were established for workers to develop their skills and employment prospects. Finally, the government-sponsored IT training programs for those with university degrees or who had been made redundant in other fields (Trauth, 1993).

It was also necessary to maintain alignment between the particular skill sets being developed in the schools and training programs, and the available types of jobs. An unintended consequence of Ireland's educational success was that Irish IT workers became a desired human resource in other countries. In response, industrial policy assessments recommended a closer match between the educational plans of the universities and the employment opportunities available in the country (Industrial Policy Review Group, 1992).

Addressing Barriers to a Wider Participation in IT work

There were barriers to full participation in Ireland's IT sector with respect to age, gender and social class. The perception of IT as a young person's field was reinforced by the extremely young population of the country. This age divide was exacerbated by the prior educational policy limiting access to secondary and, therefore, higher education. Thus, in the early 1990's, those over the age of thirty-five, those who had not had access to free secondary education, were fewer in number in the IT labor force.

Another type of barrier relates to gender. While women found the IT sector better for women than traditional industries, banking and the civil service, there was still a tension between opportunity and restriction. IT was a new industry without established patterns of gendered work. However, there was also an acknowledged stereotype of IT work as a male activity and recognition by both men and women that women were not full participants in the IT sector. The reasons have been typically linked to a culture of large families in which child rearing was a woman's responsibility (Kvasny & Trauth, 2002; Trauth, 1995).

The final type of barrier relates to social class. Despite Ireland's historic disdain for rigid social class categories, there is evidence of social class barriers in the information sector. The absence of free secondary education was a barrier to poor and working class individuals. Further, in family settings without a history of or value placed upon education, there can be pressure on young people to enter the work force as soon as possible in order to add to the family income. Other evidence of attitudinal barriers, coming from members of the middle class, was the importance of having the "correct" accent and address in order to secure employment in indigenous IT firms.

Managing IT Workers in a Cross-Cultural Work Environment

The second set of issues relates to managing IT workers in a cross-cultural work environment in which the "first wave" nation's culture is embedded in the corporate culture of the multinational firm (Trauth, 1996). A firm's corporate culture " its values, management style, method of operations and work environment" reflects the national culture in which it developed. Thus, the multinational IT workplace was a cross-cultural mix of American and Irish cultures, the IT culture, and the particular corporate culture of the firm. While the Irish workers welcomed the American management style and corporate culture, there was also tension over how far – and in what direction – the cultural influence should go. Not surprisingly, the American managers favored the American culture, believing that the multinational firms ought to have a significant cultural impact. On the other hand, Irish human resource managers argued for tailoring the corporate culture to the particular national context. The viewpoint was that while the multinationals were bringing certain values and attitudes to the workplace, there was also a significant contribution to be made by the Irish culture. But along with resistance to the multinational influence was the recognition that importing another work culture was part of the plan. By bringing in multinational firms Ireland would be able to import a well-established work ethic that would have taken considerably longer to develop if done indigenously.

FUTURE TRENDS

Managing IT workers in a cross-cultural environment requires the acknowledgment that two different national cultures are involved when a multinational IT firm sets up operations in a country. Both of these cultures have positive contributions to offer the workplace. Multinational managers should strive to understand work patterns and attitudes of the host country culture that, while different, may nevertheless be productive. They should also understand that introducing a corporate culture means introducing a different national culture. At the same time, the host country must recognize that when the intent is to import expertise in order to quickly introduce an IT sector, one side effect will be the changes in national culture.

This has been referred to in the literature as *situating culture* (Weisinger & Salipante, 2000; Weisinger & Trauth, 2002, 2003). According to this theoretical framework, culture is a socially negotiated, dynamic, practical, and locally situated process. Hence, it is a view of culture as "doing" (which places emphasis on the actual behaviors of people) rather than "thinking" (which places emphasis on shared cognitive schemas). This view sees the interaction among the group

members' different cultures as being situated in a particular context. Thus, by situating culture in a particular context, a manager may be better able to comprehend the emergence of unique local cultural processes that reflect distinct socially negotiated realities and workplace practices.

By recognizing that there is more than one way to achieve a management goal, multinational managers can develop procedures and management approaches that exploit the best features of the host country. In the presence of two distinct cultures, it is also necessary to acknowledge that cultural influence goes in both directions. It is natural that the home culture of the multinational IT firm will influence the society it enters. But it is also natural that the workers will influence the corporate culture to make it compatible with their own. By building a permeable wall, by the open exchange of values and norms, both cultures can be enriched.

For example, American managers in Ireland learned that a human relations problem could be diffused by utilizing an Irish cultural institution: the pub. By meeting in a setting that, according to cultural norms, conveys equal standing, a manager could more easily work out the problem with the employee. Clearly, this management approach fits well with Irish culture but may not suit another cultural context. Likewise, what works best in Japan or in America may not be what works best in Ireland. Another example is the approach taken to knowledge management. Knowledge management refers to the capturing and recording of the tacit organizational knowledge that has built up over time and that resides within the employees of a firm. One of the main objectives of engaging in knowledge management is to improve the flow of organizational knowledge to facilitate organizational learning of new employees and cross-training. In Ireland, managers can address some aspects of this goal by leveraging certain cultural characteristics instead of investing in expensive equipment. The cultural characteristic of interest in others and sociability leads naturally to employees knowing more about their colleague's work than might be the case in another culture that places less emphasis on sociability (Trauth, 2000). Hence, cross-training is a natural outcome of this interaction. Simply, by recognizing that this is occurring, management can reap knowledge transfer benefits.

CONCLUSION

The case of Ireland represents an early example of the issues associated with what is currently recognized as a trend toward global outsourcing. Because it was a leader in positioning itself as a destination for global outsourcing, Ireland's experiences offer insights for both nations and multinational companies interested in outsourcing. One insight is that a qualified labor force must be available. Because of the specialized skills required for employment in the information sector, education is the key to attracting outsourcing. But in order to ensure that all citizens are able to participate in this employment sector, there must be equal educational opportunity. In Ireland, and elsewhere, members of certain groups experience barriers that inhibit full and equal participation in the information economy. In order to ensure that the society can sustain its IT sector, the educational infrastructure needs to be aligned with the skills and knowledge required for IT work, and the educational plans of the universities should be coordinated with the employment objectives of the firms. Finally, management consideration needs to be given to the mix of cultures that is present when a multinational firm from one country sets up operations in another. In this new cultural context, both cultures come together to produce a new, *situated* culture. The public policy, human resource and management issues that are raised in this case reveal some of the issues that must be addressed as more and more countries "leapfrog" an IT sector in order to reap the benefits of global outsourcing. These issues must be considered from two perspectives: that of the firms engaged in outsourcing, and that of countries inviting firms to its shores.

KEY TERMS

Cross Cultural IT Management: Managing the IT function and its personnel in a globally distributed setting.

Global Outsourcing: The trend towards directing outsourcing—contracting with other firms to perform non-critical functions for a business—toward countries with low workforce costs.

Information Economy: That portion of the national economy that is based upon information processing and related activities (Porat, 1977).

Information Sector: A component of the information economy. The *primary information sector* includes those who develop hardware, software and information systems. The *secondary information sector* includes those engaged in information processing activities in the course of doing work related to some other primary activity such as insurance claims processing.

Information Society: A societal transformation in which information is the key resource.

Information Technology (IT) Worker: One who works in the primary or secondary information sector.

Post-Industrial Society: A society in which knowledge replaces capital as the key economic resource and the predominant type of work is in the service sector (Bell, 1973).

Learnability

Philip Duchastel
Information Design Atelier, Canada

INTRODUCTION

Learnability is not exactly a new concept in information technology, nor in cognitive science. Learnability has been a key concept of usability (Folmer & Bosch, 2004) in the area of software system design, where it relates to such issues as consistency, familiarity and simplicity. It has also been a traditional concept in linguistics in relation to the ease of language learning (McCarthy, 2001) and in machine learning (Valiant, 2000).

The concept of learnability has recently been repurposed within the field of instructional technology (Duchastel, 2003), building on the concept of usability in Web site design (Nielsen, 2000), and it is that learnability that is considered here. Learnability in this new sense concerns how learnable some piece of instruction is. It deals with a facet of educational resources.

The basic question is this: What makes the content of an instructional site (or of some resource) learnable? Take any one of the many thousands of online learning courses currently available on the Web and ask yourself: Does this course seem difficult to learn (assuming you have the proper background for it)? What would improve it? What would the ideal online course in this area look like? These questions all underlie the learnability of the course.

What then is learnability? Could we say that it is defined by successful learning? That would mean that students who study the course thoroughly learn its content, as evidenced on a good test for instance. Or could we say that a main criterion is ease of learning? Meaning that students experience good intellectual flow and enjoy the course.

Both of these factors, success in learning and enjoyment of learning, can be considered criteria of learnability. Are there others? That is the issue of learnability.

The skeptic will immediately insist that learning takes place within a learner and that it is that locus that mainly determines learnability – that is, the curiosity, intelligence, motivation and persistence of the learner. These are what make or break learning. The teaching materials can only go so far, the learner has to make a go of it, make it succeed.

While there is some truth to that view, it is certainly not the full picture, nor the most useful picture. Consider traditional usability in Web sites or software products. There too, the user plays a role. If he is dull-witted, or perhaps too pressed for time (showing a lack of interest), or just resistant to learning the basics (jumping in and thrashing around – as often happens), there is little scope for success no matter how usable the site or program may have been made. But we do not give up on usability in Web site creation because of that.

The point is designers do not blame the user for incompetence, for ill-will or for the lack of success of their site or program. They maximize usability, realizing well enough that usability is certainly contextual. The same applies, as it should, to learnability: success in learning can be maximized through the product, over and beyond context issues, or in spite of them.

The product view of instruction is an important one, one that is emphasized here. An alternate view, much more widespread, is a process one: learning is a process, and so is instruction in the sense of manipulating the situation so as to facilitate learning. This is why the immense amount of research on learning and education over the past century has not dealt explicitly with learnability.

The process view is not to be denigrated, but a product view can incorporate processes and has definite design advantages. Learnability is best considered in this light.

LEADING QUESTIONS

The challenge before us is to identify those features of excellent learning materials. What makes something learnable? Very learnable, most learnable?

But first, why is it so difficult to pinpoint these features? What are the deep issues underlying learnability? There are three of them we need to consider. They are learning, design, and curriculum. Each is difficult in its own right and learnability involves considering them jointly – hence the magnitude of the challenge.

The first deep question is what is learning? The field of learning has long been a core issue in psychology and numerous theories of learning have been put forth in answer (Kearsley, 2004). The issue is far from settled, as practitioners such as educators well know. There is acknowledgment of different kinds of learning, with different factors at play, but no large agreement on these or on the overall picture.

The second deep question concerns teaching. How do you design for learning? There are general principles that have evolved over time, codified broadly in what is known as the field of instructional design (Reigeluth, 1999). But

here too, there is hardly agreement. All design theorists will subscribe to general systems principles like those found in software design or in HCI. All subscribe to the value of usability testing, the trying out of the materials designed with sample students in order to verify the strength of the design and capture any ways of improvement. But given divergences in views of learning, it is natural that hard disagreements will occur here too, in how to design for learning.

The third deep question concerns what to teach - the content. That was what led educators to determine and discuss taxonomies of learning objectives half a century ago (Bloom, 1956) and why this issue remains at the heart of much debate in education (Egan, 1997).

At first thought, you might think that this is an outside issue. That first, we decide what to teach, then only after that, how to teach it, how to design it. Or we might think that teachers and curriculum specialists, or professors and institutions, determine the content "to be covered". That learnability applies to any content, whatever it is determined it should be. But that overlooks the crucial notion that the *what* and the *how* of learning are inextricably linked (Carroll, 1990), just as in communication more generally. An instructional designer must fashion the content as much as the process, in the same way an information designer fashions information well beyond the graphic design aspect. Both are information architects, but that is not yet widely recognized, which creates difficulties for the acceptance of learnability.

In the next sections, I will address these leading questions by introducing some simple models that synthesize them in a nutshell. This remains a very cursory look at the issues, but nevertheless shows the direction in which they can be further explored, as is done in Duchastel (2003).

LEARNING - THE CIM MODEL

At its most general, learning is the process of internalizing information in memory, making that information available later on when needed. But learning the names of the bones in the body and learning the principles of acoustics are rather different forms of learning. We learn them in different ways. What are the commonalties? What are the differences?

There are three types of learning, conveniently contrasted in what we can call the CIM model. CIM stands for Comprehension, Interest, Memorizing, these being the three factors involved in the learning process.

Comprehension is based on our ability to reason, to fit things together, to see how they all work together. Comprehension is the process of generating internal models of the world in all its workings, large and small. We comprehend when we see how things fit together, how it all makes sense. Understanding is a process of rational model building.

Interest, the second element in CIM, is the attentional factor in learning. If something stands out from its context, it will be more easily remembered, as will things that are extremely vivid or of great personal importance. More often, we try to learn things that are only of mild interest and then, if attention wanders, learning suffers. Interest has the function of keeping us on task.

The third element, memorizing, handles things that do not fit well together, that have no basis in rationality. For instance, the name "cochlea" to represent one of the components of the ear is quite arbitrary to us – there is no reason for it [no reason that we know]. It is [to us] purely arbitrary and no amount of reasoning will assist in "understanding" it. We just have to associate the name and the component.

DESIGN - THE MOCAF MODEL

Based on the CIM model, we can see that there will be three types of elements that are needed within an instructional product: models, cases and facts. Combining these (and any product would have all three) leads to the acronym MoCaF for the design model appropriate for the creation of highly learnable instructional products.

Models are the tools of understanding; they are what lead to comprehension. Cases are the illustrative materials that instantiate the models in particular settings. They are the main means of grabbing and holding attention. As for facts, they are just the basics that need to be brutely memorized.

Models are what drive comprehension. The aim of design in this area is to create models that embody the disparate elements of content while synthesizing them in an artifact [the model] that clearly communicates and is easily learned. Models show how elements relate to one another; they capture relationships and interactions.

The craft of developing models is one of establishing the underlying structures in a field [content expertise is essential here] and of then representing those structures in synthetic form that facilitate communication and understanding (Wurman, 2000).

Cases are the illustrative material in instructional content. They embody the living problems and the living application of the models. They range from simple examples to complex case studies. Of particular interest are those relatively complex cases that mirror difficult real-life settings, such as those used in problem-based medical education or in business education.

Cases are multi-functional in an instructional application. At least three functions can be served:

1. To illustrate the content of a model, instantiating it and situating it in real life.
2. To provide practice to the student in applying knowledge.

3. To test the student's knowledge (either self-testing for monitoring purposes or formal testing for assessment and validation purposes).

Facts are those ill-fitting elements of knowledge that are considered important to know and that hang out there on their own, only incidentally attached to some model or other.

Facts are simple to state, for instance in a textbook or in a presentation. But that does not ensure they will be learned. While simple to state, facts are hard to enrobe in a context that will make them easily learnable. Practice or an eventful context is needed. There are means to accomplish this in instructional terms, such as through games, problems, contests, high-impact media, and so forth. Often, though, when these are not developed, the student is left pretty much to his or her own devices for rehearsing the facts to be learned. This is not an optimal situation.

Learning involves interacting with information. And so it is the design of that information that is crucial to learnability. We are dealing here with the content of the instructional product, that content being modeled through design into a certain form that makes it understandable, interesting and memorizable.

Models, cases, facts are all basically information content of particular sorts, information with which the learner will interact during learning. To a very large extent, then, instructional design is mostly a matter of information design, a notion that needs to become widely recognized. Even the more recent notion of interaction design [often applied to Web site design or to exhibition design] is largely a matter of information design involving models (structures), cases (events), and facts (impressions). In sum, learnability must focus primarily on the content to be included in an instructional product, that is, on information design. That is the key contribution of the learnability approach to design and its central usefulness in the practical design of knowledge artifacts.

FUTURE TRENDS

Perhaps the greatest trend emerging in the future with respect to learnability will be the continuing merging of instructional design into information design. As access to information becomes more ready, we will likely see a reduction of our need to memorize arbitrary information beyond the frequently used or crucial to know kind. Our external memory supports will fill the need for the less needed information.

This merging of the two traditionally distinct design worlds (information and instruction) is particularly informative for the learner-control issue in education. Adult learners like to have more control (or like to think they do) over what they learn, how they learn it and when they learn. They operate more in an access mode than in a traditionally receptive educational mode.

Well-designed information/instruction products will facilitate this approach, being used at times for informational purposes and at other times for instructional purposes. Informal learning (outside of academic structures) and formal instruction both involve learning, both involve interacting with information, both profit from good information design.

The design of e-learning materials also might offer more means of controlling interaction than does for instance the design of textbook or other printed materials. This may or may not be an advantage, depending on a whole host of factors, such as maturity of the learners, prior knowledge of the learners and other context factors. But it does raise once again the general issue of content vs. process.

This philosophical issue remains a challenging one, as well as a thorn in any attempt to devise an overarching theory of learning and instruction. One facet of this issue, and I will conclude with it, is why we speak of the learnability of instructional products. After all, we learn also a great deal from interacting with the world at large, not just with artifacts.

The way to come to grips with this issue is to adopt a wide conception of information, as does the field of semiotics. Information goes far beyond the written word, and beyond the world of illustration too. Information is structure that lies within the world around us, both in its structural elements and its processes (Duchastel, 2002). Some of these are found elements, others are designed artifacts, ones the design of which we can control. This is where we can affect the learnability of a product or of a structured process.

KEY TERMS

Information Design: A similar soft technology applied to information more broadly for the purpose of successful access to information.

Instructional Design: The soft technology of organizing learning materials and events so that instruction will be most successful.

Interaction Design: A similar soft technology focusing on the processes of interacting with information, particularly in high-impact or strongly emotive contexts.

Learning: The processes used by organisms, including humans, to augment their knowledge base or their skill set for the purposes of better adaptation to their milieu.

Machine Learning: The processes used to fine-tune a program's performance or to augment its knowledge and functionality.

Online Course: A Web-based instructional program that organizes the learning of a student in a particular subject. Not all learning materials need be online and much of an online course involves dynamic interactions with other participants.

Usability: The ease with which a user can accomplish a desired task within a Web site. One also talks of a site being user-friendly.

Learning Systems Engineering

Valentina Plekhanova
School of Computing and Technology, University of Sunderland, UK

INTRODUCTION

This chapter presents a project proposal, which defines future work in engineering the learning systems. This proposal outlines a number of directions in the fields of systems engineering, machine learning, knowledge engineering, and profile theory, that lead to the development of formal methods for the modeling and engineering of learning systems. This chapter describes a framework for formalisation and engineering the cognitive processes, which is based on applications of computational methods. The proposed work studies cognitive processes, and considers a cognitive system as a multi-agents system of human-cognitive agents. It is important to note that this framework can be applied to different types of learning systems, and there are various techniques from different theories (e.g., system theory, quantum theory, neural networks) can be used for the description of cognitive systems, which in turn can be represented by different types of cognitive agents.

BACKGROUND

Traditionally multi-agent learning is considered as the intersection of two subfields of artificial intelligence: multi-agent systems and machine learning. Conventional machine learning involves a single agent that is trying to maximize some utility function without any awareness of existence of other agents in the environment (Mitchell, 1997). Meanwhile, multi-agent systems consider mechanisms for the interaction of autonomous agents. Learning system is defined as a system where an agent learns to interact with other agents (e.g., Clouse, 1996; Crites & Barto, 1998; Parsons, Wooldridge & Amgoud, 2003). There are two problems that agents need to overcome in order to interact with each other to reach their individual or shared goals: since agents can be available/unavailable (i.e., they might appear and/or disappear at any time), they must be able to find each other, and they must be able to interact (Jennings, Sycara & Wooldridge, 1998).

Contemporary approaches to the modeling of learning systems in a multi-agent setting do not analyze nature of learning/cognitive tasks and quality of agents' resources that have impact on the formation of multi-agent system and its learning performance. It is recognized that in most cognitively driven tasks, consideration of agents' resource quality and their management may provide considerable improvement of performance process. However, most existing process models and conventional resource management approaches do not consider cognitive processes and agents' resource quality (e.g., Norman, Preece, Chalmers, Jennings, Luck & Dang, 2003). Instead they overemphasize the technical components, resource existence/availability problems. For this reason, their practical utilisation is restricted to those applications where agents' resources are not a critical variable. Formal representation and incorporation of cognitive processes in modeling frameworks is seen as very challenging for systems engineering research.

Therefore, future work in engineering the learning processes in cognitive system is considered with an emphasis on cognitive processes and knowledge/skills of cognitive agents as a resource in performance processes. There are many issues that need new and further research in engineering cognitive processes in learning system. New/novel directions in the fields of systems engineering, machine learning, knowledge engineering, and mathematical theories should be outlined to lead to the development of formal methods for the modeling and engineering of learning systems. This article describes a framework for formalisation and engineering the cognitive processes, which is based on applications of computational methods. The proposed work studies cognitive processes, and considers a cognitive system as a multi-agents system.

This project brings together work in systems engineering, knowledge engineering and machine learning for modelling cognitive systems and cognitive processes. A synthesis of formal methods and heuristic approaches to engineering tasks is used for the evaluation, comparison, analysis, evolution, and improvement of cognitive processes.

In order to define learning processes, cognitive processes are engineered via a study of knowledge capabilities of cognitive systems. We are not interested in chaotic activities and interactions between cognitive agents (since cognitive tasks require self-managing activities/work), nor interested in detailed tasks descriptions, detailed steps of tasks performance and internal pathways of thoughts. Rather, we are interested in how available knowledge/skills of cognitive agents satisfy required knowledge/skills for the performance of the cognitive tasks.

The proposed research addresses the problem of cognitive system formation with respect to the given cognitive tasks and considers the cognitive agent's capabilities and compatibilities factors as critical variables, because these factors have an impact on the formation of cognitive systems,

the quality of performance processes and applications of different learning methods.

It is recognised that different initial knowledge capabilities of the cognitive system define different performance and require different hybrid learning methods. This work studies how cognitive agents utilise their knowledge for learning the cognitive tasks. Learning methods lead the cognitive agent to the solution of cognitive tasks. The proposed research considers a learning method as a guide to the successful performance. That is, initial knowledge capabilities of cognitive agents are correlated with learning methods that define cognitive processes. An analysis of impact of different cognitive processes on the performance of cognitive agents is provided.

This work ensures support for a solution to resource-based problems in knowledge integration and scheduling of cognitive processes to form a capable cognitive system for learning the required tasks.

