Preface

Influencing every facet of business, society, and life worldwide, with speed beyond imagination, the field of information science and technology has without doubt brought upon a revolution in the way the human population interacts, does business, and governs. As one takes into account the leaps and bounds experienced in information sharing and communication exchange over the last few decades, a truly admirable phenomenon presents itself and clearly shows that the results of this pivotal rising will monumentally impact the way the world thinks, subsists, and evolves.

With a long history of expeditious evolution, the growth and expansion of information technology began during the early 1950s with the main purpose of initiating scientific computing, expanding research, and utilizing the power of computers as a means to support a mass volume of computational tasks in scientific applications and discoveries. Later, during the 1960s and '70s, the use of computer technology was also extended to business applications mostly in accounting and financial areas that involved processing numbers and collecting data in a quantitative sense. As a result, the use of this technology was limited to those who had an expansive knowledge of these systems and had access to computer programming languages. With the evolution of computers and telecommunications in the 1980s, a new information technology was born with a strong focus on the management and dissemination of information by both information providers and users across the globe.

In the early 1990s, the most noticeable advancement in the information technology revolution was the creation of the Internet. During the past two decades, Internet technologies have become the driving force in allowing people worldwide to communicate and exchange information, creating a new dimension that is virtual, interactive, and provides a digital forum for global social connection. In recent years, through the use of Web-enabled technologies, organizations of all types and sizes around the world have managed to utilize these technologies to disseminate and process information with prospective customers, suppliers, students, and governments. Today, the ability to communicate and connect from many locations through personal computers has influenced different people in many different societies. These technologies allow everyone, regardless of their geographic location, to bring the information age to its full realization.

In recent years, the science of understanding the nature of information processing and management along with the computers and technologies that decipher, disseminate, and manage information has become known as information science and technology. Technology has profoundly impacted science, business, and society, thus constructing an entity that improves access to the rapidly expanding body of knowledge in almost every discipline. Society fuels this knowledge creation, as it receives, manages, educates, and collects information. The volume and intensity of research in information science and technology have exceeded many other fields of science, and research discoveries have become the impetus behind many emerging tools and applications seen at every organizational level.

In addressing this need for the representation of evolving information science and technology disciplines in academic literature, the First Edition of the Encyclopedia of Information Science and Technology, released in early 2005, positioned itself as the first of its kind in reference publications, offering an invaluable source of 554 articles highlighting major breakthroughs, discoveries, and authoritative research results in technological advancements. In providing this compendium of references, definitions and key words within this field of pivotal social and organizational movement, the Five-Volume Encyclopedia of Information Science and Technology, First Edition, supplied researchers with a definitive one-stop reference source.

With the endeavor of progressing from this precedence, and in effort to exhibit the latest research innovations, the Second Edition of the Encyclopedia of Information Science and Technology collects and uncovers the most current research findings related to technological, organizational and managerial issues, challenges, trends, and applications of information

technologies in modern organizations. The coverage of this Encyclopedia seeks to bridge existing gaps in available references on technology and methodologies with its contribution as a valuable resource of encompassing paradigms shaping the ever changing research, theory and discovery of information science and technology.

Including a thorough coverage of innovative topics and terms embodying the disciplines that construct this field, the Second Edition of the Encyclopedia of Information Science and Technology offers the most comprehensive list of research references to further support these developments. New articles focusing on emerging topics, as well as enhanced and updated articles featured in the First Edition, allow for the Encyclopedia of Information Science and Technology, Second Edition to construct an up-to-date exhibition of must know developments.

The articles were carefully selected for this publication for their presentation of the most comprehensive, innovative, and in-depth coverage of information science and technology. The topics covered in this all-encompassing publication, include the most influential areas of this field.

Articles fully cover the area of Artificial Intelligence in their examination of current applications applied within organizational spheres that are impacted by such technologies as Machine Learning, Computational Intelligence, Digital Ecosystems and Adaptive Systems. By providing these chapters, the Encyclopedia is able to supply audiences with reputable sources for identifying future trends in breakthrough computing and technologies that will direct everyday aspects of life, such as intelligent transportation, smart homes, and intelligent diagnostics.

Through introducing the changing state of business information systems, the Encyclopedia analyzes the driving force of globalization and the concept's effect on international trade, economics, and capital. Because business information systems are so far reaching, from the intranet to export tracking and manufacturing intelligence, the research results comprise a breadth of review and discussion of methodologies behind these systems and how they are implemented in the field of business.

As a growing discipline of theory, concept and science, cognitive informatics is discussed in several articles that delve into the philosophy behind knowledge, how behavior is determined through this analysis, and what impacts are made through this careful evaluation. With such areas as cybernetics and systems theory being implemented into social and organizational practice, the references provided through this research offer invaluable sources of further evaluation.

Continuously utilized for the evolution of technical applications, the areas of data mining and databases are comprehensively discussed in a significant level of articles in the Encyclopedia as a channel for introduction and advancement. In taking into account the growing incorporation of data mining into Web development and databases into engineering progress, these resources supply audiences with authoritative results and a foundation for additional research.

With a considerable effect on the global economy, electronic business applications are discussed in the Encyclopedia and offer readers a credible source of knowledge for understanding the current realms of mobile applications for business functions, technologies for marketing, and virtual enterprises. Seeing the importance of these technology-based management systems, modern electronic business is analyzed as a growing phenomenon of capitalism.

As today's form of trade, shopping and purchasing, electronic commerce is fully presented in the Encyclopedia as a phenomenon of progressive change. With significant growth since the dot com explosion of the past two decades, e-commerce is exposed as a discipline with global reach and international application for the way currency is exchanged and services are dealt.

With undeniable influence on policy making and delivery, aspects of electronic government are examined in the Encyclopedia, including electronic voting, public service delivery, and citizen management. Considering the social change developing as a result of e-government implementation, articles offer researchers and policy makers a wealth of perspective on the challenges and opportunities in directing government via information communication technologies.

Given the worldwide focus on the environment, the Encyclopedia provides audiences with emerging findings in the area of environmental informatics. As a growing area of attention, this discipline is supported by prominent international researchers studying the future of maintaining environmental functions and safeguarding the planet.

Global information technology has emerged as an area of study with growing importance as digital communications spread internationally. The Encyclopedia supplies articles that delve into the importance of the digital divide, as well as case studies exhibiting regional adaptation, resistance, and adoption of technologies.

As technological demands extend and users multiply, high-performance computing seeks to maintain the flow of communication between servers, knowledge workers, and organizations. With much recent advancement in Grid computing, and technologies to handle large amounts of data, the Encyclopedia offers readers a close look at these breaking areas of study and applications of growing necessity.

Considering the human element in making technology the paradigm it is today, the Encyclopedia provides readers with a comprehensive view of human aspects of technology. With an analysis of end-user behavior, gender differences and ubiquity of computing, readers will find an extensive amount of research results and analysis to assist in building literature in the important area of study; human computer interaction.

Following the advancements of the industrial revolution, industrial informatics is described in the Encyclopedia as a bridge between technological progress and the application of manufacturing, transportation, and construction. With growing utilization in enhancing and expediting good production, building and usage, research results examine the future trends of such technologies and how these applications will incorporate into the daily life of individuals.

As a contemporary social motivator, IT Education is comprehensively examined in the Encyclopedia. This is an area of research with philosophical and constructivist reach into all levels of learning. In discussing blended learning, distance education, tools for online learning, advanced pedagogy and computational support for teaching, IT education demands further attention in developing reliable research. As a popular area of examination, the Encyclopedia lends support to emerging trends in the discipline while supplying a venue for further discussion of terms, themes, and additional implication.

Taking into account the massive growth in technological utilization for sensitive data, government, personal and organizational functions, IT security and ethics as an area of study continues to involve expanding securitization and streamlining for the best protection of digital information. In examining such areas as digital forensics, authentication, cryptography, cyber warfare, and trustworthy computing, analysis of IT security and ethics take precedence as a point of key discussion in the Encyclopedia, with the endeavor to enrich the field.

As a result of the current structures of both public and private sector administration, the field of knowledge management has been positioned as a concept of both utility and application. Considering the need for quality sources indicating best practices in the management of knowledge workers, IT governance and information sharing, the Encyclopedia supplies readers and researchers with a considerable selection of current themes, terms and topics relating to the state of knowledge management.

With many library systems implementing digital filing and cataloguing systems, the study of bibliometrics has flourished in the scientific world. With cutting edge technologies in archiving and classification, preservation and reformatting, library science has developed into an intricate branch of information science and the Encyclopedia illustrates explanations of the vast spectrum of this study. As issues such as open access, security, and Internet property rights take center stage, legal aspects of the digitization of information are explored.

Mobile devices, wireless systems, sensors, and wearable computing applications are technologies that are shaping communication and public administration. Keeping in mind the spread of the need for reliable means of information transfer, mobile and Wireless computing is explored in the Encyclopedia as a field of widening pervasiveness. With uses ranging from machine correspondence to business interrelationships, important research findings are effectively exposed and discussed by top researchers in the field.

Whether utilized for entertainment, learning, or public policy, multimedia technology as a form of study involves behavioral and practical analysis. The Encyclopedia offers audiences with many aspects of analysis on topics such as gaming, simulation and hypermedia to best understand how the world is displaying its information for consumers and administrators.

With the expansion of wireless networks, telecommunications have flourished as users are able to get in touch from just about anywhere with the use of ad-hoc networks, Bluetooth, and RFIDs. Advancements in neural and wireless sensor networks have increased availability of the Internet exponentially. Peer-to-peer networks are discussed in the Encyclopedia, along with optical access and overlay networks.

Social computing describes the intersection of social behaviors and computer systems, intricately examining areas such as social networking sites, augmented realities, and online auctions. Tools such as blogs, Wikis, tags, and podcasts have expanded the user's online researching experience. The Encyclopedia expands on social informatics and explores instant messaging, virtual groups, mailing lists, and forums; just a few of the places that users interact with one another.

Technological engineers focus on algorithms, modeling languages, and kernel applications to design and format the machines that the world uses today. Systems analysis, visualization, and diagnostics all play a role in the design and improvement of the ever changing software being developed. The Encyclopedia takes a look at the vulnerabilities, specifications, and quality of software and its architectures.

As a result of the Internet explosion of the 1990s, Web technology as a field of study has taken the stage as a discipline of ubiquitous importance. With the Web being a single source of infinite information, responding and expanding at exponential rates, the Encyclopedia offers readers a snap shot of disciplines such as portal technologies, semantic computing, Web 2.0, and service-oriented technologies.

The Encyclopedia elaborates on the expansive area of bioinformatics. Subjects such as artificial immune systems, biomedical imaging, and biometric tools such as those used for identifying humans by biological, intrinsic traits are discussed. Topics of importance also include organic computing, proteomics, and computational chemistry.

Electronic patient records, e-health, and cybertherapy are three of the many topics explored through the Encyclopedia's investigation of health information science. With new assistive and rehabilitative technologies, medical data storage, and issues of security and privacy, Health Informatics affects the lives of human beings worldwide. Considering this growth, research results prove valuable for healthcare administrators and academic disciplines, such as nursing and health management.

Advanced medical technologies are incorporated into daily measures to secure and save lives. Medical informatics is exemplified in this second edition Encyclopedia through an intricate look at the updates and improvements in this pivotal field. Medical imaging, biosensors, and new nanotechnology modernizations for surgical procedures are just a few of the exciting and significant advances in medical technologies. Rehabilitation, disease detection, and routine medical care are assisted and revamped with advances in hospital machinery and tools.

The selected topics of this encyclopedia are to provide the best balanced compilation of concepts and issues from researchers around the world. These researchers were asked to submit proposals describing the topic and scope of their articles. All proposals were carefully reviewed for suitability by the editor-in-chief. Upon the receipt of full entry submissions, each contribution was forwarded to at least three expert external reviewers on a double-blind, peer review basis. Only submissions with strong and favorable reviews were chosen as entries for this encyclopedia. In most cases, submissions were sent back for several revisions prior to final acceptance. The goal was to assemble the best minds in the information science and technology field from all over the world to contribute entries to this encyclopedia and to apply the highest level of quality in selecting entries.

As a result, over 650 entries were selected for inclusion in this eight-volume encyclopedia, highlighting current concepts, issues, and emerging technologies. All entries are written by more than 1,512 knowledgeable, distinguished scholars from many prominent research institutions throughout the world. Over 5,000 technical and managerial terms and their definitions have been organized by the authors to enhance the articles, allowing for extensive research into core concepts and ideas. In addition, this eight-volume set offers a thorough reference section with over 14,500 sources of additional information for scholars, students, and researchers in the field of information science and technology.

Multiple detailed Tables of Contents have been organized to better assist readers in navigating and identifying information. Contents are structured through alphabetical, categorical, and contributing author listings for simple reference. The Encyclopedia includes these three comprehensive and detailed tables of contents to greatly assist readers in locating articles on topics within a particular discipline, as well as identify any particular entry per author or title.

Complimentary online access to this encyclopedia for the life of the edition will also be provided to any library with the purchase of the print copy. This complimentary online availability will allow students, faculty, researchers, and corporate managers to access the latest contents of this comprehensive and in-depth encyclopedia regardless of their location. This particular feature will prove to be an extremely valuable resource for distance learning educational programs worldwide.

The field of information science and technology today is a collection of many specific disciplines that researchers have created. No longer is this discipline limited to a few technology-related areas. Today, information science and technology as a paradigm is heavily intertwined in medicine, learning, finance, government, and many other areas. Technology is constantly changing and improving, necessitating the creation and study of innovative literature in many disciplines of information science and technology.

The diverse and comprehensive coverage of multiple disciplines of information science and technology in this eight-volume, authoritative encyclopedia will contribute to a better understanding of all topics, research, and discoveries in this evolving field. Furthermore, the contributions included in this publication will be instrumental in the expansion of knowledge in this field. This publication will inspire its readers to further contribute to the current discoveries in this immense field, creating possibilities for further research and discovery into the future of information science and technology and what lies ahead for the knowledge society.

Acknowledgment

Putting together a comprehensive publication of this magnitude requires a tremendous contribution and much assistance from everyone involved. The most important goal of editing this encyclopedia, as with most publications, was identifying and selecting quality contributors. I am indebted to all of the authors for their excellent contributions. The degree of quality that this publication reaches could not have been achieved without the valuable peer reviews the authors had provided me through their expertise and their rigorous, unbiased assessment of the manuscripts assigned to them on a double-blind basis. I am extremely grateful for their contribution to this publication. I would also like to express my gratitude and deep appreciation to the members of the Editorial Advisory Board for their wisdom, guidance, and assistance in deciding on different issues related to this publication.

I would also like to convey my deep appreciation and gratefulness to IGI Global's Vice President of Editorial, Ms. Jan Travers, for all of her wisdom and encouragement. Additionally, I would like to express my appreciation to the editorial staff of IGI Global for their assistance in this project: Jan Travers, Vice President of Editorial, Kristin M. Klinger, Director of Editorial Content, Meg Stocking, Assistant Executive Editor, Kristin M. Roth, Managing Development Editor, Jennifer Neidig, Director of Production, Deborah Yahnke, Assistant Development Editor, Heather Probst, Assistant Development Editor, and Amanda Steel, Editorial Assistant.

Finally, I would like to express my warmest thanks to my wife, Beth Peiffer, for her support, wisdom, encouragement, understanding, patience, and love. My heart also goes to my two young girls, Basha and Anar, for the joys that they have brought to my life. Finally, much gratitude goes to all those who have taught me immeasurable amounts during the past few decades.

Mehdi Khosrow-Pour, D.B.A.
Editor-in-Chief

About the Editor

Mehdi Khosrow-Pour, DBA, received his Doctorate in Business Administration (DBA) from the Nova Southeastern University (Fla.), USA. Dr. Khosrow-Pour has taught undergraduate and graduate information system courses at the Pennsylvania State University – Harrisburg for 20 years where he was the chair of the information Systems Department for 14 years. He is currently president and publisher of IGI Global, an international academic publishing house with headquarters in Hershey, PA and an editorial office in New York City (www.igi-global.com). He also serves as executive director of the Information Resources Management Association (IRMA) (www.irma-international.org), and executive director of the World Forgotten Children Foundation (www.world-forgotten-children.org).

He is the author/editor of over 20 books in information technology management. He is also the editor-in-chief of the *Information Resources Management Journal, Journal of Cases on Information Technology, Journal of Electronic Commerce in Organizations*, and *Journal of Information Technology Research*, and has authored more than 50 articles published in various conference proceedings and journals.

A

Accessibility of Online Library Information for People with Disabilities

Axel Schmetzke
University of Wisconsin-Stevens Point, USA

INTRODUCTION

After 20 years of digitization efforts, hardly a single type of library information resource remains that has not shifted, at least to some extent, to an electronic, Web-based format: information about the library itself, catalogs, indexes, dictionaries and encyclopedias, books and journals, tutorials, reserve materials, and reference services. The online migration of these resources has opened unprecedented opportunities to people with "print disabilities" who cannot independently access printed works because of lack of sight, dyslexia, or insufficient motor control (Coombs, 2000), but who are able to access electronic text with the help of assistive input and output technology such as modified computer keyboards and screen readers with speech or Braille output (Lazzaro, 2001; Mates, 2000).

The extent to which these new opportunities become realized depends on the design of the Web environment. From the perspective of accessibility, design in the online world matters as much as it does in the physical world. This article seeks to determine the extent to which the library profession addresses the need of people with disabilities for accessibly designed online resources—by reviewing the professional library literature for coverage of this issue, by summarizing empirical accessibility studies, and by analyzing pertinent policies adapted by libraries and their professional organizations.

COVERAGE OF ONLINE ACCESSIBILITY IN THE LIBRARY LITERATURE

In 1996, accessible Web design began to emerge as an issue in the professional library literature. Since 1999, there has been a noticeable increase in library-related journal publications that investigate the accessibility of Web-based library information, seek to raise awareness concerning the need for accessible Web design, and provide practical tips (for a detailed overview, see Schmetzke, 2003, p. 153-156; Stewart, Narendra, and Schmetzke, 2005, p. 267-270). Since 2001, two library journals, *Computers in Libraries* (2001), and *Library Hi Tech* (Schmetzke, 2002a, 2002b, 2007a) have devoted special-theme issues to online accessibility; *Information Technology and Disability* reports regularly on the subject. In 1999, the American Library Association began publishing monographs that addressed accessible Web design (Lazzaro, 2001; Mates, 2000; McNulty, 1999). Gradually, the need to include people with disabilities is also acknowledged in the broader library literature on electronic resources: Whereas some authors—such as Breivik & Gee (*Higher Education in the Internet Age*, 2006), Gregory (*Selecting and Managing Electronic Resources*, 2006) and the contributors to Lee (*Collection Management and Strategic Access to Digital Resources*, 2005)—continue to ignore the issue, others deal with it, at least briefly, in connection with topics such as Web page design (Garlock & Piontek, 1999), Web site usability testing (Norlin & Winter, 2002), digital resources selection and digital video (Curtis, 2005; Hanson & Lubotsky Levin, 2003; Kovacs & Robinson, 2004; Lilly, 2001), Web-based instruction (Sharpless Smith, 2006), and virtual reference service (Coffman, 2003).

EMPIRICAL RESEARCH FINDINGS

Of the online resources provided by libraries, Web pages have been studied the most. The majority of studies employed Bobby, a software-based accessibility checker, to investigate conformance to the 1999 Web content accessibility guidelines (WCAG), developed by the World Wide Web Consortium's Web Accessibility Initiative. Recently, researchers also began looking at compliance with the "access board" standards, a similar set of accessible design criteria developed under Section 508 of the U.S. Rehabilitation Act Amendments of 1998 (Architectural and Transportation Barriers Compliance Board, 2000).

At the library Web sites evaluated between 1999 and 2002, 19% to 75% of the Web pages were found to be free of major accessibility problems (Blake, 2000; Kester, 1999; Lilly & Van Fleet, 1999, 2000; Schmetzke, 2001a, 2003; Spindler, 2002, Yu, 2002); the average number of errors per page varied between 1.3 and 6.1 (Schmetzke, 2002c). Web accessibility tended to be higher at academic libraries than at public libraries. More recent data, available only for academic libraries continue to show a mixed picture. On the average, library Web sites have become more accessible. In a national sample of 49 U.S. libraries, pages free of major Bobby-detectable barriers (compliance with

priority-1 WCAG check-points) have increased from 47% in 2002 to 59% in 2006 (Comeaux & Schmetzke, 2006). With 72%, Web site accessibility is higher at University of Wisconsin libraries (Schmetzke, 2005)—in contrast to Kentucky's academic libraries, where, far fewer homepages passed similar accessibility checkpoints; 23% in December 2003 and 37% in March 2007 (Providenti, 2004; Providenti and Zai III, 2007).

Interestingly, Web sites of accredited schools of library and information science (SLIS)—those institutions that train the next generation of librarians—tend to be less accessible than the library Web pages on their campuses (Schmetzke, 2003). In 2002, only 30% of the SLIS pages (at U.S. campuses) were free of barriers. With 36%, accessibility was barely higher in Canadian schools. Although the situation has improved much in Canada (73%), it has done so only mildly in the U.S. (Comeaux & Schmetzke, in press). With only 47% of the pages conforming to the most basic WCAG guidelines, it is reasonable to assume that there is widespread unawareness about the need for accessible design among SLIS Web designers and among those library school faculty and staff who hire the designers and give them direction. Similar lack of awareness among the leadership was also reported for the area of distance education (Schmetzke, 2001b) and in connection with several high-profile technology-promoting initiatives in higher education (Blair, Goldmann, & Relton, 2004).

Although the occasion of a Web-site redesign provides an opportunity for improving accessibility (see Sloan, Gregor, Booth, & Gibson, 2002), it is not always taken advantage of. A comparison of Web accessibility at U.S. libraries between 2000 and 2002, with a break-down of Web sites into those that had undergone a major redesign during the period in question and those that did not, revealed that the percentage of accessible pages in the redesigned set had drastically declined (from 47% to 24%) whereas that in the largely unchanged set had considerably improved (from 68% to 81%) (Schmetzke, 2003). More recent data suggest a reversal of this situation. Redesigned Web sites of both academic libraries and library schools tend to be more accessible than those not having undergone a major overhaul (Comeaux & Schmetzke, in press).

Information about the accessibility of Web-based library resources other than library Web pages is comparatively scarce. Prior to 2002, little had been published in this area. Then, in 2002, *Library Hi Tech* (Schmetzke, 2002a, 2002b) published two special-theme issues that included accessibility studies on selected online catalogs, online indexes and databases, e-journals, online reference works, and courseware. Although few of the online resources reviewed were found to be absolutely inaccessible, most contained at least some accessibility problems (for an overview, see Schmetzke, 2002c). Several authors pointed out that lack of usability, rather than accessibility, was often the problem (Axtell & Dixon, 2002; Byerley & Chambers, 2002). Stewart (2003), whose studies comprised 36 databases, arrived at a similar conclusion. He cautioned that the observed improvement in accessibility, defined in terms of conformance to certain accessible-design standards, does not automatically result in usability. In a follow-up study, Stewart et al. (2005) found similar results: Most sites contained some access board standards (Section 508) violations (e.g., 85% of the sites did not include mechanisms permitting users to bypass repeatedly occurring navigation and page elements), but complete inaccessibility was the exception. A usability component of this study, designed to ascertain the ability of screen-reader users to perform basic search tasks, revealed that if the bar for success was set very low—if it did not matter how cumbersome and twisted the search process was—most databases could be searched successfully. Self-critically, the authors suggested that future studies of this sort should set out to assess usability more broadly—in terms of user-friendliness.

Until 2002, anecdotal evidence suggested that vendors showed little, if any, concern for the accessibility of their products and that their sales representatives were typically ill prepared to discuss the issue. In 2003, survey findings published by Byerley and Chambers (2003) revealed that the situation had changed significantly: Vendors have become more aware of accessibility and started to remove access barriers from their products. However, the authors discovered that vendors' efforts are largely focused on conformance to Section 508 standards. As a recent follow-up survey shows, even four years later only five of twelve companies conduct usability tests with people who have disabilities (Byerley, Chambers, & Thohira, 2007). The survey also revealed that only half of the database companies provide accessibility information on their corporate Web sites, which makes it difficult for accessibility-conscientious customers to make informed purchasing decisions. Few companies seem to regard accessibility as a selling point in their marketing efforts; only 25% of the responding companies stated that they include accessibility information in their product brochures.

ACCESSIBILITY POLICIES

Under the pressure of the Americans with Disabilities Act of 1990 (ADA Handbook, 1995) and the widening influence of Section 508, many U.S. colleges and universities have adopted campus-wide accessible-Web policies during the past years. Typically, these policies either recommend or require compliance with WCAG, the Access Board standards issued under Section 508, or some combination or variation thereof (Bohman, 2004).

Some, mostly larger, academic libraries have picked up the campus-wide mandate for accessible Web pages and addressed it in their own policies. Among the first to do so was

Yale University Library, which, in its *Library Services for Persons with Disabilities Policy Statement* (2000), requires compliance with WCAG's priority levels one and two.

Very few libraries have adopted policies that address the issue of accessibility in connection with the selection and procurement of online information products—policies crucial for the building of an overall barrier-free information infrastructure (National Center on Disability and Access to Education, 2006). An extensive Web search conducted by this author in June 2006, along with an inquiry posted to pertinent electronic discussion forums, found such policies at only eight libraries. Most of them do not require that only accessible resources must be selected; they merely emphasize the need to consider accessibility, along with other criteria, in the selection process (Florida Atlantic University Libraries, 2006; Northcentral University, 2004; University of Vermont Libraries, 2000; University of Wisconsin-Platteville Karrmann Library, 2002; University of Wisconsin-Stout Library Learning Center, 2006; and University of Washington Libraries, 2001). For example, the latter's *Selection Guidelines for Internet Resources* direct librarians to take into account accessibility when selecting online resources and to weigh the "value of the resource … against the access difficulties presented." Two policies are considerably stronger in tone. The *Principles for CSU Acquisition of Electronic Information Resources* (2005) adopted by California State University (CSU), stipulate that "[i]nformation providers should offer interfaces that comply with basic standards for accessibility by users with disabilities." In a similar vein, the University of Wisconsin Libraries' *Strategic Directions for 2005-2007* (2005) call for measures that put in place accessible "workstations, Web pages, Web-based information resources, Web-based instructional applications, and online services." These more stringent policies echo principles of good collection practice advocated by the National Information Standards Organization (2004) and the International Coalition of Library Consortia (1999). According to the former, "collections should be accessible to persons with disabilities and usable effectively in conjunction with adaptive technologies"; the latter considers its members responsible for "ensur[ing] that vendor platforms are … ADA compliant" and urges them to discuss with vendors the development of accessible products.

Recognition of accessibility as an important issue varies among professional library organizations. In 2001, the American Library Association (ALA) approved a policy drafted by one of its branch organizations, the Association of Specialized and Cooperative Library Agencies (ASCLA), that calls for "equal access to library resources" and urges libraries to use "strategies based upon the principles of universal design to ensure that library policy, resources and services meet the needs of all people." However, the need to create a barrier-free electronic environment is not mentioned at all in the policy's section that addresses, in some detail, the accessibility of library services and collections.

Whereas the call for a barrier-free Web environment is present in the ALA-ASCLA policy at least in the form of a general principle, it is completely absent in the *Guidelines for Distance Learning Library Services* (2004) issued by one of ALA's major branches, the Association of College and Research Libraries (ACRL)—guidelines that not only reflect the professional views of the broader library and higher-education community, but that also have been influential in shaping individual libraries' policies and practices. However, the *Guidelines* are currently undergoing a major revision; in light of currently proposed changes (ACRL's Distance Learning Section Wiki, 2006), it seems likely that the new version (to be approved not before 2008) will address the need for accessible online services and resources.

In summer 2007, the ALA Council approved two policies pertaining to digitization: the document "Principles for Digitized Content," which was drafted by the Task Force on Digitization Policy initiated by ALA's Office for Information Technology (OITP), fully acknowledges the needs of people with disabilities by demanding "equitable access to library materials … ensured through maximum accessibility … and barrier-free design" as well as standards and best practices that must serve "the broadest community of users, including those with disabilities." The "Resolution on Accessible Digitization Projects," authored by ALA-ASCLA, calls on ALA to "strongly encourage all libraries and other entities engaging in digitization projects to adopt Section 508 regulations …" (Schmetzke, 2007b).

FUTURE TRENDS

Even though online accessibility is gradually being recognized as important, much remains to be done. The library literature on electronic resources must routinely cover this issue, just as it does with copyright issues. Librarians need to further educate themselves and their leadership, reshape their institutional policies, and develop effective implementation strategies that ensure 100% accessibility of their homegrown Web resources and challenge vendors to make their Web-based products more accessible. Unless this happens, the online library environment is unlikely to transform into what Tim Berners-Lee (no date), WWW inventor and the current director of the World Wide Web Consortium, had envisioned: "The power of the Web is its universality. Access by everyone regardless of disability is an essential aspect."

CONCLUSION

To a large extent, disability is a social construct. Whether individuals with "disabilities" can pursue independent and fulfilling lives is not merely a matter of their particular internal conditions but also a question of enabling or disabling external factors put in place by society and its institutions. Libraries clearly are part of this nexus. By neglecting to remove all barriers from their Web pages and by not adopting policies that seek to realize the opportunities new information technology provides, many libraries currently fail to seek conditions that would enable all people, including those with "disabilities," to participate fully in the evolving information society.

KEY TERMS

Access Board Standards: Technical and functional performance criteria developed by the Architectural and Transformation Barriers Compliance Board (the "Access Board"), a U.S. government agency, under Section 508. Only electronic and information technology conforming to these standards is considered accessible.

Accessibility: As defined within Section 508, accessibility is achieved when individuals with disabilities can access and use information technology in ways comparable to those available to people without disabilities. A narrower, operational definition conceptualizes accessibility in terms of conformance to certain accessibility criteria such as the *web content accessibility guidelines* or the *access board standards*.

Accessible Web Design: Also sometimes referred to as "barrier-free Web design." Web design that strives to accommodate the needs of people with disabilities, including those using assistive technology, to access the Web environment.

Americans with Disabilities Act (ADA): U.S. civil rights legislation passed in 1990 that prohibits discrimination against people with disabilities in the areas of employment, transportation, telecommunications, and public accommodation.

Assistive Technology: Specialized software or hardware, such as screen readers, magnification software, and a modified keyboard, used by some people with disabilities to interact with the computer.

Audio Browser: Also referred to as "talking browser." Software that interprets the html code of Web pages and provides speech output for text-based components, along with information provided by the html mark-up tags. Typically, it also enables users to navigate the Web page through alternative keystrokes.

Print Disabilities: Comprises all those disabilities that make it difficult, or impossible, to read printed text. The term includes visual impairment and blindness; cognitive disabilities, such as dyslexia; and certain motor-control impairments.

Section 508: A provision within the Rehabilitation Act of 1973, as amended by Congress in 1998, that mandates that the electronic and information technology developed, maintained, procured or used by the U.S. government must be accessible to people with disabilities.

Screen Reader: Software that interprets the signals sent to the computer screen and reads aloud the displayed text with the help of a speech synthesizer.

Universal Design: A concept similar to accessible design. Its meaning is broader in that it refers to design that strives to create products that are usable by all people, regardless of age, gender, (dis)ability, handedness, etc. Its meaning is narrower in that it seeks one solution to accommodate the needs of all people.

Web Content Accessibility Guidelines (WCAG): Guidelines for accessible Web design developed by the World Wide Web Consortium's Web Accessibility Initiative. WCAG 1.0 were passed in 1999. A working draft of a revised set of guidelines, WCAG 2.0, is currently under review.

Actionable Knowledge Discovery

Longbing Cao
University of Technology Sydney, Australia

INTRODUCTION

Actionable knowledge discovery is selected as one of the greatest challenges (Ankerst, 2002; Fayyad, Shapiro, & Uthurusamy, 2003) of next-generation knowledge discovery in database (KDD) studies (Han & Kamber, 2006). In the existing data mining, often mined patterns are nonactionable to real user needs. To enhance knowledge actionability, domain-related social intelligence is substantially essential (Cao et al., 2006b). The involvement of domain-related social intelligence into data mining leads to *domain-driven data mining* (Cao & Zhang, 2006a, 2007a), which complements traditional data-centered mining methodology. Domain-related social intelligence consists of intelligence of human, domain, environment, society and cyberspace, which complements data intelligence. The extension of KDD toward domain-driven data mining involves many challenging but promising research and development issues in KDD. Studies in regard to these issues may promote *the paradigm shift of KDD from data-centered interesting pattern mining to domain-driven actionable knowledge discovery*, and *the deployment shift from simulated data set-based to real-life data and business environment-oriented* as widely predicted.

BACKGROUND

In the last decades, data mining, or KDD, has become a prominent, exciting research and development area in the field of information technology. Data-centered data mining has experienced rapid development in various aspects such as data mined, knowledge discovered, techniques developed, and applications involved. Table 1 illustrates such key research and development progress in KDD.

A typical feature of data-centered data mining is that KDD is presumed to be an automated process of identifying interesting hidden patterns in public data sets. It targets the production of automatic algorithms as well as methods that extract patterns of certain technical significance. As a result, algorithms and the tools developed lack the capability to adapt to real-life environmental constraints and dynamics. Thousands of patterns and algorithms have been published in academia, but unfortunately very few of them have been transferred into real business use.

Increasing numbers of KDD researchers and developers have realized the limitation of traditional data mining methodologies (Ankerst, 2002; Fayyad et al., 2003), noted the gap between business and academic interests (Gurali & Wallace, 1997). The research on the challenges of KDD,

Table 1. An overview of data mining

Dimension	Key research progress
Data mined	• Relational, transactional, object-relational, active, temporal, spatial, time-series, heterogeneous, legacy, Web, and so forth. • Stream, spatiotemporal, multimedia, ontology, event, activity, link, graph, text, sensor, and so forth.
Techniques studied	• Database, machine learning, or statistics-oriented, say Neural Network, Bayesian network, Support Vector Machine, Rough Set, and so forth. • Association, frequent pattern analysis, multidimensional and OLAP analysis methods, classification, cluster analysis, outlier detection, visualization, and so forth. • Scalable data mining, stream data mining, spatiotemporal data mining, multimedia data mining, biological data mining, text and Web mining, privacy-preserving data mining, event mining, link mining, ontology mining, granule mining, and so forth.
Knowledge discovered	• Characters, associations, classes, clusters, discrimination, trends, deviation, outliers, exceptions and so forth.
Application involved	• Engineering, retail market, telecommunication, banking, fraud detection, intrusion detection, stock market, social security, bio-informatics, defense, Web services, biological, social network analysis, intelligence and security, and so forth. • Enterprise data mining, cross-organization mining, online mining, dynamic mining, and so forth.

plus trustworthy and workable KDD methodologies and techniques have therefore become a significant and productive direction of KDD research. In the panel discussions of SIGKDD 2002 and 2003 (Ankerst, 2002; Fayyad et al., 2003), a couple of important challenges for extant and future data mining were identified. Among them, actionable knowledge discovery is viewed as one of the key foci, because it not only provides an important tool to business decision makers for performing appropriate actions, but also delivers reliable and actionable outcomes to businesses. However, it is not a simple task to extract actionable knowledge utilizing traditional KDD methodologies. This situation results partly from the assumption that traditional data mining is a data-centered trial-and-error process (Ankerst, 2002), data and technical interestingness have been taken as two of the major targets and criteria in algorithm and pattern development.

To bridge the gap between business and academia, it is important to understand the difference between objectives and result evaluation of data mining in research and real-world applications. In the business world, KDD must answer the question "What Makes Knowledge Identified Interesting to Businesses" (Silberschatz & Tuzhilin, 1996) not only from the technical angle but also from a business perspective. Real-world data mining needs to identify patterns in constrained environments and satisfy not only technical significance (Freitas, 1998; Hilderman & Hamilton, 2000; Omiecinski, 2003; Padmanabhan & Tuzhilin, 1998), but business expectations (Ghani & Soares, 2006; Cao & Zhang, 2007a; Kleinberg, Papadimitriou, & Raghavan, 1998). The difference referred to above is exemplified through several key aspects (Cao & Zhang 2007a), for example, KDD problem, context, patterns, mining processes, objective and subjective interestingness, business expection, balancing multiple objectives, and infrastructure supporting business-oriented mining.

To deal with this difference, experience and lessons learned in real-world data mining (Cao & Zhang 2006a, 2007a, 2007c, 2008a, 2008b) show the significance of involving domain-specific data, domain, human and cyberspace intelligence (Cao et al., 2006b). For instance, domain-related social intelligence may consist of the involvement of domain knowledge (Yoon, Henscen, Park, Makki, 1999) and experts (Cao & Dai, 2003; Han & Kamber, 2006), the consideration of constraints (Boulicaut & Jeudy, 2005), and the development of in-depth patterns (Lin & Cao, 2006). It is essential to filter subtle concerns while capturing incisive issues. Through the thorough scrutiny of domain-specific intelligence and correct involvement of domain-specific intelligence into KDD, a streamlined data mining methodology emerges to discover the hidden core of a problem. These form the grounds of *domain-driven data mining* for next-generation KDD.

KNOWLEDGE ACTIONABILITY

In order to reflect business concerns, a *two-way significance framework* (Luo, Cao, Ni, & Liu, 2007) is proposed for measuring knowledge actionability. The two-way significance framework presents a straightforward nevertheless important definition of knowledge actionability. This means highlighting the involvement of business expectations (Tzacheva & Ras, 2005; Wang, Zhou, & Han, 2002) into traditional technical-only significance scheme (Yang, Yin, Lin, & Chen, 2003). In addition, the two-way significance is reflected in terms of both objective (Freitas, 1998; Hilderman & Hamilton, 2000), subjective (Liu, Hsu, Chen, & Ma, 2000), and multi-objective (Freitas, 2004; Tuzhilin, 2002) perspectives. As a result, actionable knowledge identified is not only based on a solid technical foundation, for instance, of recognized statistical significance, but enables business users to take appropriate actions which will be to their advantage.

DEFINITION 1. (*Knowledge Actionability*) *Let x be an itemset in dataset X, given a mined pattern p associated with x, actionable capability x.act(p) is described as the satisfaction of both technical interestingness x.tech_int*(*p*) *and business expectation x.biz_int*(*p*).

$$\forall x \in X, \exists p : x.tech\_int(p) \wedge x.biz\_int(p) \rightarrow x.act(p) \quad (1)$$

Further, knowledge actionability is instantiated in terms of objective (*_obj*()) and subjective (*_sub*()) perspectives from both technical and business sides:

$$\forall x \in X, \exists p : x.tech\_obj(p) \wedge x.tech\_subj(p) \wedge biz\_obj(p) \wedge biz\_sub(p) \rightarrow x.act(p) \quad (2)$$

However, it is not rare to discover that incompatibility and uncertainty exist in bridging the gap between business and academia in real-world data mining. To solve these issues, we propose (Luo, et al., 2007) fuzzy aggregation of business expectation and technical significance, generating a fuzzy ranking of patterns reflecting and balancing both technical and business concerns. As demonstrated in mining actionable trading patterns in market order book data (Lin & Cao, 2006), this approach presents promising options for resolving the issue of business needs, as well as bridging the gap between the business and technical side.

KEY COMPONENTS

Based on our experience and lessons learned in developing domain-driven data mining for real-world applications, including the discovery of actionable trading patterns in stock markets (Lin & Cao, 2006) and activity patterns

in government social security services (Cao, Zhao, & Zhang, 2007b), we can summarize the following key KDD components. (1) Problem understanding and definition is domain-specific and must involve domain-related social intelligence. (2) The context of actionable data mining involves data, domain, human, society or cyberspace, which is constrained, open and dynamic. (3) In-depth data intelligence and patterns need to be discovered. (4) A loop-closed refinement process is essential. (5) The evaluation of pattern actionability should balance statistical significance and business expectation. (6) A human-mining-cooperated infrastructure may be necessary for involving domain-related social intelligence. (7) Effective and efficient system support such as parallel KDD support plays an important role. (8) Knowledge discovered should be reliable, trustworthy and actionable to support action-taking in business decision-making. We believe studies on these points are useful for actionable knowledge discovery.

In domain-driven framework, data mining analysts and domain-specific business analysts complement each other with regard to in-depth granularity and constrained environment through interactive system support (Aggarwal, 2002). The involvement of domain experts and their knowledge can assist in developing highly effective domain-specific data mining techniques, and reduce the complexity of knowledge discovery and production process in a practical manner. In-depth pattern mining discovers deep-rooted interesting patterns that are beyond normal expectation. The patterns mined should not only be based on solid technical foundation, but satisfy real user needs. They can be used for specific users to take action according to their various criteria. A system following this framework is a loop-closed system, which reflects and appreciates feedback from the process as well as domain experts. It can refine the life cycle of actionable knowledge discovery in an iterative manner.

Domain driven data mining can greatly complement and tackle issues in traditional data-centered KDD methodologies in terms of the full process of KDD. The involvement of domain-related social intelligence into KDD process not only strengthens technical development and performance, but highlights business expectations and actionable capability of the identified results. Table 2 summarizes such supplementation and expansion in addition to traditional data-centered methodologies.

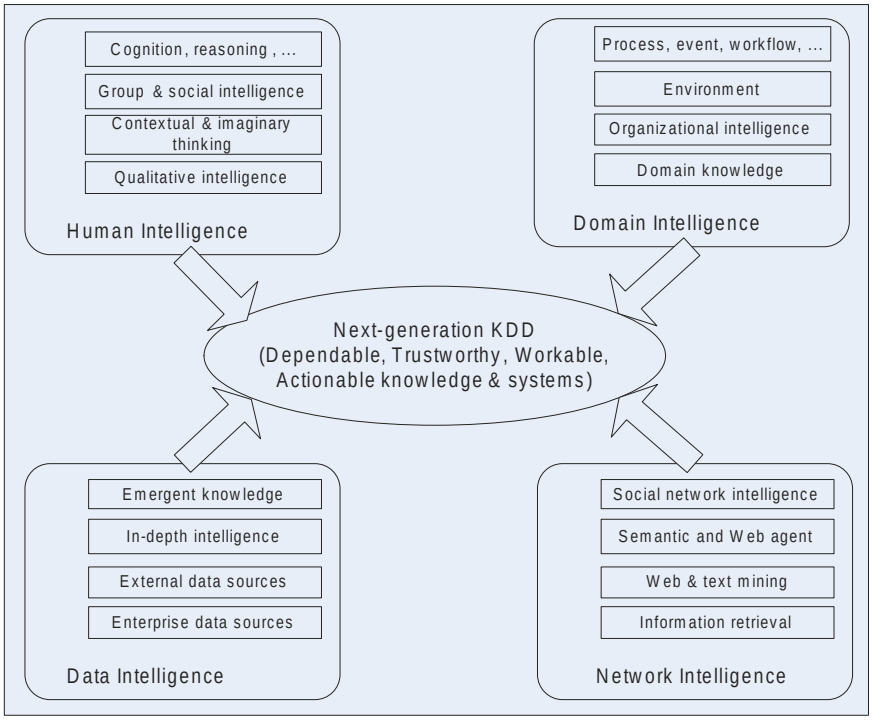
Intelligence Metasynthesis

Compared with traditional data-centered data mining methodology, a key involvement and enhancement in domain-driven data mining is *intelligence meta-synthesis* (Cao & Zhang, 2007b) of findings and progress available from the above tasks. In a high level perspective, intelligence meta-synthesis synthesizes data intelligence with domain-oriented social intelligence, including domain intelligence, human intelligence and cyberspace intelligence where appropriate. Domain-driven data mining therefore is a process full of interaction and integration among multiple kinds of intelligence, as well as intelligence emergence toward actionable knowledge discovery. Figure 1 outlines basic units and their interaction in intelligence meta-synthesis for actionable knowledge discovery.

Table 2. KDD supplementation and expansion via domain driven data mining

Aspects	Data-centered data mining	Domain-driven data mining
Object mined	Data tells the story	Data and domain-related social intelligence tell the story
Aim	Developing innovative approaches	Generating reliable and trustworthy knowledge supporting business decision-making actions
Objective	Algorithms are the core	Systems are the target
Dataset	Mining abstract and refined public data set	Mining constrained real life data
Extendibility	Usually predefined models and methods	Dynamic and personalized model use
Process	An automated process	Human-mining-interactive process
Evaluation	Strong technical significance	Strong actionable capability with solid technical foundation
Accuracy	Accurate and solid theoretical foundation	Data mining is a type of artwork
Goal	Let data create/verify research innovation; Demonstrate and push the use of novel algorithms discovering knowledge of interest to research	Let data and domain-related social intelligence tell the hidden story in business; Discover reliable knowledge that will support users to take actions to their advantage

Figure 1. Intelligence metasynthesis in actionable knowledge discovery



FUTURE TRENDS

To promote domain driven actionable knowledge discovery, many challenging issues in both theoretical and application aspects need to be studied and experimented in real world scenarios. Theoretically, there are many directions to go, for instance, what is domain-driven data mining methodology and process? How to model and involve domain knowledge into KDD? How to support human-data mining system interaction? How to mine in-depth patterns? How to adapt to dynamic mining in high frequency and high density data? What is generic business interestingness framework? How to tackle incompatibility and uncertainty in combining technical significance and business expectation? How to develop and synthesize domain intelligence, human intelligence and cyberspace intelligence? In practice, to construct actionable knowledge discovery, many practical problems need to be studied, for example, what would a domain-driven data mining tool look like? What would be an appropriate project management methodology? How to manage knowledge from multiple sources? How to support human involvement in decision making? How to balance performance and computational complexity? How to present data and knowledge satisfying business users' request? How to produce trustworthy and reliable knowledge? All the above theoretical and practical issues are worthy of further research and development in real-world scenarios.

CONCLUSION

The retrospect of traditional data-centered mining methodology has disclosed the significance of developing next-generation KDD methodologies and system support targeting actionable knowledge discovery. To this end, a significant emphasis is on involving and synthesizing domain-specific social intelligence, for instance, domain intelligence, human intelligence and cyberspace intelligence, into data intelligence during the KDD process. It adequately utilizes intelligence including domain expertise, knowledge, constraints, environment, business rules and processes, and human cooperation surrounding the problem studied. This benefits in-depth and actionable pattern mining satisfying both technical significance and business expectation. The research promotes a trend toward domain-driven data mining on top of data-centered methodology.

Domain-driven data mining provides complementary support to traditional data-centered data mining. Real-world experiments and experience have shown that domain-driven data mining has potential to strengthen traditional KDD, where a great amount of information was mined but little was of value or interest to real life business needs. With increasing theoretical and practical research and development in real-world applications, domain-driven data mining can promote the KDD paradigm shift from data-centered hidden pattern mining to domain-driven actionable knowledge discovery.

It can also benefit the deployment shift from abstract and artificial data modeling to real-life data and business environment based development as widely appreciated by business users and data mining researchers.

KEY TERMS

Actionability: The business-oriented capability of discovered knowledge offering evidence for appropriate action-taking in business decision-making.

Business Decision Making: Decisions made by business people aim to the achievement of business objectives in a manner of satisfying business needs and expectations.

Business Expectation: A pattern of interest to business needs satisfies business performance requests from aspects such as social, economic and psychoanalytic concerns.

Domain Driven Data Mining: Data mining methodologies and techniques that utilize domain-oriented social intelligence, target dependable, trustworthy and actionable knowledge for business decision making.

In-Depth Mining: Mining patterns that disclose deep hidden information and relationship of attributes, which can assist deeper understanding of data, business and decision-making.

Interestingness: Measuring the performance of discovered knowledge in terms of statistical significance, user preference, and business expectation from objective and subjective perspectives.

Intelligence Metasynthesis: The interaction and integration between multiple types of intelligence surrounding a problem solving process, including human intelligence, data intelligence, domain intelligence and cyberspace intelligence. Advanced intelligence emerges through intelligence interaction and metasynthesis.

Social Intelligence: Intelligence hidden or reflected in aspects of data, domain, human, society and cyberspace where appropriate, for instance, domain-specific background information and knowledge, expertise, expert involvement, constraints, environment, business rules and processes.

Statistical Significance: A pattern mined is statistically significant based on statistical metrics that measure and evaluate the performance of an identified pattern.

Active Patient Role in Recording Health Data

INTRODUCTION

The healing process can be viewed as a partnership between doctors and patients, nurses and physicians or, more generally, a partnership of health professionals and health care users (Anonymous, 2008, Graham, 2007). A patient-centered approach that empowers patients to participate in decisions about their treatment and health care options asks for active participation of patients themselves, specifically, in health information gathering and exchange of this information with their health or medical records (Bachman, 2007; Stolyar, Lober, Drozd, & Sibley, 2005).

BACKGROUND

Medical or Health Record

Every physician has a number of patients in his or her care. Many patients also have a number of specialists taking care of their health. It is almost impossible for physicians to keep in mind all the information about even a single patient, let alone all patients in their care. Similarly, patients need to remember and comply with many recommendations communicated to them by their doctors. Recording patients' data is, today, a necessity, especially considering a large number of available diagnostic procedures and instruments producing information relevant for making medical decisions. One implication of such recording is the creation of medical records in health institutions; they are created and accessed by health professionals. According to the National Library of Medicine, the MeSH (medical subject heading) term "medical record" considers "recording of pertinent information concerning patient's illness or illnesses" (http://www.PubMed.com).

However, the medical data gathered by health professionals are not enough for making good medical decisions. Information that is not strictly medical can be added to medical data. We therefore usually talk about a *health record*, consisting of data and information that affect or could affect the patient's health status, or simply describe it. A health record is a more general term than a medical record, nursing record, or dental record, and should be used as an immediate superior term to them. Keeping all the information pertaining to a particular patient in one place, and making it accessible at any time to authorized professionals, is a challenge. In seeking solutions, the information and communication technology should be consulted.

Personal Health Record

In trying to encourage people to take an active interest in their own health, patients are supported to manage their own personal health records. A personal health record can contain copies of data from the health record, which is created by health professionals, and also information entered by patients themselves (for example, subjective information such as description of symptoms, and objective information such as values of self-measured blood pressure or blood glucose levels, etc., recorded in a personal health diary).

Thus far, the literature does not give an adequate definition of a personal health record. Wikipedia defines it as "a health record that is initiated and maintained by an individual," but it is unclear who the individual is, the health professional or the patient. According to Tang (2006), a personal health record includes health information managed by the *individual*, who is not necessarily a *patient,* an ill person. This distinction emphasizes that the personal health record is a tool used to care for health and wellness, not only illness.

CURRENT STATUS

Electronic Health Record and Personal Health Record

There are several definitions of the electronic health record and many descriptions of its characteristics and demands (Hayrinnen, 2007). According to ISO (2004), "the EHR means a repository of patient data in digital form, stored and

exchanged securely, and accessible by multiple authorized users. It contains retrospective, concurrent, and prospective information and its primary purpose is to support continuing, efficient and quality integrated health care." One of the most exhaustive descriptions of electronic health records is given by the Advisory Committee on Health Infostructure of Canada (2001). According to the description in their Tactical Plan for a pan-Canadian Health Infostructure, an electronic health record is "a longitudinal collection of personal health information of a single individual, entered or accepted by health care providers, and stored electronically. The record may be made available at any time to providers, who have been authorized by the individual, as a tool in the provision of health care service. The individual has access to the record and can request changes to its content. The transmission and storage of the record is under strict security." This means that an electronic *health* record also incorporates electronic *medical* records, including digital medical images (computer tomography or similar) and biomedical signals (electrocardiography or similar), laboratory findings, the interpretation of all such findings, and physicians' recommendations to patients. Hospital records, nursing records, dental records, and other similar records can also be parts of an electronic health record.

It is generally agreed that patients have the right to know who is collecting, storing, accessing, communicating, or processing the data in their electronic health records, for what purpose, where the data will be kept, to whom they will be communicated, and for what purpose (Kluge, 2004).

The definition of electronic personal health records as "electronic summaries of a patient's medical record that are often portable and easily accessed by the patient" (Endsley, Kibbe, Linares, & Colorafi, 2006) is not adequate, for it does not distinguish from electronic medical records. A better description of an electronic personal health record was given as "an electronic application through which individuals can access, manage and share their health information" (Pagliari, Detmer, & Singleton, 2007). We propose the most appropriate description of an electronic personal health record would be "a digitally (electronically) saved health information, created and accessible by both health professionals and the individual, respecting privacy, security and confidentiality."

Content of the Electronic Health Record

Today, electronic health records are used in many hospitals, primary care offices, and other health institutions. Each of these sites collects specific patient data particularly relevant to the type of health care received at the site, but all the data could, and should, be mutually communicated. Pulling together health data from different sources should help doctors make better diagnostic and therapeutic decisions. However, pulling information from several different sources will require a unique identifier (Mayor, 2007). This is the first demand on electronic health records.

Patient Identifier

Health systems of different countries define patient identifiers in different ways. Sometimes patients are identified by their health insurance number, other times by the social security number, and sometimes by biometric characteristics of a patient. As a general rule, all of these identifiers are unique (i.e., any two patients have different identifiers) and should have a check digit calculated by a defined algorithm. Table 1 shows an example of creating such an identifier.

Health and Medical Data

Structured electronic medical records can result in quicker data entry, improved quality of care, and improved usefulness

Table 1. Creating a patient identifier (algorithm: module 11)

Starting with: 10000001
Add ponders to each digit: 7 6 5 4 3 2 7 6
Calculate: 7*1+6*0+5*0+4*0+3*0+2*0+7*0*6*1=13
Calculate: 13 : 11 = 1, remnant = 2*
Calculate: 11 – 2 = 9
Conclusion: 9 is a check digit and the created identification number is: 100000019

---

* in case of remnant = 0 the 8 digit number should be omitted; in case of remnant = 1 the check digit shoudl be 0

Following the same algorithm the next identifiers will be:
100000024
100000038
100000043
100000057
....

of records for daily clinical practice (Kruger, 2007). Doctors and nurses prefer structured data entry; electronic nursing records are better, and databases with structured electronic patient records can be used on a large scale to develop treatment regimes and support quality assurance (Kruger, 2007). Integration of clinical decision support systems into electronic medical records holds a promise for more efficacious and cost-effective solutions in daily medical practice. However, designing and structuring the electronic health (or medical) record is a daunting task.

The starting point of the electronic health record should be *patient history*. Patient history is produced during a conversation between the patient and the health care professional. It is not a final product made by, for example, a general practitioner at the first appointment, but it should be resummarised, recontextualised, and recreated in the light of new information, possibilities, and changing priorities during patient care. Some of these data can be structured, but some should also be written as free text.

Laboratory data are mostly structured. Some are measured and recorded as numeric values (e.g., blood glucose 5.3 mmol/L), while some laboratory data are qualitative and usually coded (e.g., blood groups: A, B, O, AB; proteins in urine: -, +, ++, +++).

Radiological data (medical images) and *biomedical signals* can be recorded digitally, and described (interpreted) by a radiologist or another appropriate specialist in the form of free text.

Diagnoses are coded according to an adequate coding system (International Classification of Diseases – ICD-10, SNOMED-CT, etc.), and *drugs* usually by the ATC classification.

Procedures are also coded, usually by using a specific coding system, depending on the country, health sector (hospitals, primary health care, etc.), and the purpose of such data. A diagnosis-related group (DRG) is based on the major diagnosis, length of stay, secondary diagnosis, surgical procedure, age, and types of services required. It is internationally accepted for acute cases in hospitals in order to determine the fixed payment per case (Hammond & Cimino, 2001), but it can be locally adjusted.

Patient *discharge letter* could be partially structured (parts including numeric and coded data), but it also includes some descriptions (free text).

Other Data

The electronic health record can contain other data such as personal data, socio-demographic and administrative data (e.g., name of the individual, date of birth, gender, education, insurance data, etc.).

Characteristics of an Electronic Health Record

Electronic health records should support the delivery of good quality patient care and improve decision making in all daily clinical situations. It should be standardized (e.g., EN 13606). In particular, an electronic health record should improve the management of chronic conditions and help maintain immunization records.

Specific characteristics of digitally recorded data are:

- They can be viewed from a variety of locations (general practice office, specialist practice, laboratory, hospital, etc.) at any moment, when needed,
- For viewing the data as a specific output (e.g., tables or graphs), a specific software is needed; viewing is not static and final, but is instead continuously modifiable,
- Users' authorization levels determine which parts of electronic health record they can access and which actions they can perform (security and protection),
- It is possible to trace who entered the data and who has seen the data, and when (any action can be recorded for the sake of patient safety and responsibility of the health professional),
- Periods of nonavailability of electronic health record data can be known (criterion for usability of the particular system).

Opposite to this, paper-based medical data can be viewed from only one location, they can be seen unconditionally, there is no possibility to specify which part of the document can be read (all or nothing), it is not possible to know who has seen the data and when (it is not recorded), and periods of nonavailability are unknown.

An electronic health record can be used not only for patient management, but also for reporting, quality assurance processes, research, and administrative processes, such as scheduling and billing. A standardised electronic health record is a prerequisite for good communication in the health care system (examples of standards relevant for electronic health record and communication are EN 13606, DICOM, LOINC and HL7).

Benefits of the Electronic Health Record

Electronic health records increase patients' confidence in their health care providers. They save patients and health care providers the repetition of various information (such as personal information – name, address, etc., previous course of the disease, test results) in different health institutions. At the same time, patients are assured that all health professionals caring for them have access to all the relevant parts of their health history. Also, online communication between

health care providers in different institutions speeds up health service. There is no need to wait for discharge letters or test results, and the number of lost test results is markedly reduced. Quality of care is improved as the electronic health record (and data in it) makes the communication with experts much easier. Consequently, another benefit of an electronic health record can be a reduction in the number of medical errors.

Content of the Electronic Personal Health Record

Individual patients have their own documents about their health, their own personal health records. These could be copies of medical documents in paper or in electronic format, for example, laboratory findings or x-ray images (Fig. 1), or even hospital discharge letters. These could also be data on drugs, herbal medications, diet, or results of home testing (blood pressure, medication, etc.) (Fig. 2). Some patients can analyze their health data (e.g., visualization of time series of blood pressure) (Fig. 3) and change their behavior accordingly. Personal health record can also contain various administrative data, such as the name of the person's physician or data related to health insurance.

Characteristics of the Electronic Personal Health Record

There is no standard for electronic personal health record, but there are many electronic applications offered for this purpose (MyPHR, iHealthRecord, etc).

Benefits of the Personal Health Record

Without doubt, the two leading benefits of personal health records are patients' empowerment and promotion of active partnership between patients and caregivers.

FUTURE TRENDS

Electronic health records have been successfully implemented in many settings. Still, they all need further development and improvement, usually linked to rapidly changing technologies. Other aspects of improvement deal with the contents and the way in which the data are recorded (such as classifications or coding systems).

Electronic personal health records are emerging and have much room for further growth. Simpler models of personal health records include passive access to data written on a compact disc or a smart card, or possibly at a Web site. Interactive systems of personal health records demand the integration of a personal health record with health providers' record systems (i.e., electronic health records). Ensuring the security of such systems remains a challenge. According to Pagliari (2007), views on values vs. risks of electronic records are highly polarized. Still, as all new initiatives take time to become fully developed and accepted by its users, this polarization is likely to be only temporary.

CONCLUSION

Electronic health records are the present and the future of contemporary health care systems. Electronic personal health records should be developed in accordance to the needs of all the participants in the health care (health care providers and health care users). It could be expected that the electronic personal health record and electronic health record will interact while not threatening privacy, security, and confidentiality. Both types of records are only parts of the same system, and both need more development and improve-

ment. The ultimate goal of high interactivity, accuracy, and safety can be assured by the information and communication technologies, but both health care professionals and health care users need to accept such a system and become partners in using it, in order to benefit from it.

KEY TERMS

Active Patient is an emerging term describing patients' active participation in the management of their health and wellness.

Electronic Health Record (EHR): A health record stored electronically.

Electronic Medical Record (EMR): A medical record stored electronically.

Electronic Personal Health Record (EPHR): A personal health record stored electronically.

Health Record (HR): A longitudinal collection of personal health information of a single individual, entered or accepted by health care providers.

Medical Record (MR): A longitudinal collection of personal data concerning patient's illness or illnesses.

Personal Health Record (PHR): A longitudinal collection of personal health information of a single individual containing copies of parts of health records, health related data measured and/or noticed by the individual, and administrative data.

Category: Software & Systems Design

Actor–Network Theory Applied to Information Systems Research

Arthur Tatnall
Victoria University, Australia

INTRODUCTION

Building an information system is a difficult task, partly due to the problem of ascertaining the requirements of the intended users, but also because of the complexity of the large number of human-machine interactions (Tatnall & Davey, 2005). This complexity is reflected in the difficulty of building these systems to operate free from error and to perform as intended. The dictionary defines innovation as "the alteration of what is established; something newly introduced" (Macquarie Library, 1981 p. 914). As the introduction or improvement of an information system in an organisation *necessarily* involves change, information systems research often involves research into technological innovation.

BACKGROUND: INFORMATION SYSTEMS AS A SOCIO-TECHNICAL DISCIPLINE

The discipline of information systems (IS) is concerned with the ways people build and use computer-based systems to produce useful information and so has to deal with issues involving both people and machines; with the multitude of human and non-human entities that comprise an information system (Tatnall, 2003). Information systems is neither merely a technical discipline nor a social one, but one that is truly socio-technical. Researchers in information systems face the problem of how to handle complexities due to interconnected combinations of computers, peripherals, procedures, operating systems, programming languages, software, data and many other inanimate objects; how they all relate to humans and human organisations, and how humans relate to them (Longenecker, Feinstein, Couger, Davis, & Gorgone, 1994).

This paper will outline a socio-technical approach, based on actor-network theory (ANT), to researching how people interact with and use information systems (Tatnall & Gilding, 1999; Tatnall 2003; Tatnall & Pliaskin, 2005). In actor-network theory the key is in using an approach that is neither purely social nor purely technical, but socio-technical.

Qualitative Research Traditions in Information Systems

Each field of academic inquiry is characterised by its own preferred and commonly used research approaches and traditions. In information systems research Myers (1997) outlines four qualitative traditions as being particularly significant: case study research, ethnography, grounded theory and action research.

Case study research is the most commonly used qualitative approach in information systems. As IS research topics commonly involve the study of organisational systems, a case study approach is often appropriate. Ethnography has grown in prominence as a suitable approach to information systems research after work such as that undertaken by Suchman (1987) and Zuboff (1988). It has been used especially in research where the emphasis is upon design, computer-supported cooperative work, studies of Internet and virtual communities, and information-related policies (Star, 1995). Grounded theory is an "an inductive, theory discovery methodology" (Martin & Turner, 1986) that seeks to develop theory that is grounded in data that is systematically gathered and analysed and involves "continuous interplay" between data and analysis (Myers, 1997). Orlikowski (1993) argues that in information systems research situations involving organisational change, a grounded theory approach can be useful as it allows a focus on "contextual and processual" elements as well as on the actions of key players.

Action research has been described as proceeding in a spiral of steps where each step consists of planning, action and evaluation of the result of the action. It is seen as aiming "... to contribute both to the practical concerns of people in an immediate problematic situation and to the goals of social science by joint collaboration within a mutually acceptable ethical framework." (Rapoport, 1970, p. 499). A variant of action research that is slowly gaining acceptance in information systems is soft systems methodology (SSM), developed by Peter Checkland and his colleagues (Checkland & Scholes, 1991). SSM attempts to give due recognition to both the human and technological aspects of a system. It acknowledges both human and non-human aspects of IS, but considers these to be entirely separate types of entities.

ANT AND SOCIO-TECHNICAL RESEARCH

Actor-network theory considers both social and technical determinism to be flawed and proposes instead a socio-technical account (Latour, 1996) in which nothing is purely social and nothing is purely technical (Law, 1991). ANT deals with the social-technical divide by denying that purely technical or purely social relations are possible.

To see better how this works, suppose that an IS researcher was investigating the uptake of a business-to-business eCommerce portal developed by a local government authority for use within a regional area, with an Internet service provider (ISP) and a software company engaged to build the portal, and a bank to provide a payment gateway (Pliaskin, 2004; Pliaskin & Tatnall, 2005). ANT asserts that the world is full of hybrid entities (Latour, 1991) containing both human and non-human elements and offers the notion of heterogeneity to describe projects such as this. The project will involve not just the entities mentioned above, but also non-human entities such as computers, computer programs, data storage devices, modems and telephone lines, and human entities including local business proprietors from small and large businesses, customers, programmers and local council staff. The utilisation of heterogeneous entities (Bijker, Hughes, & Pinch, 1987) then avoids questions of: "is it social?" or "is it technical?" as missing the point, which should be: "is this association stronger or weaker than that one?" (Latour, 1991).

Information systems researchers using an ANT approach would concentrate on issues of network formation, investigating the human and non-human alliances and networks built up by the actors involved. They would concentrate on the negotiations that allow the network to be configured by the enrolment of both human and non-human allies. Interactions and associations between actors and networks are all important, and actors are seen simply as the sum of their interactions with other actors and networks.

In the case of the portal an actor-network researcher would begin by identifying some of the important actors, starting perhaps with the local government portal project manager. An interview with the project manager would reveal why the project was instigated and identify some of the other actors. The main advice on method suggested by the proponents of actor-network theory is to "follow the actors" (Latour, 1996) and let them set the framework and limits of the study themselves, and one line of inquiry resulting from the interview with the project manager might be to approach the portal software designer and programmers. Another set of actors is the proprietors of the local businesses themselves, and the project manager may suggest some "business champions" to interview first. At least some of these business people might then point to the influence exerted by the computer hardware or software as a significant factor, so identifying some non-human actors. Negotiations between actors must be carefully investigated. Apart from the obvious human to human kind of negotiation, also included must be human to non-human interactions such as the business people trying to work out how the portal operates, and how to adapt this technology to be most suitable for their own business purposes. The process of adopting and implementing the portal can now be seen as the complex set of interactions that it is, and not just the inevitable result of the innate characteristics of this technology.

How Actor-Network Theory Handles Complexity

Longenecker et al. (1994) suggest that computer-based information systems should be regarded as complex socio-technical entities, begging the question of how this complexity should be handled. A common method of handling complexity in all subject areas lies in simplification, but the danger with simplification is that it runs the risk of removing just those things that constitute a useful description of the phenomenon under investigation by concealing the parts played by many of the actors (Suchman, 1987). The question here is which details to include and which to leave out, and who is to decide. In this respect, an appropriate research approach needs to ensure that complexities are not lost "in the process of labelling" (Law, 1991).

In actor-network theory the extent of a network is determined by actors that are able to make their presence *individually felt* by other actors. The definition of an actor requires this and means that, in practice, actors limit their associations to affect only a relatively small number of entities whose attributes are well defined within the network. An actor is not just a "point object" but an association of heterogeneous elements, themselves constituting a network. An actor can, however, in many ways also be considered as a "black box" (Callon, 1986), and when we open the lid of the box to look inside it will be seen to constitute a whole network of other, perhaps complex, associations. In many cases details of what constitutes an actor—details of its network—are a complication we can avoid having to deal with all the time.

When investigating the e-commerce portal it might be convenient, most of the time, to consider both the ISP and the portal software to constitute a black box. This would mean that this aspect of the technology could then be considered as just a single actor; the portal, and its interactions with other actors investigated on this basis. At other times it might be necessary to lift the lid of the black box and investigate the enclosed network of the ISP, telephone lines, computers, data storage, programmers, and interface designers it contains. The advantage of black-boxing though is that most of the time however, the portal can be regarded as just another actor. The important thing to note about the use of black-

boxing for simplification is that the complexity is not just put into the black box and lost as it is always possible, and indeed necessary, to periodically reopen the black box to investigate its contents.

The portal black box could be considered as shown in Figure 1 below. This black box itself also contains several other black boxes (portal software, portal hardware and payment gateway) that we do not need to consider in detail until such consideration becomes necessary. Figure 1 also shows some of the other main actors that interact with the portal. Until (and possibly after) the portal is fully operational, of course, these actors will also interact directly with each other.

Limitations and Criticisms of Actor-Network Theory

There are several main criticisms of actor-network theory. To begin, there is the criticism by Grint and Woolgar (1997) that it is not always sufficiently clear where the boundaries of a network lie or whose account of a network is to be taken as definitive. They note that the analyst's story seems to depend on a description of the "actual" network as if this was objectively available.

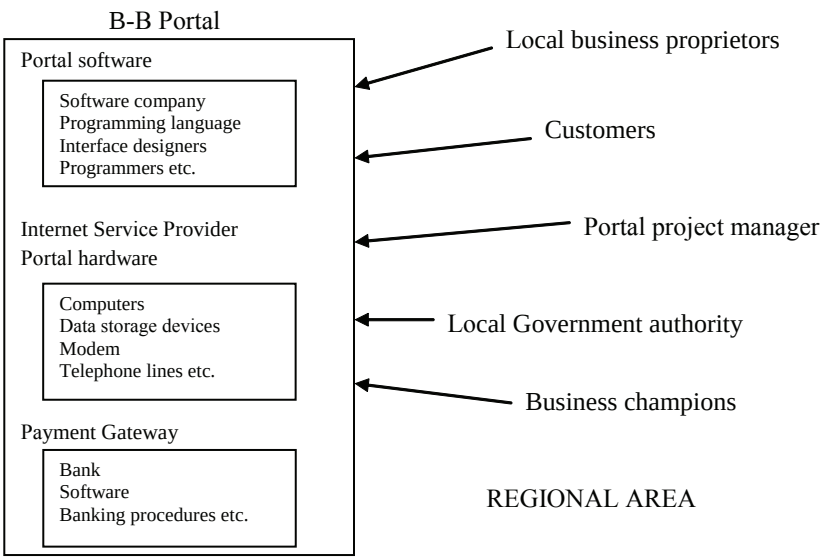
A second criticism relates to ANT's treatment of non-human actors. A critique by Collins and Yearley (1992) claims that in giving an autonomous voice to "things," ANT concedes too much to realist and technical accounts. In reply, Callon and Latour (1992) claim that technological artefacts are implicated in the very fabric of the social and are "social relations viewed in their durability and cohesion."

Thirdly, Grint and Woolgar (1997) argue that ANT retains a degree of residual technicism in its need to sometimes refer to "actual" technical capacities of a technology. They quote Callon's (1986) analysis of the attempts at building a French electric car, in which they claim that he makes reference to the "unfortunate tendency" of the catalysts to become quickly contaminated. They note that the anti-essentialist approach of actor-network theory would point to this 'actual property' being treated as a construction. Despite these minor reservations, however, Grint and Woolgar note that actor-network theory points to the possibility of an understanding of technology that does not rely on the presence of a "god within the machine."

FUTURE TRENDS

Actor-network theory offers a socio-technical approach to information systems research, and particularly to theorising technological innovation—a major aspect of IS research. It is useful in situations in which people and machines are intimately involved with each other, and this is exactly the case in most IS studies. A major use of ANT has been in the study of past events, and ANT makes no claim to be able to predict what may happen in the future. Nevertheless, ANT analysis can identify some pointers towards the successful introduction of an innovation, and the change management associate with this and so can be used to point to likely future scenarios and approaches that may be likely to succeed (Tatnall & Davey, 2004). ANT suggests that the key to successful change management in information systems involves allowing for these interactions and for the socio-technical nature of the process.

Figure 1. Actors, interactions and the portal black box



CONCLUSION

In this paper I have argued that information systems is a socio-technical discipline involving both human and non-human entities, and that information systems implementations are complex activities inevitably involving some form of technological innovation. I have also argued that simplistic views of how information systems are built, implemented and used often conceal important interactions between human and non-human actors and so give a less than complete picture of what has happened.

An actor-network approach avoids the need to consider the social and the technical, and thus human and non-human actors, in different ways. Highlighting how the human and non-human actors involved in socio-technical situations, such as the building and use of information systems, interact with each other is an important benefit of adopting an ANT research framework. In showing how these interactions may lead to the formations of stable networks, actor-network theory offers a useful way to handle the complexity of such studies.

KEY TERMS

Actor-Network Theory (ANT): an approach to research in which networks associations and interactions between actors (both human and non-human) and are the basis for investigation.

Actor: An entity that can make its presence individually felt by other actors. Actors can be human or non-human, non-human actors including such things as computer programs, portals, companies and other entities that cannot be seen as individual people. An actor can be seen as an association of heterogeneous elements that constitute a network. This is especially important with non-human actors as there are always some human aspects within the network.

Black Boxing: A technique used for simplification. Multiple actors can be put into a black box so that it is not necessary to look at them in detail. The portal mentioned in this paper could be considered as a black box containing the ISP, portal software, data storage devices, modems, telephone devices and so on. Black-boxing is done for convenience as it means that an entity can then be seen as just another actor, and saves looking at the detail until necessary. The black box can later be reopened to investigate its contents.

Socio-Technical Research: Involving both social and technical interactions, occurring is such a way that it is not easily possible to disentangle them.

Technological Innovation: The introduction or alteration of some form of technology (often information technology) into an organisation.

Category: Mobile & Wireless Computing

Adaptive Mobile Applications

Thomas Kunz
Carleton University, Canada

Abdulbaset Gaddah
Carleton University, Canada

INTRODUCTION

The convergence of two technological developments has made mobile computing a reality. In the last few years, developed countries spent large amounts of money to install and deploy wireless communication facilities. Originally aimed at telephone services (which still account for the majority of usage), the same infrastructure is increasingly used to transfer data. In parallel, wireless LAN technologies are providing hotspot coverage in many high-traffic locations. The second development is the continuing reduction in size of computer hardware, leading to portable computation devices such as laptops, palmtops, or functionally enhanced cell phones. Given current technology, a user can run a set of applications on a portable device and communicate over a variety of communication links, depending on his/her current location.

As will be explained in more detail later on, the mobile computing environment is highly dynamic. Available bandwidth changes by orders of magnitudes, based on the selected wireless access technology. Also, portable devices differ in processing power, memory, display capabilities, and other characteristics. It is generally argued that applications should "adapt" to the current environment, for example by filtering and compressing data or by changing the functionality offered to the user. Some researchers even argue that all future applications, not just the ones intended for execution on mobile devices, will have to be able to adapt to changing requirements and changing implementation environments on time scales from microseconds to years (Kavi, 1999). This article reviews the work on adaptive mobile applications and provides an outlook on future trends.

The alternative to adaptive applications is to either implement a single application that is designed for the lowest common denominator (in terms of resource availability) or multiple functionally identical or similar binaries, tuned for specific environments. The former will needlessly sacrifice application features when running in more resource-rich environments. The latter approach is an inferior solution as well, for a number of reasons. The user of a portable device has to install and maintain multiple applications, which is a drain on the limited storage capabilities typically found on those devices. It also potentially results in different user interfaces and causes high software development overheads when developing the "same" mobile application multiple times. Finally, it forces the user to identify the current execution conditions and select the "right" application.

The next section will review the motivation for adaptive approaches towards mobile application design. We will then briefly review traditional approaches to adaptive mobile applications, followed by a discussion of mobile middleware that is intended to support adaptive mobile applications. The article finishes with a brief conclusion of the state-of-the-art and identifies areas of future work.

BACKGROUND

Wireless communication and portable devices make it possible for mobile users to have access to information anywhere and anytime. Designing, implementing and deploying applications that work well across all portable devices and across a wide range of wireless access networks is non-trivial.

There are at least three common factors that affect the design of mobile applications: portable devices, network connection, and mobility. *Portable devices* vary from one to another in term of resource availability. Devices like laptops can offer fast CPUs and large amount of RAM and disk space while others like pocket PCs and phones usually have scarce resources. It is either impossible or too expensive to augment the resource availability. Hence, applications should be designed to achieve optimal resource utilization. In general, the design of portable devices strives for properties such as size, weight, durability and long battery life. Different devices will emphasize different trade-offs between CPU speed, memory, I/O capabilities, and power consumption, providing very heterogeneous execution environments for mobile applications.

Network connection in mobile scenarios is characterized by limited bandwidth, high error rate, higher cost, and frequent disconnections due to power limitations, available spectrum, and mobility. Wireless communication is more difficult to achieve than wired communication because the surrounding environment interacts with the signal, blocking signal paths and introducing noise and echoes. Therefore, mobile application designs need to be more concerned about

the network conditions than applications designed for fixed networks. Many wireless and mobile networks such as WaveLAN are organized into geographically defined cells, with a control point called a base station in each of the cells. Devices within the same cell share the network bandwidth; hence, the bandwidth rapidly decreases whenever a new device joins the cell. Portable devices may move around different areas with no coverage or high interference that cause a sudden drop in network bandwidth or a loss of connection entirely. Unpredictable disconnection is also a common issue that frequently occurs due to the handoff process or shadowed areas. Most wireless network services charge a flat fee for their service, which usually covers a fixed number of messages. Additional charges are levied on per packet or per message basis. In contrast, the cost for sending data over cellular networks is based on connection time instead. This forces mobile users to connect for short periods of time.

Physical device mobility can greatly affect network connection, which accordingly has to adapt to user mobility by reconnecting the user with respect to a new location. Portable devices may interact with different types of networks, services, and security policies as they move from one area to another. This requires applications to behave differently to cope with dynamic changes of the environment parameters. As a consequence, mobile applications also have to cope with a much greater variation in network bandwidth: bandwidth can shift from one to six orders of magnitude between being plugged into the wired network versus using (different) wireless access networks.

The constraints and limitations mobile applications face are not a product of current technology, but they are related naturally to mobility. Together, they complicate the design of mobile applications and require rethinking traditional approaches to application design. Any feasible approach to mobile computing must strike a balance between conflicting demands. This balance cannot be static, as the execution environment of mobile applications varies; it must react, or in other words, the applications must be adaptive.

ADAPTIVE MOBILE APPLICATIONS: TRADITIONAL APPROACHES

Designing adaptive applications is an active research area. Traditionally, most work focused on the wireless link(s). Early work provides general solutions that do not change the TCP semantics but focus on improving TCP throughput over wireless links; see for example Balakrishnan (1995). While this addresses issues such as high link error rates and spurious disconnections, it does not address the low and highly variable bandwidth characteristic of mobile computing.

A second group of approaches adapts to the scarce and varying wireless link bandwidth by filtering and compressing the data stream between a client application on a portable device and a server executing on a stationary host. Data compression is done at one of two places. Bolliger (1998) and Seshan (1997) enhance the server to generate a data stream that is suited for the currently available bandwidth. This typically represents an end-to-end approach, which is well known in the networking and system literature. Most other proposals (Angin, 1998; Fox, 1998) extend the client-server structure to a client-proxy-server structure, where a proxy executes in the wireless access network, close to the portable device. This proxy-based approach filters and compresses the data stream originating from the server to suit the current wireless bandwidth. Joshi (1997) incorporates both end-to-end and proxy-based approaches, using each as appropriate, to support Web access from mobile platforms. For example, tasks such as complex filtration, which require significant computational resources, are done in an end-to-end manner. The proxy-based approach, on the other hand, is used when the server is not able to generate the appropriate data stream.

A third, complementary approach, focuses on the computational effort (Kunz, 2000). Mobile applications, especially ones that require intensive computation (for example, video decoding), can be divided dynamically between the wired network and the portable device according to the mobile environment and to the availability of the resources on the portable device, the wireless link, and the wired network. The access network supports the mobile application by providing proxy servers that can execute parts of the application code. This may increase the performance of applications and reduce the power consumption on portable devices since offloading computation to the proxies in the wired network will reduce the CPU cycles and memory needed to achieve certain tasks at portable devices.

FUTURE TRENDS: MOBILE MIDDLEWARE

The early approaches reviewed in the previous section typically provide toolkits that support specific adaptation ideas. To generalize this effort, support for adaptive mobile applications should be embedded into appropriate mobile middleware. Traditional middleware systems, like CORBA and DCOM, have achieved great success in dealing with the heterogeneity in the underlying hardware and software platforms, offering portability, and facilitating development of distributed applications. However, these systems are based on the assumptions that the distributed applications will run in a static environment; hence, they fail to provide the appropriate support for mobile applications. Therefore, mobile applications need a middleware that facilitates adapting to environment variations.

Based on the mobile computing challenges reviewed previously, mobile middleware should meet the following requirements: *Asynchronous interaction* tackles the problems of high latency and disconnected operations. It allows mobile clients to issue a request for a service, disconnect from the network, and collect the result later on. This type of interaction model reduces bandwidth consumption, achieves decoupling of client and server, and elevates system scalability. *Reconfigurability* is the process of adding a new behavior or changing an existing one during system runtime. Dynamic reconfiguration of system behavior and operating context at runtime may require reevaluation and reallocation of resources. Reconfiguration could be based on context information. *Adaptivity* allows applications to modify their behavior instead of providing a uniform interface in all situations. The middleware needs to monitor the resource supply/demand, compute adaptation decisions, and notify applications about changes. *Context-awareness* of client capabilities, changes to network conditions, and the ability to change the behavior of the system as circumstances warrant are required to build an effective and efficient adaptive system. The context includes device characteristics, user's location, user's activities, and other resources. The system performance can be increased when information context is disclosed to the application to assist middleware in making the right decision. Finally, *lightweight load* should be considered when constructing middleware for mobile computing. Middleware should not increase the computational load on the most power-consuming components such as processor, network interface, and so forth. Middleware implementations often include a number of unused features that can be entirely omitted to reduce the computational load.

We identified four categories of mobile middleware: reflective, tuple space, context-aware, and event-based middleware. *Reflective middleware* like DynamicTAO (Kon, 2000) and Open-ORB (Blair, 2001) are built around the concept of component frameworks (CF). Components can be developed independently, distributed in binary form, and combined at run time. Reflection provides a *meta-interface* to inspect the internal behavior of the middleware and, if it is necessary, alter its behavior to better match the system's current operating environment. The main motivation of this approach is to make the middleware more adaptable to its environment and better able to cope with changes. Open problems are consistent dynamic reconfiguration and performance. There is some early work in this area that has focused on developing reconfiguration models and algorithms that enforce well-defined consistency rules while minimizing system disturbance (Kramer & Magee, 1990). In addition, all reflective systems impose a heavy computational load that causes significant performance degradation on portable devices.

Tuple-space systems such as LIME (Picco, 1999) and TSpaces (Wyckoff, 1998) exploit the decoupled nature of tuple spaces for supporting disconnected operations in a natural manner. A tuple space is a globally shared, associatively addressed memory space that is used by processes to communicate. Client processes create tuples and place them in the tuple space using a *write* operation. Also, they can concurrently access tuples using *read* or *take* operations. This communication paradigm fits well in a mobile setting where logical and physical mobility is involved. By default they offer an asynchronous interaction paradigm that appears to be more appropriate for dealing with intermittent connection of mobile devices, as is often the case when a server is not in reach or a mobile client requires to voluntary disconnect to save battery and bandwidth. Using a tuple-space approach, we can decouple the client and server components in time and space. In other words, they do not need to be connected at the same time and in the same place. Tuple-space systems support the concept of a space or spaces that offer the ability to join objects into appropriate spaces for ease of access. This opens up the possibility of constructing a dynamic super space environment to allow participating spaces to join or leave at arbitrary times. The ability to use multiple spaces will elevate the overall throughput of the system. One problem with tuple-space middleware systems is their excessive memory requirements, making them impractical for most portable devices available to-date.

Context-aware systems provide mobile applications with the necessary knowledge about the execution context in order to allow applications to adapt to dynamic changes in mobile host and network condition. The execution context includes but is not limited to: mobile user location, mobile device characteristics, network condition, and user activity (i.e., driving or sitting in a room). However, most context-aware applications are only focusing on a user's location. Nexus (Fritsch, 2000), for example, is designed to be a generic platform for location-aware applications. Reflective middleware may also improve the development of context-aware services and applications. For example, Capra (2003) has suggested the use of metadata and reflection to support context-aware applications. However, overall, limited attention has been given to contexts other than location. It is necessary to take into account other types of context awareness such as internal resources (i.e., memory size, battery and processor power) or external resources (i.e., network bandwidth and connectivity quality). More efforts need to be directed towards an easy context representation and simple interfaces that enable the applications to interact with the underlying middleware.

In *event-based systems*, clients first announce their interest in receiving specific events and then servers broadcast events to all interested clients. Hence, the event-based model achieves a highly decoupled system and many-to-many interaction style between clients and servers. Examples are JEDI (Cugalo, 2001) and STEAM (Meier, 2002). Most existing systems do not combine traditional middleware functionality (i.e., security, QoS, transactions, reliability, access control,

etc.) with the event-based paradigm. In addition, the developers are responsible for handling the low-level event transmission issues. Current publish/subscribe systems are restricted to certain application scenarios such as instant messaging and stock quote dissemination. This indicates that such systems are not designed as general middleware platforms. The majority of event-based middleware architectures are based on a logically centralized component called event dispatcher or broker. This component acts as a gateway between interacting components and hence has global knowledge about all the generated events and subscription requests. However, this centralized design often results in performance bottlenecks. Furthermore, not all event brokers provide a persistent buffer that can store all events for the provision of a reliable event service. There is also no support for the notion of composite events. Composite-event services allow clients to sign up with several event sources and receive event notifications in form of composite events. A special mechanism is needed to model event arrival from different sources and to specify composite events. This however may complicate the system architecture and incur extra cost.

CONCLUSION

Mobile computing is a relatively new field. While the challenges arising from mobility and the limitations of the portable devices are relatively well understood, there is no consensus yet as to what should be done to address these challenges. A comprehensive solution has to address many different aspects, such as the issue of dynamically changing bandwidth, the power, computational, and other limitations of the portable devices, or the varying availability of services in different environments. Traditional approaches to these challenges involved the design and implementation of proxies to either transparently intercept the data stream or to cooperate with the client application in the portable device in offloading computational tasks. To generalize this work, such services are expected to be embedded in middleware for mobile applications. Traditional middleware systems, such as CORBA and Java RMI, are based on the assumption that applications in distributed systems will run in a static environment; hence, they fail to provide the appropriate support for mobile applications. This gives a strong incentive to many researchers to develop modern middleware that supports and facilitates the implementation of mobile applications. To date, there is no single middleware that can fully support the requirements for mobile applications. Several solutions have considered one aspect or another; however, the door for further research is still wide open.

Table 1 provides a simple comparison of mobile middleware solutions with respect to the identified requirements for mobile computing. As can be seen, no single middleware paradigm covers all requirements. Based on our analysis, an evolution of reflective mobile middleware appears most promising, however. The key challenges are to reduce the complexity and size of such middleware for thin clients and to efficiently support asynchronous interaction styles.

KEY TERMS

Context-Awareness: Makes applications aware of the dynamic changes in execution environment. The execution context includes but is not limited to: mobile user location, mobile device characteristics, network condition, and user activity.

Event-Based Systems: Systems in which clients (*subscribers*) have to express (*subscribe*) their interest in receiving particular events. Once clients have subscribed, servers (*publishers*) publish events, which will be sent to all interested subscribers.

Middleware: An enabling layer of software that resides between the application program and the networked layer of heterogeneous platforms and protocols. It decouples applications from any dependencies on the plumbing layer that consists of heterogeneous operating systems, hardware platforms and communication protocols.

Portable Device: Computational device that is small and can be carried by its user, such as smart cell phones, PDAs, and laptops. Unlike stationary devices, the design of portable devices typically trades-off CPU speed, memory, I/O facilities, and so forth for reduced power consumption and size.

Reflective Software: Computational process that reasons about itself, comprising an ingredient process (interpreter) formally manipulating representations of its own operations and structures.

Tuple Space: A globally shared, associatively addressed memory space that is used by processes to communicate asynchronously, based on the notion of tuples and tuple matching.

Wireless Communication: Data communication that does not require a wired connection between communicating peers, typically using radio or infrared transmissions.

Adaptive Playout Buffering Schemes for IP Voice Communication

Stefano Ferretti

Claudio E. Palazzi
University of Bologna, Italy

INTRODUCTION

Audio communication over IP-based networks represents one of the most interesting research areas in the field of distributed multimedia systems. Today, routing the voice over Internet enables cheaper communication services than those deployed over traditional circuit-switched networks. BoAT (Roccetti, Ghini, Pau, Salomoni, & Bonfigli, 2001a), Ekiga, FreePhone (Bolot & Vega Garcia, 1996), iCall, Kiax, NeVot (Schulzrinne, 1992), rat (Hardman, Sasse, & Kouvelas, 1998), Skype, Tapioca, vat (Jacobson & McCanne, n.d.), WengoPhone, and YATE, are just few examples of free VoIP software available to Internet users.

Without any doubts, new (wired and wireless) high-speed, broadband networks facilitate the transmission of the voice over the Internet and have determined the success of these applications. However, the best effort service offered by the Internet architecture does not provide any guarantee on the delivery of (voice) data packets. Thus, to maintain a correct time consistency of the transmitted audio stream, these voice communication systems must be equipped with schemes able to deal with the unpredictability of network latency, delay jitter, and possible packet loss.

BACKGROUND

Several proposals to face with the effects caused by network delay, delay jitter, and packet loss rate on continuous media stream playout have been presented in literature. For instance, protocol suites (e.g., RSVP, DiffServ) and networking technologies (e.g., ATM) have been devised that provide users with quality of service (QoS) guarantees (Zhang, Deering, Estrin, Shenker, & Zappala, 1993). Yet, these approaches have not been widely adopted as usual means to provide guarantees of QoS to Internet users.

An interesting alternative that is now widely exploited in most existing Internet audio communication tools amounts to the use of adaptive playout control mechanisms. Basically, these schemes are faced with the unpredictability of IP networks by compensating for variable network delays and jitters experienced during the transmission of audio packets. In particular, delay jitter is smoothed away by employing a playout buffer at the receiver side and by dynamically enqueuing audio packets in it. Output of received and buffered packets is thus artificially delayed for some time so as to have a constant audio packet playout rate, hence absorbing negative effects introduced by the delay jitter. Such a buffering policy must be adaptive, since delay jitter on the Internet may vary significantly with time. This way, dynamic playout buffers hide packet delay jitters at the cost of additional delays at the receiver (see Figure 1).

Summing up, each audio packet transmitted on the network has an associated scheduled playout delay, being defined as the total amount of time experienced by such audio packet from the instant it is generated at the source and the instant it is played out at the destination. Such a playout delay consists of: (1) the time needed for the transmitter to collect an audio sample and prepare it for transmission, (2) the network delay, and (3) the buffering time, that is the amount of time that a packet spends queued in the destination buffer before it is played out. Based on this specific notion of playout delay, a received audio packet is defined to be late when its arrival time at the destination is after the expiration of its scheduled playout time.

Needless to say, while the approach of buffering audio packets enables delay jitter removal from audio packet streams and guarantees the speech intelligibility, a critical trade-off exists between the amount of delay that is introduced in the buffer and the percentage of late packets that are not received in time for playout (and are consequently lost, see Figures 2 and 3). In fact, the longer the additional delay due to the buffering policy, the more likely a packet arrives before its scheduled playout time, but the higher the time spent by earliest packets in the buffer. Summing up, on one side, a too large percentage of audio packet loss may impair the intelligibility of an audio transmission, but, on the other side, too large playout delays (due to buffer-

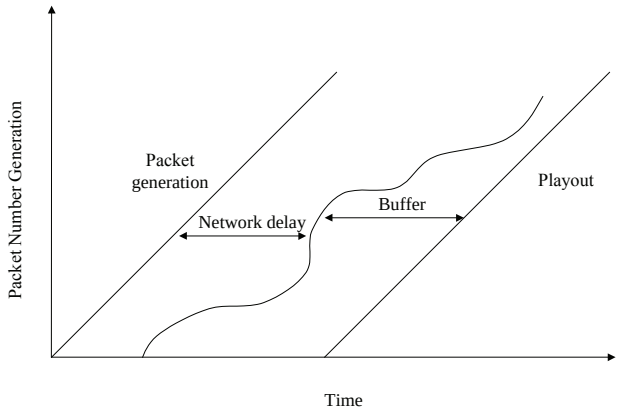

Figure 2. A small playout delay

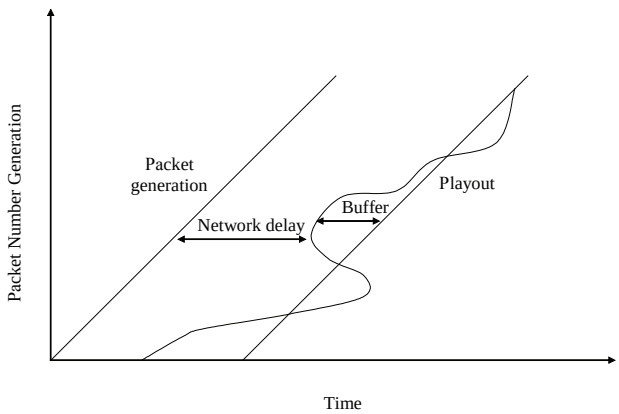

Figure 3. A large playout delay

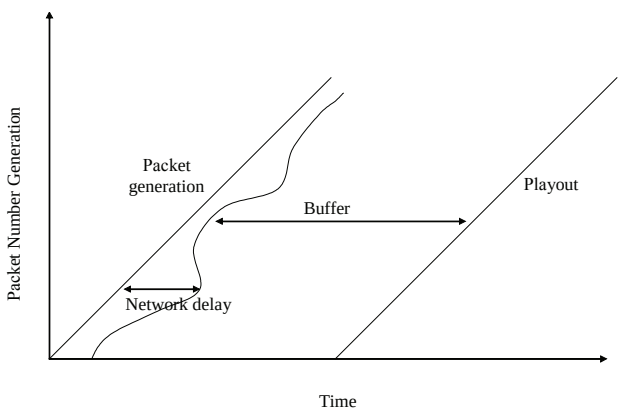

ing) may disrupt the interactivity of an audio conversation (Kostas et al., 1998; Panzieri & Roccetti, 1997). Finally, a suitable buffering policy must reduce the probability of having underflow discontinuities (i.e., the buffer should never empty so that some audio packets are always available to be played out).

With this consideration in view, playout control mechanisms adaptively adjust the playout delay of audio packets to keep the additional buffering delay as small as possible, while minimizing the number of packets received past the point at which they are scheduled to be played out (Boutremans & Le Boudec, 2003; Fujimoto, Ata, & Murata, 2004; Liang, Farber, & Girod, 2003; Sreenan, Chen, Agrawal, & Narendran, 2000).

ADJUSTING PLAYOUT DELAYS

In the remainder of this section, we survey on different adaptive playout delay control schemes that have been designed to support speech transmission over the Internet. All these approaches adopt adaptive control mechanisms that keep the same playout delay constant throughout a given talkspurt, but permit different playout delays in different talkspurts.

Naylor and Kleinrock (1982)

Probably, the first work that proposed an adaptive playout scheduler is that presented in Naylor and Kleinrock (1982).

An important concept at the basis of the scheme is that of the talkspurt (i.e., a short burst of energy) in voice communication, during which the speech activity is carried out. In essence, a packetized audio segment may be considered as being constituted of several talkspurts separated by silence periods (during which no audio packet is generated).

According to this seminal approach, the playout delay is adjusted at the beginning of each talkspurt based on a fixed number (say m) of last delay network latencies experienced during the previous talkspurt. In particular, last m delays are recorded; then, a given amount of k values ($k < m$), representing the highest values in the set are discarded, so as to eliminate isolated cases of particularly high network delays. The maximum difference between the remaining packets is exploited to obtain an estimation of the delay jitter. Such a value is used as the buffering delay of the first packet of the talkspurt.

Ramjee, Kurose, Towsley, and Schulzrinne (1994)

A popular, important, adaptive playout delay adjustment algorithm has been proposed by Ramjee, Kurose, Towsley, & Schulzrinne (1994). The scheme proposed in that work has been extensively used in several Internet audio tools such as NeVoT (Schulzrinne, 1992), rat (Hardman et al., 1998) and FreePhone (Bolot et al., 1996).

A basic assumption of the algorithm is that an external mechanism exists that keeps synchronized physical clocks of the two nodes involved in the communication. Moreover, the approach assumes that network delays experienced by transmitted audio packets follow a Gaussian distribution.

The mechanism works as sketched in the following. The receiver buffers each received audio packet and delays its playout for a time quantity. The delay value to be associated to each audio packet is dynamically calculated based on the network latency for the transmission of the data packet and on the playout delay time. Such playout delay is adaptively adjusted from one talkspurt to the next one. Then, audio packets constituting a given talkspurt are played out in the order they were emitted at the sending site and with a constant playout delay.

In essence, the playout time p_i for the first packet i of a given talkspurt is computed as:

$$p_i = t_i + \underline{d_i} + k * \underline{v_i},$$

where t_i is the time at which the audio packet i is generated at the sending site, $\underline{d_i}$ is the average value of the playout delay, $k \in [1, 2, 4]$ is a variation coefficient (whose effect can be enforced through shift operations) and $\underline{v_i}$ is the average variation of the playout delay. The playout point p_j for any subsequent packet j of that talkspurt is computed as an offset from the point in time when the first packet i in the talkspurt was played out:

$$p_j = p_i + t_j - t_i.$$

The estimation of both the average delay and the average delay variation can be carried out using different algorithms. Basically, a viable solution is that of resorting to a linear filter such that:

$$\underline{d_i} = \alpha\, \underline{d_{i-1}} + (1 - \alpha)\, n_i$$

and

$$\underline{v_i} = \alpha\, \underline{v_{i-1}} + (1 - \alpha)\, |d_i - n_i|$$

where α is a constant value, typically chosen near 0.99, and n_i is the network delay for the i^{th} audio packet.

The scheme is also equipped with a delay spike detection and management mechanism. In essence, a delay spike is a sudden, large increase in the end-to-end network delay of some data packet, followed by a series of data packets arriving almost simultaneously at the receiver side. Delay spikes are very common in Internet transmissions. Based

on this consideration, the algorithm is set to work as described above, but when a delay spike is detected (i.e, the difference between the delay of consecutive audio packets is above a given spike threshold), the mechanism enters in a special mode. In particular, the delay of the first packet of the talkspurt is used as the estimated playout delay for each packet in the talkspurt, in order to effectively react to very large change in transmission delays.

Moon, Kurose, and Towsley (1998)

Another adaptive delay adjustment algorithm for speech transmission has been presented in Moon, Kurose, & Towsley, 1998). The main idea behind this algorithm is to collect statistics on packets already arrived and then use them to calculate the playout delay. This approach has been devised based on the consideration that cases arise when the mechanism, proposed by Ramjee et al. (1994), loses several audio packets between a talkspurt and the next one.

In essence, the value of each packet delay is recorded and the distribution of packet delays is updated with each new arrival. Thus, when a new talkspurt starts, this mechanism calculates the q^{th} percentile point for an established amount of w last arrived packets, and uses it as the playout delay for the new starting talkspurt.

Similarly to the mechanism of Ramjee et al. (1994), in the presence of delay spikes, the algorithm stops collecting packet delays and follows the spike by using as playout delay the delay value experienced by the packet that commenced that spike.

Measurements took from experiments made by the authors of that work confirmed that such a scheme can outperform the approach presented in Ramjee et al. (1994).

Roccetti et al. (2001a)

Another mechanism designed to dynamically adapt talkspurt playout delays to the network traffic conditions has been proposed in Roccetti et al. (2001a). This mechanism is at the basis of an Internet audio tool called *BoAT*.

The proposed mechanism dynamically adjusts playout delays of different talkspurts based on the network traffic conditions. In particular, the scheme does not make any assumptions on the existence of an external mechanism for maintaining an accurate physical clock synchronization between the sender node and the receiver node. Moreover, the scheme neither assumes the existence of a specific distribution of the end-to-end transmission delays experienced by the audio packets.

The technique for dynamically adjusting the playout delay for a given talkspurt is based on obtaining, in periodic intervals, an estimation of the upper bound for the packet transmission delays experienced during the voice communication. Such an upper bound is periodically computed using round trip time (RTT) values obtained from packet exchanges of a three-way handshake protocol performed between the sender and the receiver. Then, the upper bound is used to dynamically adjust the playout delay from one talkspurt to the next, with the introduction of artificially elongated or reduced silence periods.

The Need for Silent Intervals

The need of silent intervals for allowing a playout delay control mechanism to adjust to the fluctuating network conditions is common to all the described Internet voice-based conversation mechanisms. In fact, it is the presence of silent intervals that permits to dynamically adjust the playout

Figure 4. Total amount of silence periods

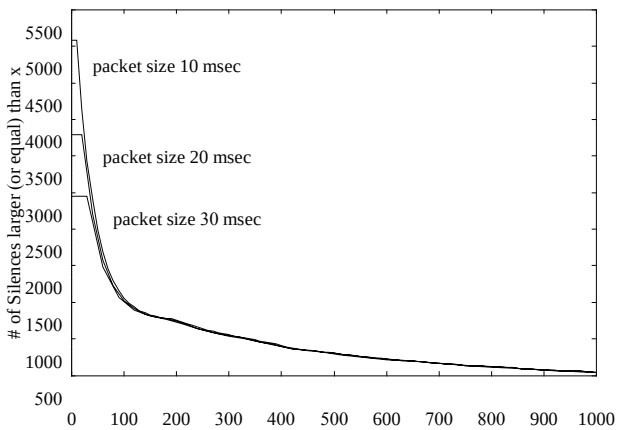

Figure 5. Percentage of silent intervals (with duration larger than x) w.r.t. the total number of silence periods

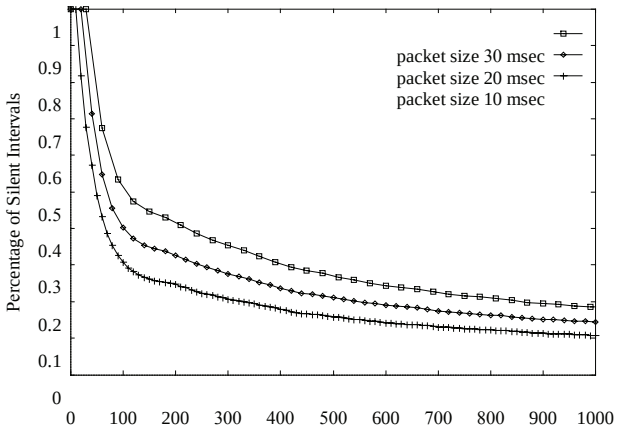

delay from one talkspurt to the next. Put in other words, the end of a talkspurt is seen as an opportunity to resynchronize different parties involved in a voice-based communication. (For this reason, spoken voice with silent periods is often thought as a *semi-countinuous* medium.)