AIMS AND OBJECTIVES

The aims of the project are to develop a formal method for the modelling and engineering of cognitive processes. Capability and compatibility factors have an impact on the formation of cognitive systems, the performance processes and define different learning methods. Therefore this work studies cognitive processes and knowledge capabilities of cognitive systems to ensure the required level of the learning and performance of the cognitive systems. In order to support the formation of a cognitive system that will be capable of learning the required tasks within the given constrains, this work addresses problems of the knowledge integration and scheduling for cognitive system modeling, taking into account critical capability and compatibility factors. Study of learning conditions in cognitive systems defines an important task of the proposed project.

The individual measurable objectives are:

- Evaluation of knowledge integration and scheduling approaches in cognitive systems.
- Evaluation of existing machine learning approaches in cognitive systems.
- Determination of the impact of capability and compatibility factors on the formation of cognitive systems.
- Development of knowledge integration metrics.
- Development of knowledge integration models for the formation of the cognitive systems.
- Development of scheduling models for learning of cognitive systems.

METHODOLOGY AND JUSTIFICATION

In order to identify the best learning processes we analyze the cognitive processes. A scenario for engineering the cognitive processes is based on the following steps (Figure 1).

The methodology of the proposed project is based on the following new theoretical basis (Plekhanova, 2003).

Profile Theory and Machine Learning: For formal modeling of complex systems we utilise the profile theory (Plekhanova, 1999a). A profile is considered as a method for describing and registering multifaceted properties of objects. There are important practical applications of the profile theory (Plekhanova, 2000a, 2000b). For instance, internal properties of the system elements such as capability and compatibility factors are critical variables in modeling, design, integration, development, and management of most

Figure 1. A scenario for engineering the cognitive processes

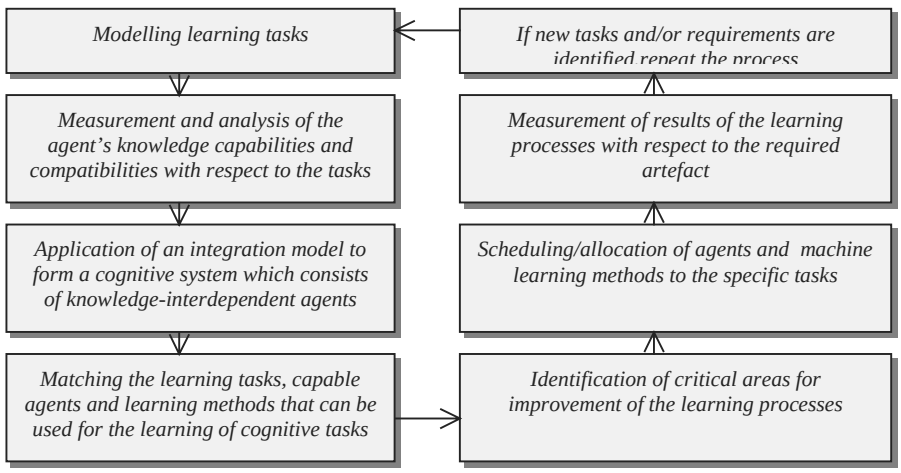

Table 1. A comparison of capability and compatibility problems

Technical Systems	Soft Systems
In *technical systems* the internal characteristics of technical elements are described in specifications, standards and formal documents [i.e. are known a-priori] from which it is not difficult to conclude whether combinations of elements are capable and compatible or not and whether they can be used for technical system design, development and construction. Each capability and compatibility factor can be represented by *one characteristic*.	There are a number of real world examples when an object factor cannot be described by just one characteristic. For example, systems such as human resources, software, information systems, cognitive agents, where the internal *multifaceted* properties can be changed with time, and capability and compatibility factors cannot be defined by one characteristic alone, and cannot be explicitly measured. These systems are termed *soft systems*. At the present time there are problems in the formal definition of specifications/standards and metrics that allow one to determine the capability and compatibility of such complex systems. For this reason, heuristic approaches are used for soft complex system modelling.

modern complex systems and their structure. Table 1 provides a comparison of capability and compatibility problems of technical and soft systems.

Profile theory is used for formal modeling of cognitive agents/systems since existing mathematical theories are limited. In particular, contemporary mathematical theories describe objects, where each internal factor is represented by one meaningful piece (e.g., set theory—an element) or two pieces of meaningful information (e.g., fuzzy set theory—an element and a membership function).

Knowledge factors are considered as basic internal factors in the modeling of cognitive agents, since agents must have particular knowledge capabilities to perform and learn their tasks. In a description of the knowledge of cognitive agents we identify the importance/weight of the factor for the performance of the task; time or factor existence/nonexistence; and other specific internal multifaceted properties, for example the property (level, grade, degree) of the factor.

In particular, knowledge of the cognitive agent is described by a set of knowledge factors; each factor is defined by multiple characteristics. A set of such factors forms a knowledge profile (Plekhanova, 1999a). Each factor is represented by qualitative and quantitative information. Quantitative description of the *i*th knowledge factor is defined by an indicator characteristic, property, and weight. In a simple way, a profile can be defined as follows (see Figure 2).

The profile theory is used for formalization of cognitive systems and cognitive processes, and for the identification of critical areas in learning performance where improvement should be taken. In particular, engineering the cognitive processes is considered to provide improvement of learning process by means of integrating adaptive machine learning into the profile theory. In order to model cognitive processes the profile theory is combined with machine learning methods, which are applied to the initial available knowledge capabilities of the cognitive system to define learning methods. (It is expected that different initial knowledge capabilities of the cognitive system require different hybrid learning methods.)

Machine learning methods are used for formalization and modeling of learning processes via applications of the profiles. It allows consideration of dynamics in learning processes (i.e., modeling of the *i*th profile factor $e_i(t) = < \varepsilon_i(t), v_i(t), w_i(t) >$ in the profile *b*). We should analyze existing machine learning methods, match them to learning tasks with relevance to available knowledge capabilities of cognitive agents and consider cognitive processes. A profile is considered as a model for the description of cognitive processes. That is, a new machine learning method will be developed and incorporated into an engineering framework for cognitive processes.

This research considers knowledge factors as critical variables in learning processes and addresses problems in the formation of a cognitive system that can be capable of learning. In particular, a cognitive system is defined by knowledge-interrelated agents, their flexible cognitive structure and cognitive processes. A teacher is defined as a learning oracle. Soft factors may be defined as a "noise" in data modeling for the training sets in machine learning.

This work addresses the problems of knowledge integration of the cognitive system in order to provide a better learning performance. A challenge for learning is to ensure

Figure 2. Definition of the profile

A profile b is defined as a set of factors $b_1, b_2, ..., b_n$: $b = \{b_i, i = \overline{1,n}\}$, where the ith factor b_i is represented by a pair $b_i = (\iota_i, e_i)$ with

- n - a number of factors
- ι_i - an identification of the ith factor, i.e. a name or label or type of the ith factor
- e_i - the 3-tuple of the ith factor as the Cartesian product: $e_i = <\varepsilon_i, v_i, w_i>$, where
  - ε_i - indicator characteristic, that indicates the factor presence in the description of a cognitive agent, the existence of certain conditions, e. g. ε_i may represent a binary case; a number of times of factor utilisation; or may be defined as a time characteristic $\varepsilon_i = \varepsilon_i(t)$
  - v_i - property of the ith factor: $v_i \geq 0$; v_i can be defined as a function of time $v_i = v_i(t)$
  - w_i - weight of a factor which defines either the factor importance or the factor priority: $w_i \geq 0$; w_i can be also considered as a function of time $w_i = w_i(t)$.

the existence of a desired level of performance of a cognitive system. There is a need to make a formal analysis of the available knowledge of cognitive agents in order to ensure the learning of the tasks at a desired performance level while utilizing the available knowledge capabilities effectively and efficiently.

This research deals with the problem of agent allocation in a cognitive system. This problem addresses not only task scheduling as in traditional approaches but also scheduling machine learning methods and knowledge of cognitive agents. The proposed project will develop a new scheduling approach where the agent allocation problem has specific emphasis on the following aspects: cognitive agents are allocated to tasks according to their multiple knowledge capabilities; the agent's knowledge capabilities must satisfy the particular combination of knowledge required for a task; agents of the cognitive systems should be compatible with each other (Plekhanova, 1999b); and learning methods are relevant to the available knowledge capabilities of the cognitive agents and system. The consideration of all these aspects defines a problem of knowledge integration in cognitive systems. This work will use formal methods for an integration of cognitive capabilities and compatibilities, and for an analysis of how system capabilities satisfy the learning of the tasks.

Capability and compatibility factors have considerable impact on the process of system integration. An integration model encompasses integration criteria, priorities of the knowledge profiles and knowledge integration goals. Knowledge integration goals are the improvement of available knowledge or generation of new/novel knowledge for better learning performance. This work addresses problems of effectiveness of the learning processes, their convergence (Vapnik, 1998), stability, and accuracy.

Therefore, the adventure in this research is that cognitive processes will be incorporated into multi-agent system development by a synthesis of systems engineering with knowledge engineering and machine learning methods. The combination of machine learning methods with profile theory will provide a more flexible adaptive framework for cognitive tasks performance. That is, the proposed method for the modeling and engineering of cognitive systems and cognitive processes can be used in systems engineering and machine learning for a formalization of cognitive processes, cognitive systems, and capability and compatibility aspects.

FUTURE TRENDS

The proposed project is particularly novel in its approach to learning processes that incorporate a synthesis of systems engineering, knowledge engineering and machine learning methods. There are no formal methods for knowledge integration and scheduling for learning of cognitive systems where capability and compatibility factors are critical variables. Existing machine learning approaches do not address scheduling problems in learning methods. We will develop a new scheduling approach where we consider scheduling machine learning methods and knowledge of cognitive agents vs. task scheduling in traditional approaches. New machine learning methods will be developed and incorporated into an engineering framework for cognitive processes. Moreover, the

proposed project brings together work in cognitive systems, systems engineering, knowledge engineering and machine learning for the modeling of cognitive processes.

The proposed project is timely because of the availability of new formal methods for engineering cognitive systems. The work is highly topical at present as demonstrated by a large interest in academia and great needs of industry, in particular, in:

- **Software/Systems Engineering:** Project resource capability and compatibility aspects have become the focus of performance process improvement. However, most contemporary approaches to the formation of project resources (Norman et al., 2003) do not examine their capability and compatibility factors. There is a need to develop evaluation techniques for people's capability, resource capability and compatibility in order to provide support for effective solutions to resource integration management in cognitive systems (Plekhanova, 2002). In particular, methods are of particular merit that incorporates a comparison of cognitive processes, resource capabilities, and compatibilities.
- **Scheduling:** Contemporary approaches to resource scheduling are based on the detailed description of tasks assuming that a resource pool is given and defined by a manager and resources are capable of performing any project task. Existing resource scheduling methods address the issues of resource availability and utilization, and are not concerned with the capability and compatibility of project resources. Furthermore, in traditional scheduling approaches, the objectives for the allocation of limited resources are to determine the allocation of resources that maximize total benefits subject to the limited resource availability. Contemporary approaches to resource allocation are founded on the assumption that different tasks require equal capability resources, and only one skill is involved. Hence, they cannot be successfully used for software projects where different software tasks require changing different sets of multiple knowledge and skill capabilities in an overall system (Plekhanova, 1998).
- **Software Tools for Resource Scheduling:** There are many scheduling tools that provide different approaches: event-oriented (PERT), activity-oriented (CPM), actions-oriented (TASKey PERSONAL), or offer a wide variety of scheduling options (SAP). Nevertheless, there are no tools that support an analysis of resource capabilities/compatibilities and their impact on project scheduling (Plekhanova, 2000c). Most existing tools (Microsoft Project, SAP, Up and Running) have facilities for entering new resources, but do not deal with an analysis of cognitive processes, and resource quality based on which resources can be added to the resource pool. Therefore, the existing scheduling tools cannot be effectively used for management of processes where resources are a critical variable.
- **Theory/Tools in Machine Learning:** Existing machine learning techniques (e.g., Boosting (Schapire, 1999), Lazy Learning (Aha, 1997), Neural Nets, Decision Tree Learning (Quinlan, 1990; Utgoff, 1989), Support Vector Machine (Vapnik, 1998), Reinforcement Learning (Sutton & Barto, 1998)), and contemporary machine learning tools (e.g., WEKA, AutoClass, mySVM) have not yet been examined in terms of agents' capability/compatibility and scheduling problems.

There is a direct relationship between the representation and the learning mechanisms. In many cases the underlying representations in machine learning have been of limited structure (e.g., vectors, trees, networks). Hybrid integration of various machine-learning mechanisms for engineering of structured objects is novel and will be examined in this project in the context of the profile theory.

CONCLUSION

Beneficiaries of the proposed research are:

Engineering the Complex Systems: Research in engineering of complex systems will provide insight into new methods and approaches to learning in cognitive systems. Research in machine learning will deliver adaptiveness to knowledge integration and scheduling of learning methods. Scientists in cognitive systems research will receive a formal method for modeling of cognitive processes. By developing integration metrics using the profile theory we can provide analysis, development, integration, modeling and management of complex systems and their elements where weight, time, and other internal multifaceted properties are critical variables. Further development of the profile theory will establish a new branch in mathematics and extend its applications.

Industry: New evaluation techniques could provide support for a solution to the resource-based problems in cognitive processes in software and IT projects such as team formation and integration in connection with process tasks.

The application of a new approach could provide learning organizations with:

- Superior management of resource capabilities and compatibilities;
- Streamlining of process development through better management of project resources and tasks;

- Increased opportunities for organizations to implement process improvement based on the constructive criticism derived from self-analysis.

It is apparent that there is a worldwide interest in the application of this research. Since most modern processes are cognitively driven our method can be used for the formal modeling of cognitive systems. It is important for the future competitiveness of the software and IT industry to employ a scientific (vs. heuristic) approach to the engineering of cognitive processes.

Technology: The profile-based approach assures a virtual prototyping of system development within different environment settings. An important application of this approach is that it gives the means of providing systemic methods of study, analysis, prediction, improvement, control and management of a system development. Moreover, this technology demonstrates a modeling flexibility that permits one to represent a fine-granularity of system components, as well as to generate different system models of a wide diversity of system development processes. Thus, any traditional system model becomes a special case of the capability- and compatibility-based modeling framework.

Formal modeling of the capability and compatibility of cognitive systems ensures the automation in system modeling. It leads to development of new technologies in system modeling. Some of the enhancements that we intend to offer through this method are to provide support for development and engineering of new knowledge capabilities of cognitive systems, that is, innovative technologies.

KEY TERMS

Agent: A complex system constituting elements that are individual performers, which can be described by their interrelationships, knowledge/skill, performance and constraints factors.

Agent's Compatibility: A capability of agent to work with other agents without adaptation, adjustment and modification.

Cognitive Process:

- The performance of some composite cognitive activity.
- A set of connected series of cognitive activities intended to reach a goal. Cognitive activities can be considered as a function of their embodied experience.

Cognitive System: A complex system that learns and develops knowledge. It can be a human, a group, an organization, an agent, a computer, or some combination. It can provide computational representations of human cognitive processes to augment the cognitive capacities of human agents.

Complex System: A collection of interrelated elements organized to accomplish a specific function or a set of functions. Complexity can be considered in terms of a number of elements and/or complexity of relationships.

Learning System: A complex system that learns and develops knowledge.

Machine Learning: The ability of a machine to improve its performance based on previous results.

Multi-Agent System: A set of interrelated agents that work together to perform tasks.

Legal Issues of Virtual Organizations

Claudia Cevenini
CIRSFID, University of Bologna, Italy

INTRODUCTION

In the present economic context, organizations, especially of small and medium dimensions, can draw a substantial advantage by collaborating and setting up flexible, temporary ICT-enabled networks.

Identifying the legal issues relevant for virtual organizations can provide a knowledge basis to regulate their activities, thus providing support for their creation and management.

BACKGROUND

The concept of virtual organization (VO) finds its origins in the United States in the early 1990s, when some authors start to give it a first theoretical outline.

Since then, a certain scientific debate has opened, and several attempts to define and concretise it have been made. The most active research sectors with respect to this appear to be business and computer science. Until recently, however, the legal research has substantially disregarded VOs, with few exceptions.

REGULATING VOS

VOs are far from being a consolidated reality; being fluid and flexible structures, they continually evolve over time and are difficult to grasp.

The starting point for their regulation is to provide a definition for the purposes of legal research: "VO's are ICT-enabled collaborations between legally independent subjects aimed at the joint provision of goods or services, where each partner contributes to specific activities. They do not aim at achieving an autonomous legal status but appear as one organization towards third parties."[1]

As a second step, a wide range of legal issues concerning them can be identified. By developing a legal taxonomy, it is possible to aggregate legal problems in major research areas. This makes it possible to focus on those issues most connected with the particular structure and nature of the VO.

The third step is to examine the identified issues in the light of the applicable legal framework at national and international level, considering the nationality of the partners and their reciprocal agreements.

A TAXONOMY OF VO-RELATED LEGAL ISSUES

Hereinafter, a synthesis of the most relevant issues is presented.

Identity and Nationality of the Virtual Organization

The VO does not embody a formal institution separate from its partners, although it may appear as a separate, autonomous entity.

National legal orders will tend to consider the VO as a structure without legal personality and, consequently, also without nationality, provided that the partners do not opt to formally adhere to a company type as foreseen by the national law of one of them.

Role of the Virtual Organization Broker

A VO can be set up and managed without the intervention of a VO broker. This, however, would imply higher coordination costs, more complex negotiations, and a slower speed of action.

The legal status of the VO broker depends upon its actual role and activities in the VO. The broker will be subject to and have to comply with the applicable legal framework set for the legal structure it has opted for in the state in which its head office is located, as well as with the state- and contract-based rules applicable to the same VO.

Virtual Organization Framework Agreement

The VO framework agreement is a set of rules aimed at governing the internal relationships between the partners of a VO.

It has to be signed before the beginning of any activity and is generally drafted with the support of the broker, who may propose business templates on the basis of which the detailed final provisions can be negotiated with the partners.

The absence of a clear agreement would possibly lead to difficulties in the management of the operation stage and, later, to possible disputes between the partners.

Contracting with Third Parties

Having no legal personality, the VO cannot directly close contracts with third parties. Therefore, if its members are to enter into contractual relationships, this will not be feasible for the VO as a separate subject; agreements can only be closed between third parties and some or all the individual members.

Once a partner—or a group of partners—has been selected, the other members can grant to it the power to act in their name and on their behalf to the purpose of closing contracts binding for all of them, or to take care of other jural acts, as it happens with mandates.

The Resolution in Disputes

The involvement in a lengthy dispute resolution procedure can cause severe economic damage or even disrupt a temporary entity like the VO. For this reason, before the final framework agreement between the partners is signed and, later, before the signing of every agreement with third parties, attention has to be placed upon developing and agreeing upon adequate dispute resolution mechanisms, which may range from legal actions before courts, to arbitration and mediation.

Liability Issues

It would be difficult to configure a liability on the VO as such, as there are no legal instruments to construct it. It thus appears more feasible to identify a liability on the individual partners. All of them may be held jointly and severally liable for the damages that can be imputed to the VO. Whenever one partner is held liable, those who have been sued without having contributed to causing the damage which is the object of the claim can resort to an internal redress.

Intellectual Property Rights

The VO activities are based on the reciprocal disclosure of relevant data and possibly on the sharing of immaterial goods. These can, in some cases, enjoy a precise legal protection, as happens with copyright, software, patents, and databases.

This applies both to the data and goods to which the individual partners are already entitled, as well as to the outcome of their collaboration. In the former case, the legitimate owner can grant to the other partners a right of economic exploitation, for example, through licensing contracts. As to the latter case, specific agreements are to be clearly set.

If the individual contributions are not to be clearly identified, it can be assumed that all partners will be entitled to the data and goods produced by the VO and of the relative rights, on the basis of a coownership.

Data Protection

All the different activities of the VO imply the processing of personal data. Within the present data protection framework, attention has to be placed, in particular, on a series of elements, such as the processing through automatic means, the disclosure of data to third parties, and the transfer of data between European Union (EU) and non-EU countries. The VO partners will actually carry out most processing with ICT tools and may need to process data originally collected by one or more of them and perform cross-border data transfers.

Competition Law

Should a VO achieve a substantial dimension in terms of its overall turnover, attention shall be placed by the partners to its compliance with rules on antitrust and the protection of competition applicable to the partners. Specific procedures may be imposed in order to get the authorization of antitrust bodies, as well as to verify the law-abidingness of the collaboration.

ICT-Related Issues

The nature of ICT-enabled entities possessed by VOs requires their compliance with the applicable rules on the use of specific technology tools, for example, with reference to security, electronic signatures, e-commerce, or teleworking. Should certain ICT-based interactions not be specifically regulated, reference shall be made to analogically applicable norms.

FUTURE TRENDS

The present economic and legal scenario does not point toward the drafting of an ad hoc legislation for VOs. However, the growing relevance of collaborative entities, such as industrial districts, coupled with the strong support of the techno-legal scientific community, will make VOs known to a wider audience and stimulate targeted initiatives.

CONCLUSION

A coherent and certain legal framework applicable to regulate VOs is presently still absent, and a clear qualification of their legal identity by the legislator is missing. Besides, their international character would require a level of harmonisation among contrasting rules that does not always appear easy to achieve, while their massive use of rapidly evolving information and communication technologies contrasts with the slow law-making process.

This makes it extremely difficult to envisage a state-based regulation for them, or the drafting of international treaties or agreements, at least in the short term.

This enhances the fundamental role of normative tools, such as codes of conduct and best practices, and especially of contractual agreements and intraorganisational rules drafted by the VO partners, developed on the basis of a clear identification of the relevant legal issues.

KEY TERMS

Arbitration: A private form of conflict resolution. The litigating parties may voluntarily submit a dispute to one or more independent, neutral experts (arbitrators), who decide upon the case similarly to a court, generally upon a shorter period of time. Arbitrations are usually regulated by law.

Intellectual Property Rights: Copyright and connected rights that include, *inter alia*, the right of copying, modifying, and distributing the protected work.

Legal Order: The set of legal norms that make up the legal system of a particular country.

Legal Personality: The capacity of a legal person (e.g., a corporation) to be holder of rights and duties.

Mediation: An alternative dispute resolution method. The litigating parties may voluntarily submit a dispute to a neutral, independent mediator. This latter does not issue a decision but supports the parties in finding a mutually agreed upon solution.

Personal Data: Any information concerning a natural or legal person that can identify it.