To assess the viability of these mechanisms, an accurate model of the talkspurt characteristics of conversational speech is necessary for understanding whether sufficient (and sufficiently long) silent intervals occur in typical human conversations.

With this in view, a simulation study has been conducted in Roccetti, Ghini, and Pau (2001b). It is shown that a sufficient amount of silent intervals occur in human conversational speech to be used at the receiver to accommodate changes of the audio packet transmission delay, while maintaining speech intelligibility.

In particular, the total quantity of silent intervals within a simulated two-party one-hour-long packetized conversation amounts to about 63-66%, depending on the voice packetization interval (see Figure 4).

As already discussed, the duration of intervening silence periods in human speech is artificially reduced or elongated to accommodate at the receiver changes of the audio packet transmission delays. Thus, a fundamental issue is concerned with the average length of the intervening silence periods. Figure 5 shows the percentage of silent periods (of length larger than a fixed amount) out of the total quantity of all the obtained silence periods. Of particular interest is the fact that the larger the packet size, the larger the average silence duration.

In conclusion, these reported results show that there is room in human speech to successfully exploit sophisticated Internet audio control mechanisms.

FUTURE TRENDS

The future of voice communication systems over IP networks seems to be still bound to the effectiveness of adaptive playout schemes. New approaches are being devised which deserve attention and further investigations (Atzori & Molina, 2006; Liang et al., 2003; Narbut & Murphy 2004; Narbut, Kelly, Murphy, & Perry, 2005).

As an example, a new scheme has been recently proposed, which is based on the idea of adjusting the playout time of audio packets not only between different talkspurts, but also during talkspurts (Liang et al., 2003). In essence, playout delay is dynamically modified by scaling individual voice using a time-scale modification scheme based on the *waveform overlap-add (WSOLA)* algorithm. Basically, *WSOLA* is an interpolation method that modifies the speech signal in order to affect the speech rate only, while preserving other specific speech aspects such as timbre, pitch and quality of the voice.

Based on this, the proposed adaptive playout scheduling scheme estimates delay latencies based on last received audio packets. Then the playout time may be adjusted also within the talkspurt. Speech quality is maintained by using the mentioned WSOLA scheme.

CONCLUSION

Delay adaptation in the presence of fluctuant network delays is a crucial issue in determining the audio quality for real time speech transmission over the Internet. With this in view, the typical approach is that of dynamically adapting the audio application to the network conditions so as to minimize the trade-off between packet playout delay and packet playout

loss. The performance figures illustrate the adequacy of those mechanisms for human speech transmission across the Internet.

KEY TERMS

Audio Packet: Packet encoding an audio sample in digital form. Each audio packet has a timestamp and a sequence number as additional information. Timestamps are used to measure the end-to-end delay experienced during the communication, and sequence numbers are used to detect packet losses. Typically, during an audio communication, audio packets are transmitted over the network, received in a playout buffer, decoded in sequential order, and, finally, played out by the audio device.

Audio Sample: The amplitude of a waveform is measured (sampled) at regular time intervals and converted into an integer value. Each of these instantaneous measurements is an audio sample.

Delay Jitter: Variance of the network delay computed over two subsequent audio packets.

Delay Spike: Sudden, large increase in the end-to-end network delay, followed by a series of audio packets arriving almost simultaneously.

Network Delay: Time needed for the transmission of a data packet from the source to the destination.

Playout Buffer: Buffer used at the receiver to store received audio packets in interactive real-time applications to compensate for variable network delays.

Playout Control Mechanism: Adaptive mechanism that fetches audio packets from the playout buffer and sends them to the audio device for immediate playout.

Playout Delay: Total amount of time experienced by an audio packet from the time instant it is generated at the source and the time instant it is played out at the destination. It consists of (1) the time needed to collect an audio sample and to prepare it for transmission, (2) the network delay, and (3) the buffering time, that is the time that a packet spends queued in the destination buffer before it is played out.

Talkspurt: In audio communication—short burst of energy during, which the audio activity is carried out. An audio segment may be considered as being constituted of several talkspurts separated by silence periods.

A

Addressing the Central Problem in Cyber Ethics through Stories

John M. Artz
The George Washington University, USA

INTRODUCTION

The central problem in cyber ethics is not, as many might think, how to address the problems of protecting individual privacy, or preventing software piracy, or forcing computer programmers to take responsibility for the systems that they build. These are, of course, legitimate concerns of cyber ethics, but the central problem is how you decide what the right thing to do is with regard to these issues when the consequences of any responses cannot be known in advance. Stated more clearly, the central problem in cyber ethics is - how do you establish ethical standards in a professional field that is defined by a rapidly evolving technology where the consequences of the technology and the impact of any ethical standards cannot be known in the time frame in which the standards must be established? Stories play a very important role in addressing this issue. Specifically, stories provide a means of exploring ethical issues for which the full range of consequences is not currently known. But, in order to justify this claim, a few words of explanation are in order.

BACKGROUND

The word "story" means many different things to different people. For example, if one of your children tells you that your dog ate the neighbor's cat, you might challenge the veracity of this claim by asking – "Is that true, or is that just a story?" The implication is that there is truth and there are stories. And if it is a story, it cannot be true. But true versus fictitious is not the same as true versus false; and a story can contain important truths while still being wholly fictitious. If we are looking for precise intellectual truths, then perhaps stories are not the best medium for exploration. However, in areas where our understanding is unclear, either because we do not fully understand a phenomenon, or the phenomenon is not available for study because it exists in a possible world, stories play a very important role in advancing our understanding. To put a finer point on this argument, science and logic fail miserably at telling us what could be, or more importantly, what should be. In these two areas stories are powerful vehicles for intellectual explorations. A story, for the purposes of the current discussion, is a rendition or a telling of a series of true or fictitious events, connected by a narrative in which a set of characters experience and react to a set of actions or events and in doing so reveal something about the human character or condition. In order to see the value of stories for the exploration of issues in cyber ethics, three prior arguments must be made.

NARRATIVE VS. LOGICAL THINKING

Narrative and logical reasoning represent two distinct methods of making sense out of the world around us. They are both legitimate and both can be very rigorous (Bruner, 1986). Sometimes they provide alternative paths to truth and understanding. Sometimes one or the other provides the only path. Logical reasoning is general, context independent, objective and leads to a single conclusion. Narrative reasoning is specific, context dependent, open to subjective interpretation, and potentially leads to multiple conclusions. The characteristics of narrative reasoning are considered flaws when applied to logical reasoning. But the reverse applies also. A story that has only one interpretation and means the same to everyone is not much of a story. While narrative and logical reasoning are different kinds of reasoning, they are not mutually exclusive. A good narrative is also often quite logical in structure, and a good logical argument can often be better understood with a good narrative example. But for the most part, they are complimentary, alternative modes of thinking that provide different paths to truth and understanding.

To some extent, logical and narrative reasoning address different domains. Logic is well suited to mechanistic processes that can be reduced to logical description. Logic is good for articulating general principles and deductive reasons. Logic is useful for describing and explaining. While logic is good for describing "what is," narrative is good for exploring "what could be" and figuring out "what should be". Narratives are a useful means for understanding the complex and ambiguous issues in human affairs. They allow us to explore possibilities and experience situations vicariously. Narrative reasoning is particularly well suited to cyber ethics because many issues are not well understood and the goal of cyber ethics is not to discover truth about the physical world, but truth about human nature. Narrative fiction gives us a means to explore and discover truths about what could

be and what should be. Through narratives we can explore possible consequences of technology, construct alternative worlds and select the one in which we would like to live.

Critics of the use of narrative in ethics point out that after exploring narratives you always have to come back to principles. Ethics, they argue, is too messy without principles and discussion of narratives does not lead to consistent conclusions. This view misses the point of narratives. First, principles are developed by extracting the principles from experience. Narratives provide some of these experiences vicariously. Hence, narratives can be used in the development of principles. Second, it is often unclear which principles apply in given situations. Narrative explorations provide insight into situations, allowing us to determine the governing principles. And narratives can be used to explore the consequences of principled decisions to determine if the outcomes are indeed what are intended. Finally, narrative reasoning does lead to conclusions - very specific conclusions about very specific situations. Narrative reasoning is lacking in generality, as was mentioned before, not lacking in conclusions.

THE ROLE OF EMOTION IN REASON

Most people believe that emotions have no role in logical reasoning. After all, reasoning should be dispassionate and free from emotional influences that may cloud our reasoning. And there is some basis for this. For example, if you lose your temper in the middle of an argument and start flinging personal insults at your opponent, rational people would not consider you as having advanced your position. Most would say that you lost the argument when you lost your temper. Yet emotions play an important role in reasoning and in order to understand this, we need to better understand exactly what emotions are.

There is considerable debate about the exact nature of emotions. The philosopher Robert Solomon (Solomon, 1994) offers one very useful observation that "emotions are judgments about the world". If you are walking down a path in the woods and it is getting dark, you might start to get a little nervous and walk a little faster. If you hear an unfamiliar noise or a rustling in the leaves your heart may begin to beat a little faster as you experience the emotional reaction of fear. This fear is a judgment about the world in which you have judged your current situation as unsafe. You did not arrive at this judgment through a rational process. Specifically, you did not think – "It is dark and hungry animals or possibly monsters come out when it is dark. I just heard a noise that I cannot identify and therefore there could be a hungry animal near me. If I walk a little faster, I might get away before the animal gets me. If I am wrong then all I have done is walked a little faster. If I am right, I might avoid being eaten. Hence, it is logical and reasonable for me to walk faster." In fact, you probably did not think at all. You just felt scared and increased your pace. If asked later why you were walking so quickly you might come up with a reasonable explanation. But that reasonable explanation is certainly constructed after the fact.

Perhaps we have conceded at this point that emotions are judgments about the world and that they can play an important role in reasoning. The obvious question is "So what?" Why do we care and why should we bother to make an effort to incorporate our emotional judgments into our reasoning? Damsio (1994) describes the case of a young man who after suffering damage to part of his brain was no longer able to feel emotions. The unexpected side effect of this malady was that he was also unable to make good decisions or assign importance to competing tasks. He seemed normal in every other way and seemed to have his intellectual facilities fully intact. Yet he seemed no longer able to feel emotions and as a result he was unable to function as a normal person. When we make a decision we evaluate alternatives. If we are unable to feel emotions we are unable to place values on the different alternatives. If we cannot place values on the different alternatives then there is no difference between the alternatives and decision-making becomes seriously flawed. Hence, without emotions rational decision-making may not be possible.

A good story about an ethical issue is much more likely to draw an emotional response that an intellectual one, whereas an abstract analysis is more likely to yield an intellectual response. Ultimately, ethical decisions are emotional decisions because they embody human values. For this reason, examining ethics from a purely rational perspective completely misses the point.

IMAGINATION AND POSSIBLE CONSEQUENTIALISM

One of the problems in establishing standards of ethical behavior in a field driven by technology is that the consequences of the technology and reactions to the technology often cannot be known. Looking to the past to provide guidance is ineffective because the past provides few clues. Marshall McLuhan is often attributed with the famous observation that looking to the past to provide guidance for the future is like driving by looking in the rear-view mirror. Although it is disputed as to whether he ever said that or not, it is a rich metaphor for understanding how we should think about the future in times of rapid technological change.

Imagination is the key to understanding the future. The problem though, in using imagination to understand the future, is that we have a cognitive bias against understanding the future. We feel quite comfortable that we understand the past, but the future is the domain of prophesies. Yet assertions about the past are never testable because the past is

gone, never to return, while assertions about the future are testable. So one could argue, on the basis of the testability criterion, that the future is more knowable than the past. However, that discussion is for another time.

Consider imagination as the creative capacity to think of possibilities. Imagination lets us see the world not as it is, but as it could be. Seeing the world as it could be allows us to make choices about how it should be. It is this ability to see possibilities that drives us to build technologies to bring about, or implement our preferences about possible worlds. Stories are both a product and a tool of our imaginations. Using stories in moral reasoning provides a means for a slightly different view of ethics that could be called "possible consequentialism". Whereas the consequentialist evaluates actions based upon their consequences, the possible consequentialist evaluates actions based upon their possible outcomes. The possible outcomes are described in stories and the likelihood of the outcome is determined by the believability of the story given our understanding of current conditions and human nature. As the literary critic Northrop Frye points out, "The fundamental job of the imagination in ordinary life, then, is to produce, out of the society we have to live in, a vision of the society we want to live in" (Frye, 1964, p. 140).

When we examine issues in cyber ethics, we cannot examine them in terms of consequentialist ethics because the consequences are not known. However, through the use of stories we can construct imaginative scenarios and examine possible consequences. Possible consequentialism may be a preferable approach to computer ethics because we can look at possible outcomes, assess the likelihood of each, and select the outcome we prefer. Imagination provides us with a means of fully examining possible outcomes and stories provide us with the means of sharing our imaginings. By writing stories and sharing them we can explore possible consequences and, through social debate, derive imaginary truths. These imaginary truths allow us to choose the kind of world that we would like to live in.

FUTURE TRENDS

While stories play an important role in the exploration of problems in cyber ethics, there is still a serious barrier to using them. That barrier is the fact that precious few stories have been written. Current work is addressing that problem (Artz, 2004). As researchers and teachers in cyber ethics become more comfortable with writing stories, the value of stories for exploring possible worlds will make this approach increasingly more attractive. Further, as the implications of information technology and the ethical problems they bring move further into the future, the ability of stories to capture possible worlds will make them increasingly more compelling.

CONCLUSION

The central problem in cyber ethics is not, as many may suppose, how to prevent software piracy or how to protect privacy on the Internet. It is instead - how do you establish ethical standards in a professional field that is defined by a rapidly evolving technology where the consequences of the technology and the impact of any ethical standards cannot be known in the time frame in which the standards must be established? Stories play an important role in addressing this problem by providing a means of exploring ethical issues for which the full range of consequences are not known. Stories allow us to construct narrative arguments to explore issues that we do not fully understand. They allow us to explore the emotional as well as rational aspects of a situation. Stories allow us to explore worlds that do not currently exist, which, in turn, allows us to examine possible consequences and make choices about the world in which we would like to live.

KEY TERMS

Cyber Ethics: A branch of ethics that focuses on behaviors that are specifically related to information technology.

Ethics: A branch of moral philosophy that examines the standards for proper conduct.

Imagination: The creative capacity to think of possibilities.

Logical Reasoning: General, context independent, objective reasoning that leads to a single conclusion.

Narrative Reasoning: Specific, context dependent reasoning that is open to subjective interpretation, and potentially leads to multiple conclusions.

Possible Consequentialism: Evaluating an ethical position in terms of its possible consequences.

Story: A rendition or a telling of a series of true or fictitious events, connected by a narrative, in which a set of characters experience and react to a set of actions or events and in doing so reveal something about the human character or condition.

Adoption of E-Commerce in SMEs

Arthur Tatnall
Victoria University, Australia

Stephen Burgess
Victoria University, Australia

INTRODUCTION

Just because e-commerce technologies seem like useful tools that may assist a small to medium enterprise (SME) do its business better, it does not necessarily follow that these technologies will be *adopted* by this business. The implementation of an e-commerce system in an SME necessitates change in the way the business operates, and so it should be considered as an innovation and studied using innovation theory.

Electronic commerce (e-commerce) is concerned with how computers, information systems and communications technologies can be used by people to improve the ways in which they do business. As e-commerce necessarily involves interactions of people and technology, any study of how it is used by a small business must be considered in a socio-technical context. Although there is no universal consensus on what constitutes e-commerce, it must be considered to contain elements of information systems, computer hardware technology, business processes, communications technologies, and people. The complexity of studies in e-commerce is due, to a considerable degree, to the interconnected parts played by human actors and by the multitude of non-human entities involved. Small business managers, sales people, staff involved in procurement and warehouse operations, computers, software, Web browsers, Internet service providers (ISP), modems, and Web portals are only some of the many heterogeneous components of an e-commerce system.

BACKGROUND: ADOPTION OF E-COMMERCE BY AN SME

In this article we will argue that the decision to adopt, or not to adopt a new technology is not a straightforward one and has more to do with the interactions and associations of both human and non-human actors involved in the project than with the characteristics of the technology itself (Tatnall, 2005). Information systems are complex socio-technical entities, and research into their implementation needs to take account of this complexity, which will only be seen if it is reported in all its "messy reality" (Hughes, 1983). Research into the implementation and operation of these systems needs to take this heterogeneity into account and to find a way to give due regard to both their human and non-human aspects.

One view of the adoption of an electronic commerce innovation by a small to medium enterprise suggests that decisions are made primarily based on perceptions, by business managers, of the characteristics of the technology concerned. Such an "essentialist" approach (Haslam, 1998) involves consideration of the "essential" characteristics of the technology. Innovation diffusion (Rogers, 1995) uses this approach and is based upon the following elements:

- characteristics of the innovation itself,
- the nature of the communications channels,
- the passage of time,
- and the social system.

Another approach that has recently gained prominence is the Technology Acceptance Model (TAM), formulated by Davis and his colleagues (Davis, 1986, 1989; Davis, Bagozzi, & Warshaw, 1989). Davis identifies three major determinants of technology acceptance (or adoption) suggested by previous research studies that relate to cognition and effectiveness:

- perceived usefulness and
- perceived ease of use

to which are sometimes added attitude toward using technology and behavioral intention. TAM then attempts to use these factors to explain technology adoption.

Using approaches of this sort, the researcher would probably begin by looking for characteristics of the specific e-commerce technology to be adopted, and the perceptions, attitudes, advantages, and problems associated with its use. The next step would be to suggest that the adoption, or rejection, of this technology by an SME was due largely to these characteristics. We contend that while there may be some validity in such an approach, it is unlikely to provide the complete explanation as it would miss other influences due to inter-personal and intra-business interactions, and to the backgrounds of the people involved.

INNOVATION TRANSLATION

We argue that actor-network theory (ANT) has much to offer in a situation like this. A researcher using an actor-network approach to study innovation would concentrate on issues of network formation, investigating the human and non-human actors and the alliances and networks they build up. They would investigate how the strength of these alliances may have enticed the small business to make the adoption or, on the other hand, to have deterred them from doing so (Tatnall, 2002; Tatnall & Burgess, 2006; Tatnall & Gilding, 1999). While some research approaches to technological innovation treat the social and the technical in entirely different ways, actor-network theory proposes a socio-technical account in which neither social nor technical positions are privileged.

Actor-network theory argues that interactions between actors are heterogeneous and denies that purely technical or purely social relations are possible. It considers the world to be full of hybrid entities (Latour, 1993) containing both human and non-human elements. Change, in the ANT view, results from decisions made by actors, and involves the exercise of power. Latour (1986) argues that the mere possession of power by an actor does not automatically lead to change unless other actors can also be *persuaded* to perform the appropriate actions for this to occur.

In our experience it is often the case that when a small or medium business is considering a technological innovation it is interested in *only some aspects* of this innovation and not others (Tatnall, 2002; Tatnall & Burgess, 2002, 2006; Tatnall & Davey, 2005). In actor-network terms it needs to *translate* (Callon, 1986) this piece of technology into a form where it can be adopted, which may mean choosing some elements of the technology and leaving out others. What results is that the innovation finally adopted is not the innovation in its original form, but a translation of it into a form that is suitable for use by the recipient small business (Tatnall, 2002; Tatnall & Burgess, 2006).

In many instances a small business proprietor will adopt e-commerce because a friend is using it, or because they know a competitor is using it, or because a son or daughter learned about it at school (Burgess, 2002; Tatnall, 2002; Tatnall & Burgess, 2006). The nature and size of each small business, the intra-business interactions in which they engage, and the backgrounds and interests of particular individuals in each are also likely to have had an important affect that would, most likely, have been ignored by the essentialist approach offered by innovation diffusion or TAM. Actor-network theory, in examining alliances and networks of human and non-human actors, provides a good foundation from which small business adoption and use of e-commerce can be researched. The ANT approach will be further amplified in the case studies that follow, particularly in respect of the identification of actors and networks.

CASE STUDIES OF TECHNOLOGY ADOPTION

This article now offers several brief case studies in which actor-network theory has provided a means by which adoption (or non-adoption) of technology can be explained. In each case, data for the study were obtained through semi-structured interviews with the proprietors and personnel of the businesses involved.

1. Adoption of a Portal by a Storage and Transport Company

The business to be considered in this study is a medium-sized Melbourne company, with about 50 employees, that stores frozen food and transports it to supermarkets and other locations around the country. It became clear from the study that the transport company had "not really been into computers" and had only recently started coming to grips with this technology.

Although the manager had some idea of the benefits to his company of using the portal, he had no clear plan for using it. It was just "a really good idea." The reasons he adopted this innovation thus had little to do with the characteristics of this technology, and much more to do with his involvement with the local business community and because of his belief that the portal had the potential to improve business in the region.

2. Adoption of Internet Technologies by a Rural Medical Practice

Rural medical general practitioners (GPs) in Australia have not been rapid adopters of ICT, and this has been of concern to both the commonwealth government and to medical industry bodies (Tatnall, 2005). Many ICT products have been developed to support GPs in all aspects of their work in Australia (GPSRG, 1998), and much research and development in this area has already been undertaken. It is apparent, however, that GPs are not making as much use of these systems as they could be (Burgess, Darbyshire, Sellitto, Tatnall, & Wenn, 2003a).

A study of 1200 randomly selected general practices from across Australia (GPCG, 2001) identified the main uses GPs make of computers. Although a large number of respondent practices (89%) were computerized, it does not necessarily follow that computers are being directly used by the GPs themselves. Major uses identified were administrative functions (85%), clinical functions (76%), script writing (60%), general referral letters (57%), and receiving pathology and other test results electronically (57%). While these figures suggest that most GPs make some use of ICT,

they are somewhat misleading in not indicating the extent of this use (Everitt & Tatnall, 2003). Burgess, Darbyshire, Sellitto, Tatnall, and Wenn (2003b) also note that the use of ICT by GPs reflects the patterns of use in small business, and it seems that if GPs do use ICT, then in many cases it is for perceived cost savings rather than for adding value (Burgess & Trethowan, 2002).

Dr. Doyle and Dr. Holmes (although this is a real case, these names are fictitious) operate a small medical practice in a country town 80km north of Melbourne, employing two secretarial assistants. Although aware that ICT could be of benefit to their practice, they currently use computers only for patient billing and secretarial functions. The interactions resulting from a complex network of actors have been responsible for this practice not using ICT to the extent that they could. This network includes the following actors: Dr. Doyle, Dr. Holmes, the regional Division of General Practice, other local GPs (friends and colleagues), patients, their secretarial staff, the local hospital, the local pathology laboratory, "Medical Director" software, Internet broadband technology, computers, and medical consulting rooms.

While the regional division of general practice, some of their patients, and several of their colleagues strongly encourage the use of ICT, many of the other actors have worked to discourage it. By providing patient data in paper, and not electronic, format, both the local hospital and pathology laboratory act to discourage the use of computers into which the GPs would have to type all this data. The difficulty of using the software and of making all the required Internet connections is also a discouragement.

A small group of actors is thus working to encourage these GPs in the use of ICT, while another group is working to discourage this use. At present the second group is winning the battle. Although Dr. Doyle and Dr. Holmes understand the benefits of the technology, they are very busy people and have not yet been persuaded by a large enough coalition of actors to adopt it.

3. Adoption of Electronic Commerce by a Small Publishing Company

The next case concerns a small publishing company where four people work on the production of textbooks and research publications. The company is a very small business with a relatively low turnover but a well-established market. The business has adopted some e-commerce technologies, but not others. Some time ago, it registered a domain name and set up its own Web page, but only for informational purposes. The site shows details of the company's products and indicates how orders can be placed, but does not support sales or other business-consumer (B-C) transactions.

When asked why the company had not considered instituting a B-B e-commerce system with the printer, the director replied that they would like to do so, but that the printer was not really interested or geared up to get into this type of order. Adoption decisions of the company thus had more to do with the technological status of their suppliers and their customers than with the e-commerce technology itself. The company was interested in using those e-commerce technologies that its business partners used and those it considered useful or timesaving. What was adopted could be seen as a translation of an e-commerce innovation to include just these things.

4. Non-Adoption of E-Commerce by a Small Chartered Accountancy Firm

The last case is of a small chartered accountancy firm, which is a family business in the western suburbs of Melbourne. Employees of the business are the main accountant, who has a degree in accounting and is a certified practicing accountant (CPA); the main accountant's father, who previously ran the business but, as he is not qualified, is limited these days mainly to supporting the taxation side of the business; another accountant (CPA); and a full-time secretary. The firm offers services that are typical of a small accounting business, and its clients include both individuals and small businesses.

For some time members of the business had been debating whether to set up a Web site. The decision seemed to come down to two major opposing viewpoints. The first, held by the main accountant, was that a Web site was "the way of the future," that customers would expect it, and that some competitors already had one. The opposite viewpoint, held by the father, was that it is a waste of time and money, that there was nothing you could put on a Web site that customers would want anyway, and "who is going to do it?" Other members of the business seemed quite apathetic about the whole matter.

The upshot was that the Web site could not be "translated" into a form where it could be adopted by this business. The main accountant was the prime motivator in attempting to define the problem and to discover the solution: he did not do this well enough, however, to gain acceptance of the innovation.

FUTURE TRENDS: ANT AND E-COMMERCE INNOVATION

The theory of innovation diffusion (Rogers, 1995) and also the related technology acceptance model (Davis, 1989) are well established and have been used as the framework of many studies. In most cases, however, the success of the diffusion model has been in explanation of innovation "in the large" when the statistical effects of big numbers of orga-

nizations and individuals involved come into play. Although TAM is somewhat less mechanistic, it suffers a similar fate. They have, typically, been less successful in explaining how particular individuals or specific organizations make their adoption decisions, and it is in situations like this that an innovation translation approach, using actor-network theory, is especially useful.

In offering a socio-technical approach to theorising innovation, ANT provides a particularly useful tool to the study of innovations in which people and machines are intimately involved with each other. The adoption of e-commerce technologies certainly involves a consideration of the technologies themselves, but also of business organizations, business processes, and the needs and likes of individual humans. ANT, we suggest, is especially useful in researching innovations like these, and in particular, when considering individual adoption decisions.

The main use made of any research approach such as ANT is in the study of past events, and ANT makes no claim to be able to predict what may happen in the future. We suggest, however, that ANT analysis can identify some pointers toward the successful introduction of an innovation, and the change management associated with this. ANT argues that it is not the characteristics of either the innovation itself or the potential adopter acting alone that are important, but rather the interactions of many actors. The key to successful change management, it would thus seem, involves allowing for these interactions and for the socio-technical nature of the process.

CONCLUSION

All of the situations described in this article point to the fact that decisions on the adoption of electronic commerce technologies are often made on the basis of more than just the characteristics of the technology and that in many cases these characteristics are not especially significant in the decision making process.

In each of these instances, the actor-network approach therefore offers a useful explanation of why a particular e-commerce initiative was or was not adopted. On the other hand, an innovation diffusion approach to investigating each of the potential adoptions would have looked for explanations for the uptake, or lack of uptake, primarily in the characteristics and properties of the technology in each case. It would not have considered, as particularly important, the human and non-human interactions described here. In our view, the decision to adopt, or not to adopt, has more to do with the interactions and associations of both human and non-human actors involved in the project rather than with characteristics of the technology.

KEY TERMS

A

Actor: An entity that can make its presence individually felt by other actors. Actors can be human or non-human, non-human actors including such things as computer programs, portals, companies, and other entities that cannot be seen as individual people. An actor can be seen as an association of heterogeneous elements that constitute a network. This is especially important with non-human actors, as there are always some human aspects within the network.

Actor-Network Theory (ANT): An approach to research in which networks' associations and interactions between actors (both human and non-human) are the basis for investigation.

E-Commerce Systems: Contain elements of information systems, business processes, and communications technologies.

Innovation Diffusion: A theory of innovation in which the main elements are characteristics of the innovation itself, the nature of the communication channels, the passage of time, and the social system through which the innovation diffuses. The main proponent of Innovation Diffusion is Rogers (1995).

Innovation Translation: A theory of innovation in which, instead of using an innovation in the form it is proposed, potential adopters *translate* it into a form that suits their needs.

Small to Medium Enterprise (SME): For the purpose of this article, SMEs are considered to be those businesses that have from 1-20 employees—small—and 21-50 employees—medium.

Technology Acceptance Model (TAM): A theory of innovation developed by Davis (1986) in which the main elements are perceived usefulness, perceived ease of use, attitude toward using technology, and behavioral intention.

Technology Adoption: The decision, by an organization or individual, to utilize and implement a technology.

Technological Innovation: The introduction or alteration of some form of technology (often information technology) into an organization.

Adoption of Electronic Commerce by Small Businesses

Serena Cubico
University of Verona, Italy

Giuseppe Favretto
University of Verona, Italy

INTRODUCTION

The role played by small business in economic growth and development in the world is officially recognized, in both the economic literature and in official documents (e.g., Organization for Economic Cooperation and Development, European Commission, U.S. Department of State).

Information and communication technology connectivity are widespread in all sized businesses, but small businesses seem slower than larger ones to adopt and use ICT and electronic commerce.

SMEs (small- to medium-sized enterprises) are independent firms that employ less than 10 (micro), 50 (small), and 250 (medium) employees (European Commission, 2003); the United States includes firms with fewer than 500 employees in the definition of an SME (OECD, 2000a).

In Europe, SMEs contribute up to 80% of employment in some industrial sectors (e.g., textiles, construction, furniture), and they are defined as "a major source of entrepreneurial skills, innovation and contribute to economic and social cohesion" (European Commission, 2005, p. 3); in the U.S. economy, small businesses represent 99.7% of all employers and "broaden a base of participation in society, create jobs, decentralize economic power and give people a stake in the future" (U.S. Department of State, 2006, p. 2).

To synthesize: more than 95% of OECD enterprises are SMEs, accounting for 60-70% of employment in most countries (OECD, 2000a).

The same proportion is indicated by the United Nations Conference on Trade and Development; in fact, SMEs account for 60-70% of all employment in developing countries (UNCTAD, 2002).

BACKGROUND

Research interests in e-commerce utilization in SMEs have been driven by a basic hypothesis that this type of technology can offer new opportunities to counterbalance disadvantages of size, resources, geographic isolation, and market reach (Wymer & Regan, 2005).

Several different disciplines (management, organizational behavior, communications, computer science, information systems, marketing, work, and social psychology) are involved in research on incentives and technology adoption barriers. In this regard, different theoretical and applied models already exist:

- The *Theory of Reasoned Action (TRA),* and its extension, the *Theory of Planned Behavior (TPB)* (Ajzen & Fishbein, 1980; Chau & Hu, 2001; Harrison, Mykytyn, & Riemenschneider, 1997) are based on assumptions that a person's intentions are the best guide to behavior, and that there is a link between attitudes and behavior.
- The *Technology Acceptance Model (TAM)* (Straub, Limayem, & Karahannaevaristo, 1995), defines models as to how users come to accept and make use of technology.
- The *Adoption, Innovation and Diffusion Theory* (Rogers, 1995) defines adopter (of any new innovation or idea) categories as innovators, early adopters, early majority groups, late majority groups, and laggards.
- *Social Cognitive Theory* (Bandura, 1996) defines human behavior as a triadic, dynamic, and reciprocal interaction of personal factors, behavior, and the environment.
- The *Unified Theory of Acceptance and Use of Technology (UTAUT)* (Venkatesh, Morris, Davis, & Davis, 2003) uses performance expectancy, effort expectancy, social influence, and facilitating conditions as direct determinants of usage intention.

Table 1 presents a synthesis of the numerous factors influencing adoption of e-commerce adoption from the literature.

As we can see, adoption of electronic commerce by SMEs is influenced by different factors. Grandon and Pearson (2004) identified and synthesized four factors that have statistically significant effects on e-commerce utilization: *organizational readiness* includes financial and technological resources and compatibility of e-commerce with company's culture, values, and preferred work activity; *external pressure* is defined by competing, social factors, dependency on other firms already using e-commerce, the industry, and the government; and *perceived ease of use* and *perceived*

Table 1. Factors influencing decision to adopt e-commerce/e-business/Internet technology (adapted from Wymer & Regan, 2005, p. 442)

Factor Name	Description
Environmental Factors	
Competitive Pressure	Competitive pressure from other Internet adopters within the industry
Government	Government rules and regulations
Market	Viable market or customer base for e-commerce
Partners/Vendors	Availability of the right partners
Supplier Readiness	Readiness of suppliers for electronic business
Knowledge Factors	
Change Experience	Employee experience with making major changes
Executive Experience	Experience of top executives with computers and the Internet
Innovativeness	Company's willingness to adopt new technology
Models	Successful models of use in the industry
Need	Perceived need for change or implementation of Web and Internet technologies
Prior Experience	Company's prior experience with new technology implementation
Trust	Trust or confidence in Web and Internet technologies
Understanding	Understanding of available opportunities and options with e-commerce
Value	Perceived value or relevance to the business
Organizational Factors	
Capital	Access to capital for start-up
Employee Reduction	Resulting reduction in number of employees
Priority	Priority relative to other projects that require existing resources and time
Profitability	Projected profitability of e-commerce
Technical Expertise	Availability of technical staff or consultants with Web skills
Technological Factors	
Cost	Cost to setup and maintain
EC Technology	Technology for selling products or services online
Infrastructure	Access to network services or infrastructure to support Web and Internet technologies
Reliability	Reliability of Web and Internet technologies
Security	Security issues
Technology Availability	Availability or adequacy of existing technology and tools

usefulness. In particular, the last two factors turned out to be most influential in adoption of electronic commerce by top managers of SMEs, while compatibility emerged as a partial factor that highly influenced e-commerce adoption, as opposed to financial and technological resources.

The benefits of e-commerce are for all sized businesses, and even SMEs could reap advantages. Studies in numerous counties reveal that SMEs have been slower to adopt e-commerce than their larger counterparts, however information technology use by SMEs is increasing (Drew, 2003).

Moreover, many studies define and analyze e-commerce and small businesses through different points of views with images and concepts that are not of help in understanding the phenomenon (Ngai & Wat, 2002).

Small business have many reasons for selling or buying over the Web. They can receive benefits from this type of commerce—that is, "adding distribution channels, increasing overall sales, expanding their reach beyond local markets, or gaining greater exposure in existing markets [in] building an Internet storefront for a retail shop" (Mehta & Shah, 2001, p. 88).

SMEs use e-commerce in three different ways:

Internet start-ups' are inventing new ways of creating value added, new service and new business models…'Established

Table 2. Percentage of small European enterprises (10 to 49 employees) that use e-commerce for purchasing and sales (data in parentheses refer to large enterprises: more than 250 employees) (adapted from Eurostat, 2006)

ELECTRONIC COMMERCE	EU	DE	ES	IT	CY	LV	HU	PL	SE	UK
Purchase	22(40)	40(52)	4(7)	4(15)	14(20)	1(1)	4(8)	9(11)	40(57)	48(72)
Sales	10(31)	14(40)	2(15)	2(13)	2(29)	1(1)	4(6)	4(14)	21(45)	22(45)

small firms' are developing their own e-commerce strategies to expand their business by entering new markets, often internationally…'Existing SMEs' are entering into electronic partnership with large corporate customers. (OECD, 2000b, p. 17)

Studies on adoption of electronic commerce by SMEs focused on different aspects:

- The benchmark on the use of the Internet emphasizes that SMEs need to think both globally and strategically, and that they must learn from competitors (Webb & Sayer, 1998).
- A learning organization style oriented to upgrade competencies and to acquire new knowledge (defined *high-order* by Argyris & Schon, 1978) is more involved in the use of the Internet and e-commerce (Chaston, 2001).
- There are significant differences in frequency and type of use, related to company size: four or more employees represents the critical dimension for more frequent and sophisticated use (Dandridge & Levenburg, 2000).
- The greater the usage of Internet technology is among entrepreneur-led family business, the more it is possible to find ties between entrepreneurial profile and growth (Davis & Harveston, 2000).
- The analysis of strategic use of the Internet and e-commerce in SMEs shows that they are opportunistic in their adoption and that the communication requirement has been a motivating factor of implementation (Sadowski, Maitland, & van Dongen, 2002).
- SMEs present different sequences of e-commerce adoption: in the early stages they use the lowest levels of e-commerce service; in the second, e-mails are used to communicate with customers, suppliers, and employees; the third level of adoption includes information-based Web sites operating and developing online ordering services; and the most advanced adopters use online ordering and are developing online payment capabilities (Daniel, Wilson, & Myers, 2002).

FOCUS: SPECIFIC DIFFICULTIES FOR SMALL BUSINESSES WITH E-COMMERCE ADOPTION

Some problems to understanding the barriers faced by smaller firms are due to the fact that they are a not uniform group and that their characteristics vary by sector:

High technology, knowledge-intensive small firms are more likely to use e-commerce than other small firms and there are differences between industry sectors in terms of e-commerce use and strategy development. (Fillis & Wagner, 2005, p. 607)

Non-adopters show some characteristics that differ from SMEs that adopt e-commerce. In fact, they present high scores related to barriers/impediment and tend to be slower in detecting changes in technologies that might affect their business, whereas the adopters are more aware of opportunities afforded by technology, are more costumer oriented, and are more sensitive to changes in their customer/competitive environment (McCole & Ramsey, 2005).

It is interesting to see the adoption of e-commerce in different areas of the world.

In European Union (EU) countries, the use of an internal computer network and intranets is progressing well, but there is space for improvement, especially among smaller enterprises (10 to 49 employees). Internet and Web sites are not enough of a support system for e-business. Enterprises need to use more of their technological potential in order to reap maximum benefits. E-commerce can be difficult to start up, and generally, enterprises tend to prefer to purchase than to sell online. According to Eurostat (2006), only 10% of EU small firms engaged in e-commerce sales activity.

Table 2 shows the most significant data from the EU.

In the United States, there were slight differences in e-commerce attitudes and experience between small/medium-sized enterprises and large establishments. This difference in e-commerce experience suggests that a considerable population of small establishments (less than 25 employees) may be less prepared for e-commerce. Routine use of e-commerce

Table 3. Mean percent of total commerce conducted online by SMEs (25-250 employees) in the U.S. (data in parentheses refers to large enterprises: more than 250 employees) (adapted from Fomin, King, Ljjtinen, & McGann, 2005)

ELECTRONIC COMMERCE	SMEs
Purchase	73.5(79.8)
Sales	5.1(4.0)

lags behind more traditional forms of commerce (Fomin, King, Ljjtinen, & McGann, 2005).

Table 3 shows the most significant data from the United States.

In many developing countries, no statistical indicators on e-business have been collected and considerations are more difficult due to the very significant differences among SMEs in different regions and countries.

The general conclusion (UNCTAD, 2004, p. 52) on the adoption of e-business in developing countries are:

"…for SMEs is that it is relatively easy to start using PCs, then connect to the Internet using e-mail, and then set up a Web page. However, the introduction of the Internet into their business activities (…including e-commerce) does not follow straightaway, and larger companies are more likely to automate their business processes (and to do so earlier) than smaller companies. One explanation for this is that most SMEs have no defined e-business strategy."

The specific difficulties in different countries by small firms in e-commerce adoption are the object of various studies (Fomin, King, Ljjtinen, & McGann, 2005; Cubico, Venturini, Russo, & Favretto, 2005; Fillis & Wagner, 2005; Jones, Beynon-Davies, & Muir, 2003; OECD, 2004; Walczuch, Van Braven, & Lundgren, 2000), and from these, we can draw a basic synthesis of the factors involved.

The most cited barriers related to smaller-sized enterprises in e-commerce adoption are:

- Concern about privacy of data or security issues,
- need for face-to-face customer interaction,
- implementation costs of e-commerce sites,
- lack of financial resources and high costs,
- customers do not use the technology
- applicability to enterprises
- finding staff with e-commerce expertise and uncertainty on how to implement,
- insufficient education/information about benefits,
- level of ability to use the Internet as part of business strategy,
- prevalence of credit card use in the country,
- taxation of Internet sales,
- making needed organizational changes,
- inadequate legal protection for Internet purchases,
- cost of Internet access, and
- business laws do not support e-commerce.

The following specific elements are limited factors: awareness of SME access to infrastructure and skills, critical mass among business partners, confidence in legal and regulatory framework/security, and adaptation of business processes.

FUTURE TRENDS

The first steps to understanding the phenomenon of e-commerce adoption in SMEs are to define their characteristics and to know the specific needs of these types of enterprises.

Furthermore, it would be interesting to understand more about specific patterns related to decisions and choices in e-commerce adoption through different disciplines. For instance, important psychological aspects that inform decisions to work with electronic markets seem to be reliability, security, confidence building, and the legal framework (selected cultural differences have been demonstrated in recent cross-cultural research by Dinev, Bellotto, Hart, Russo, Serra, & Colautti, 2006), or the effect of a specific organizational culture that impedes SMEs' decisions (Feltham, Feltham, & Barnett, 2005; Schein, 1983).

Another way could be to identify specific skills, knowledge, attitudes, and aptitudes necessary and distinctive to e-commerce adoption by SMEs.

CONCLUSION

Work on SMEs and different levels of e-commerce adoption shows that firms needs to improve specific skills (Taylor, Mcwilliam, England, & Akomode, 2004), in order to develop existing processes or to introduce new processes and to integrate their new Web-based systems (with existing internal systems and with external systems for customers and suppliers) (Jeffcoate, Chappel, & Feindt, 2000).

Help to SMEs and an increase in different types of commerce (especially in electronic commerce, which represents the future in a global market) are important to the improvement of their chances of survival and for the longevity of economic systems based on these types of enterprises.

A

KEY TERMS

Electronic Commerce (E-Commerce): Transactions conducted over Internet protocol-based networks and over other computer-mediated networks. Goods and services are ordered over those networks, but payment and final delivery of goods or services may be conducted on or off-line. Orders received via telephone, facsimile, or manually typed e-mails are not counted as electronic commerce (Eurostat, 2006).

European Union (EU): Family of democratic European countries. The six founders (on March 25, 1957, with the Treaty of Rome) are Belgium, France, Germany, Italy, Luxembourg, and The Netherlands. The European Union acts in a wide range of policy areas—economic, social, regulatory, and financial—through solidarity policies (also known as cohesion policies), regional, agricultural, social affairs and innovation policies, which provide state-of-the-art technologies to fields such as environmental protection, research and development, and energy. Currently, the EU embraces 27 countries and 490 million people (*http://europa.eu*). EU countries include: Austria-A, Belgium-BE, Bulgaria-BG, Cyprus-CY, the Czech Republic-CZ, Denmark-DK, Estonia-EE, Finland-FI, France-F, Germany-DE, Greece-EL, Hungary-HU, Ireland-IE, Italy-I, Latvia-LV, Lithuania-LT, Luxembourg-LU, Malta-MT, The Netherlands-NL, Poland-PL, Portugal-PT, Romania-RO, Slovakia-SK, Slovenia-SL, Spain-ES, Sweden-SE, and the United Kingdom-UK.

Entrepreneur: An individual who sets up a business and heads a firm.

Family Business: Organizations where two or more extended family members influence the direction of the business (through kinship ties, management roles, ownership rights) (Tagiuri & Davis, 1982).

OECD (Organization for Economic Cooperation and Development): Established in 1961, one of the world's largest and most reliable sources of comparable statistics, and economic and social data. The OECD monitors trends, analyzes and forecasts economic developments, and researches social changes or evolving patterns in trade, environment, agriculture, technology, taxation, and more (*http://www.oecd.org*). OECD countries include: Australia, Austria, Belgium, Canada, the Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Korea, Luxembourg, Mexico, The Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic,

Spain, Sweden, Switzerland, Turkey, the United Kingdom, and the United States.

Organizational Culture: A pattern of basic assumptions invented, discovered, or developed by a given group as it learns to cope with problems of external adaptation and internal integration, which has worked well enough to be considered valid and therefore is to be taught to new members as the correct way to perceive, think, and feel in relation to those problems (Schein, 1990).

Small- to Medium-Sized Enterprises (SMEs): Independent firms that employ less than 10 (micro), 50 (small), and 250 (medium) employees (U.S. SMEs include firms up to 500 employees).

The Adoption of IS/IT Evaluation Methodologies in Australian Public Sector Organizations

Chad Lin
Curtin University of Technology, Australia

Yu-An Huang
National Chi Nan University, Taiwan

INTRODUCTION

Information systems/information technology (IS/IT) represents substantial financial investment for many organizations (Lin, Huang, & Tseng, 2007; Standing, Guilfoyle, Lin, & Love, 2006). However, IS/IT managers have found it increasingly difficult to justify rising IS/IT expenditures (Lin & Pervan, 2003; Serafeimidis, & Smithson, 2003) and are often under immense pressure to find a way to measure the contribution of their organizations' IS/IT investments to business performance, as well as to find reliable ways to ensure that the business benefits from IS/IT investments are actually realized (Luftman, Kempaiah, & Nash, 2006). This problem has become more complex as the nature of IS/IT investments and the benefits they can deliver have changed rapidly (Murphy & Simon, 2002). Furthermore, evaluation of these IS/IT investments is an extremely complicated process, and it is often avoided or dealt with ineffectively, especially in the public sector (Cilek, Fanko, Koch, Mild, & Taudes, 2004). Given the complexity of the decisions and the large expenditure involved, a better understanding of the basis and practice of IS/IT investment and evaluation in the public sector organizations is essential. The difficulties of evaluation and benefits realization processes are often the determining factors in the application of any formal methodology, and must be addressed if the processes are to be understood (Counihan, Finnegan, & Sammon, 2002; Love, Irani, Standing, Lin, & Burn, 2005).

BACKGROUND

The IS/IT investment evaluation and benefits realization process is a complex but critical function in both private and public organizations. The need to justify expenditure, to assess the effectiveness of a project, and to ensure that expected benefits are eventually delivered are crucial elements in the IS/IT investment evaluation and benefits realization process. The main purpose of IS/IT evaluation is an important factor in determining how the process should be carried out. However, the IS/IT investment evaluation and benefits realization process itself is an extremely complicated and difficult process, and is not often carried out by both private and public organizations.

IS/IT Investment Evaluation and Benefits Realization

The evaluation of the business value of IS/IT investment has been the subject of considerable debate by many academics and practitioners, and the term "productivity paradox" arises from studies that reveal static productivity and rising IS/IT expenditure (Grover, Teng, Segar, & Fiedler, 1998; Tallon, Kraemer, & Gurbaxani, 2000). Despite large investments in IS/IT over many years, it has been difficult to determine where the IS/IT benefits have actually occurred, if indeed there have been any. Some studies have suggested that IS/IT investment produces negligible benefits (e.g., Strassmann (1997)), while others report a positive relationship between organizational performance and IS/IT spending (e.g., Hu & Quan (2005)). The inability of many organizations to assimilate and apply IT both inter- and intra-organizationally is resulting in missed opportunities and a lack of business value (van Grembergen & van Bruggen, 1998).

The difficulties associated with determining the benefits and costs of IT are deemed to be the major constraint to investment justification. Some of the problems associated with IS/IT investment evaluation (Counihan et al., 2002; Lin et al., 2007; Willcocks & Lester, 1997) are:

1. Organizations often fail to identify relevant risks, costs, and benefits;
2. traditional financially oriented evaluation methods (e.g., ROI, NPV) can be problematic in measuring IS/IT investments and quantifying relevant benefits and costs;
3. working with new technology introduces higher levels of risk, which affects timing, costs, and delivery deadlines;

4. organizations have failed to devote appropriate evaluation time and effort to IS/IT, and to deal with the extended investment timeframe; and
5. it is very difficult to evaluate intangibles and make relationship between IS/IT and profitability explicit.

To understand the IS/IT investment evaluation and benefits realization processes, it is important to consider the historical and methodological connection between IS/IT investment evaluation methodologies and IS/IT benefits realization methodologies. IS/IT investment evaluation methodologies have been in use at least since Melone and Wharton (1984, in Farbey, Land, & Targett, 1992), while discussion and adoption of IS/IT benefits realization methodologies appear later in the literature (e.g., Dhillon, 2005; Ward, Taylor, & Bond, 1996). IS/IT investment evaluation methodologies are typically concerned with making investment decisions about IS/IT investments. In other words, the domain of concern is more about selecting the investment or investments that at the outset seem to offer the greatest returns or benefits for the outlay. Early examples of the methodologies emphasize the adoption of accounting indicators such as payback period, ROI, and IRR, whereas later methodologies link the decision-making process more strategically (Lin, Lin, & Tsao, 2005). Some of the formal IS/IT investment evaluation methodologies published in the literature are:

- Return on Management (ROM) (Strassmann, 1990);
- Options theory (Dos Santos, 1994); and
- Kobler Unit framework (Hochstrasser, 1994).

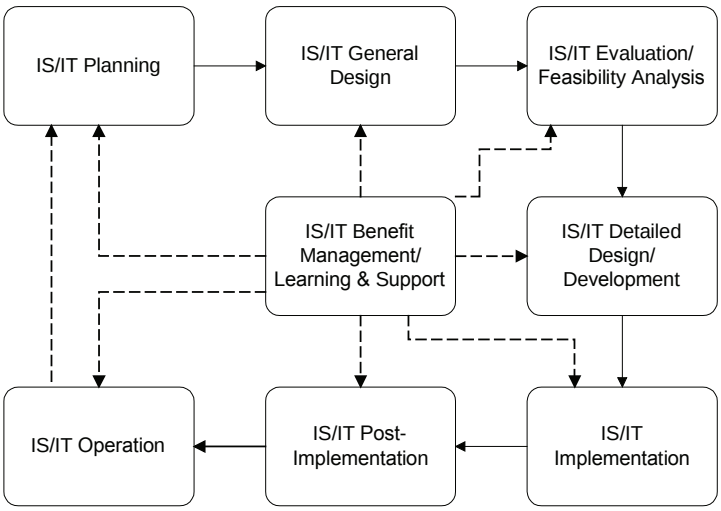
However, IS/IT investment evaluation methodologies alone are insufficient in terms of ensuring that the benefits identified and expected by organizations are realized and delivered (Dhillon, 2005). This is because IS/IT is just one enabler of process change (Grover et al., 1998), and it only enables or creates a capability to derive benefits. IS/IT benefits realization methodologies also need to be adopted by organizations to extend investment evaluation further into the investment lifecycle by ensuring expected benefits are realized once a decision to invest has been taken (Changchit, Joshi, & Lederer, 1998). This involves planning how and when benefits will be realized, and deciding who will be responsible for achieving benefits as well as actually overseeing the realization of benefits (Ward et al., 1996). Some of these formal methodologies published in the literature are:

- Cranfield Process Model of Benefits Management (Ward et al., 1996);
- Active Benefit Realization (ABR) (Remenyi, Sherwood-Smith, & White, 1997); and
- Model of Benefits Identification (Changchit et al., 1998).