Virtual Organization: An ICT-enabled collaboration between legally independent subjects aimed at the joint provision of goods or services, where each partner contributes to specific activities. It does not aim at achieving an autonomous legal status but appears as one organization toward third parties.

VO Broker: A subject who acts as an intermediary for the setting up of the virtual organization by identifying a possible business opportunity, contacting the potential partners, and proposing agreement templates.

Leveraging Complementarity in Creating Business Value for E-Business

Ada Scupola
Roskilde University, Denmark

INTRODUCTION

The rapid developments of Internet and Web-based applications has shaped the era of the digital economy and changed the way enterprises operate. Internet is increasingly becoming part of the basic business model for many companies as organizations around the world are adopting new e-business models and integrated solutions to explore new ways of dealing with customers and business partners, new organizational structures, and adaptable business strategies (Singh & Waddell, 2004). According to Kalakota and Robinson (1999), e-business is the complex fusion of business processes, enterprise applications, and organizational structure necessary to create a high performance business model. E-business is therefore more than just having an Internet presence or conducting e-commerce transactions, it is a new business design that emphasizes a finely tuned integration of customer needs, technology, and processes (Kalakota et al., 1999). When discussing e-business, it is important to make a distinction between physical and digital products. A digital product is defined as a product whose complete value chain can be implemented with the use of electronic networks, for example it can be produced and distributed electronically, and be paid for over digital networks. Examples of digital products are software, news, and journal articles. The companies selling these products are usually Internet-based "digital dot coms" such as Yahoo and Google. On the contrary, a physical product cannot be distributed over electronic networks (e.g., a book, CDs, toys). These products can also be sold on Internet by "physical dot coms," but they are shipped to the consumers. The corporations adopting e-business are distinguished into "bricks and mortar" companies, hybrid "clicks and mortar" companies (such as Amazon.com) and pure dot coms (Barua & Mukhopadhyay, 2000a).

Many studies from the early days of deployment of information technology (IT) in organizations have struggled to measure the business value and profitability of information technology (Barua et al., 2000a). Many of these studies have showed that productivity gains are small or not existent and that the effects of information technology and e-commerce have to be often looked upon from a competitive advantage point of view (Barua, Konana, Whinston, & Yin, 2001; Porter & Miller, 1985; Scupola, 2003). Recent research has argued that to increase the business value of electronic commerce to a corporation is important to shift the focus from whether electronic commerce creates value to a company to "how to create value" and "how to optimize such value" (Barua et al., 2001). This can be achieved by exploring complementary relationships between electronic commerce, strategies and value chain activities (Scupola, 2002, 2003). Here this argument is taken further to show the importance of complementary relationships for the business value of e-business.

BACKGROUND

Since the early days of IT, use in commercial organizations, researchers, and professionals have struggled to understand how and to what extent the application of IT within firms leads to improved organizational performance. The research on IT business value has been characterized by diverse conceptual, theoretical, and analytic approaches as well as has adopted different research methodologies (Melville, Kræmer, & Gurbaxani, 2004). Six main areas of IT business value research can be distinguished: information economics-based studies, early IT impact studies, production economics studies that did not find positive impacts, microeconomics studies that found positive impacts of IT, business value studies and studies involving complementarity between IT and non-IT factors. The information economics-based studies date back to the 1960s and though relevant to the economic contribution of IT investments, they mainly focus on the changes in information due to IT use and their impact on the single decision-maker. Therefore, while the information economics approach is theoretically sound and rigorous, its unit of analysis, which is either the individual or team decision, makes it difficult to obtain meaningful and insightful results in broader organizational contexts (Barua et al., 2000a).

In the early 1980s, a stream of research emerges focusing on assessing the contribution of IT investments to performance measures such as return on investment and market share (Barua et al., 2000a, Barua et al., 2001). The majority of these studies did not find much positive correlation between IT investments and firm performance metrics up to the early 1990s. The lack of correlation between IT investments and firm productivity made Roach (1999) to coin the term "IT productivity paradox."

In the 1990s, the research on measuring the economic and performance contributions of IT can be divided into two main streams: one based on production economics and one based on "process oriented" models of IT value creation. The IT production studies based on production economics hypothesize that IT investments are inputs to a firm's production function. These studies (e.g., Brynjolfsson & Hitt, 1996) finally started finding signs of productivity gains from IT. For example, Brynjolfsson et al. (1996) identify three sources of IT value to a corporation: productivity, consumer value, and business profitability. The study shows that information technology contributes to increases in the productivity and consumer value, but not business profitability. Simultaneously, process-oriented studies started hypothesizing relationships between IT and other input factors to performance measures at various levels of aggregation. These studies (e.g., Kauffman & Kriebel, 1988) have laid the foundation of the business value approach to the impact of IT on firm performance. This approach on the contrary of the production function-based approach might have the explanatory power to point out where and how IT impacts are created and where management should act to increase the payoff from IT investments. These explanations are more difficult to get with production function-based approaches since they operate at a very high level of aggregation, thus making it difficult to distinguish between different types of IT investments and their impacts on specific areas of business. After having dispelled the productivity paradox, new refinements to existing approaches are emerging to measure the contribution of IT to business performance. An important stream of research is pointing to complementarity theory to investigate the interactions between IT and other organizational factors (e.g., Barua, Lee, & Whinston, 1996; Barua et al., 2000a; Barua et al., 2000b; Barua et al., 2001). In fact, production economics and business value approaches have mostly ignored the synergy between IT and other related factors such as the level of fit with business strategies, employee empowerment, and team orientation of business processes. Barua et al. (2000a) present a generalized business value complementarity model that explores the synergies among such factors. The basic idea of their business value complementarity model (BVC) suggests that investments in IT should be first related to intermediate performance measures such as time to market, customer service, response time and extent of product mass customization to be able to see any positive results from such investments. In a second moment, the intermediate performance measures can be related to high-level performance metrics such as profitability, return on investment (ROI), market share. The focal point of a business value complementarity model is the complementarity that potentially exists at each level of the model (Barua et al., 2000a; Barua et al., 2001; Scupola, 2003).

More recent studies are also investigating the impact of information technology on the financial performance of diversified firms (e.g., Shin, 2006), multi-business firms (e.g., Tanriverdi, 2006), and often take their starting point in the resource-based view of the firm as for example the theoretical study conducted by Melville et al. (2004).

The advent of the Internet, based on open standards and a universal Web browser, raises the question of whether investing more in Internet technology lead to a better financial performance in electronic commerce and e-business. In this regard, Zhu (2004) shows that there is a positive interaction between IT infrastructure and e-commerce capabilities suggesting that their complementarity positively contributes to firm performance in terms of sales per employee, inventory turnover, and cost reduction. Further Zhu (2004) provides "empirical evidence to the complementary synergy between front-end e-commerce capability and back-end IT infrastructure (Zhu, 2004, p. 167)." Yang, Yang, and Wu (2005) investigate the relationship between enterprise information portals (EIP) and e-business performance by conducting a survey of companies. Their results show that the implementation of enterprise information portals influence e-business performance. Barua et al. (2004) investigate the processes through which business value is created by Internet-enabled value chain activities. Their analysis suggests that "while most firms are lagging in their supplier-side initiatives relative to the customer side, supplier-side digitization has a strong positive impact on customer-side digitization, which in turn, leads to better financial performance. Further, both customer and supplier readiness to engage in digital interactions are shown to be as important as a firm's internal digitization initiatives, implying that a firm's transformation-related decisions include its customers' and suppliers' resources and incentives" (Barua et al., 2004, p. 585).

These studies point out the need of more attention to the specific business processes that have to be reengineered for e-business and the way they should support the company strategy (Scupola, 1999, 2003). In fact, as Pepper and Ward (2005) say IT has no inherent business value unless this value is unlocked and this process of unlocking business value from IT investments is a journey and not a destination and this journey requires careful planning.

A BUSINESS VALUE COMPLEMENTARITY MODEL OF E-BUSINESS

A business value complementarity model of e-business could be used as a methodology to optimize e-business initiatives when entering the e-business arena (Scupola, 2003). The business value complementarity (BVC) model presented here is based on the value chain (Porter, 1980), the theory of business value complementarity (Barua et al., 1996; Barua et al., 2000a; Barua et al., 2002; Milgrom & Roberts, 1990) and the concept of strategy (Porter, 1982).

In this model it is hypothesized that complementarity (represented in the figure with dotted lines) exist between the variables of the same level and different levels of the model. It is furthermore hypothesized that the exploration of complementarities and possible synergies between the company strategy, the primary activities of the value chain, corresponding business processes and supporting technologies should (1) maximize the business value of e-business to a corporation and (2) lead to a better fit between the overall organizational strategy, the business processes that have to be transformed for the online market place, and the e-business system that should be designed and implemented to support these strategies. The exploration of complementarities, it is hypothesized, can also contribute both to avoid investments into an e-business system that could not be used at a later point if new e-business processes should be added to the system and avoid the implementation of a business model that does not correspond to the corporation's strategy. It is argued that to develop a successful e-business model it is important to reengineer the parts of the value chain and the corresponding business processes relevant to the product in question and the company strategy.

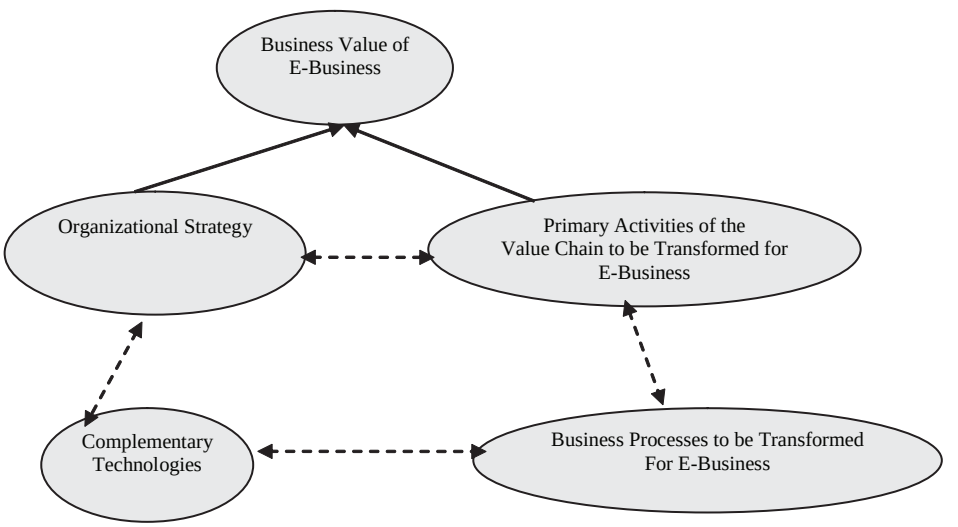
The main objective of the model is to make the business value of e-business as close to optimal as possible in terms of one of the performance measures, such as company profitability, competitive advantage, increase in market share, shareholder value or customer satisfaction. This can be done by exploring complementarities among the dependent variables of the model: the company strategy, the activities of the value chain, the corresponding business processes, and the technologies available to transform these activities and processes for the marketspace.

Furthermore, to succeed in e-business it is important to reengineer the parts of the value chain and the corresponding business processes relevant to the product in question and the company strategy. For example, the strategy or combination of strategies a company wants to pursue is relevant for the primary activities of the value chain, and the corresponding business processes that have to be implemented online. The strategy is also relevant to the classes of technologies that have to be chosen to enter the electronic market place. For example, a company can develop an e-business model to implement a cost leadership strategy, or to become the low cost producer in the industry. Once decided upon the strategy, it is important to explore complementarities between the strategy and the value chain activities in order to implement online all those activities that would support an optimal implementation of the strategy chosen.

The number of primary activities and corresponding business processes that should be transformed for the marketspace depends also on the company's type of product and strategy. It is important to take into consideration complementarities among the different activities of the value chain when designing an e-business model. The more activities of the value chain are simultaneously conducted online, the more likely it is that the business value of e-business will be optimized. The adoption of a holistic approach in redesigning the primary activities for the electronic marketplace should be a more successful strategy than reengineering only one or some at a time. This is due to potential complementarities between the different activities, which lead to a better performance in one if the others are also reengineered for online commerce.

Furthermore, each business process of each activity of the value chain could be re-engineered for e-business. This

Figure 1. Business value complementarity model of e-business



model argues that the exploration of complementarities among the different business processes and the simultaneous transformation of all the complementary processes of a particular activity for online commerce would lead to a higher business value than if only one or a casual numbers of processes were reorganized online (Scupola, 1999).

In the design phase, it is important to consider potential complementarities between the business processes that have to be redesigned for online commerce and the supporting technologies. The exploration of this complementarity should lead to an optimal system design that also offers possibilities for further expansion if other online business processes should be added in the future. For example, electronic search of the company's information will give more accurate and quicker results, the faster and more advanced the search engine is and the better built are the user interface and the repository systems.

Finally, the exploration of complementarities between the different technologies used to implement the e-business system could bring to a more robust and flexible computer system than a system built without the exploration of complementary relationships between the different component technologies. For example, end user interfaces and repositories are complementary technologies in the sense that the better designed the repository system, the simpler the user interface can be.

FUTURE TRENDS

The studies on IT productivity and business value conducted over the last decade have showed positive impacts of IT investments on firms' productivity both with respect to labor and other non-IT capital used by organizations (Barua et al., 2000a). However, Internet-based technologies, with their open standards and wide applicability, raise again the issue of profitability and business value of investing in such technologies. Furthermore, the fact that Internet is giving rise to a "new economy," raises a number of questions among which: how productive are the players in this new economy? Does e-business increase the profitability and business value of brick and mortars and hybrid click and mortars companies? For dot coms, do more investments in Internet commerce technologies necessarily lead to a better performance of the company? And especially, if all the companies have equal access to Internet-based technologies, what are the factors that differentiate their performance in e-business?

Recent literature investigating the business value and profitability of electronic commerce and e-business is focusing on the exploration of complementary relationships between Internet technologies and other factors in order to see positive returns from investments in these technologies (Barua et al., 2000a; Barua et al., 2000b; Barua et al., 2001; Scupola, 2003). For example, Barua et al. (2001) develops a framework of electronic commerce business value that identifies linkages between performance drivers such as Internet applications, processes and electronic business readiness of customers and suppliers and operational excellence and financial metrics. They argue that "firms engaged in electronic business transformation must make synergistic investments and commit resources not only in information technology, but also must align processes and customer and supplier readiness to maximize the benefits" (p. 1).

Similarly, an empirical investigation of the business value of e-commerce in small, medium, and large companies across Europe and USA (Barua et al., 2000b) identifies a set of key e-drivers such as system integration, customer orientation of IT, supplier's orientation of IT, and internal orientation of IT. The study concludes that high performance companies have invested more effort and resources in these e-business drivers than companies who have not benefited from e-business.

To conclude, these studies show that ignoring complementarities in research on business value measurement might lead to misleading results. On the other hand, from a managerial point of view, the non-exploration of complementary relationships between IT and related factors such as strategy, business processes, business models, incentives, etc. might lead to failure of investments in sophisticated e-business models and ventures. These considerations point to the need for more empirical as well as normative, prescriptive research on complementarity and business value of IT in general and e-business technologies in particular.

CONCLUSION

Many companies are very skeptical about investing into e-business technologies due to the lack of profitability, (or at least the difficulties to show positive return on IT investments) that until now has characterized the investments in IT, electronic commerce and e-business. Here a framework that can be used as a methodology to analyze organizational strategies and technology choices in reengineering for e-business has been presented. Companies should explore the potential complementarities existing between strategy, value chain activities, business processes, and supporting technologies when designing an e-business model. This should lead to investments in e-business systems that best support the company strategy, thus minimizing failures. This is a future challenge for corporations, industries, and researchers.

KEY TERMS

Business Processes: The business processes corresponding to each activity of the value chain are the specific processes into which each primary activity of the value chain can be decomposed.

Business Value: It can be defined as the overall value that an investment brings to a corporation. Examples of performance measures of the business value of electronic commerce can be: (1) profitability, that is whether electronic

commerce contributes to an increase in the profitability of the corporation; (2) competitive advantage that could be measured as an increase in market share, shareholder value or customer satisfaction.

Complementarity: Several activities are mutually complementary if doing more of any one activity increases (or at least does not decrease) the marginal profitability of each other activity in the group. Complementarities among activities imply mutual relationships and dependence among various activities whose exploration can lead to higher profitability.

E-Business: Is more then e-commerce and is a new business design based on integration of technology, business processes and customer needs.

E-Commerce: Is the buying and selling of information, products and services via computer networks and especially the Internet.

Internet Economy: Is made up of a large collection of global networks, applications, electronic markets, producers, consumers, and intermediaries.

Re-Engineering: Is the redesign of a corporation's business processes (or part of them) to take place over the Internet. The main goal is reduced costs, lower product cycle times, faster customer response, and improved service quality.

Strategy: Strategy is a planning, rational process through which the company chooses a certain mode of development, among all the possible ones, and maintains that direction through a well defined period (design view). In the process view, strategy is a process that might change on the way, giving rise to an emergent strategy. The realized strategy might be different then the original intended strategy.

Value Chain: Represents the activities of a corporation such as procurement, production, marketing and sales, and customer support.

Linguistic Indexing of Images with Database Mediation

Emmanuel Udoh
Indiana University – Purdue University, USA

INTRODUCTION

Computer vision or object recognition complements human or biological vision using techniques from machine learning, statistics, scene reconstruction, indexing and event analysis. Object recognition is an active research area that implements artificial vision in software and hardware. Some application examples are autonomous robots, surveillance, indexing databases of pictures and human computer interaction. This visual aid is beneficial to users, because humans remember information with greater accuracy when it is presented visually than when it originates in writing, speech or in kinesthetic form. Linguistic indexing adds another dimension to computer vision by automatically assigning words or textual descriptions to images. This augments content-based image retrieval (CBIR) that extracts or searches for digital images in large databases.

According to Li and Wang (2003), most of the existing CBIR projects are general-purpose image retrieval systems that search images visually similar to a query sketch. Current CBIR systems are incapable of assigning words automatically to images due to the inherent difficulty of recognizing numerous objects at once. This current situation is stimulating several research endeavors that seek to assign text to images, thereby improving image retrieval in large databases.

To enhance information processing using object recognition techniques, current research has focused on automatic linguistic indexing of digital images (ALIDI). ALIDI requires a combination of mathematical, statistical, computational, and graphical backgrounds. Many researchers have focused on various aspects of linguistic processing such as CBIR (Ghosal, Ircing, & Khudanpur, 2005; Iqbal & Aggarwal, 2002, Wang, 2001) machine learning techniques (Iqbal & Aggarwal, 2002), digital library (Witen & Bainbridge, 2003) and statistical modeling (Li, Gray, & Olsen, 20004, Li & Wang, 2003). A growing approach is the utilization of statistical models as demonstrated by Li and Wang (2003). It entails building databases of images to be used for supervised learning. A trained system is used to recognize and identify new images with statistical error margin. This statistical modeling approach uses a hidden Markov model to extract representative information about any category of images analyzed. However, in using computer to recognize images with textual description, some of the researchers employ solely text-based approaches. In this article, the focus is on the computational and graphical aspects of ALIDI in a system that uses Web-based access in order to enable wider usage (Ntoulas, Chao, & Cho, 2005). This system uses image composition (primary hue and saturation) in the linguistic indexing of digital images or pictures.

BACKGROUND

Current image indexing systems are text-based, relying on content-relevant text placed in proximity to images. There is need for Web-based automated linguistic indexing for digital images. This fact will likely accelerate the adoption of automated linguistic indexing for images in their native visual form, which basically assigns textual description automatically to images (Forsyth & Ponce, 2002; Li, Gray, & Olsen, 2000; Li & Wang, 2003). ALIDI is currently an active research area in data mining, and its application is growing in such fields as consumer photo managers, medical imaging databases and image search engines (Berman & Shapiro, 1997; Li & Wang, 2003; Tanev, Kouylekov, & Magnini, 2004; Zhang, Goldman, Yu, & Fritts, 2002).

In general, ALIDI systems aid computer object recognition and content-based image retrieval, despite inherent difficulties (Li & Wang, 2003). With statistical modeling and machine learning approach, especially supervised learning, much research progress has been achieved in this field, but it is obvious that no single method can be used to realize this endeavor. Due to varied uses, a complete linguistic indexing system is bound to implement different algorithms or methods for effectiveness. The focus of this project is on generic image composition, which can be applied for quality control in the food industry to determine intrinsic value of food products. The proposition involved parameter-based quality detection of consumable produce. Detecting such quality involved some analysis of primary hue and saturation of images. Color profiles would be constructed with acceptable levels of various quality-indicative color levels. Certain combinations of hue and saturation would yield unacceptable produce when compared with that which is acceptable. For instance, the apple fruit passes through different color stages in the ripening process. These stages can be captured and utilized in computer quality detection works. In this article,

the research is focused on assigning linguistic terms to any images based on composition, by using combinations of hue and saturation. It dwells on generic color identification and detection of images.

MAIN FOCUS

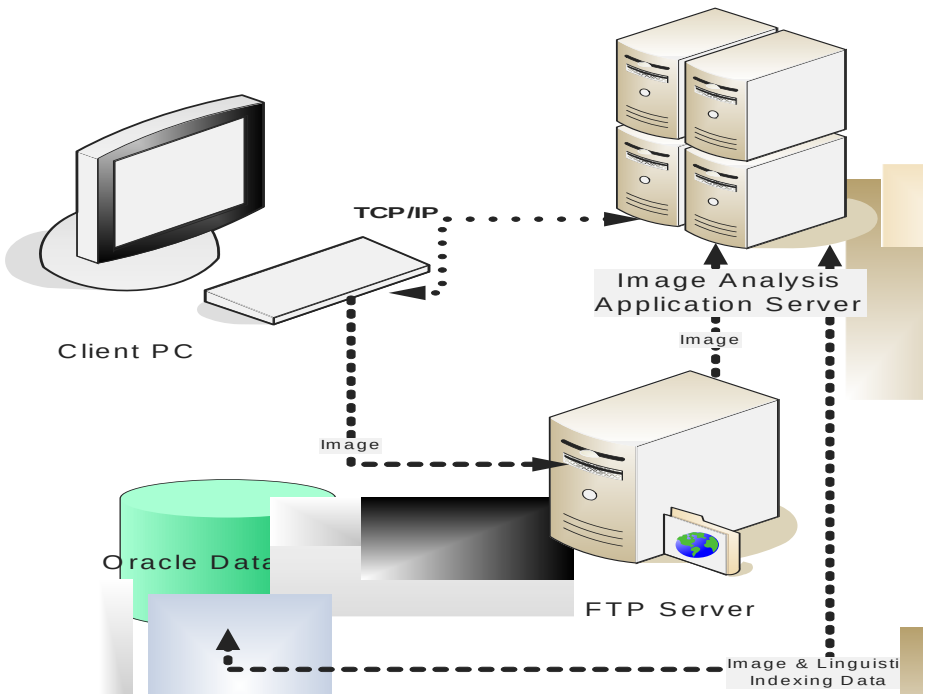
A current research theme on linguistic indexing is automating the process of assigning text to images using machine learning and statistical modeling techniques (Li & Wang, 2003). With some statistical considerations, this article focuses on the online assignment of color-based terms to images. The following describes the overall approach and Web access of the system developed by the author.