AN INTEGRATED APPROACH

There are several reasons why the value of IS/IT cannot be determined by a single measure or methodology. When IS/IT operations are measured as a profit center or as a cost center, significant differences arise and each must show numbers tied to management control (Lin et al., 2007). Senior executives are no longer satisfied to evaluate their IS/IT investments in terms of business performance, but also need to find out where value has arisen in many segments of the organization (Tallon et al., 2000). Therefore, there is a need to integrate IS/IT investment evaluation and benefits realiza-

Figure 1. IS/IT evaluation and benefit realization diagram (adapted from Burch & Grudnitski, 1986; Lin & Pervan, 2003; Willcocks & Lester, 1997)



tion methodologies during the IS/IT systems development process (Lin & Pervan, 2003; Willcocks & Lester, 1997). These two types of methodologies are needed that point to cost effectiveness and containment, as well as identify and deliver expected benefits and value (Love et al., 2005). Figure 1 illustrates the relationship between IS/IT evaluation and IS/IT benefits realization during the IS/IT system development process.

In addition, in order to make this integrated evaluation approach work, it is important to involve the stakeholders in processes that operationalize the evaluation criteria and techniques (Lin et al., 2005) – that is, to involve the stakeholders in processes that "breathe life into, adapt over time, and act upon" the evaluation criteria and techniques (Willcocks & Lester, 1997). This is an important issue for both researcher and practitioner, because evaluation of IS/IT benefits without an assessment of all relevant stakeholder benefits is incomplete, and senior executives need information not only for evaluating IS/IT benefits but also for managing the IS/IT investments and capturing the benefits in the bottom line (Dhillon, 2005; Murphy & Simon, 2002).

RESEARCH APPROACH

However, there is much evidence to suggest that the integration of IS/IT investment evaluation and benefits realization processes rarely exists in organizations (Lin & Pervan, 2003; Murphy & Simon, 2002; Willcocks & Lester, 1997). Therefore, three case studies were conducted to investigate the practices of IS/IT investment evaluation and benefits realization in large Australian public sector organizations. Semi-structured interviews were used to gain a deeper understanding of issues.

CASE DESCRIPTION

Thirty-five interviews were conducted with participants from three Australian public sector organizations and their six major IS/IT contractors. The questions were related to the formal benefits realization methodology adopted, major IS/IT contracts, contractual relationship between these public sector organizations and contractors, and IS/IT investment evaluation methodology or technique deployed. Other data collected included contract documents, planning documents, and minutes of relevant meetings. Around 200 pages of transcripts were coded and analyzed. The analysis was conducted in a cyclical manner and followed guidelines for interpretive research set out by Klein and Myers (1999).

CASE STUDY RESULTS

A number of issues arose from the analysis of this text data; the key issues are presented below.

Issue 1: Lack of Formal IS/IT Investment Evaluation Methodology

Most of the participants claimed that some sort of formal methodology or process was put in place for evaluating these contracts. However, closer examination revealed that what was described did not constitute a formal IS/IT investment evaluation methodology. Participants wrongly considered various contract control mechanisms as a formal IS/IT investment evaluation methodology.

Issue 2: Lack of Understanding of IS/IT Investment Evaluation Methodology

The confusion indicated in Issue 1 about what constitutes a formal IS/IT investment evaluation methodology demonstrated a lack of understanding of such methodologies. This may be due to the fact that these public sector organizations were unable to introduce a formal IS/IT investment evaluation methodology because it was required to follow the public sector's IS/IT investment guidelines.

Issue 3: Existence of an Informal IS/IT Investment Evaluation Process

Despite the fact that no formal IS/IT investment evaluation methodology or process was adopted, contract control and evaluation mechanisms specified within the service level agreements (SLAs) or government guidelines do represent an informal IS/IT investment evaluation process. Although these informal mechanisms may not totally replace a formal methodology (e.g., Kobler Unit framework; Hochstrasser, 1994), they were able to assist in evaluating the performance of the outsourcing contracts. These mechanisms were largely based on the standard public sector contract process and purchasing guidelines.

Issue 4: Focus on Quantitative IS/IT Investment Evaluation Measures

Most measures contained within the SLAs were quantitative in nature. Very few provisions were put in place to identify and assess the more qualitative measurements. Without employing more qualitative measures (e.g., customer satis-

faction, relationship, culture, and leadership) and a formal IS/IT investment evaluation methodology or process, the adoption of quantitative or accounting-based measures alone did not assist in full evaluation and monitoring of the performance.

Issue 5: Different Motivations for Seeking External Expertise

Several reasons were put forward as the main motivation for seeking external IS/IT expertise. Only a few of the external contractor representatives cited access to the required technical expertise as one of these public sector organizations' reasons to seek external expertise. However, all of the public sector organizations mentioned access to required technical expertise as a major reason to externalize some of their IS/IT functions. Therefore, these public sector organizations' motivation for outsourcing was somewhat different from the contractors'.

Issue 6: Success of the Contracts Perceived Differently by Stakeholders

Customer satisfaction, achieving the contractor's projected revenue, bringing value/benefits to the organization, and meeting the SLAs' provisions were mentioned. Other criteria mentioned included technical competence to deliver what is required, risk factors, contractors' experience in a relevant area, and business continuity of the contractors. Most of the external contractors mentioned achieving the projected revenue for themselves and satisfying customers as their only criteria for determining the success of their outsourcing contracts with these public sector organizations. This may indicate that most of the external contractors' aim is to maximize the profit while maintaining a certain level of customer satisfaction. However, participants from these public sector organizations seemed to have used different criteria for determining the success of the outsourcing contracts. Bringing value/benefits to the organizations, meeting the SLA provisions, and pricing/cost were mentioned by most participants.

Issue 7: Embedded Contract Mentality

Staff of these public sector organizations seemed to have a "contract mentality," as the operation of the contracts was based on the specifications set out in the SLAs within the outsourcing contracts. Most participants clearly indicated that there was a pre-agreed set of evaluation and control mechanisms in the SLAs within the outsourcing contracts such as metrics, monthly reports, reviews, and regular meetings. Moreover, most of them thought these contract control mechanisms were all part of the IS/IT investment evaluation methodology.

Issue 8: Lack of User Involvement/Participation in Contract Development

There appeared to be an organizational memory gap where units within these public sector organizations possessed knowledge of different parts of the IS/IT systems development cycle. However, the knowledge did not seem to be shared by all units because different units participated in different stages. These public sector organizations' IS/IT contract processes may have been more successful if the participants were all involved in the original tendering and contracts negotiation, as well as benefits realization processes.

Issue 9: General Lack of Commitment by Contractors

It was easy to see that these public sector organizations and contractors had different agendas in mind, despite the fact that the contract was a partnership-type arrangement. The external contractors' criteria for determining success of these IS/IT contracts seemed to be maximization of profit/revenue while keeping the customers satisfied to a certain extent. The contractors' lack of commitment could also be demonstrated by the fact that they either did not know why these public sector organizations externalize their IS/IT functions, and did not really care whether these public sector organizations had benefited from their services and expertise. However, these public sector organizations, in general, had agreed that access to the required technical expertise was a major reason for seeking external IS/IT expertise.

FUTURE TRENDS

Carr (2003) has argued that IT has become a commodity because it has become widespread, as has happened to other innovations such as engines and telephones. According to Carr (2003), IT has become an infrastructural technology and therefore is often subject to over-investment and causes economic troubles such as the "Internet Bubble." Carr's (2003) views on IT are not shared by many IS/IT practitioners and academics who argue that IT still has a lot to offer in the future and can deliver competitive advantages to both private and public organizations (Hayes, 2003).

However, recent evidence suggests that many private and public organizations simply got carried away with IS/IT and spent money unwisely during the last two decades (Farrell, 2003). According to a study by the McKinsey Global Institute, more successful organizations analyzed their economics carefully and spent on only those IS/IT applications that would deliver productivity gains, sequencing their investments carefully through a disciplined approach with innovative management practices (Farrell, 2003).

CONCLUSION

Case studies were conducted in three public sector organizations that sought IS/IT services and expertise from external contractors. While these public sector organizations appear to operate without any major problem, the mostly negative issues shown above indicate weaknesses in the way IS/IT deals with the level of formality and integration in applying the methodologies. The problems mentioned above were mostly caused by the lack of attention to IS/IT investment evaluation. For example, if formal IS/IT investment evaluation was adopted by these organizations, more qualitative measures may have been used to evaluate the IS/IT contracts.

So why did these organizations not formally evaluate their IS/IT investments? One possible explanation was that the restrictive nature of the public sector's IS/IT contract guidelines made it difficult to implement a formal IS/IT investment evaluation methodology. Another explanation was that none of the IS/IT staff was familiar with the formal IS/IT investment evaluation process and hence possessed an "embedded contract mentality" by simply following conditions set out within the SLAs. Seddon, Graeser, and Willcocks (2002) suggest that under some circumstances, cost of formal IS/IT evaluations may seem likely to exceed benefits. However, the results from the case studies indicate that the use of a benefits realization methodology enabled greater control and better management of IS/IT contracts.

Despite large investments in IS/IT over many years, it has been difficult for organizations to determine where benefits have occurred, if indeed there have been any. IS/IT investment evaluation practice remains a hotly debated topic in the IS literature. Little published work has been conducted in Australia and there is still a lot to be learned in the area of processes and practices of IS/IT investment evaluation and benefits management. We hope that more studies of the practice of IS/IT investment evaluation will benefit other researchers in this field and in the public sector, in particular. Through the case study results presented in this article, it is hoped that better approaches may be developed for Australian public sector organizations.

KEY TERMS

Benefits Management: A managed and controlled process of checking, implementing, and adjusting expected results, and continuously adjusting the path leading from investments to expected business benefits.

Information Technology (IT): Any computer-based tool used to work with information and support the information needs of an organization.

IS/IT Benefits Realization Methodologies: Approaches used to ensure that benefits expected in the IS/IT investments by organizations are realized or delivered.

IS/IT Investment Evaluation: The weighing up process to rationally assess the value of any acquisition of software or hardware that is expected to improve the business value of an organization's information systems.

IS/IT Investment Evaluation Methodologies: Approaches used to evaluate organizations' IS/IT investments.

Productivity Paradox: Despite large investments in IS/IT over many years, there have been conflicting reports as to whether or not IS/IT benefits have actually occurred.

Systems Development Process: A structured step-by-step approach for developing IS/IT.

Advanced Techniques for Object-Based Image Retrieval

A

Yu-Jin Zhang
Tsinghua University, Beijing, China

INTRODUCTION

Along with the progress of imaging modality and the wide utility of digital images (including video) in various fields, many potential content producers have emerged, and many image databases have been built. Because images require large amounts of storage space and processing time, how to quickly and efficiently access and manage these large, both in the sense of information contents and data volume, databases has become an urgent problem. The research solution for this problem, using content-based image retrieval (CBIR) techniques, was initiated in the last decade (Kato, 1992). An international standard for multimedia content descriptions, MPEG-7, was formed in 2001 (MPEG). With the advantages of comprehensive descriptions of image contents and consistence to human visual perception, research in this direction is considered as one of the hottest research points in the new century (Castelli, 2002; Zhang, 2003; Deb, 2004).

Many practical retrieval systems have been developed; a survey of near 40 systems can be found in Veltkamp (2000). Most of them mainly use low-level image features, such as color, texture, and shape, etc., to represent image contents. However, there is a considerable difference between the users' interest in reality and the image contents described by only using the above low-level image features. In other words, there is a wide gap between the image content description based on low-level features and that of human beings' understanding. As a result, these low-level feature-based systems often lead to unsatisfying querying results in practical applications.

To cope with this challenging task, many approaches have been proposed to represent and describe the content of images at a higher level, which should be more related to human beings' understanding. Three broad categories could be classified: synthetic, semantic, and semiotic (Bimbo, 1999; Djeraba, 2002). From the understanding point of view, the semantic approach is natural. Human beings often describe image content in terms of objects, which can be defined at different abstraction levels. In this article, objects are considered not only as carrying semantic information in images, but also as suitable building blocks for further image understanding.

The rest of the article is organized as follows: in "Background," early object-based techniques will be briefly reviewed, and the current research on object-based techniques will be surveyed. In "Main Techniques," a general paradigm for object-based image retrieval will be described; and different object-based techniques, such as techniques for extracting meaningful regions, for identifying objects, for matching semantics, and for conducting feedback are discussed. In "Future Trends," some potential directions for further research are pointed out. In "Conclusion," several final remarks are presented.

BACKGROUND

Early Object-Based Techniques in Content-Based Image Retrieval

CBIR techniques are distinguished from traditional retrieval techniques by many aspects. Two of the most pertinent are that CBIR is a somehow subjective process, as for a given image, its means may have different interpretations for different users; and image retrieval is often a computationally expensive process, as the image database is often large in size and contains heterogeneous information. Due to these particular aspects, the results of CBIR could not be judged objectively—human perception should be considered. In addition, performing an exhaustive search for finding optimal solutions in CBIR is not feasible, and therefore, some suboptimal solutions will be chosen.

Because of the unique aspects of CBIR, object-based representation and description must be used even in so-called low-level feature-based image retrieval, though in these works, object recognition is not evidently performed and semantic information is not explicitly searched.

One typical example is in shape-based retrieval, as the shape features are generally extracted from individual objects (Latecki, 2002). In contrast, color features and textural features are often obtained by taking the whole image as a unit. From this point of view, shape-based retrieval is already at some higher level than color-based retrieval and texture-based retrieval (Zhang, 2003).

Structural query model is another instance in which partial matches are allowed and outputs related to the score of similarity can be provided. This type of retrieval is based on the relations between the individual objects and compo-

nents in images (Zhou, 2001). In query by visual sketch, users sketch a scene by drawing a collection of objects. (It is assumed that these objects could fully define a scene.) For example, the objects are first identified and then used in a search (Chang, 1998).

Current Object-Based Techniques in Content-Based Image Retrieval

Currently, researchers seek explicit semantics and use the high-level descriptions that are common to humans, such as articles, people, places, and things. It is generally accepted that high-level features are crucial to improve the performance of CBIR up to so-called semantic-based querying. For this purpose, object-based content analysis, especially segmentation that segments the semantically meaningful objects from images, is an essential step (Zhang, 2001).

Complete image understanding should start at interpreting image objects and their relationships. Objects can be further identified in line with appropriate knowledge. For example, some object grammars based on rules for concept inference have been proposed (Petkovic, 2003). When domain knowledge is available, objects can be classified even without the explicit determination of object regions (Li, 2002b).

To extract high-level descriptions from images and to fill the gap between the low-level features and human beings' understanding of image contents, techniques to describe the whole image with a hierarchical structure to reach progressive image analysis are proposed (Castelli, 1998; Jaimes, 1999; Hong, 1999). The contents of images can be represented in different levels (Amir, 1998), such as the three-level content representation, including feature level content, object level content, and scene level content (Hong, 1999); and the five-level representation, including region level, perceptual region level, object part level, object level, and scene level (Jaimes, 1999). The problem here is how to implement these levels efficiently and effectively.

Another direction for extracting semantics information from an image is to map low-level visual features to high-level semantics. In other words, to fill the semantic gap, one makes the retrieval system work with low-level features, while the user puts in more high-level knowledge (Zhou, 2002). Two typical methods are to optimize query requests by using relevance feedback and semantic visual templates (Chang, 1998) and to interpret progressively the content of images by using interactive interfaces (Castelli, 1998). In both approaches, relevance feedback plays an important role, as humans are much better than computers at extracting semantic information from images (Rui, 1998; Ciocca, 1999).

MAIN TECHNIQUES FOR OBJECT-BASED IMAGE RETRIEVAL

A General Paradigm

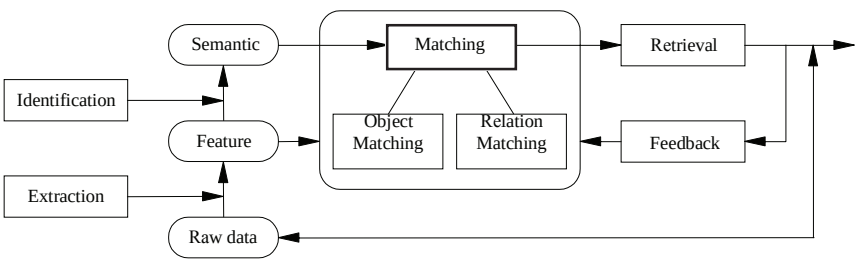
In general, people distinguish three levels of abstraction when talking about image databases: raw data level, feature level, and semantic level. The raw data are original images in the form of a pixel matrix. The feature level shows some significant characteristics of the pixel patterns of the image. The semantic level describes the meanings of identified objects in images. Note that the semantic level should also describe the meaning of an image as a whole. Such a meaning could be obtained by the analysis of objects and the understanding of images.

According to the above discussions, a multilayer approach should be used for efficiently treating image data. Though the number of layers and the definitions and functions of these layers could have some variations in different approaches, some principle steps are common for object-based image retrieval. A general paradigm is shown in Figure 1.

First, objects should be determined. Two important tasks are as follows:

1. Extract meaningful regions: To be able to base the image retrieval on objects, the interesting regions related to objects should be extracted first. This process relates the raw data level to the feature level.

Figure 1. A general paradigm for object-based image retrieval



2. Identify interesting objects: Based on the extracted regions, (perceptual) features should be taken out, and those required objects could be identified. This corresponds to the step from feature level to object level.

Once the objects in images are identified, further retrieval can be carried out by using objects as primitives. Two tasks are as follows:

1. Matching identified objects: For each identified object, suitable properties and attributes should be selected for proper description. The matching between images, such as object matching and relation matching, is then carried out.
2. Performing feedback in retrieval: This is to introduce human intelligence and to incorporate human semantics into the retrieval process.

The following sections introduce some techniques developed for each task.

Techniques for Extracting Region of Interest

Extraction of interesting regions from an image is, in general, called image segmentation (Zhang, 2001). Image segmentation is one of the most critical tasks in automatic analysis of image contents. A great variety of segmentation algorithms has been proposed in the literature. One should note that none of the proposed segmentation algorithms is generally applicable to all images, and different algorithms are not equally suitable for a particular application. This is the reason that though several thousands of algorithms have been developed, much attention and new efforts are continuously made on improving and perfecting them.

With the progress in segmentation techniques, people also realized that precise segmentation of objects in many cases is still beyond the capability of current computer techniques. On the other side, compared to some image analysis tasks that aim to obtain accurate measurements from the segmented objects, the requirement for precise segmentation of objects can be somehow relaxed in the context of image retrieval. Image retrieval is a subject-oriented process in which the precise object measurement is not the goal. In addition, for object-based image retrieval, the purpose of segmentation is for identifying the objects.

One idea derived from the above considerations is to extract approximately the so-called "meaningful region," instead of to segment the object accurately (Luo, 2001). The "meaningful region" provides an effective visual representation of objects from the point of view of object recognition. Though the "meaningful region" is not an exact representation of the objects, however, based on some domain knowledge, the semantic meaning of objects can still be recovered. On the other side, robust extraction of "meaningful regions" is easy to accomplish. This makes the object-based image retrieval with the extraction of "meaningful region" a feasible approach (Gao, 2000).

Another idea derived from the above considerations uses a particular matching procedure to reduce the requirement for precise object segmentation (Dai, 2004). The images are segmented both in a rough version and in a detailed version. The rough one is the merge result of several detailed ones and is less spatial-constrained by either oversegmentation or undersegmentation.

Techniques for Identifying Objects

From extracted regions, some perceptual features could be obtained. This can help to "recognize" what they represent in terms of human beings' perceptions. One iterative procedure uses this principle and transforms the recognition to a training-and-testing procedure (Gao, 2000). To make the problem simpler, it is assumed that there are finite types of interesting objects in a given image database. In fact, this requirement could often be satisfied in practice, as only limited image contents are considered in one application. The object recognition is then performed in an iterative way. Context-based information would be obtained during this process, helping to reach the correct recognition result.

To capture different aspects of images, multiple features are often used. The proportion of each feature in a description would be determined by training. Due to the lighting conditions and variety of object appearance, the objects belonging to the same category can have different visual aspects. To solve this problem, the most significant objects in the training set would be selected, and the trivial ones would be discarded. This recognition process can be iterated until the final recognition result is acceptable (in terms of the image composition, according to some *a priori* knowledge). With this iterative procedure, the context-based knowledge is gradually improved, and the correct recognition result is gradually approached.

Techniques for Matching Objects

Matching is one important task in image retrieval, which consists of comparison and judgment. As retrieval is a subjective process, so the decision is often made according to similarity (the distance to be reasonably small) but not according to equivalence (identical). Based on matching score, a database search can be carried out, and required images can be retrieved. Object match is more direct than feature match is in image retrieval.

One procedure is to describe the object in an image by an $M \times M$ matrix, where M is the number of all objects in the image database. It is a diagonal matrix, with each entry

indicating the attribute of every meaningful region in the image. In addition, a relation matrix is also defined. It is a $K \times K$ matrix to indicate the spatial relationship between every two meaningful regions, with K representing the number of meaningful regions in the whole image. The object-matching procedure is dependent on a decision function. This decision function is determined based on the correlation among all content description matrices. It reflects whether all the relevant images have common contents, that is, the same objects. In the case that the relevant images have common objects, the match will be based on the objects of images. In the case that the relevant images do not have common objects, the match will be based on the features of images. For object matching, the similarity information from the common objects in all relevant images will be extracted to perform the matching between the relevant images and candidate images. Details can be found in Zhang (2004).

For compounded objects, matching might be accidentally performed among different parts. To solve this problem, a two-level matching is proposed (Dai, 2004). The principal idea is to describe the query images at a relatively rough scale and to describe the database images at some more detailed scales. As the rough description is based on the merging of detailed descriptions, the matching process will be carried on in an uneven way, and the minor errors caused by segmentation will be recompensed by the approximate matching procedure.

Techniques for (Interactive) Feedback

Feedback plays an important role, especially in high-level retrieval. As indicated above, retrieval is a subjective process, so feedback is required to combine the information from users, or in other words, to incorporate human knowledge and requirements. Retrieval is also a progressive process, so feedback is required to introduce interaction and to turn the search direction to follow the user's intention.

A self-adaptive relevance feedback technique has been used in an object-based image retrieval system (Gao, 2001). In such a system, objects are first identified, the relevance feedback relying on the high-level attributes could better catch image semantics, and the retrieval results are refined according to users' wishes in an explicit manner. In practice, to make the querying more convenient for the user, the procedure of feedback could be directed, also based on high-level information, without memory or with memory to make the feedback mechanism more flexible. In the former case, each feedback is an independent procedure, in which all of the relevant images selected in previous iterations would be ignored. In the latter case, the relevant image selected in previous iterations would be taken into account in the current iteration. A time-delay curve has also been proposed to simulate human beings' memory mechanisms in feedback with memory (Gao, 2001). The main idea of the proposed scheme is to analyze the fed-back relevant images marked by the user in different levels to reach comprehensive similarity analysis.

Another approach called association feedback has been proposed (Xu, 2001b). Feature elements are first defined that can be considered a type of perceptual primitives with abstraction levels located between that of raw images and that of objects in images (Xu, 2001a). These feature elements, different from commonly used feature vectors, have obvious intuitive visual senses and are relatively independent from each other physically. A selection mechanism called feature element evaluation is also proposed, which tries to find those feature elements that are closer to the interest of people by visual meaning. A group of feature elements can be used to represent compound objects. Based on feature elements, association feedback can be applied. In contrast to the weighting adjustment in relevance feedback, here the associated relations between different feature elements are counted. New sets of feature elements can thus be formed during the retrieval process, and this property is suitable for handling the so-called "interest switch" cases. In other words, the search for images can be controlled by users with the introduction of new feature elements according to the change of interest, and the search direction will be guided toward new goals.

FUTURE TRENDS

Further research can be considered in the concrete techniques for advanced image analysis and along the general research movements for image understanding.

To perform object-based image retrieval, different image analysis techniques are to be enhanced:

1. Improving the robustness of meaningful region extraction, especially with complicated images, by taking more characteristics of images into consideration
2. Describing objects as congruous to humans' sense as possible—as human beings are still far from knowing all the cognitive details from the real world, how to automatically form semantic objects is a challenging task
3. Using more efficient feedback procedures to make the search process fast following users' aspirations in the course of retrieval

In the "Background" section, two generations of object-based techniques are discussed. From the point of view of image understanding, the next stage would go beyond objects, though the third generation will still be based on objects. The actions and interactions of objects and thus generated events (or scenes) are important to fully understand the contents of images. The images would be, in this case, described by

some metadata. The event detection and event retrieval have already played an important role in many applications (e.g., surveillance, war, etc.). However, only a few particular works are made now, and they are mainly based on audio and multiple frames (Li, 2002a). Further research in this direction, taking more advantage of human knowledge for constructing more intelligent image data would be promising.

CONCLUSION

Object-based techniques can fulfill many roles and tasks required by CBIR. Three generations of object-based techniques are reviewed and discussed in this article. Some of them have already made their contributions to the advancement of CBIR, and some of them need to be improved, and developing new object-based techniques for CBIR is even required.

The object-based techniques discussed here are mainly focused on CBIR. As content-based video retrieval (CBVR) appears like a natural combination of CBIR and content-based audio retrieval (CBAR), as well as some extensions along the temporal axis, many of these techniques would also be applicable for CBVR.

KEY TERMS

Content-Based Image Retrieval (CBIR): A process framework for efficiently retrieving images from a collection by similarity. The retrieval relies on extracting the appropriate characteristic quantities describing the desired contents of images. In addition, suitable querying, matching, indexing, and searching techniques are required.

Feature-Based Image Retrieval: A branch of CBIR that is based on specific visual characteristics called "features" and is considered at a low abstraction level. Features are commonly refereed to perceptive attributes of images, such as color, texture, shape, etc., of images.

Intelligent Image Data: A data format that embeds pixel information of images as well as higher-level information, such as indices and semantic information. This format is self-descriptive in the sense that data could explain by themselves what contents are inside and present and retrieve the related and interested portions for the users.

Metadata: A data format that may contain numerous information, including information obtained indirectly from the image, as well as information related to the actual description of the image content. At the highest level, images are often accompanied and associated by metadata.

MPEG-7: This is an international standard named "multimedia content description interface" (ISO/IEC 15938). It provides a set of audiovisual description tools, descriptors, and description schemes for effective and efficient access (search, filtering, and browsing) to multimedia content.

Query Model: An abstraction model for image querying in the context of CBIR. In this model, a submitted query would specify both a filter condition and a ranking expression, while the query result will be a rank of the images that satisfies the filter condition, according to grade of match for the ranking expression.

Semantic-Based Image Retrieval: A branch of CBIR based on descriptions with semantic meaning and considered at a high abstraction level. Semantic descriptions are more closely related to the human interpretation and understanding of images.

Semantic Gap (SG): The discrepancy between the perceptual property and semantic meaning of images in the context of CBIR. As the perceptual properties are usually described by low-level visual features that can be easily treated by computers, and the semantic meanings are commonly related to high-level object-based descriptions that are familiar to human beings, the semantic gap is also considered a gap between current techniques and human requirements.

Semiotics: The science that analyzes signs and sign systems and puts them in correspondence with particular meanings. It provides formal tools for image knowledge acquisition, generation, representation, organization, and utilization in the context of CBIR.

INTRODUCTION

Tracking and recognition of human motion has become an important research area in computer vision. In real world conditions it constitutes a complicated problem, considering cluttered backgrounds, gross illumination variations, occlusions, self-occlusions, different clothing and multiple moving objects. These ill-posed problems are usually tackled by making simplifying assumptions regarding the scene or by imposing constraints on the motion. Constraints such as that the contrast between the moving people and the background should be high and that everything in the scene should be static except for the target person are quite often introduced in order to achieve accurate segmentation. Moreover, the motion of the target person is often confined to simple movements with limited occlusions. In addition, assumptions such as known initial position and posture of the person are usually imposed in tracking processes.

BACKGROUND

The first step towards human tracking is the segmentation of human figures from the background. This problem is usually addressed either by exploiting the temporal relation between consecutive frames (e.g., background subtraction (Sato & Aggarwal, 2001), optical flow (Okada, Shirai & Miura, 2000)), by modeling the image statistics of human appearance (Wren, Azarbayejani, Darrell & Pentland, 1997) or by exploiting the human shape (Leibe, Seemann & Schiele, 2005). Efficient texture-based methods for modeling the background and detecting moving objects from a video sequence have been developed as well (Heikkila & Pietikainen, 2006), while some other recent research copes with the problem of occlusions (Capellades, Doermann, DeMenthon & Chellappa, 2003). The output of the segmentation, which could be edges, silhouettes, blobs, and so forth, comprises the basis for feature extraction.

Feature correspondence is established in order to track the subject. Tracking through consecutive frames commonly incorporates prediction of movement, which ensures continuity of motion especially when some body parts are occluded. For example, when a person is walking there are some moments when one of the legs occludes the other. Furthermore, there are scenes with multiple persons occluding one another. Depending on the scene and the chosen methodology, some techniques try to determine the precise movement of each body part (Sidenbladh, Black, & Sigal, 2002), while other techniques focus on tracking the human body as a whole (Okada, Shirai & Miura, 2000). Tracking may be classified as 2D or 3D. 2D tracking consists in following the motion in the image plane either by exploiting low-level image features or by using a 2D human model. 3D tracking aims at obtaining the parameters, which describe body motion in three dimensions. The 3D tracking process, which estimates the motion of the body parts, is inherently connected to 3D human pose recovery.

3D pose recovery aims at defining the configuration of the body parts in the 3D space and estimating the orientation of the body with respect to the camera. This work will mainly focus on model-based techniques, since they are usually used for 3D reconstruction. Model-based techniques rely on a mathematical representation of human body structure and motion dynamics. The 3D pose parameters are commonly estimated by iteratively matching a set of image features extracted from the current frame with the projection of the

model on the image plane. Thus, 3D pose parameters are determined by means of an energy minimization process.

Instead of obtaining the exact configuration of the human body, human motion recognition consists in identifying the action performed by a moving person. Most of the proposed techniques focus on identifying actions belonging to the same category. For example, the objective could be to recognize several aerobic exercises or tennis strokes or some everyday actions such as sitting down, standing up, walking, running, or skipping.

Next, some of the most recent approaches addressing human motion tracking and 3D pose recovery are presented, while the following subsection introduces some whole-body human motion recognition techniques. Previous surveys of vision-based human motion analysis have been carried out by Cédras and Shah (1995), Aggarwal and Cai (1999), Gavrila (1999), Moeslund and Granum (2001), and Moeslund, Hilton, and Kruger (2006).

This overview presents briefly some of the techniques developed during the last years. The outline of this work is as follows. Firstly, a survey about human motion tracking and 3D pose recovery is given. Next, human motion recognition is introduced; following, a summary of some application works is presented. Finally, a section with future trends and conclusions is introduced.

HUMAN MOTION TRACKING AND 3D POSE RECOVERY

Tracking relies either on monocular or multiple camera image sequences. Using *monocular* image sequences is quite challenging due to occlusions of body parts and ambiguity in recovering their structure and motion from a single perspective view (different configurations have the same projection). On the other hand, single camera views are more easily obtained and processed than multiple camera views. In the following table, some recent techniques using only one camera are presented.

In contrast to single-view approaches, *multiple camera* techniques are able to overcome occlusions and depth ambiguities of the body parts, since useful motion information missing from one view may be recovered from another view. The following table presents some recent approaches using multiple cameras.

Some currently published papers specifically tackle the *pose recovery* problem using multiple sensors. In Mikic,. Trivedi, Hunter, and Cosman (2001) a 3D voxel reconstruction of the person's body is computed from silhouettes extracted from four cameras. Body parts are located sequentially from the voxel data. Consistency with an articulated body model is guaranteed by feeding measurements to

Table 1. Monocular systems

Authors	***Description***
Sminchisescu and Triggs (2001)	A 3D human body model, consisting of tampered superellipsoids, is fitted on the image features by means of an iterative cost function optimization scheme. A multiple-hypothesis approach with the ability of escaping local minima in the cost function is proposed.
Sidenbladh, Black, and Sigal (2002)	A probabilistic approach for modeling 3D human motion for synthesis and tracking, where learning of state transition probabilities is replaced with efficient probabilistic search in a large training set.
Ning, Tan, Wang, and Hu (2004)	An approach to tracking walking human based on both body model and a motion model (learnt from semiautomatically acquired training data), in a CONDENSATION framework. A pose evaluation function combining boundary and region information is proposed. Automatic acquisition of initial model pose and recovery from severe failures are addressed.
Antonini, Martinez, Bierlaire, and Thiran (2006)	Image processing methods are combined with behavioral models for pedestrian dynamics in a detection/tracking system. Behavioral models are used to find globally coherent trajectories. Pedestrian detection is based on the behavior rather than appearance.
Liu and Chellappa (2007)	An articulated model of a real human body consisting of ellipsoids connected by joints is used. Motion in a video sequence is observed using optical flow. Optical flow using scaled orthographic projection relates the spatial-temporal intensity change of the sequence to the motion parameters.
Caillette, Galata, and Howard (2007)	A 3D human body tracker, build upon the Monte-Carlo Bayesian framework, is capable of handling fast and complex motions in real-time. Novel prediction and evaluation methods improving the robustness and efficiency of the tracker are proposed. The tracker is also capable of automatic initialisation and self-recovery.

Table 2. Multiple-camera systems

Authors	***Description***
Delamarre and Faugeras (2001)	It incorporates physical forces to each rigid part of a 3D model consisting of truncated cones. The model's projections are compared with the silhouettes extracted from the image by means of a novel approach. This technique copes with self-occlusions, fast movements and poor quality images.
Atsushi, Hirokazu, Shinsaku, and Siji (2002)	Multiple people tracking in a wide-area covered by a number of sensors. Algorithms for simple blob-based tracking of humans and object matching among views are presented.
Yang, Shih, and Wang (2004)	Color, motion and depth features are combined for robust people tracking using a stereo camera. A Kalman filter is used for feature integration and tracking.
Kehl, Bray, and Van Gool (2005)	A volumetric reconstruction of a person is extracted from silhouettes in multiple video images. Then, an articulated body model is fitted to the data with stochastic meta descent (SMD) optimization.
Kang, Cohen, and Medioni (2005)	The proposed method tracks a large number of moving people with partial and total occlusions in a surveillance scenario. The appearance of detected moving blobs is described by multiple spatial distributions models of blobs' colors and edges.
Hayashi, Hashimoto, Sumi, and Sasakawa (2004)	The method uses a stereo camera mounted on the ceiling. Captured 3D voxels are projected onto the floor, and their peaks are tracked. An algorithm is proposed to predict collisions.

Table 3. Human motion recognition

Authors	***Description***
Masoud and Papanikolopoulos (2003)	PCA-based classification of human activities from video using low-level motion features.
Parameswaran and Chellappa (2005)	Actions are represented in a compact, view-invariant manner as curves in spaces arising from 3D mutual invariants.
Robertson and Reid (2006)	Stochastic modelling and recognition of sequences of actions, based on trajectory information, local motion descriptors and HMMs.
Sminchisescu, Kanaujia, and Metaxas (2006)	Algorithms for recognizing human motion in monocular video sequences, based on discriminative conditional random fields (CRFs) and maximum entropy Markov models (MEMMs) are proposed.
Nascimento, Figueiredo, and Marques (2007)	A hierarchical approach is presented for human motion pattern classification. More specifically, high-level activities are segmented into sequences of low-level motion patterns, which are simply independent increment processes, each describing a specific motion regime (e.g., ''moving left'').

Table 4. Human body model applications

Application	*Authors*	*Description*
Virtual Reality	Hilton (2003)	Summary of computer vision technology for the modeling and analysis of people; in particular for applications in games, multimedia and virtual reality.
	Deutsch, Lewis, and Burdea, (2006)	Virtual-reality-based telerehabilitation system providing to the therapist three-dimensional representations of patients' movements and exercise progress.
	Chattopadhyay, Bhandarkar, and Li (2007)	Algorithm for compression of Human Motion Capture data, exploiting structural information derived from the skeletal virtual human model. Better compressions than standard MPEG-4 are achieved.
Surveillance Systems	Havasi, Szlávik, and Szirányi (2006)	Detection of walking human figures contained in cluttered video sequences. Spatiotemporal information is used to detect and classify human movement patterns.
	Lei and Xu (2006)	Real-time video analysis system for outdoor surveillance and monitoring scenarios.
	Babu, Pérez, and Bouthemy (2007)	Improved visual tracking by combining sum-of-squared differences and color-based mean-shift trackers.
User Interface	Starner, Leibe, Minnen, Westyn, Hurst, and Weeks (2003)	Vision-based interface between the physical and virtual worlds able to identify 3D hand position, pointing direction, and sweeping arm gestures.
	Nickel and Stiefelhagen (2007)	Visual tracking of head, hands and head orientation in the context of human-robot interaction. A multihypothesis tracking framework is used to find 3D positions of body parts, based on color and stereo data information.
Medical Applications	Zubairi (2002)	Methodology for analyzing surface shape using computer-aided rasterstereography, suitable for screening children for spinal deformities.
	Gomez, Carstensen, and Ersbøll (2006)	Integrated imaging system for acquisition of accurate standardized images. Useful for characterizing dermatological images.
	Panchaphongsaphak Burgkart, and Riener (2007)	Multimodal virtual reality system for medical education. The user can visualize and manipulate graphical information.

an extended Kalman filter. In Plänkers and Fua (2003) an articulated implicit surface model is introduced for human body modelling and algorithms for reconstruction of the model from trinocular stereo data are presented. Carranza, Theobalt, Magnor, and Seidel (2003) describe a system that uses multiview synchronized video footage of an actor's performance to estimate motion parameters and to interactively re-render the actor's appearance from any viewpoint.

HUMAN MOTION RECOGNITION

Human motion recognition may be achieved by analyzing the extracted 3D pose parameters. However, because of the extra preprocessing required, recognition of human motion patterns is usually achieved by exploiting low-level features (e.g., silhouettes) obtained during tracking. Techniques extensively used for recognizing human actions include Template matching algorithms, State-space approaches (e.g., HMMs) and/or involve semantic or other high-level descriptions (e.g.,natural language) (Wang, Hu & Tan, 2003).

APPLICATIONS

A large range of applications involve vision-based human body models, requiring both tracking and recognition. Some recent works, grouped according to their applications field, are presented in the following table:

FUTURE TRENDS AND CONCLUSION

The problem of human motion tracking and recognition has become an attractive challenge. The huge amount of articles published during the last years demonstrates the increasing interest in this topic and its wide range of applications, yet in spite of this many issues are still open. Problems such as: unconstrained image segmentation, limitations in tracking, development of models including prior knowledge, modeling of multiple person environments, and real-time performance, still need to be efficiently solved.

A common limitation in tracking, for example, is that the motion of a person is constrained to simple movements with a few occlusions. Although several multiview systems have been proposed that are able to deal with ambiguities, the occlusion problem remains a main hindrance for automatic monoscopic human tracking. Another problem to be totally overcome is the initialization of the pose parameters, and automatic self-tuning of the model's shape parameters. Significant progress has been achieved in this direction. However no completely automatic technique that is able to cope with these problems in unconstrained environments has been demonstrated up to now.

Future human motion recognition systems must be able to identify human motion even in unconstrained environments. These systems can have many useful applications in areas ranging from everyday life to medicine. Especially, robust real-time systems may offer many benefits. Of course, the reduction of processing time presupposes not only advances on computational techniques but also improvements on the current technology.

ACKNOWLEDGMENT

KEY TERMS

Image Feature: A structure in the image with interesting characteristics, for example, points, edges, lines, surfaces.

Occlusion: When one object is in front of another object in the direction of observation, a portion of the object that is behind cannot be seen. Then, the second object is occluded by the first one.

Real-Time System: System that processes and updates information always within a given time.

Self-Occlusion: When a part of the object is occluded by another part of itself. For example, when a person is walking, one leg may occlude the other leg.

Stereo Vision System: System devised to extract 3D information of a given scene. In binocular stereo systems, two images are taken from different viewpoints allowing the computation of 3D structure.

Training Set: A set of known, labelled examples used in classification, representative of the data that will be classified in the application.

Tracking: The process of estimating the parameters of a dynamic system by means of measurements obtained at successive time instances. An example is the estimation of the position of a moving object from an image sequence.

Aesthetics in Software Engineering

Bruce MacLennan
University of Tennessee, USA

INTRODUCTION

It is commonly supposed that software engineering is—and should be—focused on technical and scientific issues, such as correctness, efficiency, reliability, testability, and maintainability. Within this constellation of important technological concerns, it might seem that design aesthetics should hold a secondary, marginal role, and that aesthetic considerations might enter the design process, if at all, only after the bulk of the engineering is done. This article discusses the important role that aesthetics can play in engineering, and in particular in software engineering, and how it can contribute to achieving engineering objectives.

BACKGROUND

Certainly, aesthetic considerations have not been completely absent from software engineering. For example, the development of structured programming ideas was accompanied with conventions for the textual layout of programs, which aimed for conceptual clarity, but also aesthetic appeal. (Even the older programming techniques relied on the aesthetic layout of flowcharts.) Knuth (1992) has advocated a practice of literate programming in which composites of programs and their documentation are treated as "works of literature." Elegance has been discussed as a criterion of programming-language design since the 1960s (MacLennan, 1997, 1999). Furthermore, software engineers have tended to prefer elegant algorithms (Gelernter, 1998) where the criteria of elegance have been inherited primarily from mathematics and theoretical science, in which beauty is a widely acknowledged value (Curtin, 1982; Farmelo, 2002; Fischer, 1999; Heisenberg, 1975; King, 2006; McAllister, 1996; Tauber, 1997; Wechsler, 1988; Wickman, 2005). In these and similar cases, however, there has been little direct work on an aesthetic theory for software.

One exception to the relative lack of explicit work on software aesthetics is the research program in aesthetic computing pursued by, for example, Fishwick (2002) and Fishwick, Diehl, Lowgren, and Prophet (2003). He argues that traditional program representations (such as textual programs and graphs) do not engage our aesthetic senses, and that they are abstract and uninteresting. However, because software concepts are abstract, they do not have a natural sensuous representation, and so Fishwick argues that they should be represented metaphorically (e.g., by visual or sculptural metaphors), and that the "craft-worthy, artistic step" is the choice of metaphor and the expression of the algorithm in terms of it. This metaphorical work (not the textual program, which is secondary) is then the primary medium for the aesthetic expression and appreciation of software (Fishwick, 2002). Recent developments in aesthetic computing are collected in Fishwick (2006).

Software engineering is a new discipline, and so it does not have a long aesthetic tradition as do many of the other arts and engineering disciplines. Therefore, it is helpful to look at well-established disciplines that have significant similarities to software engineering. One of these is mathematics, in which we may include theoretical science, which has in common with software engineering the fact that formal considerations dominate material considerations (explained below). As is well known, aesthetic considerations are important in theoretical science and mathematics (Curtin, 1982; Farmelo, 2002; Fischer, 1999; King, 2006; McAllister, 1996; Tauber, 1997; Wechsler, 1988; Wickman, 2005), and we will find Heisenberg's (1975) remarks on beauty in the exact sciences to be informative.

Another source of useful analogies comes, perhaps surprisingly, from the structural engineering of towers and bridges, which has in common with software engineering the fact that teams engage in the economical and efficient design and construction of reliable, large, complex systems, the failure of which may be expensive and dangerous. We will appeal especially to Billington's (1985) insightful investigation of the role of aesthetics in structural engineering.

AESTHETICS, FORMALITY, AND SOFTWARE

Importance of Aesthetics

Billington (1985) identifies three criteria of good design—the three *E*s of efficiency, economy, and elegance—which he associates with three dimensions of the design process: the scientific, the social, and the symbolic (the three *S*s). All of these also apply to software engineering. Efficiency is primarily a scientific issue since it deals with the physical resources necessary to meet the project's requirements. In structural engineering, the fundamental requirement is safety, which is also important in software engineering, in which other

important issues are real-time response, dynamic stability, robustness, and accuracy, among others.

The second criterion, economy, which treats benefits and costs, is a social issue because it depends on a society's values, both monetary and other. Certainly, many economical considerations can be reduced to money, which is almost the common denominator of value in the modern world, but it is problematic, at very least, to treat some costs, such as human death and suffering, in financial terms. The economy of a design depends on many social factors, including the costs of materials, equipment, and other resources; the availability and cost of labor; governmental regulations; and so forth. As a consequence, the economic worth of a design is more difficult to evaluate and predict than its efficiency.

This brings us to elegance, the aesthetic criterion, and while it will probably be granted that beautiful designs are preferable for their own sakes (other things being equal), Billington (1985) gives compelling arguments for the engineering worthiness of elegant designs, which also apply to software engineering.

As will be explained, elegance is a means of conquering complexity. In terms of their numbers of components and their interactions, software systems are some of the most complicated systems that we design. Even programs as simple as text editors may have hundreds of thousands of lines of code. Furthermore, these components (the individual programming-language statements) interact with each other in complex ways so that the number of potential interactions to be considered rises to at least the square of the number of lines of code. In addition, software engineers are at a disadvantage compared to other engineers for the components of programs are abstract operations, whereas designers in other engineering disciplines can depend on their physical intuition to aid their understanding (Ferguson, 1992).

Software engineers have designed various analytical tools to help them conquer this complexity, but it is important to understand the inherent limitations of analysis. Analysis makes use of models (especially mathematical models) to understand some system of interest. These models are useful because they make simplifying assumptions that permit the models to be understood more easily than the modeled systems. An effective model simplifies matters that are irrelevant to its purpose so that our limited cognitive resources can be devoted to the relevant matters. Often, the simplifying assumptions are made consciously; for example, we may use a linear model for a nonlinear system if we have reason to believe that the nonlinear effects are irrelevant to our concerns. However, models also typically make tacit simplifications because certain factors are assumed to be irrelevant or, in some cases, because some factors have never been considered at all. For example, Billington (1985) observes that the Tacoma Narrows Bridge collapsed 4 months after it was opened because aerodynamic stability had not been considered a factor in bridge design (see also Ferguson, 1992). The problem is more severe for more complex systems because our cognitive capacities are strictly limited, therefore so is the completeness of the model; hence, the gap between the modeled factors and the system increases with increasing system complexity. The risk of intentionally or inadvertently omitting relevant factors increases with system complexity.

Billington (1985) observes that in structural engineering, elegance compensates for the limitations of analysis. This is because in an elegant design, the disposition and balance of the forces are manifest in the design's form, and therefore designs that look stable are in fact stable. More generally, designs that look good are good. For example, the Tacoma Narrows Bridge and several other bridges, which were designed on the basis of extensive mathematical analysis and computer models, collapsed because aerodynamic stability was not included in the analysis, whereas earlier bridges, whose designs were guided by aesthetic judgment, were aerodynamically stable. If we generalize from the specifics of structural engineering, we may say that elegant designs are manifestly correct, safe, efficient, and economical. But why should we expect any correlation between aesthetic values and engineering values?

Billington (1985) argues that in structural engineering, Louis Sullivan's architectural maxim "form follows function" is not as applicable as its converse, "function follows form." Sullivan's principle asserts that a building's function should strongly determine its form. In structural engineering, however, there are typically many ways to fulfill a particular function (such as bridging a river at a particular location) for "engineering design is surprisingly open-ended" (Ferguson, 1992, p. 23). Therefore, since there is wide choice of form, the engineer can choose designs that manifest a stable disposition of forces, that is, elegant designs. More abstractly, engineers who are guided by elegance choose to work in a region of the design space in which aesthetic values correspond to engineering values (that is, function follows form). Therefore they can rely on their aesthetic judgment, which is a highly integrative cognitive faculty, to guide the design process.

The same considerations apply even more so in software engineering, where there are typically very many possible software solutions to an application need. That is, software engineers can compensate for the limitations of analysis by limiting their attention to designs that are elegant, that is, manifestly correct, efficient, maintainable, and so forth. In this region of the design space, where aesthetic values correspond to engineering values—where good designs look good—designers can rely on their aesthetic judgment to guide them to good engineering solutions.

Elegance is associated with the symbolic dimension of a design because, in the appropriate region of the design space, aesthetic values symbolize engineering values. However, design aesthetics can also symbolize less tangible

values that are nevertheless important; this may be called the ethical aspect of the design. For example, a design may be straightforward or subtle, or it may be well organized or a rat's nest; it may be monolithic or modular, and so forth. That is, the design accentuates or suppresses various attitudes, concerns, and other values, which are therefore kept before the designers' eyes or are allowed to escape their attention. An aesthetically sensitive engineer will tend to conform to the aesthetic values already exemplified by the design, and so they will tend to perpetuate the nonaesthetic values symbolized by its aesthetic qualities. Elegance calls forth more elegance.

As Heisenberg (1975) remarks, the ethical dimension is especially important in long-term group projects. As an aesthetic object, the ongoing project symbolizes the constellation of values around which it is organized. In this way, new project members are encouraged to conform to these values and maintain the integrity of the project. Heisenberg compares the generations of scientists who construct a beautiful theory to the medieval cathedral builders, who "were imbued with the idea of beauty posited by the original forms, and were compelled by their task to carry out exact and meticulous work in accordance with these forms" (p. 176).

So far, I have focused on the importance of aesthetics for the designers of software systems, but it is also important for its users. It is perhaps obvious that, other things being equal, users would prefer using aesthetically attractive software to using unattractive alternatives. However, many people's occupations are dominated by interaction with software systems, and software is coming to occupy many people's leisure activities as well. Therefore, the aesthetic dimension of software can have a significant effect on users' quality of life.

Many people's experience of software is dominated by fear, which results largely from the unpredictability of their interactions with it. People interact with technological devices better to the extent that they can form a cognitive or conceptual model of the workings of the system (Norman, 1988, 1998, 2005). The model does not have to represent the actual internal operation of the system, but it has to be accurate enough to allow users to interact with it reliably. In the same way that people will use an elegantly designed bridge with more confidence—for it looks as stable and strong as it is—they will be able to use elegantly designed software with confidence for its external form will reflect and imply its internal logic.

As users become more educated about the aesthetic qualities of software, they will prefer elegant software and therefore encourage its production with a corresponding improvement in the scientific and economical aspects of software systems. Billington (1985) has pointed out the role of an aesthetically knowledgeable public in European bridge design, where the aesthetics of structural engineering projects are regularly critiqued in public.

Formality and Aesthetics

How can elegant software be achieved? The products of all the arts (technical arts as well as fine arts) can be analyzed in terms of form and matter. In this context, matter refers to the raw material of the art, the relatively neutral stuff on which an art imposes its particular kind of form. The matter of painting includes the canvas, paints, and brushes; the matter of music includes duration, pitches, timbres, and so forth, which are the raw ingredients of a musical composition. The matter of programming is the hardware, which provides relatively neutral ground (comprising memory cells, machine operations, etc.) on which a program imposes a particular form, organizing the computer's operations in time and memory space.

Any artist (or technologist) must be sensitive to both the formal and material characteristics of the art, but software engineering is unusual in the degree to which formal considerations dominate material considerations. Indeed, the correctness and efficiency of software is usually treated entirely from a formal perspective, and material concerns (e.g., the limitations and capacities of specific hardware) are addressed as second-order effects. In spite of enormous changes in the medium of computation (relays, vacuum tubes, transistors, VLSI), we still use many of the same algorithms that were used in the earliest days of computing (and in some cases even before computers were invented). This highly formal quality of the software art distinguishes it from most other artistic and engineering disciplines.