Overall Procedure

Linguistic indexing systems recognize images and textually describe them with human-readable terms like "beach" or "forest." In this article, the theoretical approach is to use image composition, and to describe the images using the color spectrum terms such as "blue" or "red." To index any image, the approach to decompose each image to pixels is adopted. After the decomposition, each pixel is assigned the values of triple composure using the red, green and blue (RGB) color model. The RGB value is then converted to the hue, saturation and brightness (HSB) color model before the color distribution in the image is determined. The quantification of the color value is carried out as opposed to the statistical similarity between the image and any concept. This approach has the potential to identify any digital image composition within a statistical error margin.

Elements of image composition require definition and human-encoded color names that are not necessarily native to computers, because computers process integers of bytes corresponding to varieties of hue, saturation, and brightness (HSB) or of the often overlapping values of red, green, and blue (RGB) from the additive color system. While RGB does reference colors directly in its indexing technique, HSB appeared to be most useful because it denotes definite color ranges with progressive hues. This informed our decision to convert RGB values to the HSB values with ease of manipulation. Due to the fact that RGB values do not translate exactly to HSB values, we statistically determined the errors associated with any conversion. It is worth mentioning that image composition offers two potential advantages over other architectural approaches: scalability and a simple programming model (Mello & Lins, 2002).

Figure 1. Implementation topology of a linguistic processing system



To enable a Web-based processing of images with associated linguistic terms, the topology shown in Figure 1 was implemented. This configuration could be considered to be three- or four-tier, depending on where the FTP server is situated. The system uses the concepts of portability, accessibility, and reusability. The system has three major components, the image analysis, the file upload and the database storage units. A combination of different technologies was used to achieve the objectives: PHP and Apache Tomcat application server (Harrison & McFarland, 2002) for Web-based programming, and the JPEG/Java technologies for image analysis. These two distinct technologies would depend on common database components and a computerized network for file transfer. Oracle 10g (Morrison, Morrison, & Conrad, 2006) served as the database for storage of the processed data, while an FTP server served as a temporary storage facility for the digital images that awaited processing. The overall topology with middleware, which handles the business rules and coordinates data access functions to the database server, provides added efficiency for a system that deals with large images and data set (Witten, Moffat, & Bell, 1999). Additionally, because of the seamless integration of the tiers of this application, any changes made to the application software or the database structure will not affect the users.

Web Access and Evaluation

To demonstrate this concept, a Web-enabled processing unit was implemented. Figure 2 shows the entry page, which leads to the page in Figure 3 that requests upload of the image to the FTP server en route to the image analysis server. The FTP server is designed to upload and then delete the image after analysis for space management. For this example, the image contains flowers, bouquet of pink roses (dimension: 640 x 480).

Assessing images based on color profiles generated pixel counts of each color identified in our spectrum. We converted these values to ratios and then to percentages for human-readable usability considerations. An error value would account for any rounding. An actual result set provided the following data from bouquet of pink roses (Figure 4). The results indicate a relatively large percentage of orange content, followed secondarily by red, with trace levels of yellow, green and blue. Such results will provide key insight into the composition of images at the pixel level for quality assurance detection routines.

We evaluated the system with about 100 different images in order to quantify its performance. The system was able to display the frequency of each color present in the image. About 95 images have error margins below 5%. Only two images can be considered to be outliers in terms of error values. Outliers exist for various reasons, and there are statistical methods to handle their effects (Li & Wang, 2003; Witten, Moffat, & Bell, 1999). Table 1 depicts the color identification result of some of the images. It lists the percentage of color in the images examined, while the last column holds the error values. This result does not depend on a categorized training database but on intrinsic color value. It is a process that can be enhanced for further studies in detection activities.

Figure 2. Web-based entry point to the linguistic system

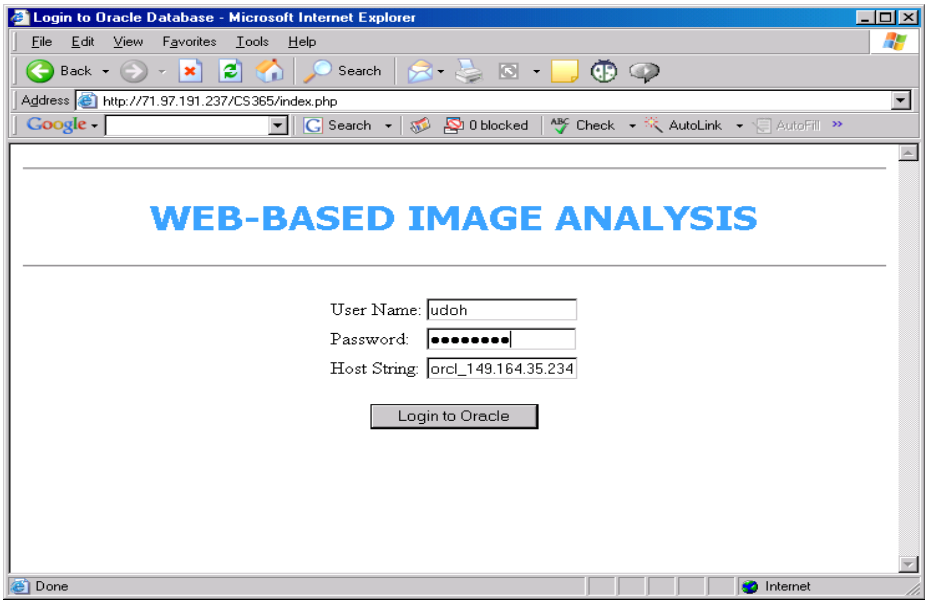


Figure 3. Upload of image to the processing servers

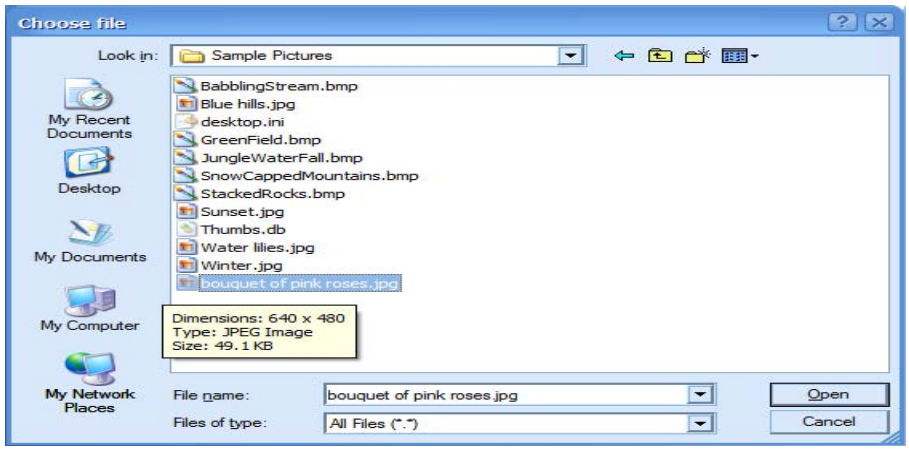

Figure 4. Display of processed image with descriptive linguistic terms (color ratio terms)

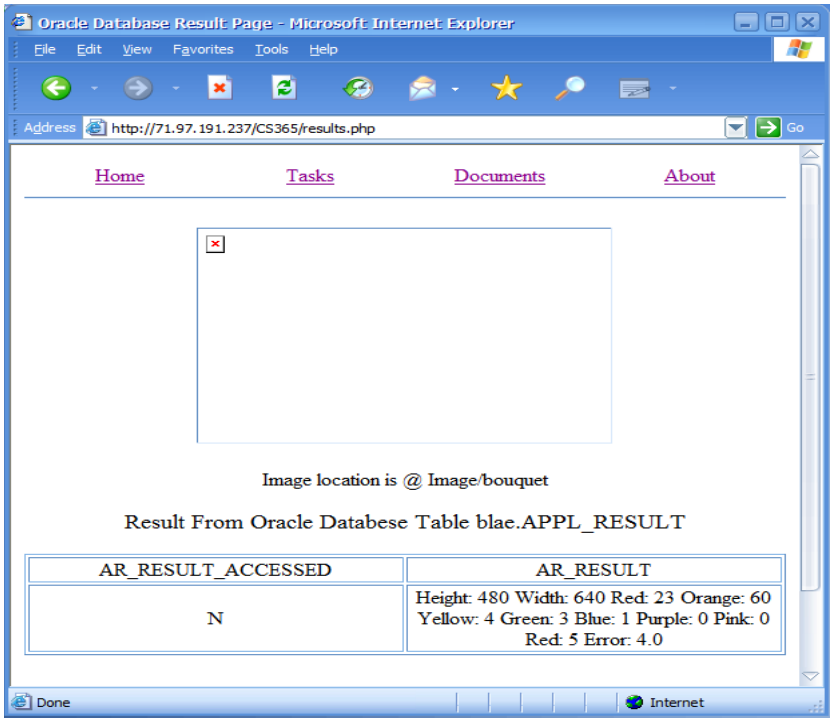

Table 1. Results of image identification experiments (color distribution in %)

Image	Red	Orange	Yellow	Green	Blue	Purple	Pink	Other	Error
Iris	2	65	5	4	20	1	1	0	2
Lawn	3	4	4	70	4	1	12	0	1
Flower	23	60	4	3	1	0	0	5	4
Forest	4	5	10	65	2	2	8	4	2

FUTURE TRENDS

The recognition of 2D or 3D objects by computers is important in various areas such as consumer photo managers, medical imaging databases, image search engines, surveillance, biomedicine, commerce, military, education and digital libraries. Computer vision complements or augments human vision activities. Linguistic indexing of images adds a positive component to object recognition that will continue to fuel research in this field. As a future trend, weights will be given to the assigned words to indicate the extent of the description appropriateness (Li & Wang, 2003). Furthermore, statistical modeling such as the Markov model, likelihood approximation and rule-based systems will impact the linguistic indexing of images and pictures. Smart technologies from artificial intelligence will also enhance progress in this field. Finally, a host of sophisticated applications will be developed to aid computer object recognition in different fields.

CONCLUSION

Widespread utilization of automated linguistic indexing for digital images will revolutionize access to visual information, especially in Internet search engines. In this article, we demonstrated a Web-based approach to assign linguistic terms to images using composition (image hue and saturation). To index any image, the image is decomposed to pixels. Each pixel is assigned the values of triple composure using the red, green and blue (RGB) color model. The RGB value is then converted to the hue, saturation and brightness (HSB) color model before the color distribution in the image is determined. To enable a Web-based processing of images with associated linguistic terms, a three- or four-tier topology is implemented on Tomcat and Oracle database servers. The evaluation of 100 different images for system performance shows that the system can be integrated into a larger linguistic processing system.

KEY TERMS

Computer Vision or Object Recognition: A discipline concerned with the science and technology of artificial systems for extracting information from images and multidimensional data. Application areas include industrial robots, indexing databases of images and industrial inspection.

Concept: A generalization or abstraction of a particular set of instances or a particular category of images at the data level.

Content-Based Image Retrieval (CBIR): This approach retrieves or searches digital images from large databases using the content of the images themselves or syntactical image features without human intervention. To aid image retrieval, techniques from statistics, pattern recognition, signal processing, and computer vision are commonly deployed. Other terms used interchangeably for CBIR are query by image content (QBIC) and content-based visual information retrieval (CBVIR).

Image Composition: General makeup or the proportion of elements in an image, for example, color.

Linguistic Indexing: Assignment of textual description or words to images or pictures as a way of identifying the image.

Machine Learning: An area of artificial intelligence that allows computers to apply rules and algorithms in a learning process. It overlaps with data mining and statistics and has wide applications in areas such as object recognition, computer vision, robot locomotion and bioinformatics.

Pattern Recognition: Part of machine learning (with supervised learning underpinnings) that classifies or extracts patterns from raw data (measurements or observations) relying on the features of the data.

Linking Individual Learning Plans to ePortfolios

Susan Crichton
University of Calgary, Canada

INTRODUCTION

Throughout the 1990s, educators working in alternative schools explored the use of individual learning plans as support for at risk students and reluctant, returning adult learners (Crichton, 2005; Crichton & Kinsel, 2002). These early learning plans were strictly paper based. Each student had her/his own cardboard folder that contained goal personal statements, benchmarks, course process, and personal information (e.g., interests, preferred learning styles). Samples of completed work were included in the folders so students could see their improvement/progress. By 1998, there was interest in exploring the potential of technology to improve the paper portfolios, noting improvements in multimedia authoring and Internet access. It was found that electronic learning plans, complete with collaborative journals, showed promise (Kinsel, 2004). This chapter suggests that ePortfolios that draw on content from personal eJournals extend those early learning plans both in concept and impact on learning.

BACKGROUND

In many ways, electronic journals and portfolios are a natural extension of individual learning plans as they encourage authentic ways for individuals to demonstrate his/her growing understanding of a content area and a developing sense of self through demonstrations of learning. Sparks (1999) suggests that rich and meaningful learning opportunities should provide a bridge to the future by helping students to learn how to learn, "… so they can keep up with the rapidly changing world" (p. 20). This is consistent with the early work of Goffmann (1959, p. 20) who states, "We come into this world as individuals, achieve character, and become persons." The development of a positive sense of self appears key to learner success, and it must be recognized that it is something that individuals must create for themselves.

Initially, the rationale for the development of an individual learning plan was predicated on the understanding that

… the development of a complex, multi-faceted sense of self can increase student achievement and self-confidence. Individualized learning links the personal and social identities of students with the academic curriculum, mapping a pathway to activities appropriate to the needs and goals and the development of an increasingly complex sense of self (Crichton & Kinsel, 2002, p. 143).

The theoretical framework for the use of early paper-based learning plans was anchored in activity theory (Vygotsky, 1994), encouraging learners to think about what they want to do, how they learn best, what supports they need, and what their prior learning has afforded them. To engage this type of thinking, the natural evolution into electronic learning plans included an interactive, personal journal area where the learner and facilitator could communicate about experiences, successes, and failures, and generally document and reflect on the learning experience. This journaling area was designed to support the notion that learning must start at a personal level, and then gradually progress to the public and applied levels (Crichton & Kinsel, 2002).

In recent years, the literature (Barrett, 2003, 2005; Fox, Kidd, Painter, & Ritchie, 2006; Jafari & Kaufman, 2006) is rife with discussion about the value of portfolios (both paper and electronic) for educational purposes. Described by the National Learning Infrastructure Initiative as "a collection of authentic and diverse evidence, drawn from a larger archive representing what a person or organization has learned over time on which the person or organization has reflected, and designed for presentation to one or more audiences for a particular rhetorical purpose" (Barrett, 2005, p. 5), portfolios typically serve the purpose of assessment for learning, narrative of discovery, and tools for reflection. This, and the literature that follows, informed the initial design of the ePortfolio initiative shared in this chapter.

In general, the structure of ePortfolios varies. Throughout the literature, mention is made of a template as "a master or pattern from which similar things can be made" (Flanigan & Amirian, 2006, p. 111). Templates range from specific portfolio software to style pages in Dreamweaver that prevent ePortfolio development from being "… simply an exercise in Web design […suggesting the templates help to] … focus attention on developing the content of the ePortfolio" (Romance, Whitesell, Smith, & Louden, 2006, p. 534) without requiring advance experience/courses in HTML.

The literature suggests that portfolios can help faculty sustain and enhance the quality of pedagogy for preservice teachers by engaging them in conversation and reflection, and assessing those interactions in meaningful, authentic

ways. The ability to do this rests in the design of a portfolio experience that encourages risk taking, good questioning, and documenting the responses to those questions/experiences in manageable, sustainable, and meaningful ways (Black & Wiliam, 1998).

Commonly expressed in the literature, portfolios emphasize analysis and reflection by honoring the process not the product (Acosta & Liu, 2006). However, as Flannigan and Amirian (2006) note, "Documents, projects, and video that student felt represented their best works and abilities were collected as artifacts for the portfolios" (p. 105). This appears to place value on the quality of product over the process, which is consistent with the generally understood notion that portfolios are collections of quality work, and tends to come from the field of architecture and art, where portfolios are used as showcases of a body of work used by the architect or artist to gain work or additional study.

Implied in the literature is the potential to incorporate digital documentation as evidence for portfolio claims. Dahlberg, Moss, and Pence (1999) describe the importance of documentation for reflective practice, noting it "enables us to see how we ourselves understand and 'read' what is going on in practice; with this as a base, it is easier to see that our own descriptions as pedagogues are constructed descriptions. Hence, they become researchable and open for discussion and change" (p. 147). The documentation process also introduces students to authentic uses of technology to support information gathering and management as well as social networking, collaboration, and community building.

The research findings presented in this chapter challenge some of the notions presented in the literature while supporting others. This chapter will report on the integration of eJournals within an ePortfolio environment to encourage the development of a community of practice among student teachers, partner teachers, and university instructors. Building from research into the use of learning plans, this chapter extends the current thinking of ePortfolios, stressing the importance of an eJournal as a personal repository from which to draw meaningful portfolio items. Continuous developments in social software allow BLOGs to be an essential tool to build and sustain a community of practice.

The relevance of this topic rests in the link between journaling and portfolio development as well as the integration of technology for authentic purposes; a core competency for full participation in the 21st century.

LINK BETWEEN LEARNING PLANS AND EDOL

The link between learning plans and eJournals and portfolios rests in the potential they offer to help participants bridge their ability to learn how to learn (Sparks, 1999), and to critically reflect on that ongoing learning. An example of this type of reflective learning within a university setting is the eDOL (the electronic documentation of learning) project, a core component of the Teacher Preparation program at the University of Calgary. All pre-service teachers (n=800) maintain an eJournal and a series of ePortfolios.

During the two-year pilot study, five core points surfaced from the research:

1. The introduction of ePortfolios alone, without a journal option, placed a premium on the quality of products. Students were not prepared to place works-in-process or examples of challenging work in their portfolios. Because the students felt the word "portfolio" suggested best work, it appeared to limit ongoing discussions of challenges or frustrations that are essential for rich learning.
    - To remedy this situation, the project shifted from being about ePortfolios alone to focusing on eDOL (electronic documentation of learning). This shift has helped the three participant groups (student teachers along with their university instructors and partner teachers) to interact and share course content, journals, and experiences, thereby, honoring process as well as product.
2. Students needed an electronic journal that they could access anytime/anyplace. Access such as this allowed the students to write in their schools, at home, and basically anywhere there was Internet access. In addition, their partner teachers and university instructors would have the same access options. Because of this ease of access, the eJournal has become a rich archive from which the students could pull portfolio items at specific times in the program.
    - The login procedures and administrative controls keep the eJournals secure. This is very important as confidential/personal information is shared there, along with images from schools and classrooms.
    - Maintaining the integrity of the DRUPAL content on a university secure server has been paramount. This has required working closely with the university's information services department to verify user accounts, ensure each module added to the core DRUPAL site is secure, and backup the content in a secure and timely manner.
3. Digital documentation aimed at capturing issues of pedagogy and school environments was essential as a basis for reflection and social interaction as it provides evidence of specific events and contexts. The use of pedagogical documentation truly supports an emphasis on inquiry and reflection. Many forms of digital data can be recorded and placed in the students' journals. Examples include photographs of blackboard illus-

trations/directions, classroom seating arrangements, bulletin boards, student work, classroom activities.

- A concern with digital documentation is the need to recognize the sensitivities of filming in classrooms and obtaining the necessary permissions required to use the documentation in student journals and portfolios.
- Another concern that surfaced was the sharing of content from the eJournals in the university classrooms. Using an LCD projector, students and their instructors could share interesting text exchanges with the entire class or project an image as a prompt for discussion. Because of the Freedom of Information and Protect Act (FOIP) in Canada, permission must be secured in advance before classroom sharing of content can take place.

4. eJournals are developed using an open source, social software, DRUPAL (a blogging software). The architecture of DRUPAL is flexible enough to allow system administrators to customize it to meet emerging needs. DRUPAL can be password protected, securing the environment and allowing for issuing of accounts to registered users.
    - To customize and administer DRUPAL site, the Faculty of Education hired an ICT support person. This is an essential position, as security and integrity of the data are paramount.
5. Because DRUPAL works on the concept of groups, university instructors create a classroom group for all their students, and the students create individual journal groups into which they invite their partner teachers and university instructors.
    - Details concerning the various user checklists and user guides can be found on the main page of the eDOL site (http://education.ucalgary.ca/edol/front)
    - The students "own" their journal group, so they can maintain access to their own content/journal after the course has been completed.
    - These journals then become individual learning object repositories from which students can draw content for subsequent journal entries or for their portfolios.

eDOL would provides a way of understanding emerging student awareness of what inquiry-based teaching and learning looks like in actual practice. The originality of eDOL rests in the importance of establishing an eJournal to accompany the ePortfolio, challenging and adding to the existing ePortfolio literature.

At recent conferences (WestCAST 2007 and 2008), students shared their experiences. We focused on five core areas: 1) journals vs. portfolios (process and/or product); 2) value of digital documentation as evidence of student ownership of learning; 3) value of a unifying project to build program coherence; 4) importance of community within a program; and 5) the notion of "finishing with a place to start."

The first core area distinguishes eDOL from learning plans and contemporary ePortfolios, as it links the development of an individual repository of reflections, artifacts, evidence of learning, assignments, interactions with the development of a portfolio that requires the development of decision-making, critical reflection, and ICT skills.

The second area, digital documentation as evidence of student ownership of learning, has been fascinating. The process of recording, analyzing, editing, and preparing the documents has encouraged an authentic and appropriate integration of technology into the students' work. For many, this has been an introduction to ICT as it supports professional practice. The students have authored Web pages (the format for their ePortfolios) to showcase their work.

The third area, the notion of the portfolio as a unifying project that linked the pre-service program elements into a cohesive, personal learning experience, appears essential for student satisfaction. By drawing from their eJournals, students reported they were able to review their experiences, reflect on previous entries/activities, and see their personal growth. They found ePortfolios encouraged goal-oriented thinking and planning that invited them to consider audience, intention, and structure. This is consistent with the initial goals of the original work into learning plans. The process of selecting, editing, and developing portfolios resisted the traditional, fragmented university experience of independent courses that eventually lead to a degree, without necessarily promoting synthesis. In essence, eDOL supported the notion of synthesis through the process of reflection. The students stated that the unity of thought, activity, experience, and multiple perspectives helped them to begin to build their cohesive "beginning teacher" identities, allowing them to consider what was important and meaningful. Because the portfolios, and the archived data stored in their journals were electronic, students could easily modify and share it to a range of audiences (instructors, partner teachers, peers, and family), allowing others to view their work and regularly join in the ongoing conversation.

Fourth, eJournals provide a way to extend real-time social interactions by allowing users to reflect on face-to-face interactions. They also honor diverse learning styles, as not all students are comfortable or confident in verbal interactions. The flexible nature of BLOGS also allowed students to provide "evidence" of their claims by linking supporting images, text, or audio files.

In many ways, the fifth area is the most profound; the notion of finishing with a place to start. The students coined this phrase, and it is eloquent in its simplicity. As students leave the university and begin their careers, they take with them rich experiences, technology skills, a sustainable online

community of support and collegiality, and structure for a dynamic professional portfolio. They know they can maintain their connections with their mentors and peers through their eJournals, and they can continue to modify and add to their ePortfolios. By reviewing the ePortfolios and participating in the eJournals, faculty know that students recognize their increasing growth and professional maturity. The evidence provided in eDOL helps the students to make tangible the intangibles (Eisner, 1998). Journaling and maintaining a portfolio, like the learning plans, helps students to recognize both their individual and their professional selves and through that recognition, begin to reflect and grow.

FUTURE TRENDS

The use of ePortfolios for learning, employment, personal growth, and workplace certification is increasing. For example, "The Learning Innovations Forum d'Innovations d'Apprentissage (IfIA) in the Americas, together with the European Institute for E-Learning (ELfEL) in the European Union, actively advocate for:

- An ePortfolio for every citizen by 2010, and
- One ePortfolio for life" (Chang Barker, 2006, p. xxvi - xxvii).

The research from the eDOL example suggests that a portfolio, by itself, will probably serve workplace certification needs, but it may not address the needs for individual learning and personal growth. Those two areas require a venue for social interaction, collaboration, and reflection. Therefore, it is critical to use of both elements (journal and portfolio).

CONCLUSION

The relationship between learning plans and electronic documentation of learning experiences is clear. In many ways, ePortfolios are simply expanded, multimedia rich, learning plans. In the example of eDOL, the introduction of a reflective, interactive journal was a critical piece to enhance the value of the portfolio. Based on the findings from both studies (Crichton, Franks, O'Rourke, & Hodges, 2007; Kinsel, 2004), it appears that students must have a way to chart their progress, and make tangible and visible what it means to learn and grow professionally. Further, Marzano (2007) notes the importance of establishing and communicating learning goals, tracking student progress, and celebrating success. Findings from the use of learning plans and eDOL echo this as well. The potential afforded by electronic options, especially those using open source software, such as DRUPAL, simply improves access, ease of use, and the type of data and evidence that can be included.

KEY TERMS

Authentic Learning: An approach that encourages students to explore, discover, discuss, and meaningfully construct concepts and relationships in contexts that involve real-world problems and projects that are relevant and interesting to the learner. Sometimes referred to as problem-based learning.

Demonstrations of Learning: Opportunities for students to **show** what they know rather than simply being evaluated using standard exams.

Digital Divide: Digital divide refers to the gap between those with regular, effective access to digital and information technology, and those without it. It encompasses both physical access to technology, hardware and, more broadly, the resources and skills needed to effectively participate as a digital citizen. In others words, it's the unequal access to some sectors of the community to information and communications technology, and the unequal acquisition of related skills (Wikipedia, 2007)

ePortfolios: An electronic portfolio, also known as an ePortfolio or digital portfolio, is a collection of electronic evidence assembled and managed by a user, usually on the Web. Such electronic evidence may include inputted text, electronic files, such as Microsoft Word and Adobe PDF files, images, multimedia, blog entries, and hyperlinks. EPortfolios are both demonstrations of the user's abilities and platforms for self-expression, and, if they are online, they can be maintained dynamically over time. Some ePortfolio applications permit varying degrees of audience access, so the same portfolio might be used for multiple purposes (Wikipedia, 2007).

eJournals: Electronic journals that allow multiple users to post comments within a secure, blogging environment. Other social software can be used, but in this chapter, DRUPAL, an open source blogging software, (http://drupal.org/) is used.

Learning Plans: A learning plan is in two parts. It is designed to make, much more explicit, the expectations of all parties (particularly student and Research Institute) in an attempt to avoid misunderstandings. In addition, students are required to keep much more detailed records of their activities as part of their research degree programme, which will help the RI better to monitor progress and become aware of any potential problems (http://www.keele.ac.uk/gradschool/learning.htm).

Open Source: Open source is a set of principles and practices that promote access to the design and production of goods and knowledge. The term is most commonly applied to the source code of software that is available to the general public with relaxed or nonexistent intellectual property restrictions. This allows users to create software content through incremental individual effort or through collaboration (Wikipedia, 2007).

Pre-Service Teaching: Typically called teacher preparation, it is a program within a college or university focused on the preparation for teachers, primary for the K-12 school environment.

Reflection: The initial act of reviewing and thoughtfully considering previous actions, events, and contexts as a form of constructive inquiry and personal growth and development.

Linking Information Technology, Knowledge Management, and Strategic Experimentation

V. K. Narayanan
Drexel University, USA

INTRODUCTION

Historically, the focus of IT infrastructure had been to capture the knowledge of experts in a centralized repository (Davenport & Prusak, 1998; Grover & Davenport, 2001; Nolan, 2001). The centralized databases contained knowledge that was explicit and historical (e.g., competitor pricing, market share), and the IT infrastructure served to facilitate functional decision making or to automate routine tasks (as in reengineering). The users of technology approached the repository to obtain data in a narrowly defined domain (Broadbent, Weill, & St. Clair, 1999). Consequently, IT originally played a significant, yet ultimately limited role in the strategy creation process. Management information systems (MISs) arguably generated information that was less applicable to strategy creation, as noted in early writings on the linkage between MIS and strategic planning (e.g., Lientz & Chen, 1981; Shank, Boynton, & Zmud, 1985; Holmes, 1985).

The active management of knowledge was similarly underdeveloped. Despite the fact that strategic decision makers had always emphasized the role of tacit knowledge, the actual importance of knowledge was not *explicitly* recognized. Formalized knowledge management (Davenport & Prusak, 1998; Dalkir, 2005), with its associated terminology and tools, is a recent development and as such did not inform the strategic planning process.

However, the shifts that have taken place in IT infrastructures over the last decade and the recent developments in knowledge management (KM) have brought them closer to the creators of strategy. Indeed, both IT and knowledge management are increasingly enablers in the contemporary strategic management practice:

1. IT infrastructure is transitioning in its focus from the functional work unit to a process orientation. Whereas computer systems were once the focal point, the new infrastructure is network centric, with an emphasis on business knowledge (Nolan, 2001). For example, traditional search engines utilized rule-based reasoning to identify elements matching specific search criteria; the "state-of-the-art" knowledge management systems employ case-based search techniques to identify all relevant knowledge components meeting the user's request (Grover & Davenport, 2001).
2. IT now takes into account contexts that include cross-functional experts, knowledgeable on a wide variety of potentially relevant issues. Additionally, there is greater emphasis on the integration of infrastructure with structure, culture (Gold, Malhotra, & Segars, 2001), and organizational roles (Awad & Ghaziri, 2004). In many ways, the newer IT infrastructures have enabled the garnering of explicit knowledge throughout the organization to speed up strategy creation.

The objective of this article is to outline how the developments in IT and KM are facilitating the evolution of strategic management to strategic experimentation to create quantum improvements in strategy creation and unprecedented developmental opportunities for the field if IT.

BACKGROUND

For the purposes of this article, *information technology* (IT) is defined as the physical equipment (hardware), software, and telecommunications technology, including data, image, and voice networks, employed to support business processes (Whitten & Bentley, 1998). The overarching plan for IT deployment within an organization is called the IT architecture. Technology infrastructure refers to the architecture—including the physical facilities, the services, and the management—that support all computing resources in an organization (Turban, McLean, & Wetherbe, 1996).

As used in this article, data are objective, explicit pieces or units, information is data with meaning attached, and knowledge is information with an implied element of action. According to Davenport and Prusak (1998):

"Knowledge is the fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information. It originates and is applied in the minds of knowers. In organizations, it often becomes embedded not only in documents or repositories but also in organizational routines, processes, practices, and norms." (p. 5)

Knowledge management is "a set of business practices and technologies used to assist an organization to

obtain maximum advantage from one of its most important assets—knowledge" (Duffy, 2000, p. 62). In other words, it is actively capturing, sharing, and making use of what is known, both tacitly, informally and explicitly, within the organization. IT often facilitates knowledge management initiatives by integrating repositories (e.g., databases), and indexing applications (e.g., search engines) and user interfaces. Awad and Ghaziri (2004) underscore the fact that KM also incorporates traditional management functions: building trust among individuals, allocating resources to KM, and monitoring progress.

The concept of "strategy" explicated in *strategic management* is one of marketplace strategy, that is, winning in the marketplace against competitors, entrenched or incipient. The underlying premise is that "to enjoy continued strategy success, a firm must commit itself to outwitting its rivals" (Fahey & Randall, 2001, p. 30). A large body of literature on strategic management has persuasively argued that effective strategy creation and execution are central to a firm's performance (e.g., Covin, Slevin, & Schultz, 1994).

Strategy creation involves both goal formulation—defined in terms of external stakeholders rather than operational milestones—and crafting of the strategic means by which to accomplish these goals (Hofer & Schendel, 1978). The means typically include business scope, competitive posture, strategic intent, and the organizational mechanisms for implementation. In practice, the process of strategy creation has often taken the form of strategic planning. Comprehensive strategic planning (Gluck, Kaufman, & Walleck 1978) has historically been practiced in large corporations: A celebrated example is the use of scenarios by Royal-Dutch Shell. It usually consisted of several sequential stages of decision making involving diagnosis, alternative development, evaluation and choice, and implementation. In each step, the strategic planners emphasized deliberate juxtaposition of "objective data" and careful analysis, with top management judgment, thus highlighting the role of tacit knowledge.

Strategic planning has evolved over the years. Writing in the 1970s, Gluck et al. (1978) identified four phases of evolution: budgeting, long-range planning, strategic planning, and strategic management. Each phase of evolution incorporated the lessons from the earlier phases, but also took into account the emerging realities faced by corporations. Gluck et al. (1978) noted that during the 1980s, the "strategic management" phase would represent the cutting edge of practice in the world.

TOWARD STRATEGIC EXPERIMENTATION

The 1990s witnessed a revolution in organizational environments often characterized as "hypercompetition." These environments have created three major imperatives for organizations: time compression, globalization, and technology integration (Narayanan, 2001). In addition, the increased environmental dynamism also contributes to an increase in the degree of uncertainty confronted by strategic managers, calling into question traditional planning practices. Consequently, a new type of strategy creation process is evolving which is termed "strategic experimentation." With this evolution, the relationship between strategy creation, knowledge management, and IT is undergoing a profound shift.

All the four phases of strategic planning documented by Gluck et al. (1978) incorporated a sequential approach to strategy creation and execution, leading to the identification of the one winning strategy that has the highest probability of success. Consequently, firms found it logical to commit the maximum available resources to the implementation of one winning strategy. The goal was to obtain a sustainable competitive advantage vis-à-vis the firm's rivals, and to reduce uncertainty ex ante using analytical forecasting techniques as well as market research. This approach to planning seems to have been effective during the 1980s, when the environment was moderately dynamic.

In hypercompetitive environments, market participants frequently confront great uncertainty over technological possibilities, consumer preferences, and viable business models. This high level of ambiguity often results in a situation where: (a) traditional methods of ex ante uncertainty reduction (e.g., market research) fail, and (b) the costs and risks of the traditional "big bet" strategic management approach outweigh its advantages in terms of focus, decisiveness, and concentrated resource commitment. It is in this situation that the emerging strategic experimentation approach holds significant promise.

Strategic experimentation (McGrath & MacMillan, 2000) draws on *real-options reasoning* (e.g., McGrath & Nerkar, 2003), discussions of *exploration vs. exploitation* (March, 1991), as well as *trial-and-error learning* (e.g., Van de Ven & Polley, 1992):

1. Companies engaging in strategic experimentation continually start, select, pursue, and drop strategic initiatives before launching aggressively those initiatives whose value is finally revealed (McGrath & MacMillan, 2000, p. 340).
2. Strategic initiatives thus serve as low-cost probes (Brown & Eisenhardt, 1998) that enable the discovery of product technology and market preferences. They also serve as a stepping stone *option* for future competitive activity in that particular product-market domain.
3. The role of the strategic manager is to administer a *portfolio of strategic initiatives* that represents an appropriate mix of high and low uncertainty projects, and to maximize the learning from these real options (McGrath & MacMillan, 2000).

Strategic experimentation represents a fundamentally different view of the practice of strategic planning and the path to competitive advantage. Movement is emphasized over position in this approach. Thus, competitive advantage is viewed as temporary at best, and hence innovation and learning are considered crucial to success. Strategic experimentation is especially appropriate for high-velocity environments such as emerging product markets with high uncertainty surrounding both technology and customer preferences (e.g., the early Personal Digital Assistant (PDA), Internet appliance, and satellite-based telephony markets). Here, low-cost probes can be very effective in gaining knowledge and reducing uncertainty while minimizing exposure to the results of faulty assumptions.

THE ROLE OF IT AND KNOWLEDGE MANAGEMENT IN THE ERA OF STRATEGIC EXPERIMENTATION

Since "strategic experimentation" represents the cutting edge of ideas in strategic management, we should expect significant advances in tool development and utilization in the next few years that will enable movement of the idea towards normal organizational practice.

Strategic experimentation necessitates several major functions to be performed by an organization. KM is critical in strategic experimentation; therefore, it is not surprising that many of the tools currently moving into practice have emerged from the KM. The four major strategic experimentation functions and the associated KM tools are:

- *Rapid Decision Making:* The ability to *quickly* garner tacit knowledge in all phases of decision making is a central requirement in strategic experimentation. Current KM tools to support this include visualization and prototyping, group decision facilitation, and knowledge representation. Each method attempts to reduce the time needed for a group to progress from problem identification to solution implementation. These tools help to coordinate the use of data, systems, tools, and techniques to interpret relevant information in order to take action (Ruggles, 1997).
- *Integration of Learning from Experiments:* Organizational learning, another core concept in strategic experimentation, requires that appropriate learning be distilled from each experiment. This orientation combines decision making and learning: initiatives judged to be failures are not merely weeded out, nor are successes simply alternatives to be financially backed. In contrast, failures become occasions for discovery of root causes; successes often generate potential best practices. Current KM tools in use for this purpose include learning histories (Roth & Kleiner, 1998), group brainstorming, and shared communication platforms (Dalkir, 2005).
- *Diffusion of Learning:* Finally, organizational learning must be diffused throughout the organization. Since formal organizational channels may stifle transmission of tacit knowledge (Williams, 2006), diffusion may require interactions among "communities of practice" (Wenger, McDermott, & Snyder, 2002; Narayanan, Douglas, Schirlin, Wess, & Geising, 2004). An organizational architecture, incorporating relevant tools and IT infrastructure, must be designed to support theses interactions. KM tools, such as knowledge maps identifying the experts in specific areas and repositories of case histories, are evolving to include dynamic updating of repositories and focused search tools to reduce information overload.
- *Managing a Portfolio of Strategic experiments:* Unlike in previous eras, strategic experimentation requires maintenance and management of a portfolio of initiatives (Narayanan, Buche, & Kemmerer, 2001). This has three major implications. First, the knowledge base for decisions must be broader and richer, simply due to the increase in the number of initiatives. Second, the knowledge base becomes much more complex, since the initiatives themselves differ in terms of the mix of tacit and explicit knowledge. Thus, newer initiatives are likely to be more dependent on tacit knowledge, whereas mature ones can be augmented by explicit knowledge. Finally, the sheer number of people involved in the process will be larger, given specialized pockets of tacit knowledge that would have grown up around specific strategic initiatives. DSSs and other rich data applications, including cognitive mapping, can be used to capture the knowledge and feedback.

IT can accelerate the development of strategic experimentation by designing infrastructures that accommodate the new KM demands (Smith & McKeen, 2003; King, Marks, & McCoy, 2002) imposed by this new mode of planning. Consider how each of the following functions can be enhanced by IT infrastructure development:

1. Future developments can significantly reduce the time expended in solution development through real-time displays and expand opportunities for geographically dispersed collaboration. Also, advanced multimedia and communication capabilities would increase the benefits of GSS and DSS tools.
2. Learning from experiments can be enriched by qualitative database construction, multimedia enhancements to communication applications, and open platforms to permit the sharing of knowledge over various communication channels, including wireless media.

3. Today, diffusion is hampered by information overload that has intensified competition for the user's attention (Hansen & Haas, 2001). To solve the problem, search tools should include separate parameters for content, rationale, and purpose of the query, in order to isolate salient responses. Additionally, knowledge repositories must be maintained to ensure the contents are accurate and of high quality. Also, maintenance, currently provided by intermediaries (Markus, 2001), might be performed by faster automated systems.
4. Expert systems or neural networks may be developed to manage and track portfolios, promoting reuse of the knowledge captured.

The significant implication for IT infrastructure from our discussion is the need for *technology integration* (Narayanan, 2001) with both hard and soft technologies. IT infrastructure should exploit the potential for integration with other *hard* technologies such as telecommunications to enhance the organizational capacity for speed and carrying capacity for *tacit* knowledge. Similarly, IT should seek to interface with *decision sciences* to embed AI-based processing tools, and with *cognitive theorists* to capture the tacit knowledge pervasive in organizations.

FUTURE TRENDS

Over the last decade, there has been a greater appreciation of both the importance of knowledge management and its links to IT. Indeed, KM as an organizational function and academic discipline is fast arriving at maturity; the linkage between KM and strategic management has been slow in building. We expect this to change in the coming decade. Platforms for strategic experimentation, built on overlay of KM and IT, are currently in the works among pioneering firms. We expect that the ideas around experimentation will begin to take off, with methods and approaches to identify, codify, and disseminate among organizational members being refined and utilized.

CONCLUSION

We have argued that the technological changes of the 1990s have ushered in the need for strategic experimentation as the metaphor for planning practice. Strategic experimentation involves: (a) maintaining a portfolio of strategic thrusts, (b) rapid decision making so that successful experiments are backed and failures are weeded out quickly, (c) learning from both successes and failures, and (d) diffusion of both explicit and tacit knowledge throughout the relevant segments of an organization. This phase requires fundamental shifts in our view of knowledge management: its significance, use, and tools. Finally, we have argued that the shift to strategic experimentation requires fundamental shifts in the development of IT infrastructure. Instead of developing in relative isolation to other disciplines, IT should focus on technology integration, by working in close collaboration with the telecommunication technologies, artificial intelligence community, and managerial cognition scholars.

KEY TERMS

Exploration and Exploitation: Exploration refers to process of discovery of knowledge, whereas exploitation refers to utilizing the knowledge. Similar to basic and applied research.

Information Technology (IT): The physical equipment (hardware), software, and telecommunications technology, including data, image, and voice networks, employed to support business processes.

Knowledge Management (KM): A set of business practices and technologies used to assist an organization in obtaining maximum advantage of its knowledge.

Options: A financial option owes the holder the right but not the obligation to trade in securities at prices fixed earlier. Options in the sense used here confer a firm the rights *and obligations* to choose a strategic alternative.

Strategic Experimentation: A form of strategic management in which firms continually start, select, pursue, and drop strategic initiatives before launching aggressively those initiatives whose value is finally revealed.

Strategic Management: The process of strategy creation and implementation. The concept of "strategy" as used here is one of marketplace strategy, that is, winning in the marketplace against competitors, entrenched or incipient. Strategy creation involves both goal formulation—defined in terms of external stakeholders rather than operational milestones—and crafting of the strategic means by which to accomplish these goals. Implementation refers to the means of execution of the created strategy.

Technology Integration: Activities involved in combining technologies. It could be combining process technolo-

gies as in incorporating biological process in mechanical equipment. Alternately it could be in product development, for example the merging of personal computers and satellite communications.

Trial-and-Error Learning: A process of learning through experimentation. Here strategic initiatives judged to be failures are not merely weeded out, nor are successes simply alternatives to be financially backed. In contrast, failures become occasions for discovery of root causes; successes often generate potential best practices.

Lip Extraction for Lipreading and Speaker Authentication

Shilin Wang
Shanghai Jiaotong University, China

Alan Wee-Chung Liew
Griffith University, Australia

INTRODUCTION

In recent years, there is a growing interest in using visual information for automatic lipreading (Kaynak, Zhi, Cheok, Sengupta, Jian, & Chung, 2004) and visual speaker authentication (Mok, Lau, Leung, Wang, & Yan, 2004). It has been shown that visual cues, such as lip shape and lip movement, would greatly improve the performance of these systems. Various techniques have been proposed in the past decades to extract speech/speaker relevant information from lip image sequences. One approach is to extract the lip contour from lip image sequences. This generally involves lip region segmentation and lip contour modeling (Liew, Leung, & Lau, 2002; Wang, Lau, Leung, & ALiew, 2004), and the performance of the **visual speech recognition** and **visual speaker authentication** systems depends much on the accuracy and efficiency of these two procedures.

Lip region segmentation aims to label the pixels in the lip image into lip and non-lip. The accuracy and robustness of the lip segmentation process is of vital importance for subsequent lip extraction. However, large variations caused by different speakers, lighting condition, or make-ups make the task difficult. The low color contrast between lip and facial skin, and the presence of facial hair, further complicate the problem. Given a correctly segmented lip region, the lip extraction process then involves fitting a lip model to the lip region. A good lip model should be compact, that is, with a small number of parameters, and should adequately represent most valid lip shapes while rejecting most invalid shapes. As most lip extraction techniques involve iterative model fitting, the efficiency of the optimization process is another important issue.

BACKGROUND

Accurate and robust lip region segmentation is of key importance for subsequent lip extraction. Techniques developed for lip segmentation are generally based on color space analysis, edge detection, Markov random field, or fuzzy clustering.