As a consequence, in establishing aesthetics for software engineering, it is helpful to look to other longer established enterprises where formal issues dominate the material. In particular, we can learn from the elegance and aesthetics in mathematics and the theoretical sciences, which have similar standards of correctness, generality, simplicity, elegance, and beauty (e.g., Curtin, 1982; Farmelo, 2002; Fischer, 1999; King, 2006; McAllister, 1996; Tauber, 1997; Wechsler, 1988; Wickman, 2005), which are also applicable to software.

Of course, the role of aesthetics in mathematics and science is itself a topic of discussion, but the analysis of Heisenberg (1975) provides a good starting point. The formality of these disciplines (and of software) suggests a Platonic approach to aesthetics, which explains beauty in terms of formal structure. Indeed, as Heisenberg remarks, aesthetic concerns were at the root of Western science in Pythagoras' correlation of musical pitch with numerical ratios: The most beautiful (consonant) intervals were found to correspond to the simplest whole-number ratios (1/2, 2/3, 3/4).

According to classical theories of aesthetics (as represented primarily by Plato and Aristotle), the beauty of a work resides in a symmetric, orderly, and harmonious relation of the parts to each other and to the whole. Our aesthetic response arises from a comprehension of these formal relationships, and thus there is a correspondence between beauty and in-

telligibility. As we saw for elegance, therefore, engineers' aesthetic responses can be used to guide software design and to evaluate its result.

These aesthetic principles can be applied both to the static relations within a software system and to the dynamic relations generated by the running system; we begin with the static relations.

As stated by Heisenberg (1975, p. 174), "Beauty is the proper conformity of the parts to one another and to the whole." Specifically, there should be a *harmonia* among the parts, which in ancient Greek meant that they fit together well. They should be arranged symmetrically and be meaningfully ordered; finally, they should be of similar size and of a size and number that is easy to comprehend. In short, the conformity of the parts to one another coincides with their intelligibility.

A beautiful design is characterized also by the conformity of the parts to the whole. Classically, this means the whole has an organic unity similar to that of a living organism. Therefore, the parts fulfill complementary functions to constitute the whole, which in turn defines the relationships of the parts to each other; the parts and the whole are mutually determinative. In short, the design has integrity.

The preceding criteria are intrinsic to the work, but classical aesthetics also addresses the extrinsic relation of the work to its perceivers: The parts should be of such number and size that they can be easily discriminated, and the whole should be of a perceptible size and capable of being held in the perceiver's memory. Obviously, when applied to software, these criteria depend in part on the visual presentation of the program, which may be enhanced by visual programming languages. More generally, an aesthetic design conforms to the perceptual, cognitive, and memory abilities of human beings; in these cases, the perceiver has the satisfaction of comprehending the system's formal structure.

Of course a program is more than an object of contemplation; it is a static structure that defines an infinite set of possible execution sequences (conditioned by possible environment states). Programming is difficult because an informal idea of these possible execution sequences must be expressed by a static structure (the program) that can control a computer to generate any of the desired sequences. Therefore, software design has similarities to the use of mathematics in the theoretical sciences, which seeks to express observed regularities in mathematical laws. Thus, we can benefit from Heisenberg's (1975) insights into the role of beauty in science, as well as those of others (Curtin, 1982; Wechsler, 1988).

Embodiment and Software Aesthetics

Fishwick (2002) has criticized traditional visual presentations of programs for being "aesthetically-challenged and Platonic" and "largely devoid of texture, sound, and aesthetic content," and he has advocated aesthetic programming with the goal of crafting software with "sensory appeal." Indeed, even Plato, who argued that beauty is rooted in formal relations among abstract ideas, advocated perceptible beauty (mirroring the formal relations) as a route toward appreciation of abstract beauty (e.g., *Symposium*, 209e–212a). Therefore the visual form of software is relevant to its aesthetics and affects our intellectual and emotional response to it.

Indeed, in recent decades psychologists have come to recognize the important role that embodiment plays in human cognition (e.g., Gibbs, 2006; Lakoff & Johnson, 1999), and Lakoff and Núñez (2000) have argued that abstract mathematical concepts and our intuitions about them are grounded in our sensorimotor skills and experiences as living beings. For example, our basic intuitions about sets arise from our experience with physical containers.

Humans have a deep, intuitive understanding of the physical world and of our embodied relation to it, which is part of our genetic heritage or is acquired in early childhood. People normally feel pleasure when acting skillfully, and that feeling of satisfied competence is part of the psychological feedback process that improves human skill. Therefore, one way to increase pleasurable interactions with software, for software engineers as well as for users, is to design it so that it conforms to our embodied sensorimotor skills, and therefore engages them pleasurably. For example, this can be accomplished by designing interfaces that use actual or simulated physical interactions as a way of interfacing with abstract structures and systems. Thus, Karlsson and Djabri (2001) suggest that when objects are manipulated on a screen, they should mimic the familiar inertia, elasticity, and so forth of physical objects (see also Norman, 1998). Therefore, an increasing focus on embodiment will bring software aesthetics closer to the less formal (more material) aesthetics of architecture and other artistic, design, and engineering disciplines.

FUTURE TRENDS

Along with increasing awareness of the importance of emotional intelligence (e.g., Goleman, 2005) and embodied understanding, there has come an appreciation of the role of aesthetics in mathematics, science, and engineering (e.g., Wickman, 2006). Historically, there has been little explicit work on software aesthetics, but that is beginning to change (Fishwick, 2006; Gelernter, 1998). I propose that we can progress by four simultaneous, interrelated activities, which I will call experiment, criticism, theory, and practice.

By experiment, I mean the conscious application of aesthetic principles in program design and the empirical evaluation of the results, including an aesthetic analysis both by the designers and by other software engineers (since software engineering is, ultimately, a social process). In

addition to experiments designed explicitly to test aesthetic hypotheses, every software engineering project should be an implicit or explicit aesthetic experiment.

Criticism is fundamental to all the arts. In addition to informing the public about the aesthetic quality of works, it raises aesthetic issues and makes them salient for consumers and artists. Artists in particular articulate a position relative to criticism, perhaps responding with their own criticism, and may adapt their art either in conformity or reaction to the criticism. Thus, criticism is an important feedback process in the evolution of aesthetics, in the formulation of aesthetic principles, and in the aesthetic education of consumers.

By theory I refer to our knowledge of cognitive and affective neuropsychology, which improves our understanding of human aesthetic response and its relation to cognition; this growing body of theory will help to explain experimental results and will suggest new experiments. Nevertheless, human aesthetic response and cognition are both complex and poorly understood, and thus for some time the application of aesthetic principles in software engineering will remain a practical matter with a weak theoretical basis.

This brings us to the matter of practice. The long history of aesthetic debate in philosophy and the fine arts suggests that beauty is not a simple matter of conformity to a few aesthetic principles. Therefore, in the art of programming, as in the other arts, we expect aesthetic principles to provide general guidelines, within which—and occasionally outside of which—designers exercise their aesthetic judgment. Indeed, all expert behavior is characterized by behavior that is broadly in conformity with normative rules, but ultimately free of them (Dreyfus & Dreyfus, 1986); so also with software design.

For the potential benefits of aesthetically designed software to become reality, we will need aesthetics to be a part of the education of every software engineer (cf. Wickman, 2005). Since the goal is for all software design to be guided by programmers' well-honed sense of elegance and aesthetic judgment, aesthetic issues should be addressed in all software design courses, not just in one course devoted to software aesthetics. To accomplish this, all computer science educators will need to become more attentive to aesthetics.

CONCLUSION

We have seen that attention to aesthetics in software engineering can have practical benefits and also improve designers' and users' emotional response to software. Elegant software results from choosing to work in that region of the design space where good designs also look good, therefore aesthetically sensitive programmers can use this highly integrative cognitive faculty to guide their design decisions. Because of the predominantly formal character of software, Platonic aesthetics is most appropriate as it is in mathematics and theoretical science; according to this aesthetics, beauty resides in the conformity of the parts to one another and to the whole. Nevertheless, the more sensuous aspects of aesthetics are also relevant for they engage our embodied understanding and sensorimotor skills. The full benefits of attention to aesthetics will require ongoing pursuit of the aesthetic principles of software and their integration into computer science education.

KEY TERMS

Aesthetics: Aesthetics is a set of principles and practices pointing toward a particular notion of beauty; it is also the discipline that studies such principles and practices.

Elegance: Refers to beauty, grace, harmony, beautiful simplicity, restraint, clarity, and precision.

Embodiment: Refers to the important role played by the human body, including the brain, in cognition, language, imagination, and other mental processes.

Ethical Dimension: The ethical dimension (or aspect) of a software design refers to the influence of the design on the behavior of the engineers working on it.

Execution Sequence: Is the sequence of instructions executed in a particular run of a program (i.e., when provided particular inputs).

Normative: Provides norms or standards of behavior, practice, and so on.

Sensorimotor Skills: Refers to those skills by which we interact fluently and competently with the world, integrating sensory perception and motor action.

Visual Programming Language: Is a programming language in which programs are displayed in some nontextual form, such as a graph, tree, or nested assembly of tiles.

African-Americans and the Digital Divide

Lynette Kvasny
The Pennsylvania State University, USA

Fay Cobb Payton
North Carolina State University, USA

INTRODUCTION

The Internet has become an integral part of America's entertainment, communication, and information culture. Since the mid 1990s, the Internet has become prevalent in middle and upper-class American households. Companies and government agencies are increasingly offering products, services, and information online. Educational institutions are integrating technology into their curriculum and are offering courses from a distance.

However, while some are advantaged by the efficiencies and convenience that result from these innovations, others may unwittingly become further marginalized by these same innovations since Internet access is not spreading to them as quickly. The 'digital divide' is the term used to describe this emerging disparity. Government analysts argue that historically underserved groups such as racial and ethnic minorities, rural and low-income communities, and older Americans are at a distinct disadvantage if this divide is not closed because American economic and social life is increasingly becoming networked through the Internet (National Telecommunications and Information Administration, 1995).

Over the last decade access to the Internet has increased significantly. A 2006 Pew Internet and American Life survey shows that 73% of U.S. adults (about 147 million adults) are Internet users, up from 66% (about 133 million adults) in 2005. And the share of Americans who have broadband connections at home reached 42% (about 84 million), up from 29% (about 59 million) in 2005 (Madden, 2006). African-Americans are increasingly accessing the Internet via home broadband connections, with a 121% adoption rate in 2005 (Horrigan, 2006). But does this mean that the problem of the digital divide has been solved? Is further research in this area warranted or has the digital divide become passé? In this article, we take on these questions by first reviewing major issues and trends in digital divide research. We do so by reviewing the digital divide literature as it relates to one historically underserved group, namely African-Americans. Next, we present a conceptual framework that contrasts 1) social and technological access perspectives, and 2) asset-based/resource and behavioral/use perspectives. The article concludes with our recommendations for future research opportunities for examining digital divide issues.

BACKGROUND

There have been numerous definitions for the digital divide, government and industry reports about the digital divide, and competing interpretations of the statistics contained in these reports. For instance, the digital divide has been defined at the What is Web site as "the fact that the world can be divided into people who do and people who don't have access to—and the capability to use—modern information technology, such as the telephone, television, or the Internet." Others (PRNewswire, 2000) offer another definition: "arguably the single, largest, and segregating force in today's world. If it is not made a national priority, a generation of children and families will mature without these tools that are proving to be the key to the future."

Most of our knowledge about the digital divide in the U.S. is based on survey research on computer and Internet access in the home, at work, and in public places. The most cited statistics are found in the digital divide series produced by the U.S. Department of Commerce (National Telecommunications and Information Association, 1998; 1999; 2000; 2002). Theses studies have found that the divide cuts along the lines of ethnicity and race, geographic location, household composition, age, education, and income level. However, these gaps are rapidly closing. In September 2001, 143 million Americans (54%) were using the Internet, and 174 million Americans (66%) used computers (U.S. Department of Commerce 2002). The gains are largest for low income families (those earning less than $15,000 per year increased at a 25% percent annual growth rate versus 11% for households earning $75,000 and above), and under represented ethnic and racial minorities (33% for Blacks, 30% for Hispanics, 20% for Whites and Asian American and Pacific Islanders). American Internet users are also engaged in a wide variety of activities—45% use e-mail, 36% use the Internet to search for products and services, 39% of individuals are making online purchases, and 35% are searching for health information (U.S. Department of Commerce, 2002).

In 2006, 73% of the U.S. adult population and 61% of African-Americans are online. These online African-Americans tend to use the Internet differently than other racial and ethnic groups. Novak, Hoffman and Venkatesh (1997)

summarize previous research on African-Americans with regard to different media as follows:

African-Americans have the highest participation in radio and TV and the lowest participation in newspapers. In terms of our classification, it means that historically, they have participated in greater measure in entertainment-oriented technologies rather than in information oriented technologies. Previous studies have also shown that African-American ownership of telephones is lower than white ownership, which may be due in part to differences in income.

They go on to theorize that culture helps to explain these results. African-Americans have found their social expression historically through the arts, and have been less successful in gaining entry to other dominant domains such as business, education, technical employment, and professional occupations. Culture may also help to explain Spooner and Rainie's (2000) observation that online African-Americans are 69% more likely than online whites to have listened to music on the Web, and are 65% more likely than online whites to have sought religious information on the Web. Music and spirituality have traditionally been integral components of African-American culture.

Although African-Americans may use the Internet relatively less than other ethnic groups, they have more positive attitudes toward the Internet than do similarly situated whites (Mossberger & Tolbert, 2003). For instance, Kvasny (2006) found that working class African-American women believed that computer skills would prepare them for higher paying jobs, and improve their parenting abilities. In a study of Internet adoption in a community technology project, Youtie et al. (2002) found that African-American women were among the highest adopters of cable TV-based Internet devices.

Although African-Americans harbored favorable attitudes towards the Internet, these same technologies may have little impact on social inclusion. In a more recent study, Sipior, Ward, Volonino and Marzec (2004) examined the digital divide in a public housing community in Delaware County, PA USA. With thirty-one African-American participants with ages ranging from 13-65, these researchers concluded that effective community-based programs could help reduce the divide. While these interventions notably have improved computing skills about under-served groups, a one time shot fails to eliminate or even reduce broader feelings of cultural isolation among minority groups.

CURRENT DEBATES

Given the rapid Internet uptake by African-Americans and other under-represented groups, one of the foremost issues is whether a digital divide still exists. We contend that these debates about the existence of the digital divide result from a rather narrow treatment of a complex social phenomenon. In fact, many of the newer studies in this genre call for a rethinking of the digital divide (Warschauer, 2002; Gurstein, 2003; Hacker and Mason, 2003; Kvasny, 2003; Payton 2003; Payton forthcoming). In what follows, we organize a discussion of the current debates in the digital divide discourse. We do so through a framework (Table 1) that contrasts two perspectives of access (technological and social) and two perspectives of use (asset-based and behavioral). Technological access focuses on the computing artifact, while social access focuses on know-how and competence. Asset-based perspectives view the divide as a deficiency in requisite resources such as income or education that enable Internet use, while behavioral perspectives tend to focus on the effectiveness of Internet use. Although these perspectives are presented as separate categories, authors tend to draw from both categories. For instance, the argument that the digital divide is based upon a lack of access to computing artifacts and computer skills suggests a technological access/asset-based perspective. An argument that the digital divide emerges from a lack of understanding about how to use the Internet to further life chances adopts a social/behavioral perspective.

Technological and Social Perspectives on Access

The technological access view, with its focus on broad statistics on Internet diffusion and use rates, has led some policy analysts to assume that the answer lies in certain characteristics of the technology. Hence, policy solutions tend to employ technological fixes, such as, wiring public schools and libraries, and providing computing resources with Internet access in poorer communities (Norris, 2001). We

Technological	Asset-based
Social	Behavioral

contend that an over reliance on descriptive statistics largely contributes to this technology-centric understanding of the digital divide. The more important question for studying as technological access increases is 'what are people able to do with this access'?

We further argue that emphasis on quantitative descriptions of who has and who lacks access fuels debates about the degree to which the divide is temporary or permanent, whether the divide is widening or narrowing, or whether a divide exists at all. We have already seen the initial have/have not thesis superseded with the more complacent have now/have later prediction. Proponents of the have now/have later position argue that given enough time, competition will eventually alleviate any natural disparities in the marketplace.

Digital divide interventions informed by a technological access perspective are likely to subside once the technology gap has been narrowed through various programs and policies designed to distribute these resources more evenly. From this perspective, the digital divide would not warrant long-term policy remedies. High profile, short-term injections of government, foundation, or corporate assistance will occur until such time as the technology diffusion problem is lessened. Then, further critical attention to social inequities that are deeper than descriptions of technology access and use may be stifled. The digital divide will be simply defined away (Kvasny & Truex, 2001). For instance, in 2002 the Bush Administration declared the end of the digital divide and proposed deep cuts to federal digital divide programs. The biggest proposed cut was levied against the Technology Opportunities Program (TOP), a federal grant program designed to bring aid to communities that are lagging in access to digital technologies. Under the Clinton administration's 2001 budget, the program distributed $42 million in grants to 74 different non-profit organizations. In 2002, that number fell to just over $12 million (Benner, 2002).

Analysts and researchers who adopt the social access perspective critique this shortsightedness, and assert that the technological access paradigm ignores social constraints, such as workforce literacy, income differentials, and the inevitable household tradeoffs required in making a PC purchase. Simply put, Marlow's Needs Hierarchy must be addressed from the most fundamental level if one is to progress to higher-order affiliation. The digital divide reflects not only differences in the structure of access, but also the ways in which historical, economic, social, cultural, political and other non-technological factors make such differences matter. Technology-centric solutions alone will do little to redress these aspects of the digital divide.

Asset-Based and Behavioral Perspectives on Use

As access diffuses to historically underserved groups, use also becomes an important basis for studying the digital divide (DiMaggio & Hargittai, 2001; Patterson & Wilson, 2000; Warschauer, 2002; Gurstein 2003). From an asset-based perspective, computer and Internet access are insufficient without the requisite skills and competencies to use the technology effectively (Mossberger, Tolbert, & Stansbury, 2003). These authors take historically underserved groups as their subjects, and point out the ways in which their use of the Internet may be hampered. For instance, in a study of African-American youths, Payton (2003) found that these youths were all too aware that the digital divide is not merely about Internet access. Rather, it involves access to the social networks that ease the path to success in high-tech careers. Hargittai (2001) introduces the concept of 'second level divides' to signify the disparities in computer skills and how these disparities are patterned along age, racial, gender and income categories. She found, for example, that search time was positively correlated with age, and negatively correlated with education and prior experience with technology.

In contrast, the behavioral perspective sees the digital divide in terms of disparities in benefits like social inclusion, economic opportunity and political participation that one derives from Internet use. These disparities provide primary justification for realizing that the digital divide is a public problem and not simply a matter of private misfortune (Warschauer, 2003). Groups that are historically underserved in their quality of employment, their level of qualifications, their level of income, their quality of education, and their consumption opportunities tend to also be marginalized in their access to and use of IT. The digital divide, therefore, is a political outcome rooted in these historical systems of power and privilege, and not simply a gap in access to technological artifacts. Promoting access and basic training to improve the computer skills of individuals is warranted, but may do little to redress the social forces that may limit these actions in the first place. From the behavioral perspective, the divide is about disparities in what individuals and groups are able to do with their Internet access. Gurstein (2003) contends that effective use of the Internet occurs when people are able to use this technology purposively and independently to improve their life chances in culturally relevant domains such as economics, employment, health, education, housing, recreation, culture, and civic engagement.

FUTURE TRENDS

Despite one's alignment regarding the nature and context (technological or social access; asset-based or behavioral use) of the digital divide, the topic warrants re-conceptualization. Holistic approaches and frameworks will assist academic, government and industry leaders to first understand the 'Other' and the social conditions under which these groups function. Technology access and skills can equip; however, taken in isolation, they cannot sustain, maintain or offer ac-

cess to the social, financial or educational networks needed for empowerment of the 'total person'.

Thus, as digital divide research matures, there is a continued need to better understand the social dimensions of access. Kling (2000) contends that we do not have a good understanding of the ways that social access to the Internet is effectively supported for ordinary people at home and in public service agencies, such as schools and libraries. This is a topic that merits significant inquiry, since a large body of research points to its importance. He also argues that it is important to examine the specific kinds of networked services that will actually be of value to ordinary people. This goes beyond the current survey research and laboratory studies that contrast the use of the Internet by various demographic groups. We need to understand why groups use the Internet in the manner that they do, be appreciative of the culture perspectives that diverse groups bring to their online interactions, and how people use the Internet in various contexts such as work, home, churches and public access facilities.

CONCLUSION

In this article, we discussed the background, current debates, and future trends in digital divide research and policy. We focus our discussion on African-Americans because historically, this group has been under-represented on the Internet. However, in 2006, African-Americans are represented online in numbers proportional to their representation in the U.S. population, and are now among the fastest growing groups of Internet users. As the number of African-Americans and other non-traditional Internet users increase, digital divide research and policy must expand from an access-centric agenda to include Internet use by diverse groups. Understanding Internet use as well as barriers to access enables the creation of socially just policies and the development of Internet-based content that serves the needs and interests of diverse Internet users.

KEY TERMS

Content: The various genres of information available on the Internet. For instance, local content is information that is specific to a community, neighborhood, or area, such as businesses, housing, neighborhood services, and recreation activities. Community content is information about the neighborhood that promotes community development and facilitates community building. Examples include a listing of places where GED courses are offered, or a newsletter. Culturally relevant content is information that is significant to people with different cultural backgrounds.

Digital Divide: Refers to the gap that exists between these who have and those who do not have access to technology (telephones, computers, Internet access) and related services.

Effective Use: The capacity and opportunity to integrate information and communication technology into the accomplishment of self or collaboratively identified goals. What is most important is not so much the physical availability of computers and the Internet but rather people's ability to make use of those technologies to engage in meaningful social practices.

Historically Underserved Groups: Refers to those who lack access to computers and the Internet. Historically this has included Americans who have low-incomes, live in rural communities, have limited education, and are members of racial or ethnic minorities.

Social Access: Refers to a mix of professional knowledge, economic resources, and technical skills to use technologies in ways that enhance professional practices and social life.

Social Inclusion: Refers to the extent that individuals, families, and communities are able to fully participate in society and control their own destinies, taking into account a variety of factors related to economic resources, employment, health, education, housing, recreation, culture, and civic engagement.

Technological Access: Refers to the physical availability of suitable information and communication technologies, including computers of adequate speed and equipped with appropriate software for a given activity.

Agent Technology

J.-J. Ch. Meyer
Utrecht University, The Netherlands

INTRODUCTION

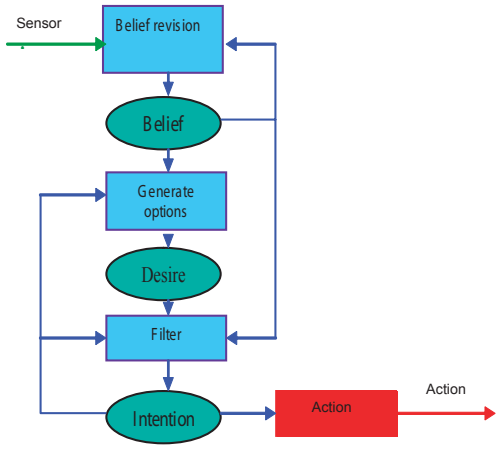
Agent technology is a rapidly growing subdiscipline of computer science on the borderline of artificial intelligence and software engineering that studies the construction of intelligent systems. It is centered around the concept of an (intelligent/rational/autonomous) *agent*. An agent is a software entity that displays some degree of autonomy; it performs actions in its environment on behalf of its user but in a relatively independent way, taking initiatives to perform actions on its own by *deliberating* its options to achieve its goal(s).

The field of agent technology emerged out of philosophical considerations about how to reason about courses of action, and human action, in particular. In analytical philosophy there is an area occupied with so-called practical reasoning, in which one studies so-called practical syllogisms, that constitute patterns of inference regarding actions. By way of an example, a practical syllogism may have the following form (Audi, 1999, p. 728):

Would that I exercise.
Jogging is exercise.
Therefore, I shall go jogging.

Although this has the form of a deductive syllogism in the familiar Aristotelian tradition of "theoretical reasoning," on closer inspection it appears that this syllogism does not express a purely logical deduction. (The conclusion does not follow logically from the premises.) It rather constitutes a representation of a *decision* of the agent (going to jog), where this decision is based on mental attitudes of the agent, namely, his/her beliefs ("jogging is exercise") and his/her desires or goals ("would that I exercise"). So, practical reasoning is "reasoning directed toward action—the process of figuring out what to do," as Wooldridge (2000, p. 21) puts it. The process of reasoning about what to do next on the basis of mental states such as beliefs and desires is called *deliberation* (see Figure 1). The philosopher Michael Bratman has argued that humans (and more generally, resource-bounded agents) also use the notion of an intention when deliberating their next action (Bratman, 1987). An intention is a desire that the agent is committed to and will try to fulfill till it believes it has achieved it or has some other rational reason to abandon it. Thus, we could say that agents, given their beliefs and desires, choose some desire as their intention, and "go for it." This philosophical theory has been formalized through several studies, in particular the work of Cohen and Levesque (1990); Rao and Georgeff (1991); and Van der Hoek, Van Linder, and Meyer (1998), and has led to the so-called Belief-Desire-Intention (BDI) model of intelligent or rational agents (Rao & Georgeff, 1991). Since the beginning of the 1990s researchers have turned to the problem of realizing artificial agents. We will return to this hereafter.

Figure 1. The deliberation process in a BDI architecture



BACKGROUND: THE DEFINITION OF AGENTHOOD

Although there is no generally accepted definition of an agent, there is some consensus on the (possible) properties of an agent (Wooldridge, 2002; Wooldridge & Jennings, 1995): Agents are hardware or software-based computer systems that enjoy the properties of:

- **Autonomy:** The agent operates without the direct intervention of humans or other agents and has some control over its own actions and internal state.
- **Reactivity:** Agents perceive their environment and react to it in a timely fashion.
- **Pro-Activity:** Agents take initiatives to perform actions and may set and pursue their own goals.

- **Social Ability:** Agents interact with other agents (and humans) by communication; they may coordinate and cooperate while performing tasks.

Thus we see that agents have both informational and motivational attitudes, namely, they handle and act upon certain types of information (such as knowledge, or rather beliefs) as well as motivations (such as goals). Many researchers adhere to a stronger notion of agency, sometimes referred to as *cognitive* agents, which are agents that realize the aforementioned properties by means of mentalistic attitudes, pertaining to some notion of a mental state, involving such notions as knowledge, beliefs, desires, intentions, goals, plans, commitments, and so forth. The idea behind this is that through these mentalistic attitudes the agent can achieve autonomous, reactive, proactive, and social behavior in a way that is mimicking or at least inspired by the human way of thinking and acting. So, in a way we may regard agent technology as a modern incarnation of the old ideal of creating intelligent artifacts in artificial intelligence. The aforementioned BDI model of agents provides a typical example of this strong notion of agency and has served as a guide for much work on agents, both theoretical (on BDI logic) and practical (on the BDI architecture, see next section).

CURRENT AGENT RESEARCH: MULTI-AGENT SYSTEMS

Agent-based systems become truly interesting and useful if we have multiple agents at our disposal sharing the same environment. Here we have to deal with a number of more or less autonomous agents interacting with each other. Such systems are called multi-agent systems (MAS) (Wooldridge, 2002) or sometimes also agent societies. Naturally, these systems will generally involve some kind of *communication* between agents. Agents may communicate by means of a communication primitive such as a *send* (agent, performative, content), which has as semantics to send to the agent specified the content specified with a certain illocutionary force, specified by the performative, for example, inform or request. The area of agent communication (and agent communication languages) is a field of research in itself (Dignum & Greaves, 2000). Further, it depends on the application whether one may assume that the agents in a multi-agent system cooperate or compete with each other. But even in the case of cooperation it is not a priori obvious how autonomous agents will react to requests from other agents: Since they ultimately have their own goals, it may be the case that they do not have the time or simply do not want to comply. This also depends on the *social structure* within the agent system/society, in particular the type(s) of coordination mechanisms and power relations employed, such as a market, network, or hierarchy, and the *role* the agent plays in it (Dignum, Meyer, Weigand, & Dignum, 2002).

Another issue related to agent communication, particularly within heterogeneous agent societies, concerns the language (ontology) agents use to reason about their beliefs and communicate with each other. Of course, if agents stem from different sources (designers) and have different tasks they will generally employ different and distinct ontologies (concepts and their representations) for performing their tasks. When communicating it is generally not efficacious to try to transmit their whole ontologies to each other or to translate everything into one giant *universal* ontology if this would exist anyway. Rather it seems that a kind of "ontology negotiation" should take place to arrive at a kind of minimal solution (i.e., sharing of concepts) that will facilitate communication between those agents (Bailin & Truszkowski, 2002; Van Diggelen, Beun, Dignum, Van Eijk, & Meyer, 2006).

Next we turn to the issue of constructing agent-based systems. Since the philosophical and logical work on intelligent agents mentioned in the introduction, researchers have embarked upon the enterprise of realizing agent-based systems. Architectures for agents have been proposed, such as the well-known BDI architecture (Rao & Georgeff, 1991) and its derivatives procedural reasoning system (PRS) and the InteRRap architecture (Wooldridge, 2002). Other researchers devised dedicated agent-oriented programming (AOP) languages to program agents directly in terms of mentalistic notions in the same spirit as the ones mentioned previously. The first researcher who proposed this approach was Shoham with the language AGENT0 (Shoham, 1993). Other languages include AgentSpeak(L)/Jason, (Concurrent) METATEM, CONGOLOG, JACK, JADE, JADEX, and 3APL (Bordini, Dastani, Dix, & El Fallah Seghrouchni, 2005; de Giacomo, Lespérance, & Levesque, 2000; Fisher, 1994; Hindriks, de Boer, Van der Hoek, & Meyer, 1999). One may also adhere to programming agents directly in generic programming languages such as JAVA and C++. Interestingly, one may now ask questions such as how to program agents in these languages in the same way that these questions are asked in software engineering with respect to traditional programming. The thus emerging subfield is called agent-oriented software engineering (AOSE) (Ciancarini & Wooldridge, 2001). In our opinion this makes the most sense in the interpretation of engineering agent-oriented software rather than trying to engineer arbitrary software in an agent-oriented way. So we advocate using an agent-oriented design together with an explicit agent-oriented implementation in an AOP language for those applications that are fit for this approach (Dastani, Hulstijn, Dignum, & Meyer, 2004). Obviously we do not advocate performing all programming (e.g., a sorting algorithm) in an agent-oriented way.

This brings us to the important question, what kind of application is particularly suited for an agent-based solution?

Although it is hard to say something about this in general, one may particularly think of applications where (e.g., logistical/planning) tasks may be distributed in such a way that subtasks may be (or rather preferably so) performed by autonomous entities (agents). For instance in situations where it is virtually impossible to perform the task centrally, due to either the complexity of the task or a large degree of dynamics (changes) in the environment in which the system has to operate. Of course, also in applications where there is a natural notion of a *cognitive* agent, such as, for example, in the gaming world where virtual characters need to behave in a natural/believable way and have human-like features, agents seem to be the obvious choice for realization. For the same reason, in (multi-)robotic applications agents may be used, too, where each robot may be controlled by its own agent, and therefore can display autonomous but, for instance, also cooperative behavior. Furthermore, also in e-commerce/e-business and in applications for the Web in general, where agents may act on behalf of a user, agent technology seems adequate.

At the moment agent research is quite big. There are many workshops addressing aspects of agents, and there is the large annual international *Autonomous Agents and Multi-Agent Systems (AAMAS) Conference*, the most authoritative event in the field, attracting over 700 people. There has been a specialization into many topics. To give an impression: AAMAS 2006 (http://www.fun.ac.jp/aamas2006/) lists, in its call for papers, the following list of topics (categorized by the author for ease of reading).

Agent Theories

- Agents and cognitive models
- Agents and adjustable autonomy
- Argumentation in agent systems
- Coalition formation and teamwork
- Collective and emergent agent behavior
- Computational complexity in agent systems
- Conventions, commitments, norms, social laws
- Cooperation and coordination among agents
- Formal models of agency
- Game theoretic foundations of agent systems
- Legal issues raised by autonomous agents
- Logics for agent systems
- (Multi-)agent evolution, adaptation and learning
- (Multi-)agent planning
- Ontologies and agent systems
- Privacy, safety and security in agent systems
- Social choice mechanisms
- Social and organizational structures of agent systems
- Specification languages for agent systems
- Computational autonomy
- Trust and reputation in agent systems
- Verification and validation of agent systems

Agent Construction: Design and Implementation

- Agent and multi-agent architectures
- Agent communication: languages, semantics, pragmatics, protocols
- Agent programming languages
- Agent-oriented software engineering and agent-oriented methodologies
- Electronic institutions
- Frameworks, infrastructures and environments for agent systems
- Performance evaluation of agent systems
- Scalability, robustness and dependability of agent systems

Agent Applications

- Agent standardizations in industry and commerce
- Agents and ambient intelligence
- Agents and novel computing paradigms (e.g. autonomic, grid, P2P, ubiquitous computing)
- Agents, web services and semantic web
- Agent-based simulation and modeling
- Agent-mediated electronic commerce and trading agents
- Applications of autonomous agents and multi-agent systems
- Artificial social systems
- Auctions and electronic markets
- Autonomous robots and robot teams
- Constraint processing in agent systems
- Conversation and dialog in agent systems
- Cooperative distributed problem solving in agent systems
- Humanoid and sociable robots
- Information agents, brokering and matchmaking
- Mobile agents
- Negotiation and conflict handling in agent systems
- Perception, action and planning in agents
- Synthetic, embodied, emotional and believable agents
- Task and resource allocation in agent systems

It is beyond the scope and purpose of this article to discuss all of these. Many issues mentioned in this huge list have been touched upon already. Some others will be addressed in the next section on future trends, since they are still much a matter of pioneering research.

FUTURE TRENDS

It is interesting to speculate on the future of agents. Will it provide a new programming paradigm as a kind of successor to object-oriented programming? Time will tell. The trends at the moment are diverse and ambitious. One trend is to go beyond rationality in the BDI sense, and include also social notions such as norms and obligations into the agent framework (Dignum, 1999), and even also "irrational" notions such as emotions (Meyer, 2004). So-called *electronic institutions* have been proposed to regulate the behavior of agents in compliance with the norms in force (Esteva, Padget, & Sierra, 2001). Another trend is to look at how one may devise "hybrid" agent systems with "humans in the loop" (Klein, Woods, Bradshaw, Hoffman, & Feltovich, 2004). Since it is deemed imperative to check the correctness of complex agent-based systems for very costly and life-critical applications, yet another trend is the development of formal verification techniques for agents and model checking in particular (Rash, Rouff, Truszkowski, Gordon, & Hinchey, 2001).

CONCLUSION

In this short article we have seen how the idea of agent technology and agent-oriented programming evolved from philosophical considerations about human action to a way of programming intelligent artificial (computer-based) systems. Since it is a way to construct complex intelligent systems in a structured and anthropomorphic way, it appears to be a technology that is widely applicable, and it may well become one of the main programming paradigms of the future.

KEY TERMS

Agent-Oriented Programming (AOP): AOP is an approach to constructing agents by means of programming them in terms of mentalistic notions such as beliefs, desires, and intentions.

Agent-Oriented Programming Language: AOP Language is a language that enables the programmer to program intelligent agents, as defined previously, (in the strong sense) in terms of agent-oriented (mentalistic) notions such as beliefs, goals, and plans.

Agent-Oriented Software Engineering (AOSE): AOSE is the study of the construction of intelligent systems by the use of the agent paradigm, that is, using agent-oriented notions, in any high-level, programming language. In a strict sense: the study of the implementation of agent systems by means of agent-oriented programming languages.

Autonomous Agent: Autonomous agent is an agent that acts without human intervention and has some degree of control over its internal state.

Believable Agent: Believable agent is an agent, typically occurring in a virtual environment that displays *natural* behavior, such that the user of the system may regard it as an entity that interacts with him/her in a natural way.

Electronic Institution: Electronic institution is a (sub)system to regulate the behavior of agents in a multi-agent system/agent society, in particular their interaction, in compliance with the norms in force in that society.

Intelligent Agent: Intelligent agent is a software or hardware entity that displays (some degree of) autonomous, reactive, proactive, and social behavior; in a strong sense: an agent that possesses mental or cognitive attitudes, such as beliefs, desires, goals, intentions, plans, commitments, and so forth.

Multi-Agent System (MAS)/Agent Society: MAS agent society is a collection of agents sharing the same environment and possibly also tasks, goals, and norms, and therefore are part of the same organization.

Pro-Active Agent: Pro-active agent is an agent that takes initiatives to perform actions and may set and pursue its own goals.

Reactive Agent: Reactive agent is an agent that perceives its environment and reacts to it in a timely fashion.

Social Agent: Social agent is an agent that interacts with other agents (and humans) by communication; it may coordinate and cooperate with other agents while performing tasks.

Agent-Based Negotiation in E-Marketing

V.K. Murthy

INTRODUCTION

This article describes in brief the design of agent-based negotiation system in e-marketing. Such a negotiation scheme requires the construction of a suitable set of rules, called protocol, among the participating agents. The construction of the protocol is carried out in two stages: first expressing a program into an object-based rule system and then converting the rule applications into a set of agent-based transactions on a database of active objects represented using high-level data structures.

BACKGROUND

An agent is a code-containing object, that along with data and execution context can migrate autonomously and purposefully within a computer network. Thus an agent knows what to do with the information obtained from its environment. Agents behave like actors and have intentions and actions. In addition, agents are flexible, proactive and have multithreaded control. In this overview, we describe in detail how a set of agents can be used for negotiation in e-marketing. For this purpose we need to have a model of the multi agent-based paradigm for executing the negotiation process analogous to what we humans do. Negotiation is an interactive process among a number of agents that results in varying degrees of cooperation, competition and ultimately to commitment that leads to a total agreement, consensus or a disagreement. It has many applications, including economics, psychology, sociology and computer science.

MAIN THRUST OF THE ARTICLE

The following subsections bring out the main thrust of this chapter, namely: what is a multi-agent system, what is planning, reasoning and negotiation, and how agents can be useful in modeling e-market and e-auction. Also we will briefly describe how a coalition among agents can cause a speculation bubble or a crash in e-share market.

A MULTI-AGENT SYSTEM

A simple model of an agent that is suitable for our purpose is shown in Figure 1. This is a unified model based on several important contributions made by the following authors: (Chen & Dayal, 2000; Dignum & Sierra, 2001; Fisher, 1995; Genesereth & Nilsson, 1987; Ishida, 1994; Murthy, 2002; Woolridge, 2002).

As shown in Figure 1, an agent consists of the following subsystems:

(1) Worldly states or environment U: Those states which completely describe the universe containing all the agents.

(2) Percept: Depending upon the sensory capabilities (input interface to the universe or environment), an agent can partition U into a standard set of messages T, using a sensory function Perception (PERCEPT): PERCEPT :U $\rightarrow$ T.
PERCEPT can involve various types of perception: see, read, hear, smell. The messages are assumed to be of standard types based on an interaction language that is interpreted identically by all agents.

(3) Epistemic states or Mind M: Weassumethattheagent has a mind M (that is essentially a problem domain knowledge consisting of an internal database for the problem domain data and a set of problem domain rules) that can be clearly understood by the agent without involving any sensory function. The database D sentences are in first order predicate calculus (also known as extensional database) and agents' mental actions are viewed as inferences arising from the associated rules that result in an intentional database, whcih changes (revises or updates) D.
The agent's state of belief, or a representation of an agent's state of belief at a certain time, is represented by an ordered pair of elements (D, P). D is a set of beliefs about objects, their attributes and relationships stored as an internal database and P is a set of rules expressed as preconditions and consequences (conditions and actions). When T is input, if the conditions given in the left-hand side of P match T, the elements from D that correspond to the right-hand side are taken

Figure 1.

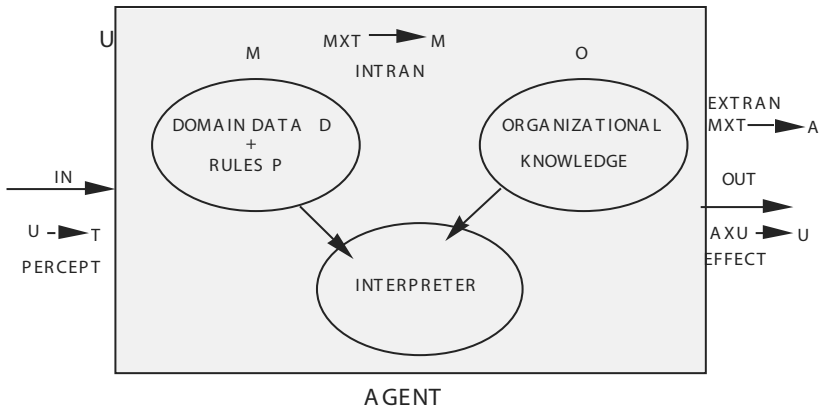

Figure 1

from D and suitable actions are carried out locally (in M) as well as on the environment.

(4) Organizational Knowledge (O): Since each agent needs to communicate with the external world or other agents, we assume that O contains all the information about the relationships among the different agents. For example, the connectivity relationship for communication, the data dependencies between agents, and interference among agents with respect to rules. Information about the location of different domain rules is in O.

(5) INTRAN: M is suitably revised or updated by the function called internal transaction (INTRAN).

Revision: Revision means acquisition of new information about the environment that requires a change in the rule system P. This may result in changes in the database D.

Example: The inclusion of a new tax rule in the tax system.

Update: Update means adding new entries to the database D; the rules P are not changed.

Example: Inclusion of a new tax-payer in the tax system.

Both revision and update can be denoted in set-theoretic notation by: INTRAN: $M \times T \rightarrow M$

(6) EXTRAN: External action is defined through a function called global or external transaction (EXTRAN) that maps an epistemic state and a partition from an external state into an action performed by the agent. That is: EXTRAN: $M \times T \rightarrow A$
This means that the current state of mind and a new input activates an external action from A.

(7) EFFECT: The agent also can affect U by performing an action from a set of actions A (ask, tell, hear, read, write, speak, send, smell, taste, receive, silent), or more complex actions. Such actions are carried out according to a particular agent's role and governed by an etiquette called protocols. The effect of these actions is defined by a function EFFECT, which modifies the world states through the actions of an agent:

EFFECT: $A \times U \rightarrow U$; EFFECT can involve additions, deletions and modifications to U.

Thus an agent is defined by a set of nine entities, called a 9-tuple:

(U,T,M(P,D),O,A,PERCEPT,INTRAN,EXTRAN,EFFECT).

The interpreter repeatedly executes selected rules in P, until no rule can be fired.

We can interpret all the abstract machine models (such as a finite state machine or a Turing machine) and parallel computational models (such as classifier systems) as subclasses of the agents, by suitably formulating the definitions.

The nature of internal production rules P, their mode of application, and the action set A determines whether an agent is deterministic, nondeterministic, probabilistic or fuzzy. Rule application policy in a production system P can be modified by:

(1) Assigning probabilities/fuzziness for applying the rule

(2) Assigning strength to each rule by using a measure of its past success

(3) Introducing a support for each rule by using a measure of its likely relevance to the current situation

The preceding three factors provide for competition and cooperation among the different rules. Such a model is useful for negotiation in learning, as well as in e-marketing that involves interactions between many agents.

WHAT IS NEGOTIATION?

A negotiation protocol is viewed as a set of public rules that dictate the conduct of an agent with other agents to achieve a desired final outcome.

A negotiation protocol among agents involves the following actions or conversational states:

(1) Propose: one puts forward for consideration a set of intentions called a proposal.
(2) Accept: The proposal is accepted for execution into actions.
(3) Refuse: The proposal is rejected for execution into actions.
(4) Modify: This alters some of the intentions of the proposer and suggests a modified proposal that is at the worst, a refuse and a new proposal; or a partial acceptance and new additions.
(5) No proposal: No negotiation.
(6) Abort: Quit negotiation.
(7) Report agreement: This is the termination point for negotiation in order to begin executing actions.
(8) Report failure (agree to disagree): Negotiation breaks down.

Note that the previous actions are not simple exchange of messages but may involve some intelligent or smart computation.

Multiagents can cooperate to achieve a common goal to complete a transaction to aid the customer. The negotiation follows rule-based strategies that are computed locally by its host server. Here competing offers are to be considered; occasionally cooperation may be required. Special rules may be needed to take care of risk factors, domain knowledge dependencies between attributes, and positive and negative end conditions. When making a transaction several agents have to negotiate and converge to some final set of values that satisfies their common goal. Such a goal should also be cost effective so that it is in an agreed state at the minimum cost or a utility function. To choose an optimal strategy each agent must build a plan of action and communicate with other agents.

PLANNING, REASONING AND NEGOTIATION

The negotiation process is usually preceded by two cooperating interactive processes: planning and reasoning (Woolridge, 2000). The ability to plan ahead for solving a problem is the key aspect of intelligent behavior. To solve a problem through negotiation, we start with a set of desired properties and try to devise a plan that results in a final state with the desired properties. For this purpose, we define an initial state where we begin an operation and also define a desirable goal state or a set of goal states. Simultaneously, we use a reasoning scheme and define a set of intended actions that can convert a given initial state to a desired goal state or states. Such a set of intended actions called the plan exists if and only if it can achieve a goal state starting from an initial state and moving through a succession of states. Therefore to begin the negotiation process, we need to look for a precondition that is a negation of the goal state and look for actions that can achieve the goal. This strategy is used widely in AI and forms the basis to plan a negotiation (Genersereth & Nilsson, 1987). Such a planning is possible for clear-cut algorithmic problems. For general AI problems, however, we can only generate a plan that may or may not work; if the plan does not work we need to either modify the plan or devise a new plan. The same approach is used for devising a multi-agent negotiation protocol that is useful in e-auction, e-marketing and in other applications (Horlait et al., 2003; Marik et al., 2003; Schillo et al., 2003; Woolridge, 2000).

We now describe how to carry out distributed multi-agent negotiation by sending, receiving, handshaking and acknowledging messages and performing some local computations.

A multi-agent negotiation has the following features (Dignum & Sierra, 2001; Murthy, 2002):

(1) There is a seeding agent who initiates the negotiation and coordinates the negotiation.
(2) Each agent can be active or inactive.
(3) Initially all agents are inactive except for a specified seeding agent that initiates the computation.
(4) An active agent can do local computation, send and receive messages and can spontaneously become inactive.
(5) An inactive agent becomes active, if and only if it receives a message.
(6) Each agent may retain its current belief or revise its belief as a result of receiving a new message by performing a local computation. If it revises its belief, it communicates its revised state of belief to other concerned agents; else it does not revise its solution and remains silent.
(7) Finally, the negotiation terminates, or fails. If there is no consensus within a set time-out limit, the negotiation fails.

FUTURE TRENDS

Agent based systems will provide new approaches to modeling and simulation of complex business systems and also provide for new software engineering approaches (Lucena

et al., 2004; Sichman et al., 2003). We will illustrate this by a simple example on modeling e-market and e-auction.

MODELING E-MARKET AND E-AUCTION

The agent negotiation system can model the e-market with many traders (agents), popularly known as buyers and sellers. These agents negotiate over the Internet to sell or buy shares or stocks in a stock market. In an e-market situation, it is possible that the negotiation ultimately leads to self-organization and criticality, causing crashes. That is, individual agents that correspond to a microscopic system can emerge as a self-organizing macroscopic system corresponding to a "percolation model" (Paul & Baschnagel, 1999).

In e-market situation (see Figure 1), to start with, the domain data D, rules P and organizational knowledge O can be based on three factors:

(1) the experience and economics knowledge of an agent deployed by a trader based totally on individualistic idiosyncratic criteria.
(2) the trader's acquired knowledge through communication with other selected agents; such a trader is called a fundamentalist.
(3) the trader's acquired knowledge by observing the trends on market from a collective opinion of other traders; such a trader is called a trend chaser.

The previous three factors play an important role in deciding the number of possible states that each agent will be in and his or her inclination to buy or sell or wait in an e-marketing decision.

In e-market, at every time instant a trader can adopt three possible states of action: buy, sell or wait, respectively represented by three states 1, -1 and 0. Each agent representing a trader can communicate with one another and this creates an imaginary bond or connectivity relationship among them, modifying the organizational knowledge O. This bond is created with a certain probability determined by a single parameter that characterizes the willingness of an agent to comply with others.

The three states of behavior are obviously a very complicated function of the behavioral property and personality of an individual and whether he or she uses elementary, derived or inferential beliefs. It is interesting to note that all the beliefs are again a function of the speed with which information is available to an agent, financial status, ability to reason and susceptibility to pressure from neighbors. Thus in a share market or auction situation we need to work out how the agents are linked in order to obtain information through communication, the personality factors such as age, financial status and the market trend. Using data mining techniques one can derive detailed information about the mechanism of bond formation among the agents. Based on this information, we can assume that any two agents are randomly connected with a certain probability. This will divide the agents into clusters of different sizes whose members are linked either directly or indirectly via a chain of intermediate agents. These groups are coalitions of market participants who share the same opinion about their activity. The decision of each group is independent of its size and the decision taken by other clusters. In this situation, using the random cluster model (Bak, 1996; Paul & Baschnagel, 1999) we can show that when every trader is on average connected to another, more and more traders join the spanning cluster, and the cluster begins to dominate the overall behavior of the system. This can give rise to "speculation bubble" (if the members all decide to buy), a crash (if the members all decide to sell) or a stagnation (if the members all decide to wait). These are cooperative phenomenon and depend upon trading rules, exchange of information- the speed and volume, and the connectivity relationship. For the three-state agents the critical probability $p(c) = 0.63$. That is, if an agent is even showing about 63% preference to the information from his or her neighbors, a crash or bubble is bound to happen. Crash is a highly cooperative phenomenon and depends upon trading rules, exchange of information- the speed and volume, and the connectivity relationship. Accordingly, an analogy exists between stock-market crashes and critical phenomena or phase transitions in physics. Thus a distributed agent system can eventually enter into a self-organized critical state or an emergent state. However, such a phenomenon is similar to an earthquake or epidemic, or fatigue in materials resulting in cracks and is hard to predict, since the cluster formation depends upon the various factors already mentioned.

CONCLUSION

This overview explained the use of multi-agent based planning, reasoning and negotiation in e-marketing. We explained how to use the techniques of AI planning to devise the multi-agent based negotiation protocol. We also explained how agents can reach a self-organized critical state that can result in crash, speculation bubble or stagnation in e-share market. The study of agent systems and their applications is a vastly expanding area for research; for more details, the following references may be consulted: (Horlait et al., 2003; Marik et al., 2003; Schillo et al., 2003; Woolridge, 2000).

KEY TERMS

Agent: A system that is capable of perceiving events in its environment, or representing information about the current state of affairs and of acting in its environment guided by perceptions and stored information (current definition by AOIS, agent oriented information system community).

Coordinator: An that acts as a coordinator among several agents to carry out the negotiation protocol.

E-Auction: This is a centralized protocol for redistributing resources among agents. Each agent attaches a value to each resource. The seller asks a price for a resource and buyer offers a price and they negotiate over the Internet to achieve a desired outcome satisfying to both; else the negotiation fails.