The color space analysis approach (Eveno, Caplier, & Coulon, 2001) identifies the lip pixels solely by their color information. However, color space-based methods are sensitive to poor color contrast and noise, and would give large segmentation error if the color distributions of lip and background regions overlap. The edge detection approach (Caplier, 2001) relies on the luminance or color edge information to detect the lip boundary. It works well when the speakers use lipstick or reflective markers. However, it would have difficulty dealing with unadorned lips. Markov random field (MRF) technique has also been used in lip region segmentation (Lievin & Luthon, 1999). MRF exploits local neighborhood information to enhance the robustness of the segmentation. However, MRF-based segmentation usually produces erroneous patches outside and inside the mouth region due to the presence of pixels with the wrong color distribution class.

Fuzzy clustering is another powerful tool for image segmentation. **Fuzzy clustering** attempts to assign a probability value to each pixel in order to minimize the fuzzy entropy. Since it is an unsupervised learning method, fuzzy clustering is capable of handling lip and skin color variation caused by make-up. Recently, we have proposed several novel fuzzy-clustering-based segmentation techniques that take the local (Liew, Leung, & Lau, 2000, 2003) and **global spatial information** (Leung, Wang, & Lau 2004; Wang, Lau, Liew, & Leung, 2007) into account to improve the segmentation performance. In our approaches, **spatial information** is seamlessly incorporated into the cost function and the optimization process.

Many techniques have been proposed for **lip modeling and extraction,** and they differ from each other in the following aspects:

- **The lip model used:** Active contour models (Snakes) (Eveno, Caplier, & Coulon, 2003; Lievin, Delmas, Coulon, Luthon, & Fristot, 1999), deformable templates (Hennecke, Prasad, & Stork 1994; Liew et al., 2002), active shape models (ASM) (Cootes, Hill, Taylor, & Graham, 1994; Luettin, Thacker, & Beet, 1996), and

active appearance models (AAM) (Cootes, Edwards, & Taylor, 2001; Matthews, Cootes, Bangham, Cox, & Harvey 2002) are some of the widely used lip models.

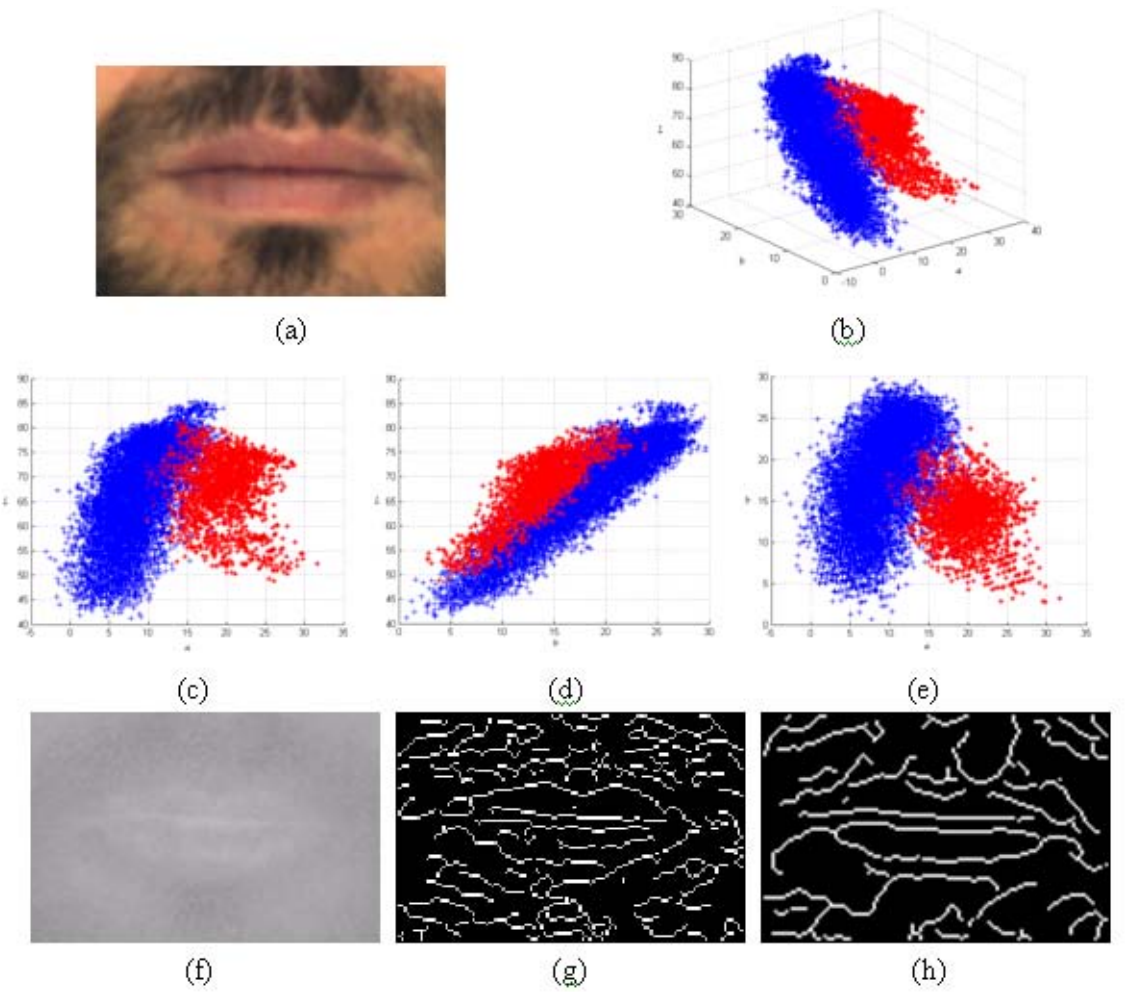
- **The cost function used:** Edge-based, intensity-based, and region-based cost functions are some of the typical approaches for evaluating the model fitness.
- **The optimization procedure:** Since iterative technique is often required to search for the best parameters, the convergence speed and the stability are the two important issues in optimization. The choice of cost function would affect the optimization scheme.

In our recent work (Wang, Lau, & SLeung, 2004), we have proposed a new lip modeling and extraction algorithm that fits a 16-point lip model by minimizing a region-based **cost function** using a point-driven **optimization scheme**.

FUZZY-CLUSTERING-BASED LIP IMAGE SEGMENTATION

Lip region segmentation is a difficult problem. Figure 1 shows a lip image and its corresponding color distribution for the lip and non-lip pixels in the CIE-1976 CIELAB color space, where * and + represent the lip and background (or non-lip) pixels, respectively. The hue image, with the hue definition given in Zhang and Mersereau (2000), and the edge map are also shown. We see that lip and non-lip pixels overlap severely in the color space, and cannot be easily

Figure 1. (a) Original lip image; (b) Color distribution in CIELAB color space; Color distribution projection on (c) L-a plane, (d) L-b plane, (e) b-a plane; (f) Hue map of the lip image; (g) Edge map based on hue information; (h) Edge map based on intensity information



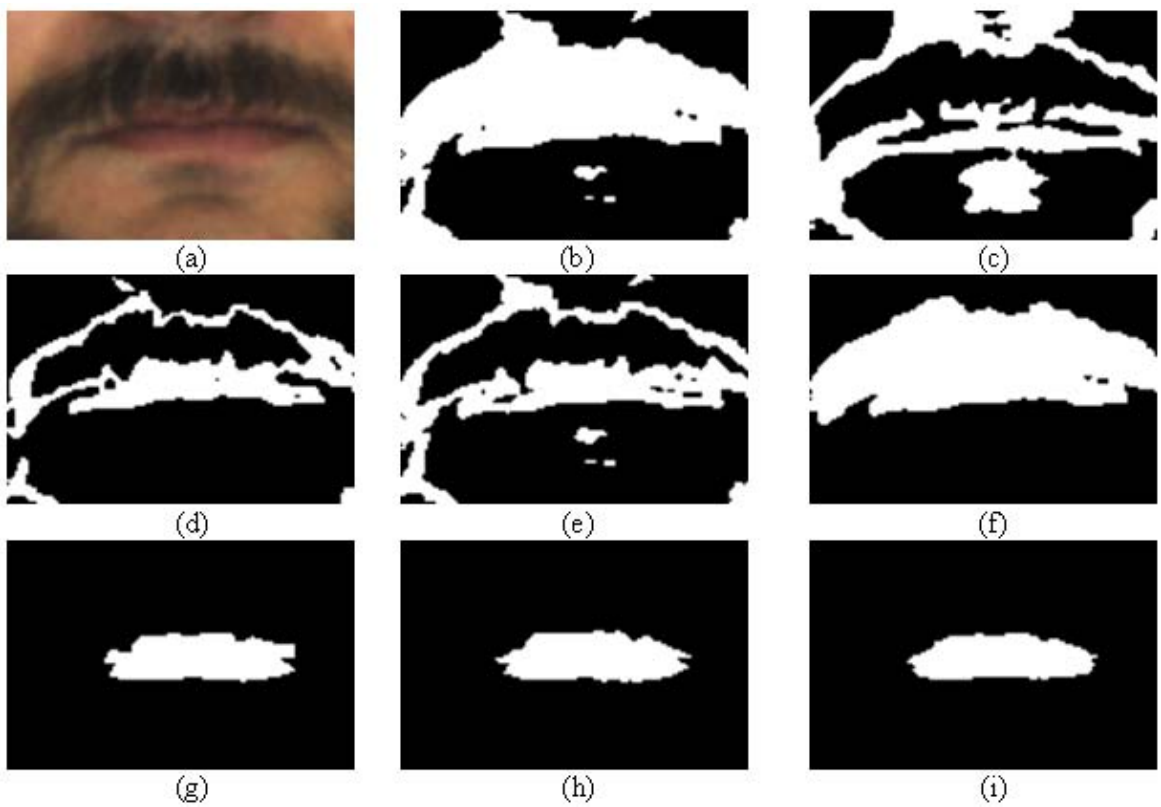
separated based on color information alone. The presence of facial hair results in many luminance and hue edges in the image, and the use of edge information for lip boundary detection becomes difficult. Moreover, the traditional two-class partitioning methods are utterly not appropriate, since the background region is too complex and inhomogeneous. In order to overcome these difficulties, we recently proposed a **fuzzy-clustering**-based lip-segmentation algorithm that can handle complex background, called multiclass, shape-guided fuzzy c-means (MS-FCM) clustering.

Fuzzy c-means (FCM) clustering aims to assign a membership value to each pixel, based on the distance to the cluster centroids in the feature space, in order to minimize a fuzzy entropy measure. In the conventional FCM algorithm, the clustering process depends solely on the feature space distribution, and each pixel is treated independently. However, for data with an inherent spatial ordering, such as image, additional information from the spatial connection among pixels should be exploited (Liew et al., 2000, 2003). Furthermore, for the specific task of **lip segmentation**, prior knowledge about the lip region could also be exploited (Leung et al., 2004; Wang et al., 2004, 2007).

Since lip pixels form a large patch, their distances from the lip center provide useful information to differentiate the lip region from the background. In MS-FCM, such prior shape information is seamlessly incorporated into the objective function to discriminate the non-lip pixels located at a distance away from the lip. **The spatial term** in the objective function penalizes the lip membership value of non-lip pixels outside the lip boundary, even though they might have similar color distribution as the lip pixels. The shape information utilized in the "shape-guided" algorithm helps to overcome the color overlap problem between the lip and background region.

The color information of the background pixels usually has a multimodal distribution due to background inhomogeneity. Modeling it using one spherical cluster would incur large segmentation error. In order to improve the modeling accuracy, multiple clusters are employed to describe the complex background region. An adaptive method is designed

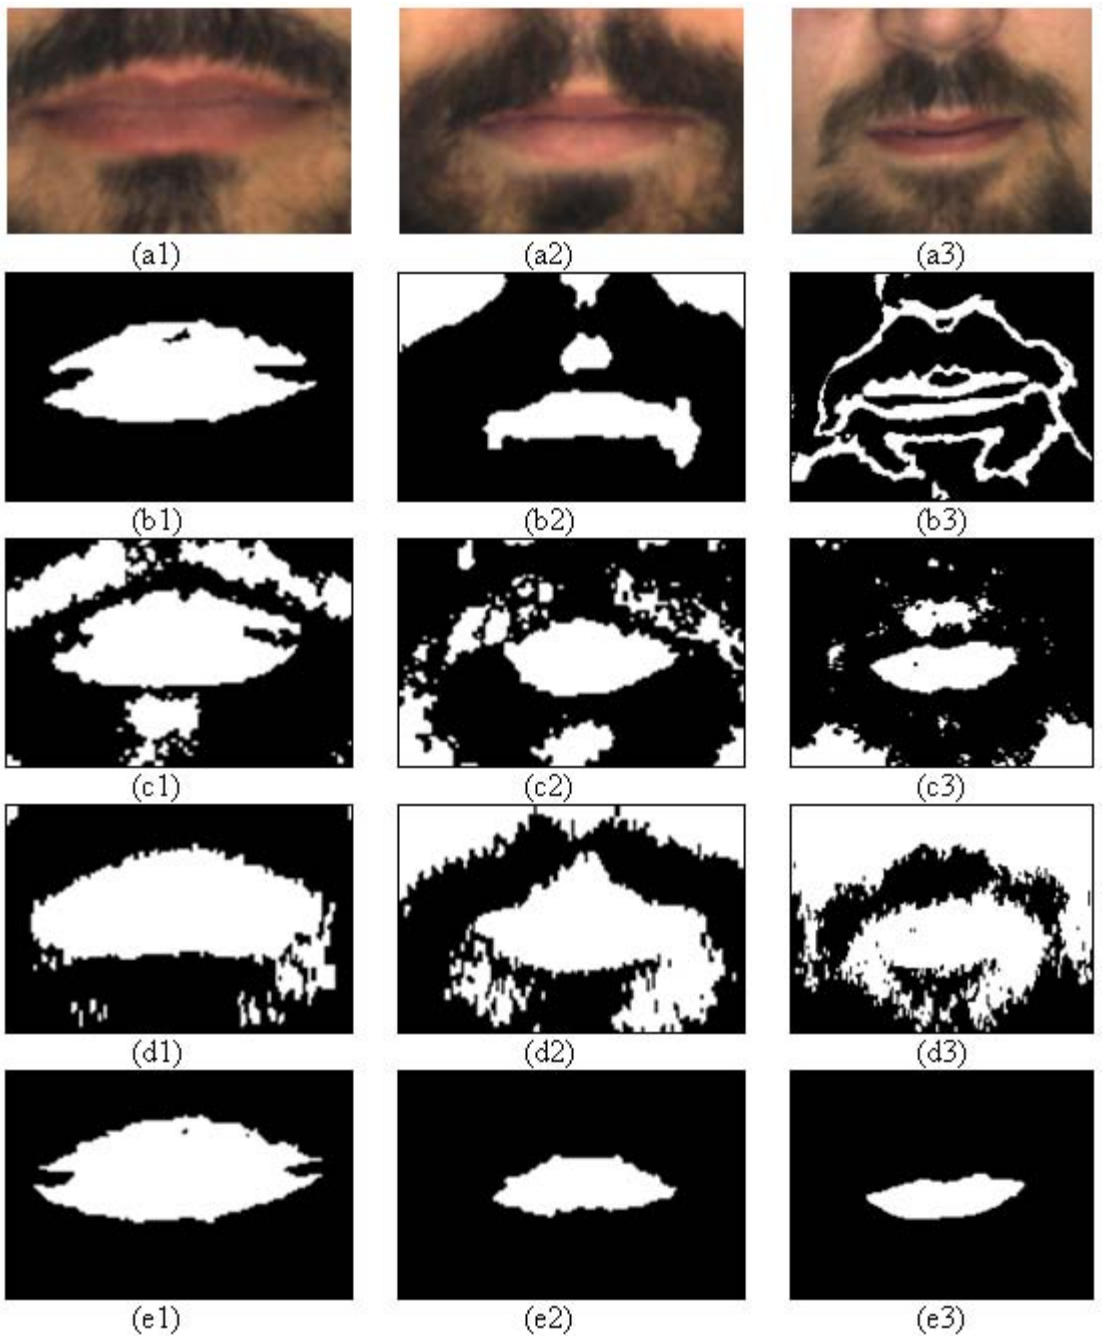
Figure 2. (a) Original lip image; lip-segmentation result obtained by the conventional FCM with (b) C=2, (c) C=3, (d) C=4, (e) C=5; lip-segmentation result obtained by MS-FCM with (f) C=2, (g) C=3, (h) C=4, (i) C=5



to select the appropriate number of background clusters to collectively model the complex background distribution. The "multiclass" feature of our algorithm helps to reduce misclassification caused by inadequate background modeling.

The "multiclass" and the "shape-guided" features are the two key novelties of our algorithm, and they work together to overcome the difficulties of segmenting lip images with complex background. Figure 2 shows the typical segmen-

Figure 3. (a1),(a2),(a3) Original lip images. Segmentation results of: (b1),(b2),(b3) conventional FCM, (c1),(c2),(c3) Lievin's method, (d1),(d2),(d3) Zhang's method, and (e1),(e2),(e3) MS-FCM.



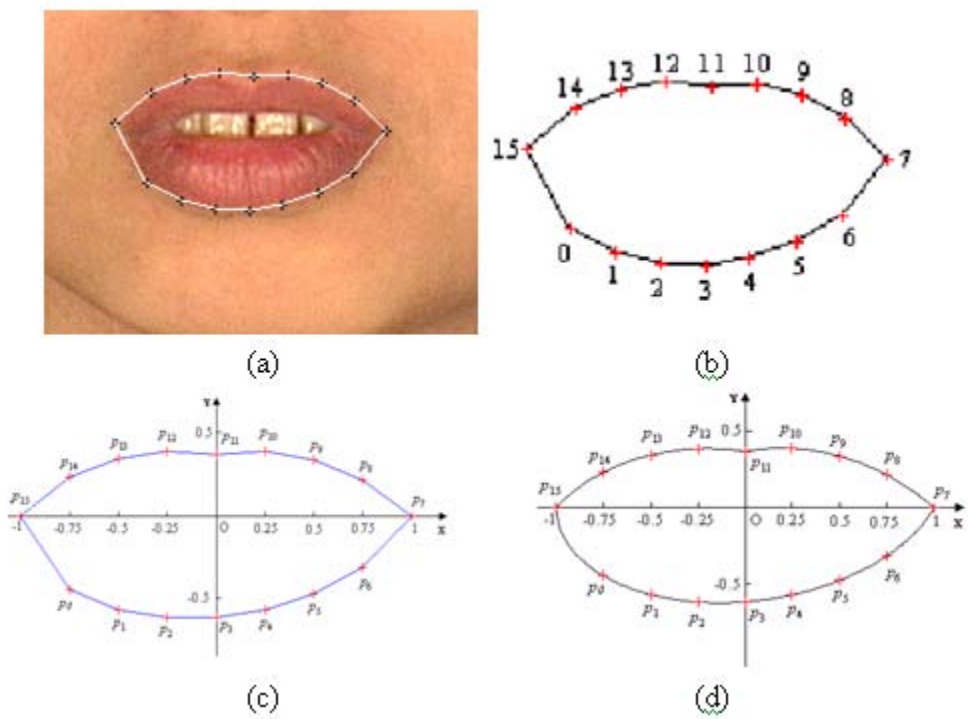
tation results obtained from the conventional FCM and the MS-FCM algorithm using different numbers of background clusters (where C is the total number of clusters). It is observed that the conventional FCM is unable to segment the lip region accurately for an image with complex background, even with different setting of C; whereas MS-FCM is able to clearly segment the lip region for C larger than 2 . The results indicated that the use of prior shape information and multiple background clusters are both necessary to ensure a good segmentation. Without using multiple background clusters, large segmentation error occurs due to insufficient background modeling, even if shape information is considered (Figure 2(f)). Without the prior shape information, poor segmentation result is obtained, even if multiple background clusters are employed (Figure 2(c)(d)(e)).

In Figure 3, three difficult lip images are used to compare the performance of the proposed algorithm with the conventional FCM, Lievin and Luthon's method (Lievin's for short) (1999), and Zhang and Mercereau's method (Zhang's for short) (2000). It can be seen that the conventional FCM can deliver acceptable results if the lip and the background are well differentiated (see Figure 3(b1) with three clusters). However, when the lip color and part of the background color are close, the conventional FCM is unable to produce good segmentation, even with more clusters (see Figure 3(b3) with five clusters). In Lievin's and Zhang's methods, basically two clusters are used to segment the image using the hue information. When the hue of the lip region and the background are close, the two-class assumption becomes inappropriate, resulting in poor segmentation (see third and forth rows in Figure 3). Zhang's method further makes use of edge information to aid the segmentation. It produces large segmentation errors, since the edge map is noisy for lip image with beards. Finally, the last row shows the segmentation results obtained from our algorithm with three clusters. It clearly outperforms the other three methods.

MODEL-BASED LIP CONTOUR EXTRACTION

In our method, a 16-point lip model is used to describe the lip contour, as shown in Figure 4(b). These points are divided into three groups: p_0 to p_7 and p_{15} describe the lower lip; p_7 to p_{11} and p_{11} to p_{15} describe the upper-right lip and the upper-left lip, respectively, p_7 and p_{15} are the lip corners, and

Figure 4. (a) Lip image with contour shown in white; (b) original 16-point lip model (before normalization); (c) normalized 16-point lip model; (d) lip contour points constrained by the geometric lip model.



p_{11} is the dip point. In order to reduce the number of free parameters in the model, a normalization process is used to translate the lip corner points p_7 and p_{15} to lie on the *x*-axis and the dip point p_{11} on the *y*-axis (see Figure4 (c)). Moreover, a geometric model, consisting of three connected quadratic curves, is used to constrain the extracted lip contour to be physically valid (see Figure 4 (d)). The geometric model is flexible enough to describe different lip shapes in that: (i) the asymmetry between the left and right sides caused by skewing is allowed; (ii) no bounded assumption is made about the relationship between the upper lip and lower lip except for the connections on the corner points and dip point. As the geometric model is only used to constrain the 16-point lip model, there is no need to explicitly estimate the parameters of the geometric model from the image.

Given the probability map generated by the MS-FCM, the initial lip model can easily be derived. The left and right lip corners can be found by scanning the columns. The top and bottom boundaries can then be derived from the center axis between the left and right corner points. Then three quadratic equations are used to fit the upper and lower lip points independently. Finally, the initial 16-point model λ_p is obtained from this initial fit.

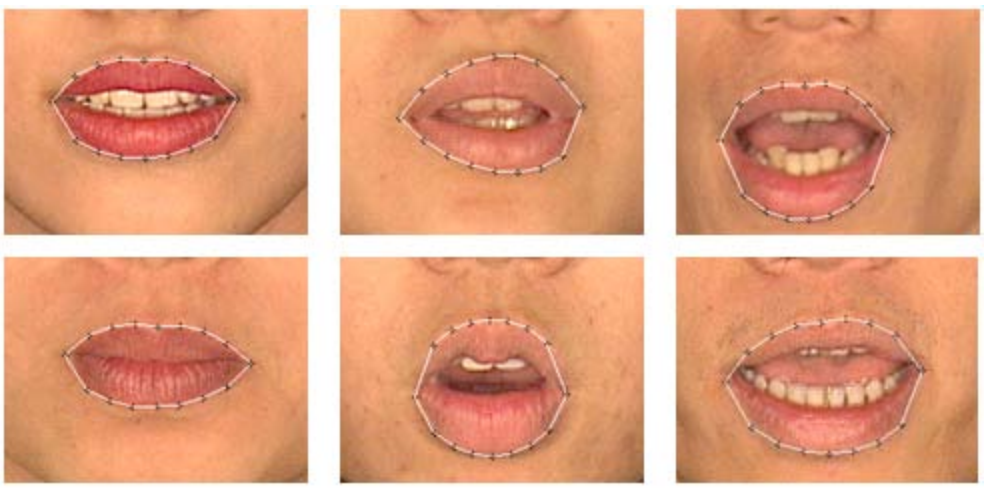
We use a region-based cost function to find the optimum model parameters such that the pixels inside the lip region have high probability of being lip pixels, while those outside have low probability. Region-based cost functions have larger capture range than their edge-based and intensity-based counterparts. They are also more robust and tolerant against changes in noise and illumination. We employ **an iterative point-driven optimization method** to adjust the lip-point locations. Since the optimization is point-driven rather than parameter-driven, the lip contour update becomes better controlled and, consequently, faster convergence is achieved. In each iteration, the displacement vector $\Delta\lambda_p$ and the new lip model can be updated by calculating the partial derivatives of the cost function with respect to λ_p (Sum, Lau, Leung, Liew, & Tse, 2001). Then after normalization, three quadratic curves are fitted to the 16-point model to obtain the parameters of the geometric model λ_g, which is subsequently used to constrain the 16-point model to form a valid lip shape.

Over 5,000 lip images of size 216×162 have been used to test the performance of our algorithm, and accurate lip contours can be obtained. Some lip extraction results are shown in Figure 5.

FUTURE TRENDS

Currently, the lip model parameters, found in the previous frame, are used as the initial parameters for the next frame. However, this simple approach is inadequate if the lip shape changes rapidly between successive frames due to fast articulation. Online prediction, based on Kalman filtering, can be used to provide a better initial estimate for tracking. The lip segmentation algorithm should also be made more robust to low image quality. In many applications, the captured videos are usually in compressed form. The degradation in image quality, due to compression, would undermine the fuzzy clustering process by biasing the color information. Transforming the color image to the S-CIELAB

Figure 5 Lip contour extraction results of different isolate lip images.



color space might be a possible solution for improving the segmentation accuracy.

CONCLUSION

Accurate lip extraction from lip image sequence is an important first step in automatic **lipreading** and **visual speaker authentication**. In this chapter, we described a lip segmentation and extraction algorithm that is accurate, robust, and efficient. In our segmentation algorithm, the shape information is incorporated into the fuzzy clustering process such that pixels with similar color, but in different regions, can be differentiated. In addition, multiple clusters are collectively used to model the complex background distribution. In our lip extraction approach, a 16-point lip model with geometric constraint is used to capture the lip shape. A point-driven optimization scheme is employed to speed up the iterative optimization process. Our algorithm is able to accurately extract the lip contour from video sequences in real time.

Zhang, X., & Mersereau, R. M. (2000). Lip feature extraction towards an automatic speechreading system. *Proc. of IEEE ICIP'2000, 3*, 226-229.

KEY TERMS

Cost Function: Also called objective function. A function associated with an optimization problem which determines how good a solution is.

Fuzzy C-Means Clustering: Fuzzy C-means clustering is the most well-known partition-based clustering algorithm. The algorithm starts by choosing *k* initial centroids, usually at random. Then the algorithm alternates between updating the cluster membership value of each data point with different cluster centroids and updating the centroids based on the new clusters until convergence.

Lip Contour Extraction: A process to derive the lip contour information from the lip image.

Lip Modeling: An approach to describe the lip region by a number of model parameters. Model definition, cost function formulation and the optimization process are the key issues of the lip modeling technique.

Lip Region Segmentation: Lip region segmentation is a process by which all the pixels in the lip image are partitioned into two categories, that is, the lip pixels and the non-lip ones.

Local and Global Spatial Information (for lip segmentation): In lip region segmentation, spatial information is incorporated to improve the segmentation performance by the color information only. The local spatial information is referred to the spatial continuity among neighbouring pixels while the global spatial information is referred to the spatial position of a pixel with respect to the lip region (i.e., inside the lip region, outside the lip region or around the lip-background boundary).

Normalization Process: Normalization is a process to refine the input data initial data so as to reduce various undesirable effects (such as translation, rotation in our application).

Point-Driven Optimization (for lip modeling)**:** Point-driven optimization is an iterative procedure to fit the lip model to the actual lip contour. In each iteration, each contour point is adjusted to a better position so as to increase the cost function. Compared with the other optimization methods, such as the parameter-driven optimization, the point-driven optimization approach usually requires less number of iterations and thus is more efficient.

Visual Speaker Authentication: Visual speaker authentication aims to perform speaker's identity authentication based on the identity-relevant visual information, such as the dynamic visual information of the lip movement.

Visual Speech Recognition: Visual speech recognition, also called lipreading, is a process to perform speech recognition only by the speech-relevant visual perception, such as the dynamic visual information of the lip movement.

A Literacy Integral Definition

INTRODUCTION

Due to the lack of a unique definition of literacy and the need for redefining this conception in a context characterized by the changes generated by the inclusion of new technologies in all aspects of the society, this explicative research article is oriented toward proposing a definition of literacy from an integral conception which is based on three main kinds of literacy: functional, informational and ethical.

This integral conception must orient the basic contents in the school curricula in all current educational models, mainly at the university level. We consider that knowledge is unique; it should not be divided into pieces. Therefore, it is necessary to integrate the new technologies, from this new paradigm, in the contents of the school curricula.

The present article compiles some general considerations about literacy, proposes a new definition of literacy from an integral conception, as well as each one of its components.

BACKGROUND

It is undeniable that info technology has an influence on human issues. It is also true that this influence has become more intense since the end of the 20th century with the rise of the Internet, when several changes appeared in regard to information treatment and interpersonal relationships by offering communication facilities never observed before.

Two breakthrough inventions formed the information society's foundation: computers and telecommunications, which play roles similar to those that the steam engine and electricity played during the industrial revolution (Cellary, 2003). In this sense, the Internet and the current scientific and technological development are the results of society's evolution which has gone through dedifferentiated and clearly defined stages: agrarian society, industrial society, and currently, *information society*.

Cellary (2003) explains in a very simple way the form in which both inventions have a notorious influence on society. On one hand, he shows that although computers can only capture a fraction of their programmers' real intelligence, computers behave like people in that they make correct decisions based on the knowledge encapsulated in the programs they run. On the other hand, telecommunications ensure common access to all computers connected to the Internet, giving the entire society the chance to share and spread information.

This information revolution tends to deprive humans of their decision-making monopoly, given their tireless speed and mathematical precision; computers will always outdo humans in performing any intellectual activity that can be explicitly defined (Cellary, 2003) and the facility for sharing results through the Internet.

This is consistent with the ideas of Gutiérrez (2003) who affirms that this convergence of languages and technologies and the arising of cyberspace as a relational environment promote three important changes: 1) new kinds of predominant documents, 2) new forms of communication, and 3) new education and communication environments.

Additionally, the main features defining the *information society,* according to Castells (2001) are firstly, an informational and technological revolution as basis. Secondly, a socioeconomic reorganization process known as globalization. Thirdly, a change in organization processes (not less deep than the previous one) as the transition from vertical organizations to Web organizations. Gutiérrez (2003) adds that these three factors and the interaction among them, generate important social and cultural changes.

However, the process has not produced purely benefits. Even when science, and in particular technology, has been produced by social progress, and both have undeniably offered great contributions in different areas: health, communication, education, culture, socio-politics, among others, inconveniences have also been produced.

Nowadays, it is necessary to educate citizens from a new perspective: the new citizens must be literate in the use of new technologies, but at the same time they must have a critical thinking, a reflexive and participative sense and be committed to society in order to be able to consciously and responsibly use sources. In other words, they must be integrally literate.

INTEGRAL LITERACY

Through the decades of 1980s and 1990s, the definitions of literacy have been widened to take into account the challenges of globalization, including the repercussions of the new technologies, modern media and the rise of the economies of knowledge (UNESCO, 2004). The definition of literacy employed in the Education for All 2000 Assessment is the following: "Literacy is the ability to read and write with understanding a simple statement related to one's daily life. It involves a continuum of reading and writing skills, and often includes also basic arithmetic skills (numeracy)" (UNESCO, 2004, pp. 12-13).

A proposed operational definition was formulated during an international expert meeting in June 2003 at UNESCO. It states: "Literacy is the ability to identify, understand, interpret, create, communicate and compute, using printed and written materials associated with varying contexts. Literacy involves a continuum of learning in enabling individuals to achieve their goals, to develop their knowledge and potential, and to participate fully in their community and wider society" (UNESCO, 2004, pp. 13).

Other authors have defined literacy from different perspectives. Bawden (2001) suggests that the first and simplest meaning implies only the ability to read and write. The second certainly implies this ability, but also requires something beyond it. Gilster (1997, cited in Badwen 2001) advises that the concept of literacy goes beyond simply being able to read; it has always meant the ability to read with meaning, and to understand. It is the fundamental act of cognition.

Similarly, as Clifford (1984, cited in Bawden, 2001) suggests, expert opinion has abandoned the dichotomous framework, of literate or illiterate, in favor of the conception of literacy as a continuum; at one end lies some ability to reproduce letter combinations. At the other end, lie such language learning behaviors as logical thinking, higher order cognitive skills, and reasoning.

Bawden (2001) indicates that for most of the centuries the term has been in use, it has meant being well educated, well-read, versed in literature and "letters" (the "learned" aspect of the definitions quoted at the start). More recently, it has taken on a more prosaic meaning of being able to make effective use of *information*, gained from written material.

However, all authors cited agree in the nonexistence of a unique concept of literacy and express that this concept must be redefined in a context of the changes generated by the introduction of new technologies in all areas of society.

In this sense, the current technological revolution has favored the existence of a new definition of literacy that goes beyond the abilities to use computers and the Internet, and to create, save, broadcast or download information. For this reason, the most appropriate notion in the 21st century is the one related to "integral literacy" based on three main aspects: functional, informational and ethical literacy.

Integral Literacy includes not only the basic tools that an individual must have an individual like reading, writing and calculation; but also the socio-affective skills in combination with the new technologies used, in the search of changes of attitudes to construct a more humane and free society.

Functional Literacy

"Literacy lies at the heart of UNESCO's concerns and makes up an essential part of its mandate, being entwined with the right to education set forth in the Universal Declaration of Human Rights of 1948. These concerns have to do with promoting the meaningful acquisition and application of literacy in laying the basis for positive social transformation, justice, and personal and collective freedom. Despite tremendous progress made over the past 55 years, universal literacy remains a major challenge for both developing and developed countries in terms of commitment and action. There are over 800 million illiterate adults in today's world, a figure projected to remain unchanged in 2015 if current trends continue unabated" (UNESCO, 2004, pp. 1).

The term "Functional literacy" has been understood as the ability to read, write and to perform basic mathematical calculations. This term was originally introduced by UNESCO (1986), which states:

A person is literate who can with understanding both read and write a short simple sentence on his everyday life (…) A person is functionally literate who can engage in all those activities in which literacy is required for effective functioning in his group and community and also for enabling him to continue to use reading, writing and calculation for his own and the community's development. (UNESCO, 1986, p. 4)

Functional literacy is a matter to be developed by initial education; however, this is not totally achieved because, as Schleicher and Tamassia (2002) indicates, the students enrolled in the high school have very low levels of competence for written expression and reading comprehension. This problem is observed in developed and developing countries, getting worst in the latter, where indexes of reading are below OECD reading abilities statistical averages.

Therefore, it is considered that functional literacy as well as ethical and informational literacy also become a concern for higher education. In this sense, we consider that study plans at higher education must include subjects for reading and writing that guide students in the use of strategies, working on topics and texts of their interest, in order to overcome the limitations generated by this reality.

Informational Literacy

There is a broad discussion about the definition of "Informational Literacy." In this respect, Oxbrow (1998, cited in Badwen, 2001) sees information literacy as differing from, and going beyond, computer literacy by virtue of a changed *focus*: on "the content that flows through the technology - a focus on information and knowledge."

Similarly, Johnston and Webber (1999, cited in Badwen, 2001) suggest that information literacy is "emphatically not just computer literacy: but rather the ability to identify and evaluate information (using whatever tools are appropriate, such as those provided by IT) and learn to "read" information within its cultural and social context."

In relation to the above, we consider that informational literacy is referred to as the capacity to have access to information (in electronic and printed format), selecting, critically classifying as well as assimilating and turning it into knowledge, in other words, to build meaning. It is also referred to as the capacity to turn that meaning into new information (digital or printed). It also includes being able to make that information available for anybody in the cyber society by using the services for that purpose on the Internet.

This capacity to read digital and printed information with critical thinking is mandatory nowadays because the amount of information that currently exists is so large that a human being would spend a lifetime assimilating it and still would not finish. For this reason, according to Espinoza (2003) it is necessary to consider new schemata in which reliability of information can be stated in order to make its selection easier and more critical. This allows the development of higher processes of thought through the use of clearly defined criteria that demand the user to perform an analysis of the material. This analysis should include the document origin, author, topics and issues developed in it, the message itself and the potential audience to which it is addressed.

In this sense, the construction of meanings guarantees each individual the comprehension of the world as well as his or her participation in the processes of social transformations and in the construction of the world we expect to live in. This is another reason for which ethical literacy is needed.

Ethical Literacy

It is necessary to go toward a more humane information society, a society in which, according to Acosta (1996), we can find solutions to the ethical and moral problems we currently face. In this way, according to the aforementioned author, we can find solutions to all the other problems: world illiteracy rate, disappearing of natural resources (renewable, biological and mineral), pollution, demographic problems, hunger, undernourishment, energy supply, among others, as long as the situation seems to be a matter of values instead of a technological matter.

It is for that reason that not only is it necessary to be literate at the functional and informational level, but also at the ethical one. In this sense, Emery and Anderson (1995) indicate that reading and writing constitute simultaneous and interactive social processes that involve respect for human rights. A reader does not establish the meaning of text in an isolated manner, but rather does so through social interaction. The form in which the individuals speak or use what they have read reflects and gives form to their own cultural identities. Writing is also a social process in which writers construct speech from certain communities or sociocultural contexts using complex rhetorical strategies that allow them to express as much who they are as what they mean.

Ethical literacy refers to assuming reading and writing with a critical thinking, showing respect to other people's positions, with conscious use of the information, with respect to the intellectual property, and to rescue the moral principles and the ethical values established in the information society.

In this sense, at the present time it is necessary to form concerned, responsible citizens, committed to the social and economical development of society that satisfy the demands of the public and private economic sector, that contribute to technological and scientific research and newly direct moral and ethical values through the construction of a society based on solidarity, the shared use of information, free promotion and development of technology from a more human perspective and respect for human rights (De Gortari, 1984). These issues have been recognized by the Universal Declaration of Human Rights and become more important in the scientific and technological activities because the development of scientific research demands respect for those rights and the enjoyment of freedom (UN, 1948).

FUTURE TRENDS

Literacy from this new paradigm is extended to all levels of education and new technologies are an integral part of this process. This provides benefits in the teaching-learning process of the language in other dimensions, and gives new opportunities for its knowledge and use.

Additionally, integral literacy favors the understanding of the world in which each individual develops, so that he or she can act critically, creatively and consciously in that world.

CONCLUSION

In this *information society*, it is mandatory to start facing the challenge of integral literacy in all current educational models. To achieve this, we must develop a change of attitude because we cannot just be consumers of information. We

need to redefine our role by becoming actors and interacting in a dynamic, changing process demanded by the current model of society.

In this sense, literacy understood from an integral conception, based on these three kinds of literacy, functional, informational and ethical, acquires great importance.

Integral literacy lets citizens acquire better written expression as well as better reading comprehension in all the media. This fortifies one's autonomy, self-esteem, self-confidence, and attitude before the decision-making and solution of problems. Integral literacy also contributes to the enrichment of interpersonal relationships and the consideration of new forms of communication, which would contribute to one's personal and social development.

We are conscious that this proposal does not completely cover the issue. However, it opens new ways for reflection and debate about such a complex definition that is currently the object of interest for many researchers.

KEY TERMS

Ethical Literacy: Refers to assuming reading and writing with a critical thinking, with respect toward the position of others, with conscious use of the information, and with respect to the intellectual property, and to rescue the moral principles and the values established in the information society.

Functional Literacy: This has been understood as the ability to read, write and to perform basic mathematical calculations.

Informational Literacy: Referred to as the capacity to access information (in electronic and printed format), select, critically classify as well as assimilate and turn it into knowledge; in other words, to build meaning.

Information Society: A specific form of social organization in which information generation, processing, and transmission are transformed into the fundamental sources

of productivity and power (Castells, 1997*)* due to two human inventions: computers and telecommunications.

Integral Literacy: It is based on three kinds of literacy: functional, informational and ethical. Includes the basic tools that an individual must have like reading, writing and calculation; and the socio-affective skills in combination with the new technologies used in the search of changes of attitudes to construct a more humane and free society.

Reading: A dynamic, transactional, sociopsycholinguistic process of constructing meaning and making sense of print (Goodman, 1994; Goodman & Goodman, 1983) and digital information.

Writing: Is a process of constructing meaning in which writers actively integrate thought and language (Smith, 1981a, 1981b; Goodman, 1994; Goodman & Goodman, 1983).

INTRODUCTION

The mobile computing advent brings a set of new applications that benefit from the constant need of information, diminishing communication costs and favoring the popularization of mobile devices, to reach an increasing number of users.

The mobility characteristic opens a new area for software applications. Associated to the mobility we have the location identification, which turns into a critical attribute, once it allows the development of a great variety of new services and applications. The systems that benefit from the use of that location information are named location-based systems (LBS); alternatively, these applications are also known as location-aware, context-aware, or adaptive information systems

More precisely, we can define LBS as applications that use the location information to supply services, based on this position context, to their users (Kupper, 2005; Schiller & Voisard, 2004).

The user location information makes available completely new and innovative service concepts, offering information to the user based on its own context (e.g., climatic information in the region where the user is located), increasing considerably the utility of these services. We know that location-based applications increase the services effectiveness, as they give a customized access to the data based on the user's preferences and on its actual position. This enhances the personalization content, giving several benefits to users and to the application developers.

In our daily life, several activities may use these services, like the emergency call centers, the car navigation services, and even location-based friend finder.

We may verify that, beyond the already cited characteristics and benefits, what also gave the LBS applications a growing perspective were the location techniques modernization and the mobile devices popularization, enabling the offer of more precise, objective, and useful information. In Shiode et al. (Shiode, Li, Batty, Longley, & Maguire, 2002), research shows the trend of LBS market and the market potential reserved to this class of applications that, each year, turns out to be more important to the users, becoming the area that dominates the applications for mobile devices. According to Sayed (2005), the forecast annual revenues for location-based services was estimated in US $3.3 billions for United States in 2006/2007, and in US $11.7 billions on the other countries.

In summary, we may say that the positional information has the potential to explore the user's geographical context as one of the most important variables for content and services personalization for mobile devices users.

BACKGROUND

The processes to manage data in location-based applications are especially challenging, as we need to deal with information as the user is moving from one place to other, in an environment with limited resources and also with

heterogeneity. Diverse research areas contribute to ease the process of LBS application development to make possible to use all the spectrum of functionalities that can be implemented through these applications.

Developments in diverse areas such as databases, positioning technology, software engineering, and others, have been made, trying to ease the construction of LBS applications in a way to provide a large spectrum of services in this kind of applications.

Diverse works were proposed dedicated to developing frameworks that provide reuse in the development of LBS applications.

In Wolfson (1999), moving objects databases that store mobile objects location information are considered, especially the location information. The work concentrates on the query and update problems. For the update problem, an information cost model based on the communication cost and information accuracy is proposed.

Large-scale architecture for location services is proposed in Leonhardi and Rothermel (2002). The architecture presents a model of a location service (or generic API), defining the semantics of position queries (position), area queries (range), and proximity queries (nearest neighbor). To be scalable, it defines a distributed and hierarchical organization for the servers.

In Agre et al. (Agre, Akinyemi, Ji, Masuoka, & Thakkar, 2002), layer-based architecture is presented as basis for the construction of location-sensible systems. The paper defines a location service module (LSM) that is a middleware layer that simplifies the development of location-based services, as it gives a uniform interface that encapsulates the details related to the location information capture, and also gives several useful functionalities as location determination technology commutation, error estimation, location determination technology combination, and cooperative location determination

In Nord et al. (Nord, Synnes, & Parnes, 2002), an architecture for location aware applications is proposed, where positioning source devices, such as GPS, WaveLan, and Bluetooth, may be easily combined or intercalated to provide positioning services in a more precise way. The proposed architecture also supports a peer-to-peer communication, allowing the clients to know the others location, and also combining the location information with other contextual information.

Between several initiatives for the development of frameworks for location-based applications, we may highlight the ICING project (Kilfeather, Carswell, Gardener, Rooney, 2007). It has focused on multimodal, multidevice communications to provide enhanced services

Several location-based applications may be cited; among the most promising, we have the emergency call (Hargrave, 2000) (E911, 2001), navigation systems (ApontadorDuo, 2007), and support systems (Boondao, Esichaikul, & Kumar, 2003).

Also, there is an effort of standardization by the OpenGeoSpatial Consortium. The OpenLS (OpenLS, 2008) initiative, one of these efforts, is focused on the development of interfaces for the easiness of location information and other spatial information use over a wireless infrastructure. Its main aim is to integrate geospatial data and geoprocessing tools in location services, making available these functionalities for a large number of applications.