E-Market: An Internet based market with many traders (agents) popularly known as buyers and sellers. These agents negotiate over the Internet to sell or buy products in any market (e.g., shares or stocks in a stock market).

Negotiation: This is an interactive process among a number of agents that results in varying degrees of cooperation, competition and ultimately to commitment that leads to a total agreement, consensus governed by a voting policy, or a disagreement.

Negotiation Protocol: A negotiation protocol is viewed as a set of public rules that dictate the conduct of an agent with other agents to achieve a desired final outcome.

Protocols: A set of rules that dictate the behavior of objects for communication and interaction.

Self-Organized Critical State or Emergence: A group of interconnected communicating, interacting and negotiating agents reach a state of self-organization resulting in an unpredictable decision—such as a share-market crash, a stagnation or a speculation bubble.

Leon Sterling
The University of Melbourne, Australia

INTRODUCTION

Over the past decade, the target environment for software development has complexified dramatically. Software systems must now operate robustly in a dynamic, global, networked environment comprised of distributed diverse technologies, where frequent change is inevitable. There is increasing demand for flexibility and ease of use. Multi-agent systems (Wooldridge, 2002) are a potential successor to object-oriented systems, better able to address the new demands on software. In multi-agent systems, heterogeneous autonomous entities (i.e., *agents*) interact to achieve system goals. In addition to being a technological building block, an agent, also known as an *actor*, is an important modeling abstraction that can be used at different stages of software engineering. The authors while teaching agent-related subjects and interacting with industry have observed that the agent serves as a powerful anthropomorphic notion readily understood by novices. It is easy to explain to even a non-technical person that one or more software agents are going to perform a set of tasks on your behalf.

We define *software engineering* as a discipline applied by teams to produce high-quality, large-scale, cost-effective software that satisfies the users' needs and can be maintained over time. Methods and processes are emerging to place software development on a parallel with other engineering endeavors. Software engineering courses give increasing focus to teaching students how to analyze software designs, emphasizing imbuing software with quality attributes such as performance, correctness, scalability, and security.

Agent-oriented software engineering (AOSE) (Ciancarini & Wooldridge, 2001) has become an active research area. Agent-oriented methodologies, such as Tropos (Bresciani, Perini, Giorgini, Giunchiglia, & Mylopoulos, 2004), ROADMAP (Juan & Sterling, 2003), and RAP/AOR (Taveter & Wagner, 2005), use the notion of agent throughout the software lifecycle from analyzing the problem domain to maintaining the functional software system. An agent-oriented approach can be useful even when the resulting system neither consists of nor includes software agents. Some other proposed AOSE methodologies are Gaia (Wooldridge, Jennings, & Kinny, 2000), MESSAGE (Garijo, Gomez-Sanz, & Massonet, 2005), TAO (Silva & Lucena, 2004), and Prometheus (Padgham & Winikoff, 2004). Although none of the AOSE methodologies are yet widely accepted, AOSE is a promising area. The recent book by Henderson-Sellers & Giorgini (2005) contains a good overview of currently available agent-oriented methodologies.

AOSE approaches loosely fall into one of two categories. One approach adds agent extensions to an existing object-oriented notation. The prototypical example is Agent UML (Odell, Van Dyke, & Bauer, 2001). The alternate approach builds a custom software methodology around agent concepts such as roles. Gaia (Wooldridge et al., 2000) was the pioneering example.

In this article, we address the new paradigm of AOSE for developing both agent-based and traditional software systems.

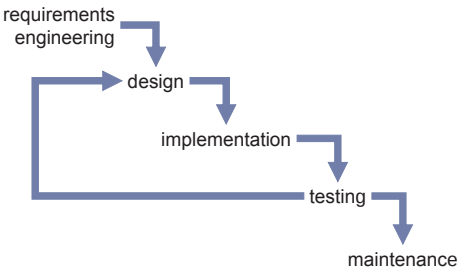
BACKGROUND

Software engineering deals with sociotechnical systems. Sommerville (2004) defines a *sociotechnical system* as one that includes hardware and software, has defined operational processes, and offers an interface, implemented in software, to human users. Software engineering addresses developing software components of sociotechnical systems. Software engineering is therefore critical for the successful development of complex, computer-based, sociotechnical systems because a software engineer should have a broad awareness of how that software interacts with other hardware and software systems and its intended use, not only the software itself (Sommerville, 2004).

A conventional *software engineering process* represented in Figure 1 contains the stages of requirements engineering, design, implementation, testing, and maintenance.

Requirements engineering—understanding, and specifying the user's needs—is followed by *software design* consisting of both high-level architectural design of the system and detailed design of the software components. Implementation follows, increasingly in the form of code generation using different Computer-aided software engineering (CASE) tools. The code must then be tested to uncover and correct as many errors as possible before delivery to the customer. Pressman (2001) provides an overview of many potentially

Figure 1. A software engineering process



useful testing strategies and methods. Finally, there is ongoing maintenance.

Object-oriented software engineering (OOSE), which numerous AOSE methodologies build on, adopts these conventional steps. Object-oriented approaches characterize the problem as a set of objects with specific attributes and behaviors (Pressman, 2001). Objects are categorized into classes and subclasses. Object-oriented analysis identifies classes and objects relevant to the problem domain; design provides architecture, interface, and component-level detail; and implementation (using an object-oriented language) transforms design into code.

To facilitate OOSE, the Unified Modelling Language (UML) (Object Management Group (OMG) 2003a, 2003b) for software analysis and design has become widely used in the industry over the past decade. A widely used OOSE process is the *Rational Unified Process* (RUP) (Kruchten, 1999) derived from UML and the associated *Unified Software Development Process* proposed by Jacobson, Booch, and Rumbaugh (1999). The core software engineering disciplines of RUP are domain modeling, requirements engineering, design, implementation, testing, and deployment.

In parallel with RUP, agile methodologies, such as *Extreme Programming* (Beck, 1999), have emerged. They emphasize lightweight processes such as test-case-based development and rapid prototyping. They de-emphasize detailed modeling on which they blame the heavy weight and inflexibility of traditional methodologies. In contrast, the *Model-Driven Architecture* (MDA, http://www.omg.org/mda) approach of the OMG identifies modeling as the key to state-of-the-art software engineering. In the MDA, computation-independent domain models are transformed into platform-independent design models that are then turned into platform-specific models and implementations.

NEW SOFTWARE ENGINEERING PARADIGM

Dynamic adaptive systems in open environments create new challenges for software engineering. For such systems, current software engineering techniques cannot guarantee quality attributes such as correctness to hold after deployment. Correctness is traditionally assured by testing the system before release, against documented requirements. Such assurance is lost if system behavior changes due to continuous adaptation or environment change. For example, a sociotechnical business system may change its structure (architecture) to mirror changes in the human organization.

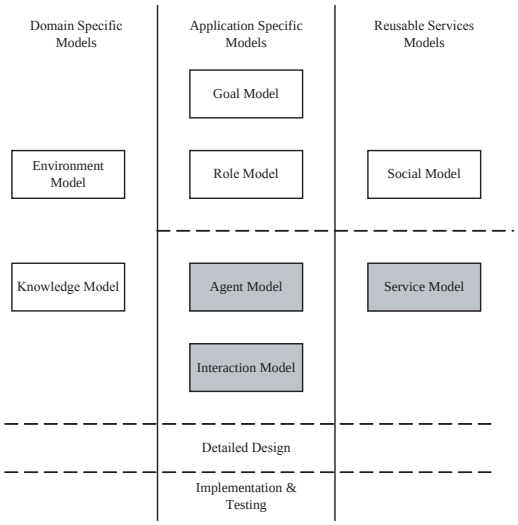
Similarly, system performance, reliability, security, usability, and maintainability can be compromised due to adaptation or environmental changes. Without explicit representation of system requirements and constant validation at run time, there is no guarantee that the system functions correctly.

To address the challenges described, a sociotechnical system should be analyzed and designed in terms of agents (actors), roles, and goals at the stage of requirements engineering, as well as at design, implementation, testing, and maintenance stages of the software lifecycle. From the start of a software engineering process, a distinction should be introduced between active and passive entities, that is, between agents and (nonagentive) objects of the real world. We define an agent as an autonomous entity situated in an environment capable of both perceiving the environment and acting on it. The agent metaphor subsumes *artificial* (software and robotic), *natural* (human and animal) as well as *social/institutional* agents (groups and organizations). According to Wagner (2003), the agent metaphor lies beyond UML where actors are only considered as users of the system's services in *use cases*, but otherwise remain external to the sociotechnical system model.

We define a *role* as a coherent set of functional responsibilities specifying what the agent playing the role is expected to do in the organization within some specialized context or domain of endeavor: with respect to both other agents and the organization itself. Roles may be subject to constraints.

Roles go hand in hand with goals. For example, in a business domain, a human or institutional agent acting in the role of "customer" has a goal of accomplishing something. To achieve its goal, the agent uses some service provided by another agent. An agent's autonomy means that the service provider performs the service requested if it is able to do so but the service provider also has an option to refuse the service request. Even though the agent requesting the service may not explicitly communicate its goals to the service provider agent, the latter always "internalizes" the whole or part of the customer's goal in attempting to provide the service. For example, given a customer wanting to rent a car, the goal of a car rental company is to provide the customer

Figure 2. Overview of the ROADMAP methodology



with a car, which is, of course, a subgoal of the company's higher-level goal—to earn money through renting cars. The car rental company tries to achieve this higher-level goal by "internalizing" as many customer goals as possible.

A goal can thus be defined as a condition or state of affairs in the world that the agent wants to bring about. Some people, like van Lamsweerde (2003), have chosen to model goals formally but this is not always necessary or even possible. For example, how would one formally model a goal of being greeted by someone?

An agent realizes goals by performing activities. Each activity belongs to some *activity type* defined as a prototypical job function in an organization that specifies a particular "way of doing" by performing elementary epistemic, physical, and/or communicative actions. An *action* is an atomic and instantaneous unit of work done by an agent. We thus view an agent's action more broadly as something that the agent does. In OOSE an action is often understood narrowly as something changing the state of a data object.

An action performed by one agent can be perceived as an event by another agent. Wagner (2003) distinguishes between an *action event type* (an event created through the action of an agent, such as starting a machine) and a *nonaction event type* (for example, temporal events or events created by natural forces). Action event types are further divided into *communicative action event* (or *message*) *types* and *noncommunicative* (*physical*) *action event types* like providing another agent with a commodity. An agent can also perform *epistemic actions* that change its knowledge state.

The popular belief-desire-intention (BDI) agent model by Rao and Georgeff (1995) includes the notions of belief and plan. Padgham and Winikoff (2004) define a *belief* as some aspect of the agent's knowledge about the environment, itself, or other agents. They define a *plan* as a way of realizing a goal.

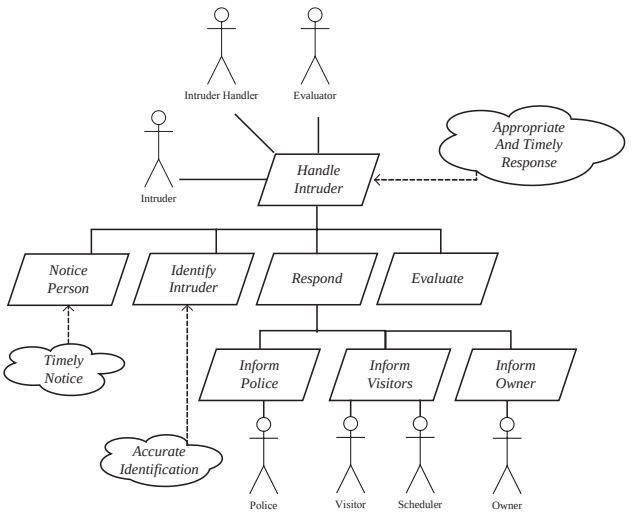
An AOSE methodology consists of the stages of requirements engineering, design, implementation and testing, and maintenance. Figure 2 shows the models employed at different stages of the ROADMAP methodology (Juan & Sterling, 2003). In ROADMAP, models are split horizontally by dotted horizontal lines according to the requirements engineering and design stages so that the environment model, knowledge model, goal model, role model, and social model are parts of the requirements engineering stage, while the agent model, interaction model, and service model belong to the architectural design substage. The models are also divided vertically into domain specific models, application specific models, and reusable services models. The environment model and knowledge model represent information about a specific domain and belong to multiple phases in the software development lifecycle. The goal model, role model, agent model, and interaction model are tied to the system being modeled. Generic and reusable components in the system are captured by the social and service models.

During requirements engineering, goals and roles are defined pertaining to the intended sociotechnical system. The goal model provides a high-level overview of the system requirements. Its objective is to enable both domain experts and developers to pinpoint the goals of the system and thus the roles the system needs in order to meet those goals. Quality goals (nonfunctional goals) may be attached to regular goals to constrain or document how goals should be fulfilled. Quality goals reflect more intangible goals of a system, such as privacy and timeliness.

Roles are attached to goals, indicating responsibility for achieving a particular goal. Role models, in turn, detail what responsibilities a specific role carries, as well as constraints that must be heeded. The concepts of roles and agents facilitate understanding of and elicitation of requirements because they parallel humans taking on roles within a particular organizational unit with (full or partial) responsibility for a set of goals within that unit.

Figure 3 gives the goal model of a scenario for handling intruders in an intelligent home. The role Intruder Handler has a single goal, to handle an intruder. This goal is characterized by the *quality goal* to provide an appropriate and timely response to a possible intruder detected. The Handle Intruder goal is decomposed into four subgoals: Notice Person, Identify Intruder, Respond, and Evaluate. There are quality goals Timely Notice and Accurate Identification pertaining to the subgoals Notice Person and Identify Intruder, respectively. The subgoal Respond, in turn, is divided into subgoals Inform Police, Inform Visitors, and Inform Owner. To accomplish these, the additional roles Police, Visitor, Scheduler, and Owner are introduced.

Figure 3. The goal model of intruder handling

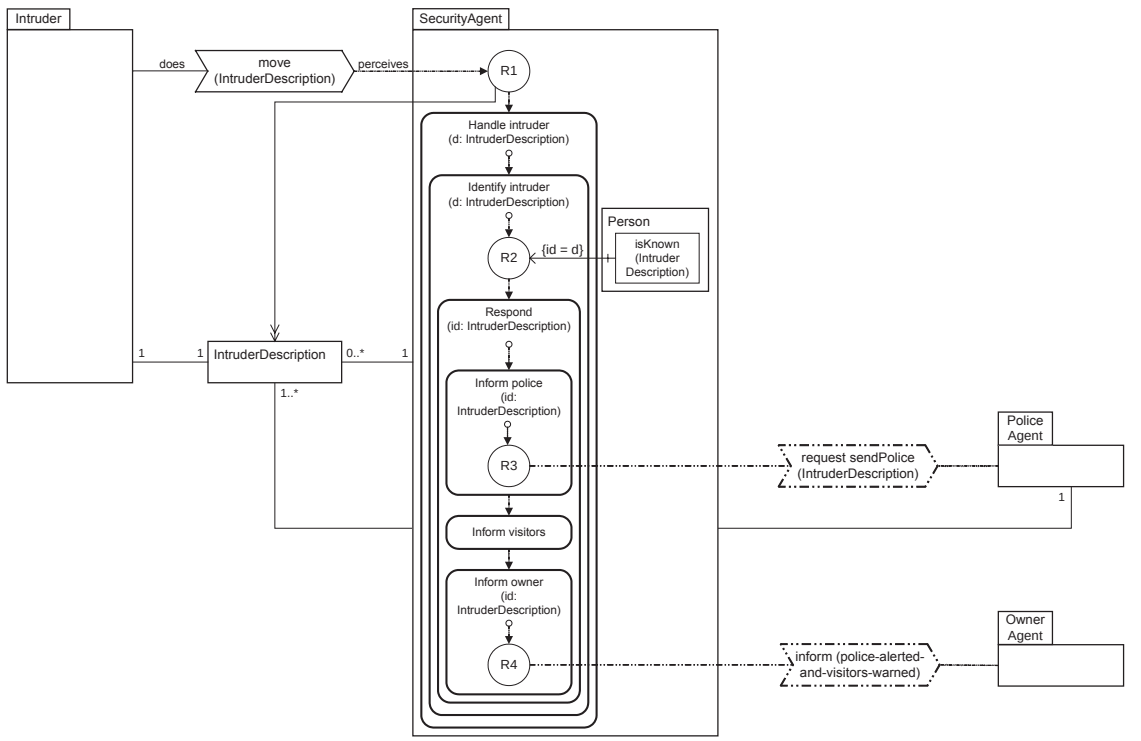


The environment and knowledge models constitute an *ontology* providing a common framework of knowledge for the agents of the problem domain. The social model captures relations between roles in the system and policies for interaction encompassing such areas as security, privacy, and communication.

During design, the types of software agents required, as well as the types of interactions and services provided by agents are defined, based on the models created during requirements engineering. These descriptions are refined during detailed design. An AOSE process ends with generating or coding the software agents or with other implementations such as object-oriented ones.

Various agent-oriented methodologies and the associated agent architectures can be used for design and implementation, for example, Prometheus (Padgham & Winikoff, 2004). To facilitate fast prototyping, we use the RAP/AOR methodology by Taveter and Wagner (2005). RAP/AOR is an agile AOSE methodology based on both MDA and RUP. RAP/AOR proposes an agent architecture with behavior modeling constructs called reaction rules. *Reaction rules* (also known as *event-condition-action* rules) govern the execution and sequencing of physical, communicative, and epistemic actions in response to perception and communication events. Reaction rules also start activities. Figure 4 represents an Agent-Object-Relationship (AOR) diagram comprising the agent, interaction, and service models for the intruder handling scenario. Reaction rule R1, triggered by an action event of type move(IntruderDescription), starts the scenario's outermost activity. This action event is created by a human agent Intruder through a sensor and perceived by the software agent SecurityAgent. Note that activity types modeled in the AOR diagram in Figure 4 correspond to goals represented in Figure 3. For example, an activity of type "Respond" achieves a Goal to respond to the detection

Figure 4. A design model of intruder handling



of an intruder. The subactivity type "Inform visitors," which involves the agent type SchedulerAgent, is not refined in Figure 4. Reaction rule R2 represents checking the Boolean predicate isKnown, attached to the object type Person. If the predicate evaluates to false, that is, if the person described by the IntruderDescription is not recognized, an activity of type "Respond" is started. This activity involves informing the PoliceAgent and the OwnerAgent embedded in a handheld device.

Taveter (2004) demonstrates that AOR diagrams can be straightforwardly transformed into programming constructs of the Java Agent Development Environment (JADE, http://jade.cselt.it/) software agent platform (Bellifemine, Poggi, & Rimassa, 2001).

FUTURE TRENDS

As decision support systems become more intelligent, new and imprecise quality attributes, such as privacy and politeness, emerge. The exact meanings of these quality attributes depend closely on actual system users and context of use. Whether quality attributes are fulfilled is open to user interpretation and perception. For example, we may expect our personal assistant agents to know our daily routines, habits, and preferences. Yet, we also expect user privacy and do not wish such knowledge to become public. The meaning of privacy and the level of privacy needed by each user is subjective and usually different. For many intelligent systems, the sheer complexity of their tasks renders it difficult to fully define and test the systems for correctness. To address this issue, we suggest that the AOSE paradigm must make available constructs to define such quality attributes in a flexible manner so that the definitions can be easily customized for each user at run time, as has been started within ROADMAP (Juan & Sterling, 2003).

CONCLUSION

In this article, we described the new paradigm of AOSE. The article thus presented an overview of some of the latest advances in the area of software engineering which are due to the emergence of novel analysis notions, the most fundamental ones of them being agent (actor), role, goal, and activity, as well as new implementation units—software agents. While agent-oriented analysis notions can always be used, software agents are recommended when the problem domain is distributed and the environment is open and unpredictable.

KEY TERMS

Action: An atomic and instantaneous unit of work done by an agent.

Action Event Type: The type of an event created through the action of an agent, such as starting a machine, sending a message to another agent, or providing another agent with a commodity.

Activity Type: A prototypical job function in an organization that specifies a particular "way of doing" by performing elementary epistemic, physical, and/or communicative actions.

Agent: An autonomous entity situated in an environment that is capable of perceiving the environment and acting on the environment.

Agent-Oriented Software Engineering: A new paradigm within software engineering involving novel analysis notions, the most fundamental ones of them being agent (actor), role, goal, and activity, as well as new implementation units—software agents.

Goal: A condition or state of affairs in the world that the agent wants to bring about.

Multi-agent System (MAS): A new paradigm in distributed computing where the system characteristics are: (1) no global system control; (2) decentralized information; and (3) each participating agent has incomplete information and limited capabilities.

Quality Goal: A goal which constrains or documents how a regular goal should be achieved by an agent.

Reaction Rule: A rule that specifies behavior of an agent by determining a triggering event to which the agent must react, a condition that the agent must check in its internal knowledge base and one or more actions to be performed by the agent.

Role: A coherent set of functional responsibilities specifying what the agent playing the role is expected to do in the organization within some specialized context or domain of endeavor: with respect to both other agents and the organization itself.

Software Engineering: A discipline applied by teams to produce high-quality, large-scale, cost-effective software that satisfies the users' needs and can be maintained over time.

Software Engineering Process: A set of activities whose purpose is development or evolution of a software system. Generally consists of the stages of requirements engineering, design, implementation, testing, and maintenance.

Agents and Payment Systems in E-Commerce

A

Sheng-Uei Guan
National University of Singapore, Singapore

INTRODUCTION

An emerging outcome of the popularization of the Internet are electronic commerce and payment systems, which present great opportunities for businesses, reduce transaction costs, and provide faster transaction times. More research has been conducted with new technologies like mobile Internet used by business models (Baek & Hong, 2003). However, before using the Internet, it is essential to provide security in transferring monetary value over the Internet. A number of protocols have been proposed for these secure payment systems, including NetBill, NetCheque, Open Market, iKP, Millicent, SET (Sherift, 1998), E-Cash (Brands, 1995), NetCash, CAFÉ (Mjolsnes, 1997), EMV cards (Khu-Smith & Mitchell, 2002), etc. These systems are designed to meet diverse requirements, each with particular attributes.

Automation and intelligence is another issue that poses challenges in the development of e-commerce. Agent technology has been incorporated into the area of e-commerce to provide automation and intelligence for the e-trade process. An agent is a software program capable of accomplishing tasks autonomously on behalf of its user. Agents must provide trustworthy consistency and fault tolerance to avoid eavesdropping and fraud. Also, agents should have roaming capability so as to extend their capability well beyond the limitations of owners' computers. To meet these requirements, this chapter will discuss some related components under the SAFER (Secure Agent Fabrication, Evolution, and Roaming) architecture (Zhu & Guan, 2000) and propose an agent-based payment scheme for SAFER.

Different types of electronic payment systems have been developed to meet its diverse requirements, which generally include integrity, authorization, confidentiality, availability, and reliability for security requirements (Asokan, 1997). Payment systems can be classified in a variety of ways according to their characteristics (Dahab & Ferreira, 1998), such as the exchange model (cash-like, check-like, or hybrid), central authority contact (online or offline), hardware requirements (specific or general), payment amounts (micropayment), etc.

Among the available payment schemes in the market, E-Cash is one of the best in terms of security, flexibility, and full anonymity. E-Cash is a cash-like online system that uses electronic coins as tokens. E-Cash has unique advantages, such as flexibility, integrity, and full anonymity that cannot be found in electronic check and credit card based systems. It uses cryptographic techniques to provide full anonymity. The agent-based payment scheme for SAFER adopts some similar principles and concepts of E-Cash.

MAIN THRUST OF THE ARTICLE

This chapter presents a brief overview of agents and payment system attributes used in e-commerce. An agent-based e-payment scheme built for the SAFER e-commerce architecture is proposed, which is aimed at providing a flexible and secure financial infrastructure for Internet commerce.

Software Agents in Electronic Commerce

Attributes of Agent-Based Systems for Electronic Commerce

Agents are bits of software performing routine tasks, typically in the background, on behalf of the user. Gathering, filtering, and presenting information are some of the small and well-defined tasks given to simple agents. An agent distinguishes itself from any other software by its intelligence. Intelligent agents are capable of "thinking" and producing intelligent feedback (Guan & Yang, 1999). Agents are increasing in the degree and sophistication of automation, on both the buyer's and seller's sides, commerce becomes much more dynamic, personalized, and context sensitive. These changes can be beneficial to both buyers and sellers (He, Jennings, & Leung, 2003).

The requirement for continuity and autonomy derives from our desire that an agent be able to carry out activities in a manner that is responsive to changes in the environment without requiring constant human guidance or intervention. According to Bradshaw (1997), agents have the following attributes, as shown in Table 1.

There are several software agent prototypes under development that will be capable of doing even more on behalf of buyers and sellers. One is Kasbah, wherein agents would proactively seek potential sellers and negotiate with them on the buyer's behalf, making the best possible deal, based on a set of constraints specified by the buyer, including the highest acceptable price and a transaction completion date (Chavz, 1996). A disadvantage of this software agent is that it always

Table 1. Attributes of software agents

Attribute	Description
Reactivity	The ability to selectively sense an act
Autonomy	Goal-directness, proactive and self-starting behavior
Collaborative behavior	Can work in concert with other agents to achieve a common goal
Communication ability	The ability to communicate with persons and other agents
Personality	The capability of manifesting the attributes of a believable character, such as emotion
Temporal continuity	Persistence of identity and state over long periods of time
Adaptivity	Being able to learn and improve with experience
Mobility	Being able to migrate in a self-directed way from one host platform to another

accepts the first offer that can meet its asking price, when even better offers might exist. This disadvantage is resolved by AuctionBot, a general-purpose Internet auction server. *AGENTics* is another agent prototype that develops what is referred to as "*online catalog integration for e-commerce*." AGENTics products shield the user from the technicalities of "where" and "how" the information was gathered, while it synthesizes many information pieces into a coherent whole (Mougayar, 1997).

Some agents can select desired items based on preferences, search databases to look for selected pieces of information, and conduct transactions. An example of such an adaptive agent is the SAFER architecture for e-commerce.

SAFER (Secure Agent Fabrication, Evolution, and Roaming) is a Web-based distributed infrastructure to serve agents to query, buy, and sell goods in e-commerce. It establishes necessary mechanisms to transport, manufacture, and evolve all different types of agents. The goal of SAFER is to construct open, dynamic, and evolutionary agent systems for e-commerce (Zhu & Guan, 2000). There will be SAFER-compliant and noncompliant communities coexisting in the e-commerce network. Each SAFER community

Figure 1. Cooperating agents for the SAFER payment scheme

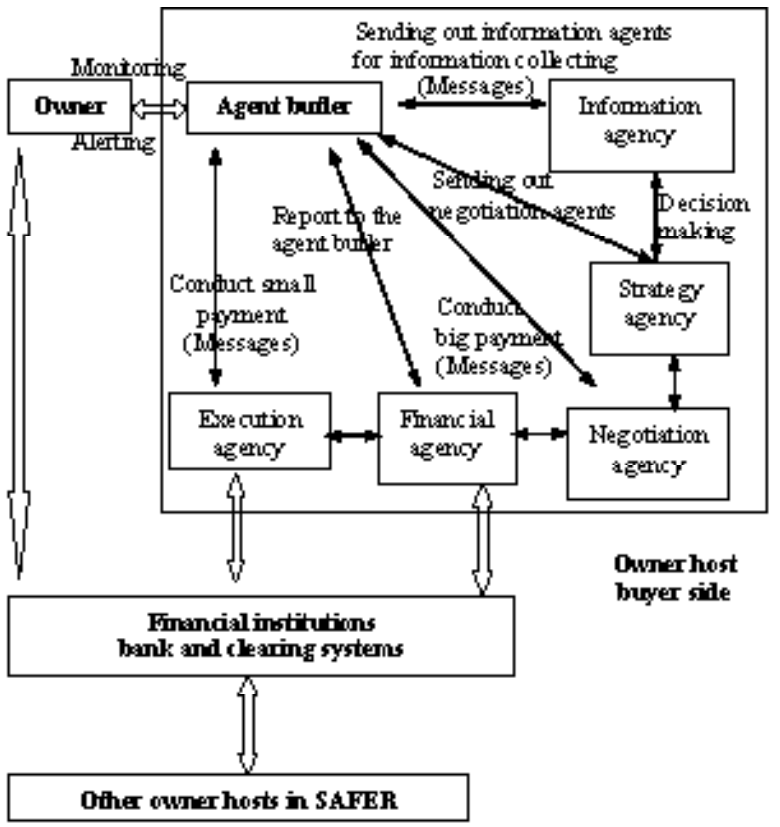

Figure 2. Prototype of agent butler

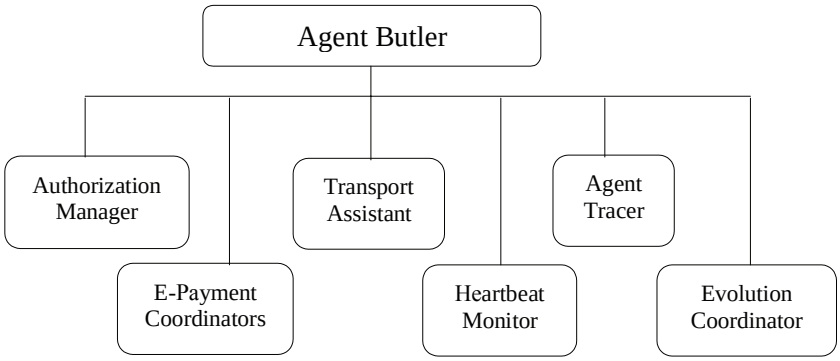


consists of several mandatory components: owner, butler, agent, agent factory, community administration center, agent charger, agent immigration, clearinghouse, and bank. Agent community is the basic unit in SAFER e-commerce, which offers virtual regions and vehicles to host and administrate mobile agents during roaming, transaction, and evolution. An owner is in charge of all his agents and of making respective authorizations to mobile agents and his agent butler, which is a 24-hour online watcher that would handle most of the tasks on behalf of the owner. When agents are sent roaming in the network, the butler has the responsibility of keeping track of agents' activities and locations by sending messages to agents and receiving messages from agents. At least one financial institution, usually a bank, that can link all value representations to real money, must also be involved. The payment scheme designed for SAFER is expected to fulfill flexibility and interoperability, which means that diverse representations of value will have the possibility of emerging in one framework for users' convenience. Given that, it is important that funds represented by one mechanism be easily converted into funds represented by others (Neuman, 1995).

An Agent-Based E-Payment Scheme for SAFER

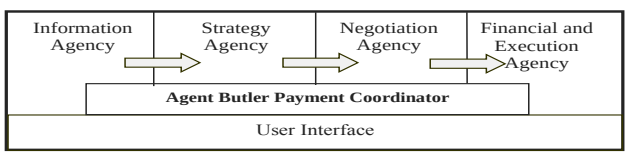
The payment module in the agent-mediated SAFER e-commerce architecture must contain several essential components: the marketplace, agents (including mobile agents, static agents, and agent butlers), financial institutions, and users. In SAFER, a community will offer virtual regions, factories, administration tools, vehicles to manipulate and administrate mobile agents during any activity, and provide security so that users can trust it.

Different types of agents fabricated by an agent factory of SAFER are running under the payment scheme for respective functions and tasks. They are briefly described in Figure 1.

In this scheme, a subsystem called agency is mentioned. Similar to the definition given by Dr. Larry Kerschberg in his Defense Personnel Support Center (DPSC) project, an agency can be thought of as a multilayered agent group or a federation of agents with specific goals and functional roles in the architecture. It is also like a collection of cooperating intelligent agents with particular expertise (Kerschberg, 1997).

If the owner is interested in some items, he will assign tasks to his butler and agents. The agent butler will then send out information agents from the agency, taking note of the items of interest, and set parameters such as due date (by which the item should be purchased), desired price, and highest acceptable price. The information agents used to sift, filter, and process information will roam in SAFER or even non-SAFER communities under a certain transport protocol, which is explained in the literature (Guan & Yang, 1999). It can help with dozens of purchasing decisions, thus lowering the cost and gaining efficiency. While roaming, agents are well tracked by the agent butler, by sending messages to report their activities and locations, which is described in detail in Zhu and Guan (2000). After gathering enough information, the information agent forwards all to

Figure 3. Payment coordinator



the strategy agency, which will analyze the new data and settle on a decision for the user. All the recommendations will be reported to the agent butler first. Once a recommendation has been reported, the agent butler activates the negotiation agency that will send out negotiation agents to the shortlist merchant hosts. Negotiation is defined as follows in Green (1997), "negotiation is the communication process of a group of agents in order to reach a mutually accepted agreement on some matter" (21). If the negotiation agent and the receptionist agent reach an agreement, the result will be reported to the butler. The butler will inform the financial agency to initiate the contract for certain goods and make a transaction decision according to the amount of money involved, the distance from host to the destination vendor, etc. Financial agents will take charge of the goods reception and payment transaction under the authorization of the butler. They communicate with the merchant host, autonomously make a payment request, and sign a contract order against the right good.

Implementation

The implementation of SAFER is under way. The overall architecture consists of several closely related but separate modules: roaming, evolution, fabrication, negotiation, and electronic payment.

The implementation of the payment module began with the development of the agent butler, which is defined as a combination of several separate functions, as shown in Figure 2. They are authorization manager, e-payment coordinator, transport assistant, heartbeat monitor, agent tracer, and evolution coordinator.

In the e-payment coordinator module, communication channels are set up between agent butler and all agencies of diverse functionalities, each of which is running in a separate thread. User interfaces are designed so that the user can assign tasks, define needs and requirements, check records, and read alerting messages reported by his or her agent butler.

Making all types of agents and merchant hosts available to fit in the same framework will be difficult in the current research stage, because the attributes that agents require to communicate may differ. Given that, we have chosen to implement a limited number of typical agents to test the system functionality and will consider how the work could be generalized to e-commerce in the future.

FUTURE TRENDS

The foremost important feature of e-commerce is transaction security. If the system is not trustworthy, there will be no incentive for participants to cooperate. A prerequisite is the prevention of double spending of electronic cash or coins. Ensuring this is the crux of any system, and it will incur significant overhead. Electronic currency in the context of mobile-agent-based systems has one particular caveat: the credits that an agent may carry are essentially just data, to which the host potentially has access. To ensure system reliability and reduce overhead, there are still many open issues for further consideration and discussion in future work:

- Privacy issues in collecting data and negotiation, e.g., to prevent agents from divulging private information to other hosts and to protect agents from malicious hosts
- The extent that users will let agents make decisions for them (based on their preference)
- The agent's ability of negotiation (This should be protected to prevent a host from having access to the agent's negotiation function and then affect the agent's buying power.)
- Agent traceability (An agent butler keeps in contact with his mobile agents periodically.)
- Fault tolerance and credits recovery in case of sudden crash of remote systems or unexpected attack on mobile agents
- Protection of agent's public and secret key during agent roaming

CONCLUSION

The agent-based SAFER e-commerce payment scheme incorporated agent technologies and took advantage of some well-known secure payment transaction protocols. It aims to simulate and even enhance physical cash and is designed to support a multitude of currency types. By incorporating the concepts of agent, the system is expected to provide security, efficiency, flexibility, autonomy, and intelligence. It is designed to provide anonymity against other parties and audit ability (traceability) for the owner (or agent butler). At last, a number of potential improvements, practical aspects, and some open issues have been identified for future work.

KEY TERMS

Adaptability: The ease with which software satisfies differing system constraints and user needs (Evans, 1987).

Agents: A piece of software that acts to accomplish tasks on behalf of its user.

Anonymity: The degree to which a software system or component allows for or supports anonymous transactions.

Confidentiality: The nonoccurrence of the unauthorized disclosure of information (Barbacci, 1995).

Cryptography: The art of protecting information by transforming it (encrypting it) into an unreadable format, called cipher text. Only those who possess a secret key can decipher (or decrypt) the message into plain text.

Flexibility: The ease with which a system or component can be modified for use in applications or environments other than those for which it was specifically designed (IEEE, 1990).

This work was previously published in Encyclopedia of Information Science and Technology, edited by M. Khosrow-Pour, pp. 93-97, copyright 2005 by Information Science Reference, formerly known as Idea Group Reference (an imprint of IGI Global).

Agile Information Technology Infrastructures

Nancy Alexopoulou
University of Athens, Greece

Panagiotis Kanellis

Drakoulis Martakos
National and Kapodistrian University of Athens, Greece

INTRODUCTION

Operating in highly turbulent environments, organizations today are faced with the need to continually adjust their infrastructure and strategies in order to remain competitive. Globalization and continual technological evolution are the main drivers of this turbulence (Dove, 1999b). To adapt at the same pace as their changing environment, organizations have to be agile. Loosely defined, an agile enterprise is one that is characterized by change proficiency. Change proficiency is the defining characteristic of agility and denotes the competency in which an adaptive transformation occurs (Dove, Benson, & Hartman, 1996). In a more detailed definition, an agile enterprise is one that is characterized as a fast moving, adaptable, and robust business, which is capable of rapid adaptation in response to unexpected and unpredicted changes and events, market opportunities, and customer requirements (Henbury, 1996).

According to Dove (1999b), agility is very much related to the ability to manage and apply knowledge effectively. Dove (1999b) felicitously associates agility with cats. A cat is both physically adept at movement and also mentally adept at choosing useful movement appropriate for the situation. If a cat has merely the ability to move quickly but moves inappropriately and to no gain (e.g., a cat on a hot tin roof), it might be called spastic or confused but never agile. On the other hand, a cat that knows what should be done but finds itself unable to move (e.g., a cat that's got itself up a tree), might be called catatonic, confused, or paralyzed but never agile.

This example implies that agility cannot be easily attained. It requires knowledge, experience, and skill. Enterprise agility depends on many factors such as personnel capabilities, information technology (IT) infrastructure, business strategy, and so forth. When an enterprise is agile, all its constituents are agile and vice versa. This article focuses particularly on IT infrastructure. It defines agility in IT infrastructure and explains how it contributes to enterprise sensing and response agility. *Sensing agility* is defined as a firm's ability to rapidly discover and interpret the market opportunities through its information systems, and it concerns not only an ability to distinguish information from noise quickly, but also to transform apparent noise into meaning faster (Haeckel, 1999). *Response agility* relates to the organizational capability to quickly transform knowledge into action in response to the environmental signals (Haeckel, 1999).

BACKGROUND

The term *agility* has over a decade of use in manufacturing practices, where it has been defined as a principle competitive issue (Kidd, 1994; Dove, 1994a; Goldman, Roger, & Kenneth, 1995). Dove (1999a, 2005) has introduced the principles for agile systems at an abstract level so that they can be interpreted either from a business or a technical perspective. The term *system* is used to characterize a group of interacting modules sharing a common framework and serving a common purpose. At the business level, modules represent groups of people while at the technical level correspond to software components or machines. These principles are summarized in Table 1.

Dove (1995) has also defined four agility metrics, namely *time, cost, robustness,* and *scope*. The first concerns the time required to complete a transformation. The second defines the cost regarding the transformation implementation. Robustness measures the strength and quality of the change process. Scope indicates how much latitude for change can be accommodated. Kidd (1994) has additionally defined a fifth agility metric which is the *frequency of change*.

The concept of agility has also been employed in the research area of information systems (IS) development where the term is much more recent (Aydin, Harmsen, Slooten, & Stegwee, 2004; Levine, 2005). Agile IS development concerns a new methodology paradigm proposed as an alternative to traditional disciplined methodologies for software development because these methodologies are no longer successful for rapidly changing environments due to their bureaucratic nature (Conboy & Fitzgerald, 2004; Nerur, Mahapatra, & Mangalaraj, 2005). Agile development

Table 1. Agile design principles (Source: Dove, 1999a)

Encapsulated Unit Modularity	System of interacting unit not intimately integrated. Internal workings unknown externally.
Plug Compatibility	System units share common interaction and interface standards, and are easily inserted or removed.
Facilitated Unit Reusability	Standardized unit replication information, unit modification tools, unit capability catalogs.
Non-Hierarchical Interaction	Empowered self-directed units that communicate negotiate and interact directly among themselves.
Dynamic Late Binding Relationships	Relationships are transient when possible; fixed binding is postponed until immediately necessary.
Distributed Control & Information	Units respond to objectives; decisions made at point of knowledge; data retained locally but accessible globally.
Self-Organizing Relationships	Dynamic unit alliances and scheduling; open bidding; and other self-adapting behaviors.
Scalable Size	Unrestricted unit populations that permit large increases and decreases in total unit population.
Unit Redundancy	Duplicate unit types or capabilities to provide capacity fluctuation options and fault tolerance.
Extensible Framework	Evolving open system framework capable of accommodating legacy, common, or completely new units.

methodologies (Abrahamsson, Salo, Ronkainen, & Warsta, 2002), such as Extreme Programming (Beck, 1999) and SCRUM (Schwaber & Beedle, 2002), promise faster development times and higher customer satisfaction. Extreme Programming and SCRUM constitute instantiations of the Agile Manifesto (Fowler & Highsmith, 2001), which was published by the Agile Alliance in 2001 (www.agilealliance.com). The basic principles of the Agile Manifesto are: first, individuals and interactions over processes and tools; second, working software over comprehensive documentation; third, customer collaboration over contract negotiation; and fourth, responding to change over following a plan (Williams & Cockburn, 2003).

In IT and IS literature, the term agility has not been broadly used. A relevant concept for IT infrastructure that has been defined instead is that of *flexibility*. *IT Infrastructure flexibility* is defined as the ability of the IS department to respond quickly and cost-effectively to system demands, which evolve with changes in business practices or strategies (Duncan & Bogucki, 1995). In this definition, however, the

ability to respond to unexpected or unpredicted change is not explicitly stated. As a matter of fact, agility and flexibility are not synonyms. Their main difference is that flexibility is a planned response to variations which have been planned, whereas agility concerns minimizing the inhibitions to change in any direction based on unanticipated change (Dove, 1995). In this respect and as deduced from the previous discussion, agility is used in a broader sense. This being the primary reason for the focus on IT infrastructure agility instead of flexibility.

AGILE IT INFRASTRUCTURES

IT infrastructure plays a critical role in an organization's competitive advantage as it is the enabling foundation of shared information technology capabilities upon which business depends (McKay & Brockway, 1989). IT infrastructure includes the hardware, operating systems, software applications, data, and the underlying network required to support business operations, as well as the enterprise personnel that interacts with it. Consequently, it comprises two interrelated but distinct components: (a) technical IT infrastructure and (b) human IT infrastructure (Broadbent & Weill, 1997). Enterprise agility requires both components to be agile. The following paragraphs explain the meaning of agility in human and technical IT infrastructure.

Agility in Human IT Infrastructure

Agility in human IT infrastructure implies that the relevant employees have adopted the perspective that they work in an unstable environment where any change may occur at anytime and that they have the skills, knowledge and expertise to cope with change efficiently. To be specific, managers should be able to make the right decisions at the right time, while other employees, such as software engineers and business process owners, should have the knowledge to immediately configure or implement a solution. According to Lee, Trauth and Farwell (1995), human IT infrastructure needs four types of knowledge and skills: technology management, business functional, interpersonal, and technical. Technology management knowledge and skills concern an understanding of where and how to deploy IT effectively and profitably by achieving the strategic goals of an enterprise. Business functional knowledge and skills refer to the ability to understand business problems and develop the required technical solutions. Interpersonal and management knowledge and skills involve abilities such as planning, organizing, teaching, and leading. Lastly, technical knowledge and skills include abilities in technical areas, such as computer operating systems, telecommunications, application specific software, and so forth.

Agility in Technical IT Infrastructure

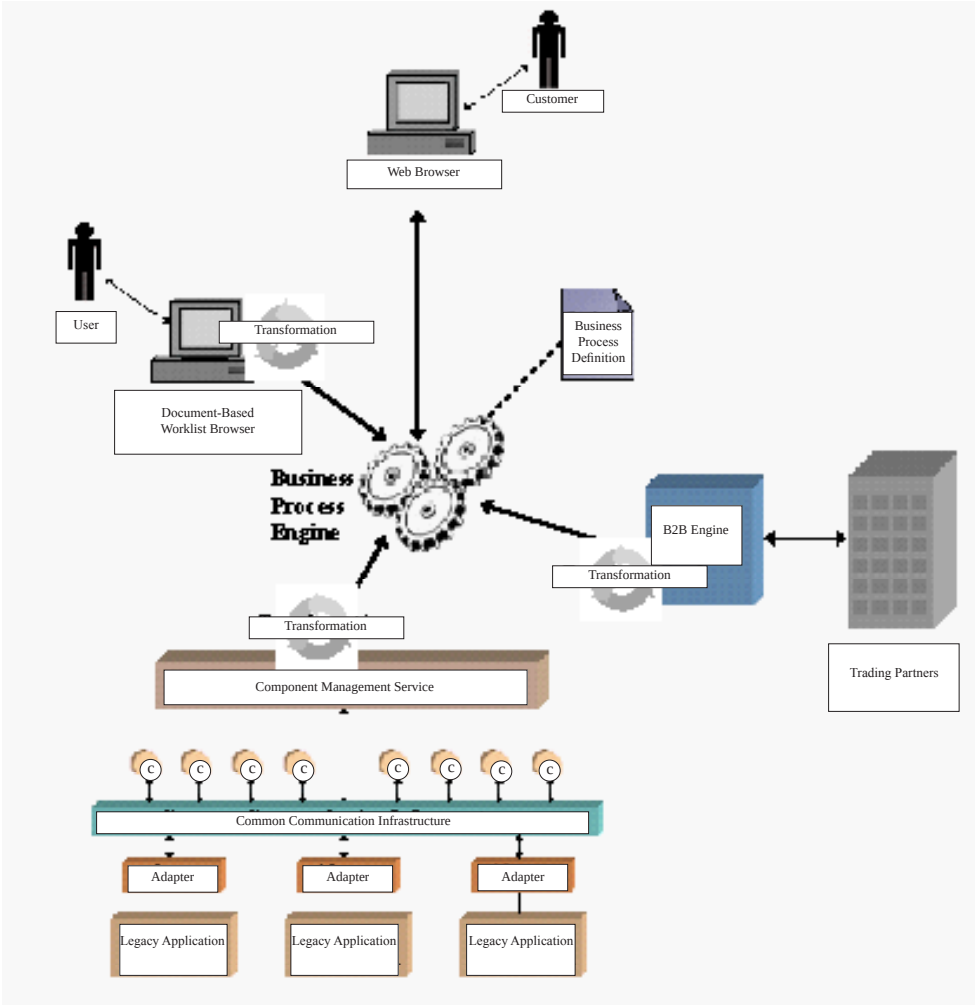
Agile IT infrastructure is one that has been developed according to an agile IT architecture. IT architecture is a framework which forms a guide for an IT infrastructure implementation by indicating technology components in an integrated view that shows how they collaborate to deliver business or technical services. Earl (1989) suggests a typical IT architecture has blueprints for the computing, data, communications, and the application systems of the organization. When an IT architecture is not developed down to a detailed technical level and forms a more abstract view instead, it is called *conceptual architecture*.

In order to be deemed agile, a technical IT architecture should offer a high degree of automation, integration, and flexibility (Alexopoulou, Kanellis, & Martakos, 2004). A conceptual agile IT architecture is illustrated in Figure 1. This architecture ensures high automation because it is based on executable business processes. An executable business process is a kind of enterprise process, whose life cycle is controlled by a business process engine (Nickull et al., 2001). Executable business processes are described in XML-based business process languages such as Business Process Modeling Language (Assaf, 2001), XLANG of Microsoft (Thatte, 2001) and Business Process Execution Language (Thatte et al., 2003), which are machine-readable.

As shown in Figure 1, the Business Process Engine (BPE) constitutes the heart of the architecture since it interacts through the exchange of messages with: (a) users via a document-based Worklist Browser, (b) customers via a Web Browser, (c) trading partners via the B2B engine, and (d) applications and components via the component management service (CMS). The BPE reads and executes business logic defined in process definition documents and acts as a coordinator of activities spanning across the enterprise entities, invoking for each activity the entity that is responsible for performing it. Whenever messages sent by the BPE need to be transformed into another format, a transformation mechanism is used. For example, if a message is to be directed to a worklist browser, it must be first transformed into HTML. Likewise, at the application component level, if for example CORBA (Common Object Request Broker Architecture) is used, then the messages sent by the BPE will have to be transformed into CORBA IDL messages. Overall, the B2B engine will have to transform them onto the format required by the protocol used in the specific business collaboration, since the B2B engine is able to support various B2B protocols (Dabous, Rhabi, Ray, & Benatallah, 2003).

The CMS finds and invokes the appropriate application components that deliver the requested business service. These components are called business aware components, while the components implementing the fundamental

Figure 1. Agile IT architecture (Source: Alexopoulou et al., 2004)



infrastructure services are called framework service components (Raymer, Afrin, & Trivedi, 2001). The components can intercommunicate over a common communication infrastructure. Legacy applications can be connected to the communication infrastructure via adapters. The CMS together with this infrastructure constitute an enterprise application integration (EAI) (Puschmann & Alt, 2004) which follows some of the principles of the NGOSS (New Generation Operations System and Software) framework (Raymer, Afrin, & Trivedi, 2001). NGOSS is an initiative of the TeleManagement Forum set to develop a framework for rapid and flexible integration of operations and business support systems in telecommunications, but it can be equally applied to other business areas as well. NGOSS defines a service-oriented modular system framework, which is based on a collection of loosely coupled, re-usable components that perform business services. Two very good candidates for the implementation of NGOSS are Web Services (Fremantle, Weerawarana, & Khalaf, 2002) and the Java 2 Platform Enterprise Edition (J2EE) architecture (Sun Microsystems, 2003). Web services are loosely-coupled, re-usable software components that semantically encapsulate discrete functionality and are distributed and semantically accessible over standard Internet protocols (Stencil Group, 2001). J2EE is a set of specifications for developing multi-tier enterprise applications in Java.

The integration and flexibility capabilities of this architecture are described at three different levels, namely application components, data, and business process level, in Table 2.

Table 2. Integration and flexibility capabilities of agile IT infrastructures (Source: Alexopoulou et al., 2004)

	Integration	Flexibility
Business Processes	Support for business processes that span multiple applications regardless of whether these applications belong to a single or to different companies.	A business process definition can be altered without requiring modification of the application components.
Data	Data reside in any data source anywhere and can be used by any application or system anywhere.	Data can be easily transformed from one format to another at run time.
Application Components	Components can communicate efficiently with each other as well as with legacy applications.	New components can be easily embodied into the existing architecture and also components can be re-used across multiple business scenarios.

HOW AGILE IT INFRASTRUCTURES CONTRIBUTE TO ENTERPRISE AGILITY

The sensing agility of an enterprise is facilitated by agility in human IT infrastructure, since timely discerning an imminent need for change depends on the knowledge, experience, and skills like perspicacity of the relative enterprise personnel. However, the acquirement of the necessary knowledge is significantly facilitated by an agile technical IT infrastructure as the latter ensures the availability of the right information at the right time by enabling a seamless flow of information.

As far as response enterprise agility is concerned, it is equally facilitated by agility in both human and technical IT infrastructure. Human agility implies that the right decisions are timely made in response to a change. On the other hand, an agile technical IT infrastructure provides for a rapid and cost-effective implementation of the decided-upon solutions. Following, we will further elaborate on the way the agile IT architecture described earlier accommodates change.

According to Dove (1994b), an agile enterprise can employ business process reengineering as a core competency when a transformation need arises. In the described architecture, abstraction of the business process flow into an entity (BPE) separate from the application components themselves allows an easier and more flexible way to alter the business process logic whenever new circumstances arise or a modification is needed. The only action required in such a case is an update in the business process definition that is executed by the BPE, while no modification is needed at the application component level. Separating process control removes the need for the individual components to have knowledge of the business logic associated with process operation. When invoked by process control, a component simply performs the service offered through its interface. Also, components can be re-used across multiple business scenarios.

To achieve even greater flexibility at runtime, business process definition could follow the methodology described by ShuiGuang, Zhen, ZhaoHui and LiCan (2004). According to this methodology, a business process is composed of *general activities*, which are predefined in detail at design time, and *flexible activities,* which are like a "black box", representing an undetermined sub-process without detailed specification at build-time. In other words, flexible activities encapsulate the uncertain sub-process at run time. At run time, depending on current circumstances, a flexible activity can be replaced by a concrete sub-process composed of selected activities from existing or newly-added activities (constituting a pool of activities) based on selection and composition constraints.

However, this method implies that activities included in the aforementioned pool correspond to predictable situations, but what about the case of a situation that has not been predicted? Agility, as we mentioned earlier concerns also efficient response to unexpected change. In case of an unexpected change, the required services to accommodate it may not be offered by the existing IT infrastructure simply because the relevant application components may not exist. In such a case, the most important role is played by the human IT infrastructure because it has to be decided whether the

required services will be outsourced or developed in-house or acquired through commercial, off-the-shelf products. As agility is a function of both cost and time (Dove, 1995), it cannot be claimed that a specific solution will be a panacea to all situations.

From the perspective of an agile technical IT infrastructure, the only contribution that can be offered is the facilitation of an easy and rapid incorporation of the new application into the existing infrastructure; either this application has been developed in-house, purchased, or outsourced. The aforedescribed IT architecture supports plug and play components, which means that new components can be easily embodied into the infrastructure and communicate with the already existing applications via the common communication vehicle.

FUTURE TRENDS

As stated earlier, software implementation may be inevitable in case new services are required upon an environmental change. However, as programming is a difficult and time-consuming task, developing models instead of code would significantly augment enterprise agility. Toward this direction, several initiatives have already emerged. Borland is developing a software product called Themis, which will have a module that will turn models automatically into programming code (*The Economist*, 2004). OMG has proposed the Model Driven Architecture (MDA) (www.omg.org/mda) initiative that addresses the problem of integration and interoperability by making UML models and modeling artifacts more executable. In other words, MDA is about using modeling languages as programming languages rather than merely as design languages. Likewise, Web Modeling Language (WebML) (www.webml.org), which is a notation for specifying complex Web sites at a conceptual level, enables a model-driven approach to Web site development. It is expected that this shift of emphasis on models and their automatic translation to source and object code underlines the trends for both research and practice in this area.

CONCLUSION

The pace of business change drives organizations to respond as quickly as possible. In order to cope with continually changing environments they have to be agile. IT infrastructure facilitates and enables agility within an organization. From a technical perspective, an agile IT infrastructure requires a high degree of automation, integration and flexibility. The fact that this paper focuses mainly on technical IT infrastructure does not imply that the human part has less impact on enterprise agility. In fact, human IT infrastructure also plays a critical role in an organization's ability to sense environmental change and respond efficiently and effectively to that change. Even if a "super agile" technical IT infrastructure has been developed, it will be of no value at all if the relative personnel are unable to understand and adjust to new circumstances. Humans are key players; they discern environmental changes and make the appropriate decisions to cope with these changes. Of course, they must always be supported by an agile technical IT infrastructure. Otherwise stagnation will follow with the enterprise being unable to implement its strategies and hence ensure its continuous profitability and survival.

KEY TERMS

Agile Enterprise: A fast moving, adaptable and robust business, which is capable of rapid adaptation in response to unexpected and unpredicted changes and events, market opportunities and customer requirements.

Agile IT Infrastructure: A highly automated, integrated and flexible IT infrastructure which enables efficient and effective response to planned, as well as unanticipated change.

Agility: Efficient and effective response to planned as well as unanticipated change.

Executable Business Process: A kind of enterprise business process, whose life cycle is controlled by a Business Process Engine.

IT Architecture: A framework which forms a guide for an IT infrastructure implementation by indicating technology components in an integrated view that shows how they collaborate to deliver business or technical services.

IT Infrastructure: The enabling foundation of shared information technology capabilities upon which business depends.

Response Agility: The organizational capability to quickly transform knowledge into action in response to the environmental signals.

Sensing Agility: A firm's ability to rapidly discover and interpret the market opportunities through its information systems.

System: A group of interacting modules sharing a common framework and serving a common purpose.

Agile Knowledge Management

INTRODUCTION

This article is based on the assumption that Knowledge Management (KM) is a vital part of any project. Based on this working assumption, the purpose of this article is to introduce the term *Agile Knowledge Management* (AKM) by illustrating how the *Agile Software Development* (ASD) approach is suitable for the introduction of KM processes.

The ASD approach emerged over the past decade in response to the unique problems that characterize software development processes (Highsmith, 2002). In general, ASD emphasizes customer needs, communication among team members, short releases and heavy testing throughout the entire development process. These ideas are implemented quite variedly by the different ASD development methods.

Knowledge Management (KM) and Agile Software Development (ASD) are two organizational processes that face common barriers when introduced and applied. This article suggests that because the field of KM presents a less disciplined approach compared with ASD, it is logical that KM practitioners should learn how ASD has coped with very similar barriers. We further illustrate how it is but natural to emphasize the concept of *Agile Knowledge Management* (AKM) in order to improve KM processes, because ASD already encompasses the organizational and cultural infrastructure needed for KM.

The pairing of KM and ASD is not new; a connection between the two concepts has been acknowledged by various researchers. For related discussions, see, for example, Dove (1999) and Holz, Melnik and Schaaf (2003). This connection, however, is not surprising because both disciplines deal with organizational culture and change management.

In what follows, we further highlight the connection between the two fields. First, we show that the two processes, KM and ASD, face the same barriers when introduced into an organization. We also include some suggestions for coping with such barriers. Second, we highlight the way in which KM is already embedded into ASD processes. Thus, in order to improve KM in such processes, it should be made more explicit. Accordingly, we introduce an *agile* KM manifesto.

BACKGROUND

In today's competitive global market, companies are required to manage their intellectual resources as well as their financial ones. KM is therefore recognized as a legitimate management practice that helps organizations distribute the right knowledge to the right people at the right time (Van der Spek & Carter, 2003). Furthermore, KM is considered to be the main source of competitive edge for companies when facing new opportunities, time-to-market demands and frequent changes in their technological and business environments. At the same time, however, research reveals that some organizations do not apply systematic KM processes and support, but rather rely mostly on common sense. Barriers, such as competition instead of collaboration, cultural differences, the pressures of daily challenges, lack of communication tools and places to meet, stubbornness of people or lack of discipline within the company, might interfere (Van der Spek & Carter, 2003). In addition, cultural and job security issues prevent managers from investing in KM initiatives (Drucker, 1998).

Similarly, the main barrier when introducing ASD into software organizations is the need to cope with the conceptual change, mainly the organizational cultural change, that ASD brings with it. Following are two illustrations of the conceptual change required when applying the ASD approach.

First, cooperation should replace the knowledge-is-power perception. ASD introduces a management paradigm that encourages collaboration, communication and the *whole team* concept. At the same time, however, the software development culture, which has evolved over the years, sometimes encourages opposite values and manners, as expressed, for example, by the concealing of information and the isolating of people in cubicles. Second, in ASD processes, a change is required also in the customer's conception and involvement, as well as in customer-developers relations. ASD requires intensive and frequent communication with the customer. Clearly, this is a significant difference compared with the common level of interaction with the customer as practiced today in many software organizations.

Studies reveal that the introduction of KM and ASD processes increases productivity, shortens time-to-market and results in higher product quality (see, for example, Bennet & Bennet, 2003; Reifer, 2002). Yet, as mentioned above, it

is but logical that practitioners feel insecure when required to undergo such change. What is needed then in many cases is a realization that the new paradigm, whether it is KM or ASD, in fact constitutes a new and different infrastructure within it concerns can be addressed.

It is in this spirit that we further illustrate the close relationship between the two processes by presenting nine arguments that are often raised when KM and ASD processes are introduced. For each argument, we present one frequently-heard statement for KM and ASD, and suggest an approach for overcoming the said argument. This presentation format reflects both the similarity in the resistance to the two processes, as well as the similar way in which this resistance can be addressed in both cases.

I. "It is not needed at all"

KM: "Someone in the organization is already taking care of the KM process."
ASD: "Our organization already has a very well-defined development process that works just fine."
Possible response: "Can you please elaborate on the benefits and weaknesses of your current process?" In many cases, an attempt to answer this question reveals the problems that exist.

II. "Time does not permit"

KM: "I must deliver the project on time and I'm behind schedule. I can't devote any time to knowledge sharing." OR: "Do I have to invest any more work in order to manage knowledge?"
ASD: "I must deliver the project on time and I'm behind schedule. I can't devote any time to testing." OR: "How much extra time is needed in order to collect the metrics? Is it worth investing?"
Possible response: "What are the main reasons for the gaps between the project planning and the actual progress?" In many cases, it is found that the reasons given here further highlight the importance of some elements of KM and ASD processes.

III. "The current tools work very well"

KM: "We have tools for KM, such as WSS, which hosts many discussion forums."
ASD: "We already have a mechanism for sharing our metrics using an online tool that is accessible to all; why should we sit together in one lab/informative workspace?"
Possible response: "In your opinion, how frequently do people use or open this tool?" This question highlights the spirit of the first principle of the Agile Manifesto (see Table 1); namely, that we should address the people, not the tools. In other words, tools are useless unless they are simple and accessible and their use is integrated naturally into the work process itself.

IV. "We can't change the status of documentation"

KM: "We have documents that reflect the project knowledge."
ASD: "How can we develop software without comprehensive documentation? After all, the customer asks for it."
Possible response: "Based on your experience, are the documents always compiled along with the actual projects? Also, can you please estimate how often, if at all, the documentation is read?" In many cases, this question leads practitioners to realize the gap that exists between the perceived image and reality. Specifically, it highlights the fact that the documents produced in many typical processes are not the ones truly required (some do not reflect reality at all; others are never read). Rethinking the role of documentation reveals that documentation should not be skipped, but rather carried out in a way that allows for timely and relevant knowledge and information maintenance.

V. "I have had very bad experience with all these buzzwords"

KM: "KM is prosaic, what it is actually?" OR: "Has any business already implemented it? How do you even start a KM project?"
ASD: "There are so many buzzwords in software development. You must convince me that this is not just another one." OR: "It sounds good on paper as a theory. Does it really work?"
Possible response: "You can try to initiate a small scale KM/ASD project and observe its benefits. Also, you can read testimonies that will enable you to move from the abstract to the concrete." In both KM and ASD, experience shows that these processes work well in practice. In the ASD arena, this is manifested by the fact that more and more software houses are starting to work according to the agile software development paradigm[1]; in the case of KM, it is reflected by the increasing numbers of KM initiatives in organizations and the designation of a specific person to manage the organization's KM processes (Van der Spek & Carter, 2003).

VI. "The current working environment provides the mentioned benefits"

KM: "If I need information, I just go to the right person and ask him or her."
ASD: "It's impossible to sit together in one lab. It's too noisy. If I need to ask something, I just go to the right person and ask."
Possible response: "Can you describe what happens when

you find a bug and can't manage to fix it for several days." In many cases, the process described in response to this question starts with the person asking his or her roommate, then the lunch group and, if the person is lucky, he or she will sooner or later come across someone who knows the answer. It is also admitted that sometimes the answer is never actually found and the person asking the question must decide how to proceed without the required knowledge. The outcomes of such circumstances are clear.

VII. "But knowledge is power"

KM: "It is naïve to think that when I need the information, someone will share it with me."
ASD: "I'm the expert in this domain. How can I pair-program with someone who is new to this area?"
Possible response: "Let's think about your argument from a win-win perspective, rather than as a lose-lose situation. If you know something and you don't share it, the organization loses; furthermore, when you need help, you won't get it from your colleagues. This is a lose-lose situation. Let's change it to a win-win situation by sharing." Indeed, in both cases (KM and ASD), a process that ensures mutual trust should be established. See, for example, how it is accomplished in Extreme Programming (Beck, 2001, Beck & Andres, 2005), one of the leading ASD methods. Hazzan and Dubinsky (2003) analyze software development processes from the perspective of game theory and illustrate how Extreme Programming establishes a trustful development environment in which teammates are assured that their cooperation will be reciprocated. Thus, teammates apply agile practices. Although on the face of things, these actions can be perceived as a loss of power, a deeper understanding reveals the benefits that result from the collaborative atmosphere inspired by ASD.

VIII. "Too much money is needed"

KM: "Who should pay for KM?"
ASD: "We aren't sure that we can invest in the infrastructure needed for ASD. We need more computers and we must make changes in the physical space."
Possible response: "Can you please estimate how much you pay for extra hours/delays or for reinventing the wheel?" When this question is answered, it is appropriate to present data on the expected improvements due to KM and ASD processes. For example, with respect to KM, Bennet and Bennet (2003) claim that "those organizations that have found ways to compete successfully within this nonlinear, complex, and dynamic environment can dominate their competitors by as much as 25% in growth rate and profitability relative to the average in their industry" (p. 9). Similarly, Reifer (2002) shows a 25%-50% decrease in time-to-market for ASD processes.

IX. "But the stakeholders are happy now"

KM: "KM is not a standard in our processes."
ASD: "The customers are happy now. They don't ask for it, so why should I invest in it?"
Possible response: "This might be the case now. But let's think about a time when your customer no longer agrees to pay more if your competitors, who manage knowledge or develop software using an agile process, manage to develop a better product in a shorter period of time." Realization has recently set that KM and ASD processes are expected to become more prevalent because customers will no longer agree to pay more when they can receive a better product in a shorter period of time if KM/ASD processes are applied. Accordingly, KM/ASD processes can be viewed as disruptive technology—in the near future customers will start requiring it and organizations that have not adopted it will fall behind.

KNOWLEDGE MANAGEMENT IN AGILE SOFTWARE PROJECTS

The message conveyed in this section is that KM has the potential to be easily accepted into ASD environments. Following are two explanations for this perspective. First, the agile cultural infrastructure already includes values such as cooperation and knowledge sharing; specifically, ASD processes include some practices that support KM, such as stand-up meetings, the planning game, pair programming and the informative workplace. Second, KM is about learning, and ASD establishes an environment that supports learning processes (Hazzan & Dubinsky, 2003).

We suggest that although many software project managers believe in the importance of KM, the resistance exhibited toward KM results from the fact that the actual knowledge on the application of KM does not exist. We therefore propose that by making KM elements more explicit in ASD environments, the barriers presented above, as well as others, can be at least partially overcome. Furthermore, because ASD is based on knowledge sharing and communication, we suggest that ASD also benefits from the fact that the KM elements are clearly specified. This approach is compatible with Holz and Melnik (2004) and Doran (2004).

Following are several illustrations of the natural integration of KM into ASD processes. The AKM activities presented in what follows can be integrated into each of the specific agile software development methods (e.g., Extreme Programming and Scrum).

- **The role of knowledge manager:** Because different agile methods outline different role schemes[2], we suggest assigning one team member to be in charge of the KM process. In large organizations, the group of

people who are in charge of KM can form a KM team that is entrusted with leading the entire organization's KM. The KM officer in each team gathers the relevant issues that are to be discussed in the global organization meetings and brings back new information to his or her team.

- **Retrospective meetings:** A special session can be dedicated to KM issues in the framework of the retrospective meetings. This session might include topics such as new tools used in the latest release and lessons learned during the development of new features. It implies that the entire KM process is also carried out in short releases, as ASD is.
- **Planning game:** In each planning game, time will be allocated during the next iteration for specific KM activities, if needed, as practiced with respect to other tasks that improve the developed product and the development process.
- **Informative workplace and collective ownership:** Each new piece of knowledge can first be posted on the project's whiteboard. Then, these pieces will be evaluated in the framework of retrospective meetings. If they are found to be significant, they will be stored at the end of the iteration/release in a predetermined place.
- **Metrics:** Metrics related to KM will be measured on a regular basis as customary with respect to other aspects of ASD projects. If they are found to be useless, they will be adjusted accordingly.
- **Adaptability:** The development of AKM should gradually encompass all phases and activities of the development process (e.g., requirements, design). The suitable AKM solution for each phase will be shaped and its applicability checked continuously. Because, as previously mentioned, knowledge management activities sometimes create antagonism, we suggest that the agile spirit of the change introduction will render the AKM activities more agreeable.

FUTURE TRENDS

We propose that KM processes should be approached like any other project in the organization. This attitude is compatible with Bailey and Clarke (2000), who state that their "definition of KM as how mangers can generate, communicate and exploit knowledge (usable ideas) for personal and organizational benefits" highlights not only the organizational importance of KM, but also its relevance for individual managerial action. "The challenge therefore is to make KM ideas current, relevant and actionable to diverse organizational/managerial user groups" (p. 237).

As mentioned previously, we suggest that at least part of the resistance exhibited toward KM results from the fact that the actual daily application of these processes is not clear. The agile community has already, at least partially, overcome this barrier, whereby specific agile methods, based on a general manifesto[3], are applied on a daily basis.

In this spirit, we present the Manifesto for Agile *Knowledge Management* (AKM) projects based on the Manifesto for Agile *Software Development*, highlighting the changes we made in bold-face type (see Table 1).

For illustration purposes, we show how the Manifesto for AKM can be implemented with respect to Extreme Programming values:

- **Communication:** Use communicative channels in order to make implicit KM an explicit process.
- **Simplicity:** Use simple solutions that can be embedded in the work process in order to exploit the essence of KM.
- **Feedback:** The team members are the AKM activities' customers. Their feedback should be heard to create a vivid AKM environment.
- **Courage:** Team members should feel comfortable when reviewing and reporting on good or bad practices.
- **Respect:** Team members should respect each other by knowledge sharing, not considering knowledge

Table 1. The manifesto for AKM and the manifesto for ASD

Manifesto for AKM	Manifesto for ASD
We are uncovering better ways of **managing knowledge** by doing it and helping others do it.	We are uncovering better ways of **developing software** by doing it and helping others do it.
Through this work we have come to value:	
- *Individuals and interactions* over processes and tools. - **Sharing knowledge** over comprehensive documentation. - *Customer collaboration* over **persuasive** negotiation. - *Responding to change* over following a plan.	- *Individuals and interactions* over processes and tools. - **Working software** over comprehensive documentation. - *Customer collaboration* over **contract** negotiation. - *Responding to change* over following a plan

retaining as power. Time should be devoted to knowledge sharing activities, respecting it as a means that augment the work process for the benefit of all team members.

CONCLUSION

KM and ASD are essentials in the competitive global market in which organizations are required to respond to customer demands in a timely manner (Bennet & Bennet, 2003; Van der Spek & Carter, 2003). Both disciplines are abstract, deal with intangible artifacts in a competitive market and face common barriers. In this article, we suggest that agile processes can be an appropriate infrastructure for the enhancement of KM. Good practices adopted from ASD, which is a more mature discipline, can help managers overcome their initial resistance to KM, initiate KM projects and embed the KM process into the working process. We call this approach *Agile Knowledge Management*.

KEY TERMS

Agile Knowledge Management: Agile knowledge management is the working framework introduced in this article and it is based on good practices adopted from agile software development. Agile Knowledge Management can help managers overcome their initial resistance to knowledge management, initiate knowledge management projects and embed the knowledge management process into working processes.

Agile Knowledge Management Manifesto: This manifesto, which we suggest in this article, adopts and enhances the common principles of agile software development for knowledge management processes.

Agile Manifesto: This manifesto reflects the common principles of all agile software development methods. It is presented at http://agilemanifesto.org/.

Agile Software Development: Agile software development is a management paradigm for software development projects. It emphasizes customer needs, communication among team members, short releases and heavy testing throughout the entire development process. These ideas are implemented quite variedly by the different agile software development methods.

Extreme Programming: Extreme programming is one of the agile software development methods. It is based on a list of principles and practices that reflect the method's values. It is accepted as one of the prevalent agile software development methods.

Extreme Programming Values: Extreme programming is based on five values: Communication, Simplicity, Feedback, Courage and Respect. We suggest adopting those values for AKM processes.

Knowledge Management: Knowledge management is the way knowledge-based companies manage their intellectual assets in order to gain a competitive advantage. Knowledge management includes three dimensions: technology infrastructure, business processes and cultural change.

ENDNOTES

1 Although there is less than 10 years of accumulated experience using the agile approach, it is currently being applied as the development paradigm by about 20% of the companies in North America and Europe. Source: http://www.versionone.com/pdf/AgileMyths_BetterSoftware.pdf

2 See Dubinsky and Hazzan (2006) for a summary of these role schemes.

Agile Methodology Adoption

John McAvoy
University College Cork, Ireland

David Sammon
University College Cork, Ireland

INTRODUCTION

Discussions on agile software development methodologies have a tendency to develop into an argument between proponents of agile methods and proponents of more traditional process-oriented methodologies. The terminology used in these debates is often unhelpful, and in many cases are inaccurate and biased representations. It needs to be accepted that there are no "silver bullets" providing universal solutions (Jeffries, 2001). Bearing this in mind, the decision to adopt a particular software development methodology is a difficult one, and the decision to choose an agile method is no exception. In theory, as in practice, definitions and descriptions of the various agile methods are presented, yet the factors considered in the decision to adopt, or not adopt, an agile method are not addressed. While agile methodologies try to avoid the excessive use of procedures or tools (Beck & Fowler, 2001), one agile methodology, dynamic systems development method (DSDM), does recommend the use of appropriate tools during the development process (Coesmans, 2003). However, it appears that none of the available agile methodologies suggest a tool to assist decision makers at the project initiation phase, therefore, the debate on agile suitability is usually a debate on agile versus traditional methods (DeMarco & Boehm, 2002), rather than an examination of the suitability of agile methods for a particular project. While the "agile debate" rages, individual projects are not adequately assessed prior to the adoption of a method.

BACKGROUND

To describe the agile method is a misnomer. The agile software development method does not exist; it is instead a collection of methodologies with common core values, where examples of agile approaches include: Extreme Programming (XP); Crystal Methods; SCRUM[1]; DSDM; Feature Driven Development (FDD); and Adaptive Software Development (ASD) (Highsmith, 2001; Sutherland, 2001). For many proponents of the agile methodologies, the epoch of the agile movement was February 11th, 2001, when representatives of the different agile methodologies convened in the mountains of Utah to create the "Manifesto for Agile Software Development."

The agile manifesto is a collection of values that underlie all agile methodologies:

- Individuals are more important than processes and tools.
- Working software is more important than comprehensive documentation.
- Customer collaboration is more important than contract negotiation.
- Responding to change is more important than following a plan.

Therefore, agile methods are a response to the inability of traditional methods to embrace change in a turbulent business environment that demands software to meet its needs quickly (Highsmith & Cockburn, 2001), and Rising and Janoff (2000) describe it as the need to "meet customer needs and turn this chaos to our advantage" (p. 3). The manifesto, its origins, and its importance to the agile methods are discussed in a variety of research including: Boehm and Turner (2003, 2004); Fowler and Highsmith (2001); Highsmith (2004); Koch (2004); and Lindvall et al. (2002).

VIABILITY OF ADOPTING AN AGILE APPROACH

Throughout the available literature relating to agile methodologies, factors important to the success of an agile project are discussed, yet these factors are not specifically used to determine the viability of adopting an agile approach. For example, the agile manifesto, described in Abrahamsson, Salo, Ronkainen, and Warsta (2002), is a list of aspirations or ideals, and as such is not readily quantifiable as a method of adoption assessment. However, some researchers have provided a number of approaches to assessing various aspects of suitability for agile.

Boehm and Turner (2003, 2004) provide five factors (or dimensions, to use their term) in a graphical approach to assess whether an organization is an agile or more traditional organization. Boehm and Turner's (2003, 2004) graphical

analysis provides an evaluation of whether an agile or process-oriented (they use the term disciplined) approach represents the current state of a project or organisation. The graphical output highlights, by the location of ratings on five axes, whether the project or organisation, is leaning towards agile or disciplined (see Figure 1).

Boehm and Turner (2003, 2004) list five critical agile/disciplined decision factors:

- the criticality of the project (the level of loss due to the impact of defects),
- the dynamism of the project (level of requirements change),
- the size of the project,
- the expertise of the team, and
- the culture of the project or organisation (empowerment versus process driven).

McAvoy and Sammon (2005) investigate the suitability of an agile approach for a project through conducting a series of workshops in a number of software development companies. McAvoy and Sammon developed a simple decision support tool, referred to as an Adoption Assessment Matrix, as illustrated in Figure 2, based on critical adoption factors relating to agile methods, addressing a need in industry; namely, to improve the overall understanding of the constituent parts of agile systems development methodologies. The critical adoption factors are described in more detail later on when discussing the groupings of critical adoption factors. It is argued by McAvoy and Sammon (2005) that the use of a decision support tool, aiding decision makers, to determine the viability of an agile method for a specific software project has proved hugely beneficial, for example, a major benefit of the tool is that it guides discussion, concentrating the debate on the critical factors, applied to the individual project. According to McAvoy and Sammon (2005), these discussions proved to be as valuable as the output of the tool itself. The results of these workshops show that an argument can be made for the use and benefit of such a decision support process in industry, in supporting the decision to adopt an agile approach.

The research work of Boehm and Turner (2003, 2004), and McAvoy and Sammon (2005) presents a high-level grouping of factors which can form the basis for a discussion around the agility of an organization, a particular project and its suitability for an agile approach, while assessing the likelihood of success. These groupings referred to as *project; customer; team;* and *organisation* are open to debate and refinement. Like any list, for example, be it top 10 athletes or favorite music, there will never be universal agreement on its constituent parts. The list is not set in stone, but an extremely important starting point. For example, both Boehm and Turner (2003, 2004), and McAvoy and Sammon (2005) agree on the issue that criticality of a project is an important factor (life-critical projects should be automatically excluded as possibilities for an agile approach), while McAvoy and Sammon add factors relating to the relationship with the customer as also warranting consideration. These groupings are discussed in the next section.

Figure 1. Boehm and Turner (2003, p. 5) graphical scatter plot

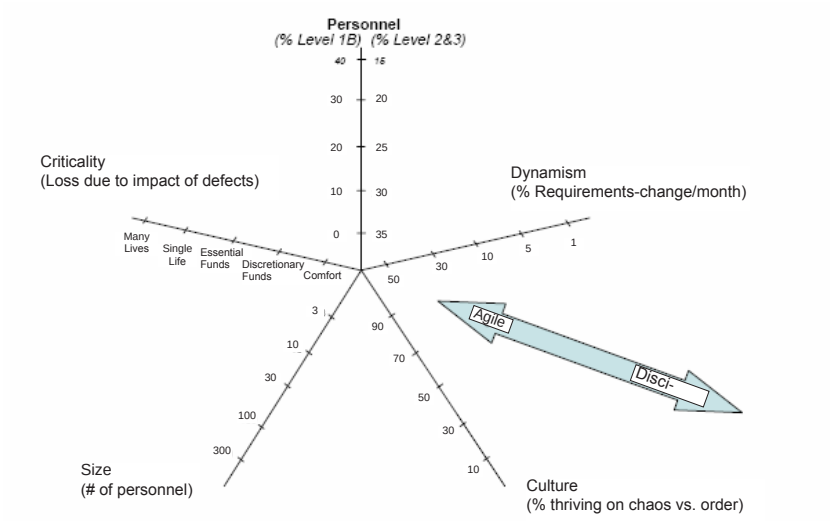

Figure 2. Adoption Assessment Matrix

Critical Adoption Factor	Weighting	Rank Case	Result Case
Duration of the project 1=more than 5 years 2=less than 6 months	4		
Location of the customer 1=many customers in many countries 5=In house	4		
Customer involvement 1=will have no interaction 5=willing to interact	4		
Acceptance of change (to requirements) 1=rigid 5=flexible	4		
Team size 1=more than 20 5= up to 3	3		
Skill of team 1=inexperienced 5=very experienced	3		
Organisational and reporting structure 1=many reporting layers 5=flat structure	2		
Process 1=5 or more standards to follow 5= no standards to follow	2		
Documentation requirements 1= a lot of documentation required 5= very little documentation required	1		
Layout of Workspace 1= individual cubes, people isolated 5= open plan, no walls	1		
Confidence Rating	**28**		

Note on Workings of Matrix:

[1] Rankings (between 1 and 5) are applied to each of the critical adoption factors. These rankings are based on a workshop participants assessment of the factors applicability to a particular project.

[2] Each ranking is multiplied by the weighting for each critical adoption factor, providing a result for each critical adoption factor.

[3] Finally, the totalled output, referred to as the 'confidence rating' is calculated as follows:

Confidence Rating Calculation = (SUM(Result Case)/(28*5))*100

A DISCUSSION ON THE GROUPINGS OF CRITICAL FACTORS

The *project* grouping describes the relevance of critical adoption factors when considering the mechanics of the project being undertaken. Issues of importance that can impact on the appropriateness of adopting agile methods include: the duration of the project; increasing uncertainty and changing requirements within the project; and the criticality of the project. "Today's project manager must deliver concrete results in shorter time frames while being constantly bombarded with myriad changes and risk laden decisions" (Highsmith, 2001, p. 260). This concern aligned with Kruchen's (2001) criteria of reacting quickly to market, impose a shorter time frame on agile projects. A core value of agile development is the acceptance of change, usually visible through changing requirements. Highsmith (2002) proposes that as the uncertainty associated with a project increases, the suitability of the agile approach will also increase. Kirkpatrick, Walker, and Firth (1992) describe the changing of requirements (requirements volatility) as one of the major sources of risk in a project. However, this directly contradicts the agile viewpoint, while stories and requirements definitions in the agile methodology continue to be written throughout the project. This is regarded as one of the basic edicts of the agile approach (Beck & Fowler, 2001). Finally, agile techniques, such as ASD are unsuitable for critical systems, such as air traffic control software. However, this is not a major concern as the majority of systems do not have this degree of criticality (Emery, 2001).

The *team* grouping highlights the importance of the project team, in terms of team size and skill level of the team, for adopting agile methods. While the team size is important, it is not of vital importance. Boehm (2002) describes how agile development is optimal when used in small teams. The skill level of the team is a continually stated requirement in research into agile methods. Martin (2003) further defines skill level by stating that a strong player does not necessarily have to be an expert programmer, though they must work well with others. Good communication skills and an ability to interact with others are of higher importance than expertise in a programming language. Furthermore, Reifer (2002) makes an interesting observation, which may have repercussions for agile research and implementation. Reifer (2002) surveyed 31 agile projects across eight industry sectors and comments that the teams involved were made up of motivated, experienced programmers in cohesive teams.

The *customer* grouping describes the customer, or customers, of the project, identifying location of the customer and customer involvement as critical adoption factors to consider in adopting an agile methodology. Beck and Fowler (2001) are willing to compromise on the definition of customer. The customer is the person who makes the business decisions, that is, completion date, scope, and so forth. This person can be an internal product manager or an individual who will purchase the software. Young (2003) describes how a DSDM project in British Airways addressed the necessity for user involvement in DSDM projects. The project was in the area of e-commerce, so its user base was extensive and difficult to categorise. British Airways used sales and marketing staff to represent the customers.

The *organisation* grouping highlights the criticality of the organisational environment, which comprises the following: organisational and reporting structure; process; documentation requirements; and layout of workspace. Boehm (2002) states that agile methods require both responsive people and organisations. The relationship between managers and developers is one of collaboration rather than the traditional command and control structure (Cockburn & Highsmith, 2001).

It is clear that process, or the lack of process, plays a significant role in agile methods (Highsmith, 2000). Discussing the agile concept and the importance of individuals over process highlights that "a good process will not save the project from failure if the team doesn't have strong players" (Martin, 2003, p. 4). Therefore, the absence of rigid processes is embraced. "Fast companies have a defining sense of purpose, supported by a few simple rules. They determine

what is essential and ignore the rest" (Gandossy, 2003, p. 32). For example, Greening (2001) describes the difficulties involved in the implementation of XP, in a company that has a formal software development process. A variation, or continuation, of the discussion on process is the documentation requirements of an agile project. Greening (2001) stresses that XP does not prohibit documentation, it merely stresses that documentation has a cost. Any documentation to be used must be evaluated to ensure that it has a benefit and that it is definitely necessary. The layout of the workplace receives considerable attention in literature on agile methods. Poole and Huisman (2001) describe the efforts made in Iona Technologies to enhance team communications. The previous environment they describe resembles that of the Dilbert cartoon. The multiple bays of shoulder height cubicles were replaced by a common area, or group workspace. This was an attempt to increase awareness of the team, as opposed to individuals in their own tiny spaces. Kalita (2003) demonstrates that colocated teams, although not a formal principal of DSDM, should be used in DSDM projects to facilitate the necessity of communications.

FUTURE TRENDS

The assessments of Boehm and Turner (2003, 2004), and McAvoy and Sammon (2005), while similar, are addressing different needs. However, there is benefit in combining both approaches to determine the "as is" state and the potential future or "to be" state of an organisation or project team. Ultimately, if an agile approach is indicated as having value and merits consideration, following the two assessments, further work could be done in determining how to adopt an agile method. An example of this "how" is presented in Pikkarainen and Passoja (2005), who describe a case study of how an assessment was conducted to determine which of the agile practices were suitable for a product development organisation. They recommend the tailoring of the agile approach to match the needs of the organisation. Although the case study describes one organisation, they propose that the assessment could be used in further organisations. Finally, in analysing these perspectives it is important to raise an extremely important point concerning the use of these tools proposed by Boehm and Turner (2003, 2004), and McAvoy and Sammon (2005), such that; although agile methodologies recommend limited use of tools, the purpose of the tools proposed by Boehm and Turner (2003, 2004), and McAvoy and Sammon (2005) is to support decision makers in (1) identifying the current state of an organizations agility and (2) assessing the suitability of adopting an agile approach to a project and the likelihood of success. Therefore, one should consider the use of these support tools to be a precursor to the selection and use of an agile methodology.

CONCLUSION

Agile methods have been described as glorified hacking by those who argue against their adoption and use. A more structured approach to the assessment of the adoption of an agile method would help to dispel these views. Some work has been carried out highlighting this argument; for example, Svensson and Host (2005) investigated the introduction of an agile method and concluded that an assessment should have been done before the project. As an example, by aligning all the assessment methods discussed in this chapter, an investigation could provide the following insights:

1. Identify the current state of an organizations agility.
2. Identify if an agile approach would be successful.
3. Identify what processes to use when adopting an agile approach.

As managers look to agile methods as a solution for the myriad of problems inherent in software development, there can be a rush to judgment, where an assumption is made that an agile approach will work for a project. Projects are rarely assessed prior to the adoption of an agile method. Ultimately this will increase the likelihood of problems and ultimately the failure of projects. However it is worth considering that problems that occur during agile projects could have been predicted if a proper assessment had been conducted and steps taken to mitigate these potential problems. On the other hand, an assessment could determine that an agile method would be unsuitable for a project, and considerable time and effort could be saved. The debate is moving on from pro- and anti-agile to one of the acceptance of agile in certain circumstances. The view of the agile method as a "silver bullet" should not exist so there is a necessity to determine which projects could benefit from an agile approach and which projects need a more traditional process-based approach.

Applying an "engineering" approach to the adoption of agile methods in no way diminishes the core values of the agile approach. Agile recommends against the overuse of tools, but this applies to the use of tools within the project. Using assessment tools to determine if a project should be an agile one is a necessary precursor to adopting an agile method.

KEY TERMS

Adoption Decision: The decision to adopt a methodology where the various relevant factors are considered and discussed to determine the viability of adoption.

Agile Approach: The primary goal of agile approaches is to ensure adaptability in the ever changing environment that teams operate in, to ensure quick delivery of product to the customer, matching the customer's requirements.

Agile Manifesto: The Agile Manifesto is a list of four values that the different agile methods consider to be their common core values.

Disciplined Approach: These approaches utilise standards and processes to ensure conformance to acceptable standards and best practices. The primary goal is to ensure delivery of software products of high quality.

Life Critical Projects: The criticality of the project is determined by its impact on its users, rather than the impact on the development organization. There are degrees of criticality with life critical at one extreme (life critical implying the potential loss of life through malfunctioning of the software product) or at the other extreme the effect on the comfort of the user (a poorly designed screen causing eyestrain).

Software Development Methodology: A codified set of practices that are adhered to, to ensure a successful project.

Software Development Project: A temporary endeavour undertaking the creation of a unique software solution for a customer.

ENDNOTE

[1] SCRUM is not an abbreviation, it is a rugby term used to depict a strategy meeting which gets an out of play ball, back into play.

Alignment of Business and Knowledge Management Strategy

El-Sayed Aboud Zeid
Concordia University, Canada

INTRODUCTION

The role of knowledge as a crucial asset for and enterprise's survival and advancement has been recognized by several researchers (e.g., von Krogh, Ichijo, & Nonaka, 2000). Moreover, by having knowledge (intellectual resources), an organization can understand how to exploit and develop its traditional resources better than its competitors can, even if some or all of those traditional resources are not unique (Zack, 1999). Therefore, knowledge management (KM-) strategy has to be solidly linked (aligned) to business (B-) strategy in order to create economic value and competitive advantage.

Several authors clearly indicate the importance of mutually aligning business strategy and KM efforts and how this alignment helps enhance organizational performance (e.g., Earl, 2001; Ribbens, 1997). For example, Maier and Remus (2001, 2002, 2003) propose a process-oriented approach that considers market-oriented factors in a KM strategy. In this approach KM strategies can be described according to the process focus and type of business processes supported (Maier & Remus, 2001). The process focus can extend from a single business process to an organization-wide perspective, including all relevant business processes (core and service). The type of process is related to the identification of knowledge-intensive business processes. In addition, Sabherwal and Sabherwal (2003) empirically found that the cumulative abnormal stock market return (in the five-day event window) due to a KM announcement is positively associated with the alignment between the firm's business strategy and the attributes of the KM initiative announced. They use four attributes to characterize KM initiatives: KM level, KM process, KM means, and knowledge source. KM level concerns the hierarchical grouping of individuals upon which the KM effort described in the announcement is focused. The KM processes (or K-manipulating processes) involve the sharing, utilization, or creation of knowledge, while KM means involve organizational structural arrangements and technologies that used to enable KM processes (Earl, 2001; Hansen, Nohria, & Tierney, 1999). Finally, knowledge source reflects from where the knowledge originates.

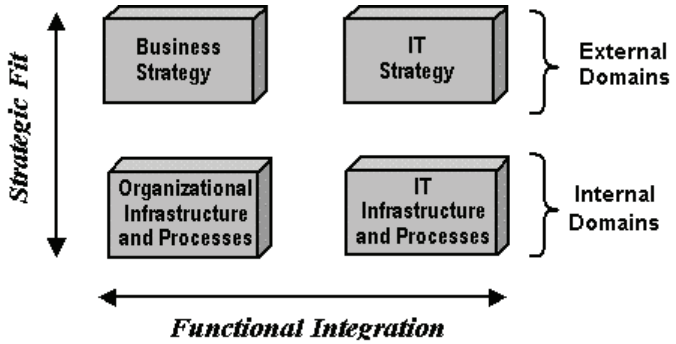
However, realizing the importance of aligning B- and KM-strategies in creating value and in gaining competitive advantage is only the first and the easiest step in any KM initiative. The second and almost as important step is to answer how and where to begin questioning (Earl, 2001). In fact this link has not been widely implemented in practice (see Zack, 1999, and the empirical studies cited there), and "many executives are struggling to articulate the relationship between their organization's competitive strategy and its intellectual resources and capabilities (knowledge)" (Zack, 1999). This is due to the lack of strategic models to link KM-strategy (knowledge [K-] scope, K-systemic competencies, K-governance, K-processes, K-infrastructures, and K-skills) and business strategy. As Zack (1999) argued, they a need pragmatic yet theoretically sound model. It has been highly accepted that a pragmatic and theoretically sound model should meet at least two criteria. First, it should explicitly include the external domains (opportunities/threat) and internal domains (capabilities/arrangements) of both B- and KM-strategies and the relationships between them. Second, it should provide alternative strategic choices.

In order address this issue a "KM strategic alignment model (KMSAM)" is presented. It stems from the premise that the realization of business value gained from KM investment requires alignment between the B- and KM-strategies of the firm and is based on the Henderson-Venkatraman (1993) Strategic Alignment Model for information technology (IT).

OVERVIEW OF THE HENDERSON-VENKARTAMAN STRATEGIC ALIGNMENT MODEL

The KM strategic alignment model is based on the theoretical construct developed by Henderson and Venkatraman (1993). In their model, business success is viewed as the result of the synergy between four domains. The first two, the external domains, are business-strategy and IT strategy. The strategy domains are described in terms of (business/technology) scope, (distinctive business/IT systemic) competencies, and (business/IT) governance. The second two, the internal domains, are organizational infrastructure and processes and IT infrastructure and processes. Both internal domains are described in terms of (administrative/IT) infrastructure, (business/IT) processes, and (business/IT) skills. This synergy is achieved through two types of relationship:

Figure 1. IT Strategic Alignment Model (Henderson & Venkatraman, 1993)



- **Strategic fit:** Emphasizes the need for consistency between strategy (external domain) and its implementation (internal domain).
- **Functional integration:** Has two modes and extends the strategic fit across functional domains. The first mode, *strategic integration*, deals with the capability of IT functionality both to shape and to support business-strategy. The second mode, *operation integration*, focuses on the criticality of ensuring internal coherence between organizational infrastructure and processes and IT infrastructure and processes.

Figure 1 shows the elements of the IT Strategic Alignment Model (ITSAM).

KM STRATEGIC ALIGNMENT MODEL

The premise of the original ITSAM is that "the effective and efficient utilization of IT requires the alignment of IT strategies with business strategies" (Henderson & Venkatraman, 1993). In a parallel way, the premise of KMSAM, in which knowledge strategy replaces IT strategy, is that "the effective and efficient use of organizational knowledge requires the alignment of knowledge strategies with business strategies." Since strategy, whether B-strategy or K-strategy, can be seen as a balancing act between the *external domain* (opportunities/threats) and the *internal domain* (capabilities/arrangements) of the firm (strengths and weaknesses) (Henderson & Venkatraman, 1993; Zack, 1999), the external and internal domains of K-strategy have first to be defined.

K-Strategy External Domain

In the case of K-strategy, the *external domain* involves three dimensions: *K-scope* (what the firm must know), *K-Systemic competencies* (what are the critical characteristics of the required knowledge) and *K-governance* (how to obtain the required K-competencies). The first dimension, K-scope, deals with the specific domains of knowledge that are critical to the firm's survival and advancement strategies. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability (von Krogh et al., 2000).

Determining the K-scope can be achieved by constructing a B-domain/K-thing matrix that documents the current and required state of organizational knowledge concerning some or all business domains. The first group of elements that constitutes this matrix includes the list of B-domains (B_i). The second group of elements includes the K-things (K_j) that describe the current state of knowledge associated with each of the relevant B-domains. To relate this knowledge to enterprise business-strategies, K-things are further classified according to the roles they play in such strategies. Von Krogh et al. (2000) have suggested that there are two types of strategies: survival and advancement. Survival strategies aim at securing current enterprise profitability, while advancement strategies aim for future profitability. Therefore, organizational knowledge, and consequently K-things, is classified into two categories: survival (K_S) and advancement (K_A). Figure 2 shows the generic form of this matrix.

The second dimension of the K-strategy external domain is K-systemic competencies. The focus of this dimension is the set of utilization-oriented characteristics of knowledge that could contribute positively to the creation of new business-strategy or better support of existing business-strategy. This set includes characteristics such as:

- **Accessibility:** The extent to which organizational knowledge is made available to its members regardless of time or location (Buckman, 1998).
- **Transferability:** The extent to which the newly acquired knowledge can be applied in other contexts, for example, organizational and cultural (Grant, 1996).

Figure 2. The generic form of B-things/K-things matrix (Abou-Zeid, 2002)

Survival Knowledge				**Advancement Knowledge**			
B_1	K_{S11} (Current/Required States)	….	K_{S1n} (Current/Required States)	K_{A11} (Current/Required States)	….	K_{A1m} (Current/Required States)	
B_2	K_{S21} (Current/Required States)	….	K_{S2k} (Current/Required States)	K_{A21} (Current/Required States)	….	K_{A2l} (Current/Required States)	
….	….	….	….	….	….	….	
B_N	K_{SN1} (Current/Required States)	….	K_{SNk} (Current/Required States)	K_{AN1} (Current/Required States)	….	K_{ANl} (Current/Required States)	

- **Appropriability:** The extent to which knowledge can be imitated. Things are said to have "strong" appropriability if they are difficult to reproduce by another organization. The converse is "weak" appropriability. A related concept is that of "sticky/slippery," that is, sticky knowledge is such an integral part of a regime that it cannot be extracted in a meaningful whole (Grant, 1996; Narasimha, 2000).
- **Depth and Breadth** (Narasimha, 2000).
- **Compositionality:** The amenability of knowledge to be synthesized from existing knowledge.
- **Integrateability:** The extent to which the newly acquired knowledge can be integrated with existing knowledge.

Finally, K-governance dimension deals with the selection and use of mechanisms for obtaining the required K-competencies. The following are examples of some "acquisition mechanisms" (Probst, Raub, & Romhardt, 2000):

- Bringing experts to the firm by recruiting specialists as full-time or temporary staff. Temporary hiring is becoming an increasingly interesting alternative.
- Tapping knowledge held by other firms through different inter-organizational co-operation forms such as joint ventures or strategic alliances.
- Utilizing the knowledge of stakeholders, for example, customers, suppliers, employees, and owners. For example, involving customers early in the product-development process could generate valuable information about their needs.
- Acquiring knowledge products such as software, patents, and CD-ROMs.

K-Strategy Internal Domain

In the case of K-strategy, the internal domain involves three dimensions: *K-processes, K-infrastructures,* and *K-skills*.

K-processes, the first dimension of the K-strategy internal domain, can be classified into two main categories: K-manipulating processes and K-enabling processes. The first category, K-manipulating processes, includes all the organizational processes needed to change the state of organizational knowledge such as K-generation, K-mobilization, and K-application (Abou-Zeid, 2003). The second category, K-enabling processes, includes organizational processes that support K-manipulating processes such as managing conversation, mobilizing knowledge activists, creating the right context, and globalizing local knowledge (von Krogh et al., 2000).

Organizational knowledge processes are socially interaction-intensive. They involve social interactions and direct communication and contact among individuals and among members of "communities of practice." Therefore, they require the presence of social capital. Social capital is "the sum of actual and potential resources embedded within, available through, and derived from the network of relationships possessed by a social unit" (Nahapier & Ghoshal, 1998). Recognizing the importance of social capital, Gold, Malhotra, and Segars (2001) have identified three key K-infrastructures, the second dimension of the K-strategy internal domain—technical, structural, and cultural—that enable social capital. The *K-technical infrastructure* includes IT-enabled technologies that support KM activities such as business intelligence, collaboration and distributed learning, K-discovery, K-mapping, opportunity generation, and security. The *K-structural infrastructure* refers to the presence of enabling formal organization structures and the organization's system of rewards and incentives. Finally, the *K-cultural infrastructure* involves elements such as corporate vision and the organization's system of values (Gold et al., 2001).

The last dimension of the K-strategy internal domain is K-skills. KM processes are by their very nature multifaceted. They involve many dimensions such as technical, organizational, and human. This characteristic of KM processes reflects on the nature of skills required to perform them. For example, Malhotra (1997) defines a senior knowledge executive, such as a chief knowledge officer (CKO) or an organizational knowledge architect, as the person who

Figure 3. The dynamics of the strategic alignment process

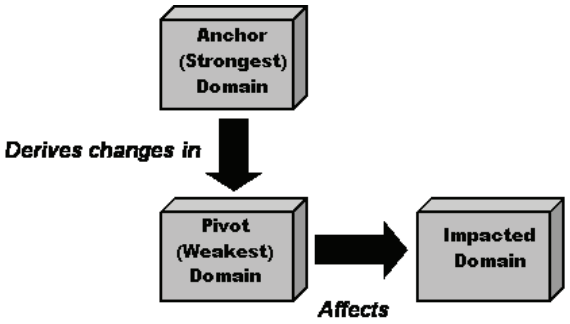


Figure 4. Knowledge potential perspective

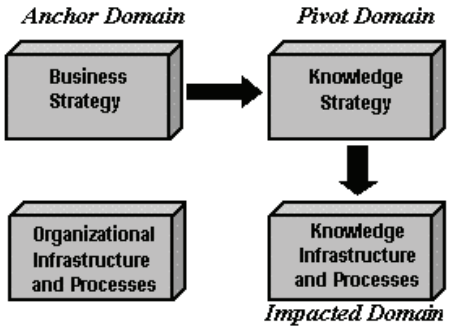

Figure 5. K-infrastructure fusion perspective

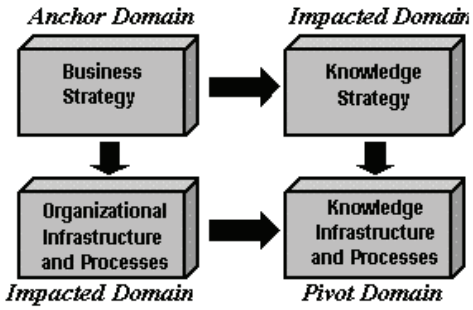

should have the combined capabilities of a business strategist, technology analyst, and a human resource professional. The ability to facilitate the ongoing process of knowledge sharing and knowledge renewal, the ability to develop the human and cultural infrastructure that facilitates information sharing, and the ability to utilize the available technologies for serving the creation, sharing, and documentation of knowledge are some examples of the required skills.

The Dynamics of KM Strategic Alignment Model

Effecting a change in any single domain may require the use of three out of the four domains to assure that both strategic fit and functional integration are properly addressed. Therefore, applying KMSAM requires the identification of three domains: pivot, anchor, and impacted (Luftman, 1996). The pivot domain is the weakest and offers the greatest opportunity for improvement. The anchor domain is the strongest and will be the driver of change. Finally, the impacted domain is the area affected by a change to the pivot domain. Figure 3 shows the dynamics of the strategic alignment process.

Based on this distinction, different perspectives of strategic alignment can be identified. Each perspective represents a pattern of linkages between at least three elements of the four elements of KMSAM, that is, the two external domains (business-strategy and knowledge-strategy) and the two internal domains (organizational infrastructure and processes and knowledge infrastructure and processes). By identifying the strongest (anchor) domain and the *adjacent* weakest (pivot) domain, it becomes possible to identify the area that will be affected by the changes (the impacted domain). The direction the perspective flows is based on which domain is the strongest and which is the weakest.