The management of location information is a central point in location-based applications development. Thus, all these applications share a common component, that is, in charge of the location information acquisition, communication, and storage, which we call location information management. This led us to the need for these functionalities reusing as a way to hasten the development process. In the next section, we describe an architecture that may be reusable, and a specification of a framework to permit the reutilization of the information location management.

LOCATION INFORMATION MANAGEMENT

Location information management is the management of location information of objects that may move, being in different locations in different times. This is an important aspect for several applications (Wolfson, 2008) such as flythrough visualization, context awareness, augmented reality, and cellular communication.

In the context of cellular communication systems, the location management problem has two main problems: point query to locate a cellular user that must be located, and point update to set the new cell that the user is when he/she moves beyond its original cell boundary. The problem, in this case, is restricted to how frequently it updates, and how to search a database of location records. For more information on this specific topic, see Pitoura and Samaras (2001).

In general, location-based applications, the problem is much broader. We need finer resolution, possibly with queries on the current, past, and future location, and triggers are very important; all these based on sets of objects. Actually, we see that a common approach for LBS applications development is to build a separate, independent location management component for each application. That results in significant complexity and duplication of efforts. Thus, as stated in Wolfson (2008), we need to develop location-management technology that addresses the common requirements and serves as a development platform.

To model the location of mobile objects, a commonly used approach is to model the location as a pair composed of location information (l) and time stamp (t) that is gener-

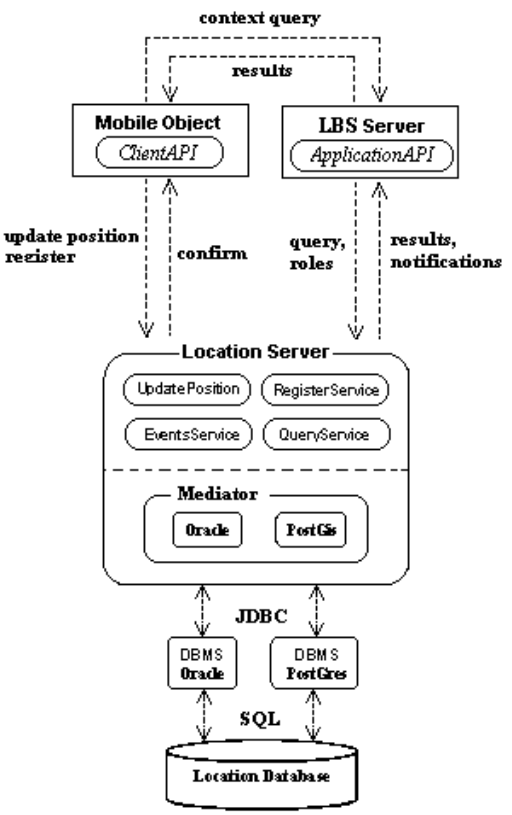
ated periodically. This pair is stored in a database, and SQL is used to retrieve the location information.

As the location information pair (l,t) is acquired on the mobile object, or computed by a network-based process, it has to be transmitted and stored in a location server. Both cases involve wireless communication. To control the transmission of location information, different update protocols can be used.

According to Leonhardi (2000), we can classify the updating protocols in three classes: querying, reporting, and combined protocols, and each class has a typical number of variations.

A protocol is classified as querying if the server decides when to request the location information from the information source. In this case, the implemented location information source becomes very simple. This becomes important for thin clients. This protocol results in a high location precision level, but may also result in a high number of messages if the location is frequently requested. The server response time is also comparatively high, as it needs to contact the client at each request. But, when the user privacy request does not allow its storing in the server, this protocol must be used.

Figure 1. General FRAGIL's architecture



When the server stores the last location information updates, we have the cached querying. In this case, when the object location information is requested, the server analyses if the information that is stored has enough precision to be used, requesting explicitly an update if necessary. Finally, there is the technique where the server requests the location information at each time interval t, named periodic querying.

To handle the questions that arise from the location information point management, we propose a specific framework that allows a complete reuse of the location information management functionalities that is independent of the database management system and is easy to be connected to an LBS application; it is named FRAGIL. The FRAGIL architecture (Monteiro, Paiva, Silva, & Baptista, 2005) is depicted in Figure 1; we can see that the framework is composed of three layers: location server, ClientAPI and ApplicationAPI.

The location server (LS) is responsible for the management of the mobile objects (mo) location information; offering to the LBS application, the services related to the mo position. The location server is composed of several components that are in charge of specific tasks, such as definition and control of the location information update protocol to optimize the access, register a new object to be tracked, queries submission, control of events related to objects location and location information updating.

The ClientAPI is a communication interface that is implemented by the mobile client to communicate to the LS. Using this API, the client requests its registration and send its location information according to the defined update policy. On the other side, the ApplicationAPI is an interface that is used by the LS to communicate with the server that has the LBS application semantics, here is named LBS Server (LBSS).

To make the framework independent from the spatial query languages specificity, a mediator component that is in charge of the translation of queries, was created; built in accordance with the OpenGeospatial standard to the language specific of each data source,. Initially, we have two implemented data sources for Oracle and PostGreSQL.

The LS provides the following services: UpdatePosition, which enables the mo updating; RegisterService manages the registration of new objects to be tracked, being in charge of the definition of location updating; QueryService provides a set of queries based on the mo location; and the EventService, which permits the set up and control of events related to the mo location.

One of the LS services is the RegisterService. This service is used to register a mobile object into the framework, necessary to initiate its location information management.

To control the information location transmission from the mobile object to the server, there are different update protocols. The FRAGIL architecture allows the use of diverse

updating politics, providing the application developers the option to choose the actualization technique better suited to the application requirements.

The ability to answer several queries related to the mobile objects location is implemented by the component named QueryService and its associated API. The application may submit the following queries: positionQuery, that needs the mo Id and returns the actual mo position; temporalPosition-Query, that returns the position of a mo related with a time in the past; temporalRegionQuery(Area,Time), in which the application submits a geographical area as parameter and gets as response a list of objects that are inside of the area; pathQuery, returns the path covered by a mo; and proximityQuery, that verify the proximity of other mo from a specified location or from other mo.

Another service made available is the registration of events based on the mo position related to fixed geographical locations or area and to others mo. Initially, the application server (LBSS) may, through the ApplicationAPI, register those events named RegionEvent and DistanceEvent. As it is registered a RegionEvent the client is notified when the mo enter o leave the pre-defined area. To the DistanceEvent, the notification is sent when the mo is at a specified distance of the other mo or geographical location. The events are defined as: RegionEvent and DistanceEvent.

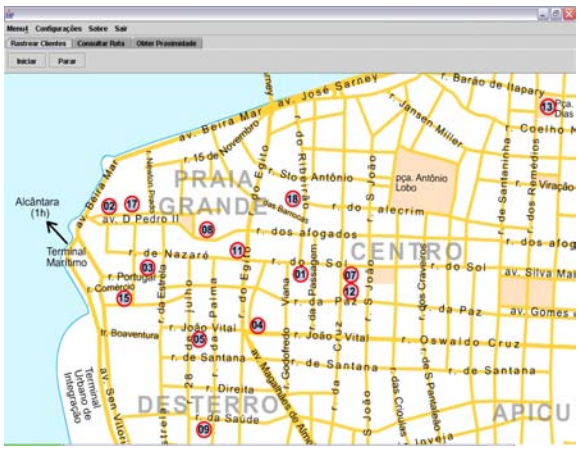
The framework uses an independent data schema for the mo location information that stores the mo location information along the time and its management based on sessions. There are four relations: OBJ_MOB_HST, OBJ_MOB, OBJ_SESSION and VW_MO_LOCATION.

The table OBJ_SESSION has the information of all tracking sessions, with a tuple that identifies the mobile object identification (obj_id), the session identification (id_session), the session init time (init), the session end time (finish), actual session status (status), and the actual update protocol (protocol). In the OBJ_MOB table are the location and time stamp of the mobile objects that have an open session. As the session is closed, the mobile object tuples are moved to the OBJ_MOB_HST.

Finally, we have the view VW_MO_LOCATION that represents the actual location of all objects with open session.

In order to validate the framework system, a prototype was developed to work as a central tracking station of users moving in the historical town of São Luis- MA, Brazil. The application provides a graphical user interface that makes possible to visualize the mobile users' position, determine proximity relations, query mobile users' path, and others. The experiment was done using the framework in a simulated environment, where the mobile users' paths were predefined. Figure 2 presents the application user interface.

Figure 2. Monitoring tool interface



FUTURE TRENDS

We may see that the location-based services are just the initial manifestations of the new applications classes. These new applications classes will, in a certain way, be a revolution in the way that we build and use the information systems. Then, we will reach the advent of pervasive and mobile computing.

One of the challenges that must be addressed in the location information management research is the creation of a technology-independent, high-level software application programming interface (API) for location sensing (Patterson, 2003). That is required as no single location-sensing technology is likely to become dominant, and its choice depends strongly on usage context.

Other aspects also need more investigation. We have a need for data models and query languages that are more adequate to the mobile objects location information nature. Also, there must be research into novel methods for mining objects that are moving in the geographical space. And finally, we believe that new strategies must be developed to include other sensory channels in the interaction of the mobile users to support augmented reality. This, we believe that will be the key application for the next generation of location based services.

CONCLUSION

The users need to get access to information anywhere and anytime. This characteristic leads to a natural demand of services that provide information to the users accounting

to their location context. This generates the class of applications named LBS. These applications allow the users, through a wireless connection, to use services based on their geographical location. Also, they have a set of functionalities that may be reused.

We described, in this work, the actual challenges in the location information management presenting a framework named FRAGIL, which is an alternative to help LBS software developers to create applications supporting the management of location information for a set of mobile objects. The proposed framework may be used by diverse LBs applications, being independent of the location determination technology and from the geographical context of the application.

The framework, in a general way, met the expectations with respect to its functionality, portability, and flexibility. The handling of their APIs furnished to the developers of the applications a total abstraction of the management process of the localization information realized by the LS. Such a deed let the efforts towards the system building process be concentrated only in the issues related with the application domain and with the users' interaction with the graphic interface, allowing a significant gain in the time spent for building the system.

KEY TERMS

Framework: A set of software routines that provide a foundation structure for an application. Frameworks take the tedium out of writing an application from scratch.

Location-Based Services: Location-based services refers to a class of applications or services that are based on, or enhanced by, information about the spatial location of a user and/or device.

Location Update Protocol: This is the politic used by the location-based service to maintain the mobile object location information updated in a server.

Location Technology: The set of hardware and software tools that may be used to compute the location of a mobile object.

Middleware: Software that functions as a conversion or translation layer. It is also a consolidator and integrator. any programming that serves to "glue together" or mediate between two separate and often already existing programs.

Wireless Network: A type of network that uses radio waves rather than wires to communicate between nodes.

Location-Based Services

INTRODUCTION

The past decade has seen advances in wireless network technologies and an explosive growth in the diversity of portable computing devices such as laptop computers, handheld personal computers, personal digital assistants (PDAs), and smart phones with Internet access. Wireless networking technologies and portable devices enable users to access information in an "anytime, anywhere" fashion. For example, a mobile user (MU) on the highway may query local weather, traffic information, nearby gas stations, next rest areas, or restaurants within 10 miles. Such new demands introduce a new type of services, ***location-based services*** (LBS), where certain location constraints (e.g., the user's current location) are used in the service provision.

The idea of queries with location constraints is originally introduced by Imielinski and Badrinath (1992), in which mobile users are likely to query information relating to their current positions, leading to the need for LBS. Such services are also termed as location dependent information services (LDIS) in Lee, Lee, Xu, and Zheng (2002). LBS system is the context sensitive systems in a mobile computing environment that consider the user's location as a significant and dynamic factor affecting the information and services delivered to the users. The major LBS applications include:

- Destination guides with maps, driving directions, and real time prompt
- Location-based traffic and weather alerts
- Wireless advertising and electronic coupons to nearby mobile devices
- Movie, theatre and restaurant location and booking
- Store locating applications helping users to find the desired services
- Telematics-based roadside assistance (e.g., OnStar from General Motors)
- Personal content and messaging (Live Chat with friends)
- Mobile Yellow Pages provide local information
- Information Services (News, Stocks, Sports)
- E911: (Wireless carriers provide wireless callers' numbers and locations.)

Generally, LBS services can be classified into three general categories: telematics LBS, Internet LBS, and wireless LBS (Telc).

Telematics LBS is the integration of wireless communications, vehicle monitoring systems, and location devices. Telematics LBS applications include automated vehicle location, fleet tracking, online navigation, and emergency assistance. For example, a trucking company can track all their fleet, proactively warn about traffic ahead, and estimate the arrival time. Commercial LBS providers are beginning to offer important management applications that help direct vehicle fleets and ensure optimal usage of key assets. Telematics LBS is a multibillion dollar service industry and is currently the largest segment of the LBS market (Telc).

Internet LBS provide Internet users the services relevant to their specified locations. Because they use a user-specified location instead of the user's current location, no positioning technology is required. For example, one can find turn-by-turn driving direction from one location to another and search for tour information about the destination. These services are targeting applications with stationary users, relatively powerful computers, and reliable network connections. As a result, Internet LBS support sophisticated services, such as local business searching and comparison, trip planning, online virtual tours, and so forth.

Wireless LBS deliver location relevant content to cell phones, PDAs, and other wireless devices. Equipped with automated positioning technologies, MUs can query local weather, nearby traffic information, and local businesses close to them. For example, a user can search neighboring post office or coffer shop from the PDA. The wireless LBS market is currently in a nascent stage, but it will potentially become the largest segment of the LBS market. The deployment of third generation (3G) mobile network, which support handsets that are both mobile and location sensitive, will lead to more wireless LBS subscribers and more useful LBS applications.

This article focuses on the discussion on wireless LBS system, and the term LBS refers to wireless LBS in the rest of this article. It compares LBS and traditional database system, introduces existing LBS systems, and reviews the related research works. Next, it describes a representative LBS system model and explains the functionality of the LBS

system. It introduces the major components, their roles, and interactions. The discussion also covers issues related to mobile devices, positioning technologies, spatial databases, location aware queries, and so forth. In particular, this article will provide a detailed review on location dependent query processing and caching. Issues such as query processing algorithms, validity region, and query result caching are discussed. Then, it foresees the new service demands, emerging applications, and trends in future LBS systems. Finally, the article provides a summary on the above discussion and concludes this article.

BACKGROUND

Compared to traditional database (DB) services, new characteristics of LBS lead to significant differences between LBS databases and traditional databases. A database in LBS is a ***spatial database*** (SDBS) (Guting, 1994), which is capable of representing, querying, and manipulating spatial data (such as point, line, and region) to efficiently process queries with spatial restrictions and support applications such as the ***geographical information system*** (GIS). An SDBS is required to handle continuously changing data, locations of moving objects, and provide location aware services to mobile users. LBS also face other research challenges (Jensen et al., 2001) in order to support the following features: nonstandard dimension hierarchies in database; imprecision and varying precision; movement constraints and transportation networks; multiresolution objects and maps in data modeling; spatial data mining on vehicle movement; and continuous location change in query processing techniques. Interested readers are referred to Jensen et al. (2001) for more details.

LBS have introduced two types of queries with location constraints. The ***location aware query*** (LAQ) is the query with certain location constraints (Seydim, Dunham, & Kumar, 2001). As a special type of LAQ, the ***location dependent query*** (LDQ) (Barbara, 1999) is the query whose result depends on querying location, that is, the mobile user's current location. For example, "Phone numbers of all McDonald's in New York City" is an LAQ, while "Phone number of the nearest McDonald's" is an LDQ. LDQ is one of the core functions of LBS. Two common types of LDQs are the ***nearest neighbor*** (NN) query, that retrieves the qualifying database object closest to the querying position, and the ***window query*** that retrieves all satisfying database objects within an axis-parallel rectangle centered at the querying position.

LDQ processing and result caching have new characteristics not observed in traditional database systems. An LDQ may have different results in different region called ***validity region*** (VR). LDQs can be answered by the cached result of the same LDQ, if the MU remains within the cached result's VR. There are several algorithms for the DB server to determine the VR for NN and window query result sets (Zheng, Lee, & Lee, 2004; Zheng & Lee, 2001). To improve the performance, in certain applications, the limited validity region for LDQ result sets needs also be considered in LDQ caching. The following section describes the LBS system model and important research issues including positioning technology, LDQ processing, and LDQ caching.

LBS SYSTEM

LBS System Model

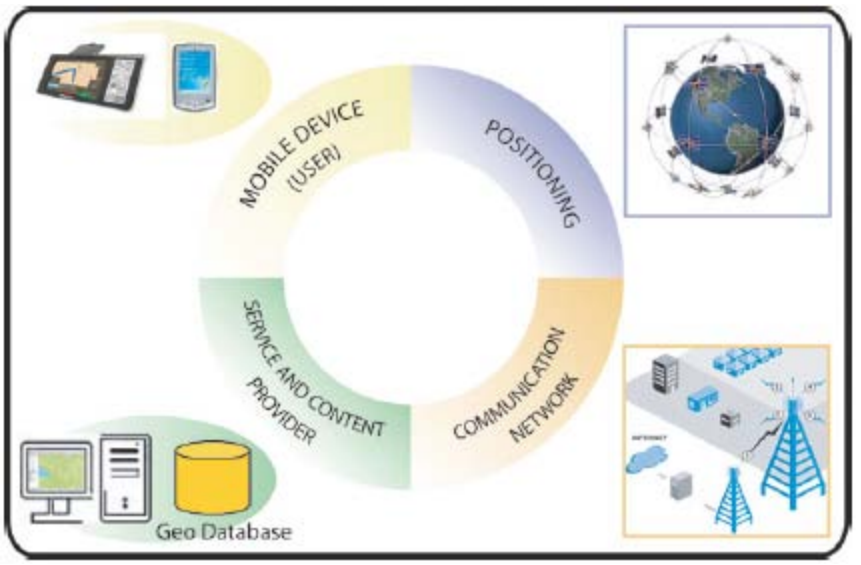
A typical LBS system consists of four components (Steiniger, Neun, & Edwardes, 2006) as shown in Figure 1:

- **Mobile devices:** LBS users request services and receive data using mobile devices, which can be personal digital assistants (PDA), mobile phones, laptops, and vehicle-mounted devices.
- **Communication network:** The communication network can be a wireless cellular network, wireless LAN, or other type of wireless network. It transfers the users' data and service requests to the service provider and forwards the requested information back to the users.
- **Positioning component:** User's location is an essential part of the LDQ, and it can be a symbolic entity (e.g., a street address) entered by the user or a geometric entity (e.g., the latitude and longitude coordinates) automatically acquired using positioning mechanisms. The user position can be obtained either by using the mobile communication network or by using the devices equipped with Global Positioning System (GPS). Further possibilities to determine the indoor position are active badges and radio beacons.
- **Service and content provider:** The service provider offers a number of different services to the user and is responsible for the service request processing. The requested data is usually stored and maintained at separated databases.

Positioning, Querying, and Caching Issues

- **Positioning technologies:** LBS require user's location, which can be input by the user manually or acquired by the device or network automatically. A user can input his/her street address or natural area code, which represents a location using alphanumeric characters code that is shorter than the latitude/longitude equivalent. Alternatively, one acquires a user's location via device-based techniques and network-based techniques.

Figure 1. LBS system components



The premium example of device-based techniques is the GPS and the Assisted GPS (A-GPS). GPS is the worldwide satellite-based radio navigation system consisting of 24 satellites launched by the U.S. Department of Defense. The mobile device equipped with a GPS receiver locates itself by comparing signals from four satellites. A GPS system has a high accuracy, ranging from 5 to 30 meters. In A-GPS, the mobile network or a third party service provider can assist the mobile device to achieve a very high accuracy, between 1 to 10 meters. A similar system is the GLObal NAvigation Satellite System (GLONASS) system comprised of 24 satellites launched by Russia. In 2005, the European Union launched its Galileo navigating system, which consists of 30 satellites and has a higher accuracy than GPS.

Due to the cost and power constraints of a GPS receiver, most handsets in cellular network are not equipped with GPS receivers, and network-based techniques are widely used in cellular networks to locate wireless subscribers. The commonly used network-based positioning techniques include Cell ID, angle of arrival (AOA), time of arrival (TOA), time difference of arrival (TDOA), and enhanced observed time difference (EOTD). Cell-ID, the simplest location approach in cellular networks, uses the serving base station (BS) to approximate the user's location. The accuracy is low and potential deviation depends on the radius of service cell, which is normally between 200 and 3000 meters. Other techniques use triangulation technology: finding the user's location by measuring at least three different signals between the user and fixed servers. Using AOA, the position can be determined if the user's signal is received by at least three BSs with additional electronics to detect the compass direction from which the signal arrives. The BSs send this compass data (i.e., angles) to a mobile switch to calculate the geographical location of the MU with the accuracy in the range of 100 to 200 meters. If the user's signal is received by at least three BSs with a synchronized atomic clock, TOA can compare the user's signal to compute the user's geographical location. The accuracy is between 100 and 200 meters. Zeimpekis, Giaglis, and Lekakos (2003) provides an in-depth analysis and evaluation of the commonly used indoor and outdoor wireless positioning technologies.

- **LDQ processing:** The two most common types of LDQs are nearest neighbor (NN) queries and window queries that have been intensively studied in the literature. A more general form of NN query *is* *k*-NN query that returns the *k* nearest neighbors to the querying location. The *k*-NN queries can be classified into six major categories: simple *k*-NN queries, approximate *k*-NN queries, reverse *k*-NN queries, constrained *k*-NN queries, *k*-join queries, and continuous *k*-NN queries. The most representative algorithm for NN query processing is a branch-and-bound R-tree traversal algorithm (Roussopoulos, Kelley, & Vincent, 1995). The algorithm searches R-tree in a depth first man-

ner, starting from the root node. It records the nearest neighbor found so far and the distance. This algorithm skips the nodes if the distance to node is farther than the shortest distance found so far. For the *k*-NN query processing, the procedure is similar expect maintaining *k* nearest neighbor and their distances to the querying location.

Window query retrieves all objects in an axis-parallel rectangle. This characteristic makes R-tree very attractive in efficient window query processing. A typical algorithm answers the window query in R-tree. The algorithm first retrieves the root node and compares the entries of its children nodes with the querying window. Nonintersecting entries will not contain qualifying points, and are therefore skipped. The searching algorithm recursively retrieves those entries intersecting with the querying window. When it reaches the leaf level, it will return the qualifying data object(s), if any.