For example, Figure 4 shows knowledge potential perspective in which business-strategy, the strongest domain, derives changes to the adjacent weakest domain, knowledge-strategy, and these changes will impact knowledge infrastructure and processes. In general, each alignment perspective has to include two types of relationship. The first is between external and internal domains of its business and knowledge components, that is, strategic fit. The second is the functional integration between business and knowledge domains. Eight single-path alignment perspectives can be then identified, namely form anchor domain to adjacent pivot domain to impacted domain.

When the pivot and the anchor domains are not adjacent to one another, but rather across from each other on the diagonal, there will be two possible "paths" from the anchor domain to the pivot domain. This yields four fusion perspectives that result from fusing two of the eight single-path perspectives (Luftman, 1996). For example, Figure 5 shows K-infrastructure fusion perspective in which business-strategy derives changes to the K-infrastructure and processes domain through organizational infrastructure and processes, and K-strategy domains.

Table 1 summarizes the 12 alignment perspectives.

CONCLUSION

Based on the premise that the realization of business value from KM investments requires alignment between the busi-

Table 1. KM strategic alignment perspectives

	Domain / Strategic Perspective	Anchor Domain	Pivot Domain	Impacted Domain
1	**Strategy Execution**	B-strategy	Organizational infrastructure and processes	K-infrastructure and processes
2	**Knowledge Potential**	B-strategy	K-strategy	K-infrastructure and processes
3	**Competitive Potential**	K-strategy	B-strategy	Organizational infrastructure and processes
4	**Service Level**	K-strategy	K-infrastructure and processes	Organizational infrastructure and processes
5	**K-/Organizational Infrastructure**	K-infrastructure and processes	Organizational infrastructure and processes	B-strategy
6	**K-Infrastructure/K- Strategy**	K-infrastructure and processes	K-strategy	B-strategy
7	**Organizational/K- Infrastructure**	Organizational infrastructure and processes	K-infrastructure	K-strategy
8	**Organizational Infrastructure/B-Strategy**	Organizational infrastructure and processes	B-strategy	K-strategy
9	**K-Infrastructure Fusion** (Perspectives 4 + 7)	B-strategy	K-infrastructure and processes	▪ Organizational infrastructure and processes ▪ K-strategy
10	**Organizational Infrastructure Fusion** (Perspectives 1+ 5)	K-strategy	Organizational infrastructure and processes	▪ B-strategy ▪ K-infrastructure and processes
11	**B-Strategy Fusion** (Perspectives 3+ 8)	K-infrastructure and processes	B-strategy	▪ Organizational infrastructure ▪ K-strategy
12	**K-Strategy Fusion** (Perspectives 2+ 6)	Organizational infrastructure and processes	K-strategy	▪ B-strategy ▪ K-infrastructure and processes

ness- and knowledge-strategies and on the IT strategic alignment model (SAM) developed by Henderson and Venkatraman (1993), a KMSAM is developed. Moreover, it provides executives with a logical framework for analyzing and assessing alternative strategic choices with regard to aligning K-strategy and B-strategy.

Extension of this work would move in two directions. The first would be to use KMSAM in cross-sectional study of KM initiatives in order to identify the dominant patterns of K-strategy and B-strategy alignment. As "strategic alignment is not an event but a process of continuous adaptation and change" (Henderson & Venkatraman, 1993), the second direction would be a longitudinal study of each enterprise cycle around the alignment perspectives and how the adopted perspective is related to the degree of maturity of the KM initiative.

KEY TERMS

Anchor Domain: The area that provides (drives, catalyzes, or enables) the change forces applied to the pivot domain.

Impacted Domain: The area affected by a change to the pivot domain.

K-Systemic Competencies: The set of utilization-oriented characteristics of knowledge that could contribute positively to the creation of new business strategy or better support of existing business strategy.

Pivot Domain: The problem or opportunity being addressed.

Alignment with Sound Relationships and SLA Support

AC Leonard
University of Pretoria, South Africa

INTRODUCTION

International data corporation surveyed 283 top executives across three vertical industries: finance, manufacturing, and retail/wholesale. They found "a strong correlation between the effectiveness of the IT department (IS organization) and the relationship between the CIO and the CEO." "We suspect that this relationship, if it is close, permits the CIO to develop the IT department (IS organization) into a service that delivers competitive advantage for the company, thus enhancing the careers of every IT professional in the organization." In other words, "a certain amount of mutual esteem will help IT (IS) function as a business partner."

In terms of alignment, sound relationships between IT and the business become even more important. Boar (1994) states that aligning with anything other than the customer leads to momentary success. For the IT function to achieve a state of alignment with the business, it must align with the business scope, and through that business scope enable all business functions and processes to serve the customers in a superior manner.

BACKGROUND

In their research, Reich and Benbasit (1999) point out that there are two dimensions to strategy creation: the intellectual dimension and the social dimension. Research into the intellectual dimension is more likely to concentrate on the contents of plans and on planning methodologies. Research into the social dimension is more likely to focus on the people involved in the creation of alignment. The social dimension of alignment is defined as "the state in which business and IT executives within an organizational unit understand and are committed to the business and IT mission, objectives, and plans."

Another theoretical perspective supporting the concept of the social dimension of alignment is the social construction of reality. This view would suggest that, in addition to studying artefacts (such as plans and structures) to predict the presence or absence of alignment, one should investigate the contents of the players' minds: their beliefs, attitudes, and understanding of these artefacts.

This article focuses on the social dimension in terms of the construction and nature of sound IT-end user relationships and the role such relationships play in aligning IT with the business. Research in this field has shown that relationships between IT professionals and their end users are intriguing and complex, and should be seen and managed as a multi-dimensional environment. Furthermore, the supportive role of service level agreements (SLA's) in this regard is also highlighted.

IT END-USER RELATIONSHIPS: HISTORICAL FOUNDATIONS

For many years, the *culture gap* between IT departments and their end users has been characterized by unfortunate differences like distrust, scepticism, and cynicism. This situation impacts negatively on the relationship of IT departments with their end users, and as such on their ability to produce service and support of high quality.

Historically, the gap was caused mainly by the difference in management culture, as well as human behaviour problems on both sides. Umbaugh (1991) states in his argumentation of organizational imbalances that too often IT exists as an adjunct to the organization and not as an integral part of the whole. This situation unfortunately still exists today and contributes to the so-called *culture gap* between IT departments and their end users. Du Plooy (1995) explains this gap as follows:

...the 'culture gap' should be understood as a gap of misunderstanding in the sense of two different organizational 'cultures' that, according to Grindley, coexist in most organizations. The two cultures under discussion here are the 'culture' of the IT profession and the 'culture' of the rest of the organization.

The culture on both the IT department and the business side is also an important obstacle in building mutual trust, and eventually in building sound relationships between IT and its end-user environment, and as such in creating alignment between IT and the business. According to Moad (1994), the IT professional has been fighting for recognition and relevance at the CEO level for the last 25 years. He gives

many examples illustrating the kind of culture that exists, which could be described as the main reason for misunderstandings and misconceptions about IT amongst today's end users.

THE NATURE OF IT-END USER RELATIONSHIPS

The preceding paragraphs briefly describe the history of how poor relationships emerged over the years between IT departments and their end users, as well as some basic characteristics of such poor relationships. The question one can ask is, what are the characteristics of sound relationships between IT departments and their end users, and how are they established? To answer the question, this section gives a definition of IT-end user relationships and briefly discusses the nature of the different elements.

A relationship between an IT professional and an end user consists of two dimensions, namely a physical dimension and an abstract dimension. The physical dimension describes those elements that are necessary in order to enable contact between IT professional and its end users, whereas the abstract dimension describes the soft issues of such a relationship. These two dimensions enable one to fully describe the holistic nature of such a relationship and encapsulate the important elements of a support-oriented organization, namely mutuality, belonging, and connection, as mentioned by Pheysey (1993) in her book *Organizational Cultures*.

Without going into all the details of the different elements of the physical and abstract dimensions as described by Leonard (2002), the article focuses on describing the most important characteristics of these elements. This will give the reader enough understanding of the social nature of IT-end user relationships.

Physical Elements

As far as the physical dimension is concerned, the following elements could be seen as the most important:

- **People:** A relationship consists of all the responsible people who are involved in the systems development life cycle at a given time. "Responsibilities are negotiated and shared between systems developers, and users" (Dahlbom & Mathiassen, 1993).
- **Technology:** Technology may be seen as one of the most important elements in such a relationship, enabling the people who participate in the relationship to communicate with one another. The importance of proper communication structures, both vertically and horizontally, are emphasized by Bommer, Gratto, Gravander, and Tuttle (1991) and could be seen as one of the most important organizational characteristics associated with unethical activity.
- **Procedures:** Two types of procedures are of importance, namely organizational procedures (such as standards and policies), which already exist and which can be seen as a given, and new procedures that are being created by people because of their interaction with the given procedures and technology (DeSanctis & Poole, 1994).
- **Structures:** Depending upon the "type" of end user, and therefore the service and support that will be offered, relationships will differ in content as far as formal and informal social communication structures are concerned. The most common of these structures are project meetings, JAD sessions, and end-user group meetings.

Abstract Elements

As far as the abstract dimension is concerned, the following elements are the most important:

- **They are dynamic:** The nature of the relationships between the IT department and its end users will, among other things, depend upon the type of end user, as well as upon regarding the end user as a human being. According to Stokes (1991), when talking to end users, the IT professional should always bear in mind their concerns, problems, environment, and responsibilities in terms of opportunities for IT services and support.
  Furthermore, he says, continuous contact with end users gives IT the opportunity to gain more insight into their problems.
- **They are sensitive to change:** Because of the social nature of relationships, any form of change initiated on either the IT or the end-user side may disturb a relationship. It is argued that any kind of change having an effect on any of the elements of both the physical and abstract dimensions of a relationship will in fact disturb the relationship because of its holistic nature, which will be described later.
- **They have a knowledge base:** The complex world of perceptions, attitudes, and approaches toward developing software products by IT professionals for the end user forces us to a point where it can be said that in order to overcome the most serious problems during this communication process in a relation-ship, a knowledge base of some kind is required before entering a relationship.
- **They have a supportive culture:** In order for a relationship to be sound, continuous support and mutual understanding, among other things, need to be elements of such a relationship. According to Pheysey,

a support-oriented organization has the elements of mutuality, belonging, and connection. Furthermore, an appreciative form of control should be applied, which means: "management is seen to be a process focused on maintaining balance in a field of relationships" (Pheysey, 1993).

- **A cooperative behaviour pattern is followed by the participants:** Cooperation is not a fixed pattern of behaviour, but a changing, adaptive process directed to future results. The representation and understanding of intent by every party is therefore essential to cooperation, and as such emphasizes the importance of communication during cooperation (Clarke & Smyth, 1993).
  Cooperation can also create new motives, attitudes, values, and capabilities in the cooperating parties, which will help create and maintain a supportive culture.
- **They have a holistic nature:** The important elements making up a relationship between the IT department and its end users at a given time should be organized together as a whole. If any of these elements are disturbed in a negative sense, the whole relationship between the IT department and its end users is undermined.
- **Sustainability:** A most obvious characteristic of the abstract dimension is its sustainability over a period of time. In this regard, time refers to the life span of an IT-end user relationship. One can therefore argue that from an information systems viewpoint, a relationship of this kind will only last until the product or service reaches the end of its life cycle.
  In this regard, Introna (1994) states: "Structures as relationships are contingent, it appears and disappears. It could be brief (a few seconds) or long lasting (several years)."
- **Commitment:** Kinlaw (1989) states that one of the primary tasks of a manager is to create commitment and focus on employees. He furthermore states that managers who help employees increase their knowledge, skill, and experience also are building employee commitment. In this regard it is important that managers should take note of the four sturdy supports of commitment, namely: (a) clarity of goals and values; (b) employee competencies that ensure success; (c) the degree of influence that employees have; and (d) the expressed appreciation given to employees for their contributions. Commitment should be seen as a solid block that rests on these four supports or legs (Kinlaw (1989)).

All the elements described previously form important sub-dimensions of the physical and abstract dimensions. Each of these elements plays a specific social role in an IT/ end-user relationship environment, which impacts on the soundness of such a relationship as well as the success of alignment between IT and the business. The way in which the application of this paradigm could enhance alignment is addressed in the following paragraphs.

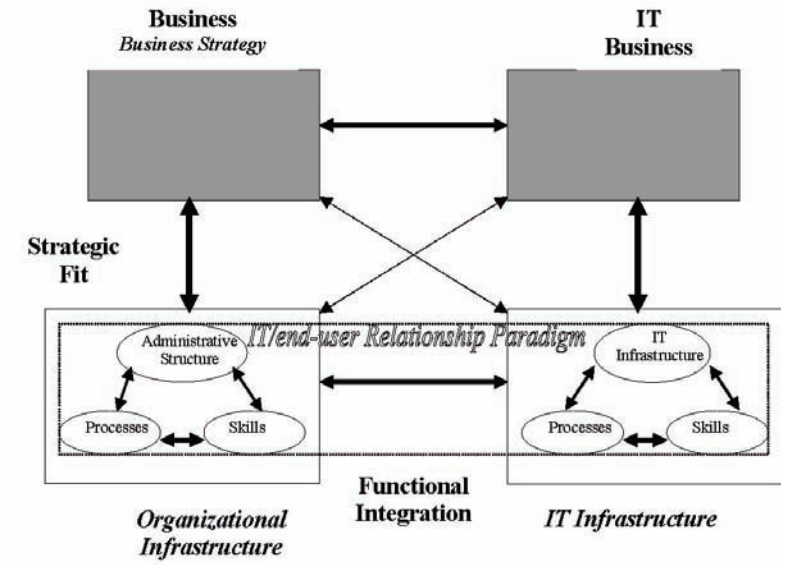
ALIGNMENT MODEL FOR APPLYING THE IT END-USER RELATIONSHIP PARADIGM

The theoretical construct of strategic alignment (Henderson & Venkatraman, 1992) indicates that in terms of alignment there are two distinct linkages, namely a strategic fit and functional integration. According to the model, strategic fit is the vertical linkage concerned with the integration of the external environment in which the firm competes (e.g., partnerships and alliances) and the internal environment, which focuses on administrative structure (e.g., human resources and product development). Functional integration, according to the model, is the corresponding horizontal link between business and IT. These two linkages are used to determine the relation-ships between IT and business (Papp, 2001).

It is clear that the paradigm of IT-end user relationships, which is based on two dimensions, namely the physical and abstract dimensions (as described earlier), addresses the two lower domains indicated by the dotted rectangle in Figure 1. In other words, the paradigm enhances alignment in terms of organizational infrastructure and processes, and IT infrastructure and processes. The physical dimension addresses structures, skills, and processes while the abstract dimension addresses all the soft issues required to ensure that relationships prevail. Therefore, it is argued that if the paradigm of IT end-user relationships is applied when service and support activities[1] are performed by IT professionals, it will enhance the functional integration between IT and the business. This is the case because all the elements of the physical and abstract dimensions are of a sound nature, which directly impacts on structures, processes, and skills in the infrastructure domains of the alignment model in Figure 1.

According to Larson (1998), a service level agreement (SLA) is a formal contract between the IT service provider and the business unit within an organization. The SLA provides a common understanding of the quality of service that the IT service provider will provide. It also helps create reasonable expectations among end users at a specific business unit. As Coye (2004) states it, end users have expectations regarding services and support and the quality thereof provided by the supplier; they compare their expectations to the received service to assess the service quality. Apart from defining the standard of service quality and setting customer expectation, the SLA outlines the role of the end users and the role of the service provider. Therefore, an SLA will enable the end users to be fully aware of the service delivery capabilities

Figure 1. The role and impact of IT-end user relationships in the alignment of business and IT departments (based on the work of Henderson et al., 1992)



and limitations of the service provider, while the service provider will understand the expectation and IT service needs of the end users. This common understanding about the service delivery between the IT service provider and end users is an important component for establishing a successful IT service provider-end user relationship as indicated by Smith (1996). With this in mind, it is argued that SLA's could be seen as the supportive basis for the establishment and maintenance of sound relationships because it provides a continuous "reminder" for all role players of what is expected in terms of service and support. Furthermore, sound IT-end user relationships will enable end users to have a highly effective commitment with the service provider. End users who have such commitment are less likely to switch to a new service provider (Mattila, 2004). Therefore, there is a large possibility that the end users will continue using the service of the current service provider or develop new SLA's with them instead of searching for a new provider in case of poor services or support. To conclude this argument, it is important to take note of IOMA's report on customer relationship management which says that customer relationship commitment will never stand if staff members are focused on "how many" customers they can handle in stead of quality service (IOMA (2004)).

Once there are common interests and mutual understanding between the end users and IT service providers, it will enable the IT service provider to include the services and quality of service needed by end users in the draft SLA. According to Pratt (2003), the SLA will only be of value if the IT service provider has a clear understanding of the end user organization's core business operations and business needs.

FUTURE TRENDS

Theories in terms of how relationships between an IT department and its end users could be managed are scarce. Those who do address issues in this regard (Beard & Peterson, 1988; CSC research foundation, 1994; Wike et al., 1984) do not look into soft issues, nor do they give substance to the contents of such relationships. Furthermore, none of these theories deal with the important issue of how to understand and manage the soft issues involved during the establishment and maintenance of sound IT-end user relationships.

Managing relationships and alignment is especially critical in the outsourcing of information technology services or extending of business applications to systems in other enterprises in order to form extended enterprises. It is clear that in the future much more research needs to go into the management of relationships and service level agreements to ensure that sound relationships and alignment will be maintained.

CONCLUSION

In this article, the paradigm of IT-end user relationships was defined in terms of its physical and abstract dimensions. It was argued that these two dimensions enable one to fully

describe the holistic nature of such relationships. Although the construction and use of SLA's is not something new in terms of service and support, in this article it is given a new dimension by which it serves as a supportive basis for the establishment and maintenance of sound relationships. Furthermore, in terms of business and IT alignment, it was argued that IT-end user relationships should be applied in the infrastructure domains (both IT and the business) and will therefore enhance alignment in terms of functional integration.

KEY TERMS

Abstract Dimension: The abstract dimension describes the soft issues of such a relationship.

Commitment: A state of mind that holds people and organizations in the line of behaviour. It encompasses psychological forces that bind an individual to an action.

Culture Gap: It should be seen as a gap of misunderstanding in the sense of two different organizational cultures that coexist in most organizations. The two cultures under discussion here are the culture of the IT profession and the culture of the rest of the organization.

Holistic Nature of an IT-End User Relationship: The important elements making up a relationship between an IT professional and its end user(s) at a given time should be organized together as a whole. If any of these elements are disturbed in a negative sense, the whole relationship between the IT professional the end user(s) is under-mined. In other words, the relationship as a whole is more than the sum of its elements.

IT-End User Relationship: A relationship between IT and the end user consists of two dimensions, namely a physical dimension and an abstract dimension. The physical dimension describes those elements that are necessary in order to enable contact between IT and its end users, whereas the abstract dimension describes the soft issues of a relationship.

Physical Dimension: The physical dimension de-scribes those elements that are necessary in order to enable contact between IT professional and its end users.

Social Dimension of an IT-End User Relationship: Refers to all the elements in the abstract dimensions. Each of these elements plays a specific social role in an IT-end user relationship environment, which impacts on the soundness of such a relationship as well as the success of alignment between IT and the business.

Ambient Intelligence in Perspective

INTRODUCTION

Ambient intelligence (AmI) is a relatively new and distinct interpretation of the mobile computing paradigm. However, its recognition that embedded intelligence, either in actuality or perception, is an essential prerequisite if mobile computing is to realize its potential distinguishes it from other mobile usage paradigms. Though stressing the need for intelligence, and implicitly the adoption of artificial intelligence (AI) techniques, AmI does not formally ratify any particular approach and is thus technique agnostic. In this article, we examine the constituent technologies of AmI and provide a brief overview of some exemplary AmI projects. In particular, the question of intelligence is considered and some strategies for incorporating intelligence into AmI applications and services are proposed. It is the authors hope that a mature understanding of the issues involved will aid software professionals in the design and implementation of AmI applications.

BACKGROUND

In 2001, the EU Information Society Technologies Advisory Group (ISTAG) launched a report that proceeded to define the term Ambient Intelligence (ISTAG, 2001). Over a decade earlier, the late Mark Weiser had defined his vision for ubiquitous computing (Weiser, 1991). This vision was far ahead of its time but has been perceived by computer scientists as a vision worth pursuing. As the various technological hurdles were being progressively overcome, ISTAG recognised the inevitability of ubiquitous, pervasive technologies being widely deployed. In practice, this would mean entire generations growing, learning, working and relaxing in an environment saturated with smart sensors and other embedded artifacts. However, a key problem was identified: how to facilitate intuitive interaction with the prevailing embedded technologies. In particular, the scale of these interactions could potentially give rise to situations where numerous artifacts would be clamouring for the individual's attention. Given that human attention is a scarce and precious resource, this course of action could have undesired consequences, and a situation could be envisaged arising where a user might perceive environments saturated with embedded technologies as being places best avoided. Hence, the objective of AmI is to facilitate seamless intuitive interaction between users and their environment.

CONSTITUENT TECHNOLOGIES FOR AMBIENT INTELLIGENCE

Ambient intelligence (AmI) (Aarts & Marzano, 2003; Vasilakos & Pedrycz, 2006) has evolved conceptually and practically, resulting in a common agreement on its core constituent technologies. Three technologies have been identified as being essential to AmI: ubiquitous computing, ubiquitous communications and intelligent user interfaces.

Ubiquitous Computing

Ubiquitous computing envisages the embedding of computational artifacts in the physical environment and their subsequent intuitive access by users. Concerned with the prominence of the then current range of computing systems and their unwieldy interaction modalities, Weiser hoped that ubiquitous computing would herald in an era of what he termed *calm technology*. However, before this could take place, significant advances would have to take place in a number of computing disciplines. One area of particular interest is that of smart environments, as such environments seek to deliver a practical realisation of the ubiquitous computing vision in everyday scenarios, including the home and office. Integration of microprocessors into people's everyday living space objects, such as furniture, clothing, toys and so on, allows the immediate living space to become sensitive and responsive to its inhabitants, rather than just remaining inanimate. Hence, the origin of the term ubiquitous, which

implies that something exists or is everywhere within a living environment on a constant level. A concept closely associated with ubiquitous computing is that of context (Dourish, 2004). In ubiquitous computing, and indeed, other computer usage paradigms, it is envisaged that a model of the user and their environment is available, thus enabling the delivery of services to users that have been dynamically adapted according to the user's current context. Here, context may entail such factors as temporal information, elements of their individual profile (sex, languages spoken, etc.) and current location. In the latter case, absolute positioning, for example, geographic coordinates, or relative positioning, for example, west of a certain landmark, could be used, depending on the nature of the service in question. From a software perspective, the continuous process of capturing context and interpreting it is computationally expensive, and significant scope exists for incorporating intelligent techniques. Such techniques may be used to incorporate reasoning about incomplete knowledge, or perhaps infer future user behavior based on past experiences.

Ubiquitous Communications

Computing technology is increasingly pervasive in everyday life, though under a number of guises, for example, cellular phones and standard embedded household electronics. With continually decreasing hardware costs, relentless miniaturisation and the adoption of high speed data networks, this trend is likely to continue. For example, modern automobiles already contain dozens of microprocessors, while the increasing popularity of Third Generation (3G) mobile phones means that mobile computing is now within reach of people in all facets of their daily lives. Indeed, the widespread deployment of wireless technologies has ensured that mobile computing is spawning a dominant new culture (Rheingold, 2002), as encounters with people using their cellular phones, PDAs, MP3 players, digital cameras and so on is a regular occurrence. Traditionally, these islands of technology would have existed in isolation. However, AmI takes a more holistic view and demands that the existence of a multiprotocol communications infrastructure for integrating disparate technologies such that a unison between all electronic data and equipment pertinent to the user's immediate context can be achieved. Thus, ubiquitous communications seeks to enable embedded objects to communicate with each other and the user by means of various fixed, wireless and ad-hoc networking techniques.

Intelligent User Interfaces

Intelligent user interfaces (IUIs) form the third, and arguably the most important, component of AmI. Human attention is a precious resource. Thus, it must be used judiciously when available, and should be requested cautiously and prudently. It is this prominence given to the need for new innovative interface technologies that distinguishes AmI from other mobile computing paradigms, and also motivates the need for intelligence. The urgent need for IUIs is seen when the nature of the AmI environment is considered. A multitude of embedded or smart artifacts all competing for explicit user attention does not constitute a usable system. Thus, for the sanity of the user, alternative techniques must be considered. Three issues are of particular interest: the need for new physical interface technologies, support for more sophisticated interaction modalities, and the need for collaboration between the constituent components of the environment such that intelligent behaviour can be utilised to the maximum.

Traditional graphical user interfaces (GUIs) are well understood from an ergonomic and implementation perspective. Such GUIs comprise devices such as a keyboard, mouse, and visual display unit; however, at present, the large ambient space that surrounds the user is unused. Thus, AmI demands more sophisticated interaction modalities that utilises this space but which may be difficult to implement and interpret. Examples of such modalities include voice, handwriting, gestures and gaze. The situation is exacerbated when it is considered that a mixture of modalities, for example, voice and gesture, may be used. Interpreting these modalities may require the availability of significant computational resources which may give rise to serious difficulty. A complementary strategy may involve the deployment of embedded dedicated sensors that aid the AmI environment monitor the user, develop sophisticated behaviour models, and enables it to proactively pre-empt user requests. However, no single interaction modality or interface technology can achieve this on its own. Rather, a degree of collaboration and intelligence is necessary to harness and interpret the data before a decision can be made as to whether an explicit interaction session with the user should be initiated.

REALIZING PRACTICAL AMBIENT INTELLIGENT ENVIRONMENTS

A number of organisations, in an effort to understand how AmI environments would work in practice, have designed and developed realistic test environments in which AmI scenarios can be quickly prototyped and evaluated. Philips HomeLab (Aarts & Eggen, 2002), launched in 2002, is one well known example. In essence this lab is a real home, modeled on a two level, two bedroom home. Volunteers live in this house 24 hours a day and their interactions with various electronic devices are observed by researchers. In this way, it is hoped to gain a deeper understanding of how people interact with technology in the home, resulting in

better products and an improved product development cycle. Other initiatives include the Aware House at Georgia Tech (Kidd, Orr, Abowd, Atkeson, Essa, MacIntyre et al., 1999), the MIT Oxygen project (Rudolph, 2001) and the Fraunhofer inHaus initiative (Miller, 2001).

Though homes and offices are logical places for deploying AmI solutions, there are many others. Key obstacles hindering the widespread saturation of AmI in the home environment are economics and the possibility of security breaches. Within business organisations, the obstacles may include a resistance to new work practices or certain legal and ethical difficulties. From a human perspective, it may be anticipated that cultural issues will affect the deployment of AmI solutions. A reticence is frequently observed in consumers when adopting a new technology, and is understandable particularly in the case of the elderly where the overwhelming desire is for affairs to remain constant. Though reluctance to embrace new technologies is not universal, nevertheless, it should not be underestimated by proponents of new technology.

Ambient Assisted Living

Ambient assisted living (AAL) seeks to aid people, particularly the elderly, live independently for a longer time period than would otherwise be possible. The motivation behind AAL is a consequence of the demographical profile of western countries in particular. In short, the number of elderly people as a portion of the population will grow significantly in the next twenty years for many countries. This is a societal issue and one for which there is no easy long term solution. The cost of supporting this increasingly aged population will grow dramatically; a cost that may have to be borne by a smaller workforce. Anticipating this problem, the EU via its Sixth Framework initiative has actively funding projects that seek to enable older people live independently for as long as possible. This initiative, AAL, envisages the use of AmI technologies in particular as a means of achieving this goal.

As just one exemplary illustration of how AAL might operate in practice, the case of a bathroom monitoring system (Chen, Zhang, Kam, & Shue, 2005) is now considered. The system uses acoustics to monitor and classify bathroom activities. At the end of each day, a personal hygiene behavioural report is compiled, for the benefit of care-givers and clinicians, respectively. A number of issues of interest to AmI researchers are raised here. Firstly, no dedicated expensive infrastructure is required. Rather, the only technologies required are an infrared sensor and a microphone. A sophisticated algorithm based on Hidden Markov Models classifies the sound events in real time, thus enabling the raising of alarms quickly. Finally, no significant usability issues arise as the system is quintessentially unobtrusive. Its passive and noninvasive nature increases the possibility of it being accepted by users.

Designing Ambient Intelligent Solutions

Given the importance that AmI ascribes to artificial intelligence, the question of how to realize this intelligence in practice arises. Recall that AmI envisages a world saturated with small computational artifacts. Such artifacts may be mobile, as exemplified by the average mobile telephone or PDA, or may be static, as exemplified by embedded sensors. For the purposes of this discussion, it is assumed that a data communications network is available, without specifying topology or protocol. Three approaches for delivering the necessary intelligence functionality may be adopted.

1. **Networked AI:** In this scenario, the AI software may be deployed on fixed nodes in the network. The advantage of this approach is that the software engineer is not limited by computational constraints that characterise mobile devices and embedded technologies. Thus, computationally expensive solutions, including neural networks and machine learning techniques, can be employed. However, the realisation of this approach is dependent on the availability of a sophisticated communications infrastructure. Recall that implicit in the AmI concept is the need for continuous monitoring of the state of the environment. Any changes to the status quo need to be relayed over the network to the appropriate node where the implications of this change can be gauged and any necessary feedback returned to the embedded artifact. This process needs to take place in near real-time conditions if the net usability of the system is not to be adversely affected.
2. **Embedded AI:** Embedding AI augmented software on the mobile device or embedded artifact is, conceptually, a preferred solution in some, though not all, circumstances. Historically, this approach would have been computationally intractable. Ongoing developments in mobile technologies, however, are rendering this approach feasible, and certain AI technologies may now be incorporated on mobile devices, and, increasingly, on embedded computational artifacts such as wireless sensor networks. At present, the possibility of deploying intelligent agents on such devices is progressing and has already been described in the literature (Carabelea & Boissier, 2003). In general, the approach that has been taken to extend well known agent toolkits such that the runtime engine operates on the mobile device. Of course, most of these toolkits come with additional tools for design and debugging, but these are not ported onto the device. It is only necessary

to deploy a runtime interpreter for the agent logic. One disadvantage of the embedded approach per se is that such applications may tend to be insular. This contravenes the AmI vision in practice as an implicit collaborative effort is necessary in AmI if explicit user interaction is to be kept to a minimum.

3. **Distributed AI:** A third approach to realising intelligence in AmI environments is to distribute the AI technologies between the embedded computational artifact and a fixed server node. This is a flexible solution, and for suitably equipped application domains, may offer the software engineer significant opportunities for mixing and matching the techniques needed for realizing the application in question. Interestingly, distributed AI (DAI) (O'Hare & Jennings, 1996) is itself a distinct and mature sub-branch of AI, and is primarily concerned with issues such as distributed reasoning and knowledge management. Thus, software engineers can call on a wealth of research in the course of their projects. Indeed, there seems to be an uncanny synthesis between the DAI discipline and the AmI concept. More importantly, one of the more advanced implementations of DAI concerns intelligent agents and Multi-agent Systems (MAS).

Intelligent Agents in Computationally Restricted Environments

Intelligent agents are a distinct and viable mechanism for the design and implementation of applications. Agents are usually adopted in highly complex and dynamic situations where traditional software techniques do not seem to encapsulate the necessary constructs essential for effectively modeling the situation. A number of characteristics are synonymous with agents including autonomy, proactivity, reactivity, mobility and sociability (Wooldridge & Jennings, 1995). To what degree each MAS implementation incorporates these characteristics varies. From an AI perspective, agents are viewed as being endowed with a sophisticated reasoning ability. One well-known example of this is the Belief-Desire-Intention (BDI) architecture (Rao & Geogeff, 1995). It should of course be noted that the characteristics supported in fixed networked environments may not necessarily be supported in the runtime engine for embedded devices, and is an issue that prospective developers of agent-based systems should be acutely aware of.

A number of mature MAS environments have been extended with runtime engines for devices of limited computational capacity. All are described extensively in the research literature and most are available in open source format. Examples of interest include 3APL-M (Koch, 2005), LEAP (Adorni, Bergenti, Poggi & Rimassa, 2001) and MicroFIPA-OS (Laukkanen, Tarkoma & Leinonen, 2001). In the case of the BDI architecture, JACK (http://www.agent-software.com), a commercial product, and Agent Factory Micro Edition (Muldoon, O'Hare, Collier & O'Grady, 2006), a derivative of Agent Factory (Collier, O'Hare, Lowen & Rooney, 2003), have also been ported to mobile devices.

FUTURE TRENDS

The potential of AmI is undisputed, but researchers and commercial companies need to be acutely aware of pertinent issues that must be addressed prior to unleashing AmI technology on the general population. These include the issue of privacy and its protection, economics, and the need for basic fault-tolerant networks that are continually alert and can react quickly to changing circumstances. Above all, AmI systems must maintain the privacy of its clients and not compromise their safety in any way. This will be a critical concern of clients when considering whether the advantages outweigh the economic burden. As a priority, companies developing AmI technologies need to emphasise the security benefits they will adhere to contractually. Finally, in the critical issue of practically realising intelligence in AmI applications, it can be realistically envisaged that mobile devices and embedded technologies will increase in power and sophistication, thus increasing the range of AI techniques that can be harnessed by the software engineering community.

CONCLUSION

Ambient intelligent environments may well form a significant portion of the next generation of computing systems. Such environments build on a number of state-of-the-art technologies and seek to effectively harness them such that the needs of users in select domains are adequately addressed. It is this user-centric approach to application and service access that distinguishes AmI from other initiatives in the mobile computing sphere, and over time, the incorporation of increasingly sophisticated AI techniques may further spur the adoption of AmI in a broad range of new and challenging domains.

KEY TERMS

Ambient Intelligence: Intelligence embedded in everyday objects and the surrounding environment such that the use of these smart objects is intuitive to the inhabitants of the environment.

Ambient Assisted Living: This concerns the use of ambient intelligent techniques to enable elderly people live independently for as long as possible.

Context-Awareness: The property of a system that allows it to adjust its behaviour based on environmental cues, such as location or user presence or absence.

Human Computer Interaction (HCI): The study of how people and computers interact, combining aspects of computer science, psychology, sociology, aesthetics and ergonomics, as well as many others.

Intelligent Agents: In this article, the word agent refers to software entities which are capable of displaying autonomous, cooperative and flexible behaviour directed toward achieving a set of internal goals or objectives.

Intelligent User Interface: Intelligent User Interfaces harness various techniques from Artificial Intelligence to adapt and configure the interface to an application such that the end-user's experience is more satisfactory.

Ubiquitous Computing: Also known as pervasive computing, this is the study of how computing can be integrated into the environment in a way that makes it easily accessible to users.

Analysis and Modelling of Hierarchical Fuzzy Logic Systems

Masoud Mohammadian
University of Canberra, Australia

INTRODUCTION

Computational intelligence techniques such as neural networks, fuzzy logic, and evolutionary algorithms have been applied successfully in the place of the complex mathematical systems (Cox, 1993; Kosko, 1992). Neural networks and fuzzy logic are active research area (Cox, 1993; Kosko, 1992; Lee, 1990; Mohammadian & Stonier, 1995; Welstead, 1994; Zadeh, 1965). It has been found useful when the process is either difficult to predict or difficult to model by conventional methods. Neural network modelling has numerous practical applications in control, prediction, and inference.

Time series (Ruelle, 1998) are a special form of data where past values in the series may influence future values, based on presence of some underlying deterministic forces. Predictive model use trends cycles in the time series data to make prediction about the future trends in the time series. Predictive models attempt to recognise patterns and trends. Application of liner models to time series found to be inaccurate, and there has been a great interest in nonlinear modelling techniques.

Recently, techniques from computational intelligence fields have been successfully used in the place of the complex mathematical systems for forecasting of time series. These new techniques are capable of responding quickly and efficiently to the uncertainty and ambiguity of the system.

Fuzzy logic and neural network systems (Welstead, 1994) can be trained in an adaptive manner to map past and future values of a time series and thereby, extract hidden structure and relationships governing the data. The systems have been successfully used in the place of the complex mathematical systems, and have numerous practical applications in control, prediction, and inference. They have been found useful when the system is either difficult to predict and/or difficult to model by conventional methods. Fuzzy set theory provides a means for representing uncertainties. The underlying power of fuzzy logic is its ability to represent imprecise values in an understandable form. The majority of fuzzy logic systems, to date, have been static and based upon knowledge derived from imprecise heuristic knowledge of experienced operators, and where applicable, also upon physical laws that governs the dynamics of the process.

Although its application to industrial problems has often produced results superior to classical control, the design procedures are limited by the heuristic rules of the system. It is simply assumed that the rules for the system are readily available or can be obtained. This implicit assumption limits the application of fuzzy logic to the cases of the system with a few parameters. The number of parameters of a system could be large.

Although the the number of fuzzy rules of a system is directly dependant on these parameters. As the number of parameters increase, the number of fuzzy rules of the system grows exponentially.

In fuzzy logic systems, there is a direct relationship between the number of fuzzy sets of input parameters of the system and the size of the fuzzy knowledge base (FKB). Kosko (1992) call this the "Curse of Dimensionallity." The "curse" in this instance is that there is exponential growth in the size of the fuzzy knowledge base (FKB), where k is the number of rules in the FKB, m is the number of fuzzy sets for each input and n is the number of inputs into the fuzzy system.

As the number of fuzzy sets of input parameters increase, the number of rules increases exponentially. There are a number of ways that this exponential growth in the size of the FKB can be contained. The most obvious is to limit the number of inputs that the system is using. However, this may reduce the accuracy of the system, and in many cases, render the system being modelled unusable. Another approach is to reduce the number of fuzzy sets that each input has. Again, this may reduce the accuracy of the system. The number of rules in the FKB can also be trimmed if it is known that some rules are never used. This can be a time-consuming and tedious task, as every rule in the FKB may need to be looked at.

Raju and Zhou (1993), Mohammadian and Kingham (1997), and Mohammadian, Kingham, and Bignall (1998) suggested using a hierarchical fuzzy logic structure for such fuzzy logic systems to overcome this problem. By using hierarchical fuzzy logic systems, the number of fuzzy rules in the system are reduced, thereby, reducing the computational time while maintaining the systems robustness and efficiency. In this chapter, the design and development of a hierarchical fuzzy logic systems using genetic algorithms to model and predict interest rate in Australia is considered. Genetic algorithms are employed as an adaptive method for design and development of hierarchical fuzzy logic systems.

HIERARCHICAL FUZZY LOGIC SYSTEMS

The hierarchical fuzzy logic structure is formed by having the most influential inputs as the system variables in the first level of the hierarchy, the next important inputs in the second layer, and so on. If the hierarchical fuzzy logic structure contains n system input parameters and L number of hierarchical levels with n_i the number of variables contained in the ith level, the total number of rules k is then determined by:

$$k = \sum_{i-1}^{L} m^{n_i} \tag{1}$$

where m is the number of fuzzy sets. This equation means that by using a hierarchical fuzzy logic structure, the number of fuzzy rules for the system is reduced to a linear function of the number of system variables n, instead of an exponential function of n as is the conventional case. The first level of the hierarchy gives an approximate output, which is then modified by the second level rule set, and so on. This is repeated for all succeeding levels of the hierarchy. One problem occurs when it is not known which inputs to the system have more influence than the others. This is the case in many problems. In some case, statistical analysis could be performed on the inputs to determine which ones have more bearing on the system.

INTEGRATED HIERARCHICAL FUZZY LOGIC AND GENETIC ALGORITHMS

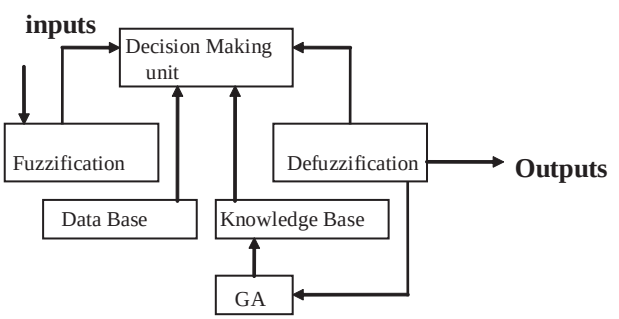
Genetic algorithms (GAs) (Goldberg, 1989; Goonatilake, Campbell, & Ahmad, 1995) are powerful search algorithms based on the mechanism of natural selection, and use operations of reproduction, crossover, and mutation on a population of strings. A set (population) of possible solutions, in this case, a coding of the fuzzy rules of a fuzzy logic system, represented as a string of numbers. New strings are produced every generation by the repetition of a two-step cycle. First, each individual string is decoded and its ability to solve the problem is assessed. Each string is assigned a fitness value, depending on how well it performed. In the second stage, the fittest strings are preferentially chosen for recombination to form the next generation. Recombination involves the selection of two strings, the choice of a crossover point in the string, and the switching of the segments to the right of this point, between the two strings (the cross-over operation). Figure 1 shows the combination of fuzzy logic and genetic algorithms for generating fuzzy rules.

For encoding and decoding of the fuzzy rule for a fuzzy logic system, first the input parameters of the fuzzy logic system is divided into fuzzy sets. Assume that the fuzzy logic system has two inputs α and β and a single output δ. Assume also that the inputs and output of the system is divided into five fuzzy sets. Therefore, a maximum of 25 fuzzy rules can be written for the fuzzy logic system.

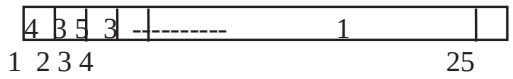
The consequence for each fuzzy rule is determined by genetic evolution. In order to do so, the output fuzzy sets are encoded. It is not necessary to encode the input fuzzy sets because the input fuzzy sets are static and do not change.

The fuzzy rules relating the input variables (α and β) to the output variable (δ) have 25 possible combinations. The consequent of each fuzzy rule can be any one of the five output fuzzy sets. Assume that the output fuzzy sets are **NB** (Negative Big), **NS** (Negative Small), **ZE** (Zero), **PS** (Positive Small), and **PB** (Positive Big). Then the output fuzzy sets are encoded by assigning 1 = **NB** (Negative Big), 2 = **NS** (Negative Small), 3 = **ZE** (Zero), 4 = **PS** (Positive Small),

Figure 1. Combination of fuzzy logic and genetic algorithms for fuzzy rule generation



and 5 = **PB** (Positive Big). Genetic algorithms randomly encode each output fuzzy set into a number ranging from 1 to 5 for all possible combinations of the input fuzzy variables. A string encoded this way can be represented as



Each individual string is then decoded into the output linguistic terms. The set of fuzzy rules thus developed, is evaluated by the fuzzy logic system based upon a fitness value that is specific to the system. At the end of each generation, (two or more) copies of the best performing string from the parent generation is included in the next generation to ensure that the best performing strings are not lost. Genetic algorithms then perform the process of selection, crossover, and mutation on the rest of the individual strings. Selection and crossover are the same as a simple genetic algorithms while the mutation operation is modified. Crossover and mutation take place based on the probability of crossover and mutation respectively. Mutation operator is changed to suit this problem. For mutation, an allele is selected at random, and it is replaced by a random number ranging from 1 to 5. The process of selection, crossover, and mutation are repeated for a number of generations till a satisfactory fuzzy rule base is obtained. We define a satisfactory rule base as one whose fitness value differs from the desired output of the system by a very small value.

HIERARCHICAL FUZZY LOGIC SYSTEM FOR INTEREST RATE PREDICTION

There is a large interest by investors and government departments in the ability to predict future interest rate fluctuations from current economic data. Economists, and investors, have been unable to find all the factors that influence interest rate fluctuations. It is agreed, however, that there are some major economic indicators released by the government that are commonly used to look at the current position of the economy. These indicators used in this chapter are as follows

- *Interest Rate, which is the indicator being predicted. The Interest Rate used here is the Australian Commonwealth government 10-year treasury bonds.*
- *Job Vacancies is where a position is available for immediate filling or for which recruitment action has been taken.*
- *The Unemployment Rate is the percentage of the labour force actively looking for work in the country.*
- *Gross Domestic Product is an average aggregate measure of the value of economic production in a given period.*
- *The Consumer Price Index is a general indicator of the rate of change in prices paid by consumers for goods and services.*
- *Household Saving Ratio is the ratio of household income saved to households disposable income.*
- *Home Loans measure the supply of finance for home loans, not the demand for housing.*
- *Average Weekly Earnings is the average amount of wages that a full time worker takes home before any taxes.*
- *Current Account is the sum of the balances on merchandise trade, services trade, income, and unrequited transfers.*
- *Trade Weighted Index measures changes in our currency relative to the currencies of our main trading partners.*
- *RBA Commodity Price Index provides an early indication of trends in Australia's export Prices.*
- *All Industrial Index provides an indication of price movements on the Australian Stock Market.*
- *Company Profits are defined as net operating profits or losses before income tax.*
- *New Motor Vehicles is the number of new vehicles registered in Australia.*

By creating a system that contained all these indicators, we would be in a much better position to predict the fluctuations in interest rates. A fuzzy logic system that used every indicator and had five fuzzy sets for every indicator would result in a large FKB consisting of over six billion rules! As can be imagined, this would require large computing power to not only train the fuzzy logic system with a genetic algorithm, but also large storage and run-time costs when the system is operational. Even if a computer could adequately handle this large amount of data, there is still the problem in having enough data to properly train every possible rule. To overcome this problem a hierarchical fuzzy logic structure for the fuzzy logic system can be constructed. By using a hierarchical fuzzy logic system, the number of fuzzy rules of the system is reduced, hence, computational times are decreased, resulting in a more efficient system. A novel way to tackle this problem would be to group the relevant indicators and to build a fuzzy knowledge base for each group. The first step is to divide the indicators into smaller-related groups. This problem was investigated in Mohammadian and Kingham (1997) and Mohammadian et al. (1998), and is shown as follows:

1. **Employment** (Job Vacancies, Unemployment Rate**)**
2. **Country** (Gross Domestic Product, Consumer Price Index)
3. **Savings** (Household Saving Ratio, Home Loans, Average Weekly Earnings)

4. **Foreign** (Current Account, RBA Index, Trade Weighted Index)
5. **Company** (All Industrial Index, Company Profit, New Motor Vehicles)

The Interest Rate is included with each of these groups. To learn the fuzzy knowledge base for each group, a genetic algorithm was implemented. The genetic algorithms had a population size of 500 with a crossover rate of 0.6 and a mutation rate of 0.01, and it was run for 10,000 generations over 10 years (a period of 40 quarters) data. Fitness of each string of the genetic algorithm was calculated as the sum of the absolute differences from the predicted quarter and the actual quarters interest rate. The fitness was subtracted from an "optimal" fitness amount, which was decided to be 30, as it was unlikely the error amount would be higher than this over 10 years (Mohammadian & Kingham, 1997; Mohammadian et al., 1998). The fitness of the system is calculated by the following formula:

$$fitness = 30 - \sum_{i=0}^{30} abs(PI_i - I_{i+1}) \quad (2)$$

An elitist strategy was used in that the best population generated was saved and entered in the next generation (two copies of the string with best fitness was included to the next generation). The five fuzzy knowledge bases created form the top layer of the hierarchy are shown in Figure 2. Mohammadian and Kingham (1997) designed and connected together the fuzzy knowledge bases to form a final fuzzy knowledge base system. The final fuzzy knowledge base system, shown in Figure 2, then uses the predicted interest rate from the five listed groups to produce a final interest rate prediction. The number of fuzzy rules for each group is shown in Figure 2.

The final hierarchical FKB contains 3,125 rules (Mohammadian & Kingham, 1997), giving the total number of rules learnt as 5,250. This is a significant reduction from the 6 billion rules that would have been used previously. This allows quicker training time without the need for huge computer resources (Mohammadian & Kingham, 1997). Good prediction of Australian quarterly interest rate can be obtained using this system. The number of fuzzy rules used are also reduced dramatically.

However, there is still a question: Does a two-layer hierarchical architecture provide the best solution?

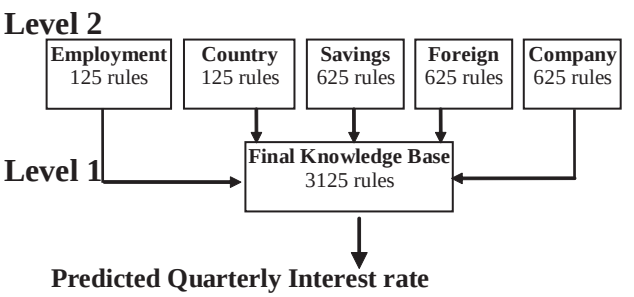
To answer this question, one can start building three, four layer hierarchical fuzzy logic system by trial and error to possibly find the correct number of layers required. This could be a cumbersome problem. We need to know how many layers are required, and which fuzzy knowledge base should be used in each layer. Genetic algorithms can be used to solve this problem by determining the number of layers in the hierarchical fuzzy logic system and the correct combination of FKBs for each layer, see Figure 3.

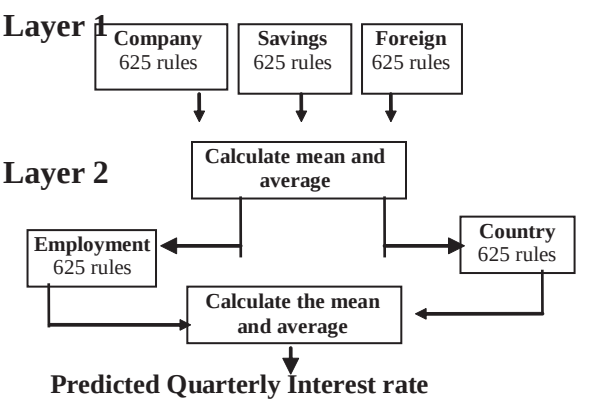
Next, the performance of genetic algorithms for design and development of hierarchical fuzzy logic systems is considered. The system is developed in such a way to provide the possible best architecture for designing hierarchical fuzzy logic systems for prediction of Interest Rate in Australia. Using the economic indicators, five fuzzy logic systems were developed from five groups, each producing a predicted interest rate for the next quarter. Genetic algorithms were then used to design and develop a hierarchical fuzzy logic system.

The hierarchical fuzzy logic system developed was then used to predict interest rate For each of these groups, the

Figure 3. A three-layer hierarchical fuzzy logic system – 3,125 fuzzy rules

Figure 2. Hierarchical fuzzy logic system (Mohammadian & Kingham, 1997; Mohammadian et al., 1998)

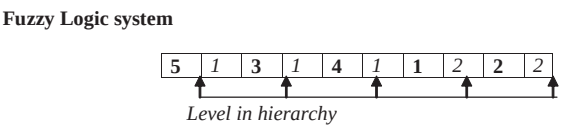




current quarter's interest rate is included in the indicators used (Mohammadian & Kingham, 1997). The advantage of using this hierarchical fuzzy logic structure is that the number of rules used in the knowledge base of fuzzy logic systems has been reduced substantially. For encoding and decoding of the hierarchical fuzzy logic system, first a number is allocated to each fuzzy logic system developed from group of indicators. For this simulation, the number allocated to each group is shown below:

1 = Employment, 2 = Country, 3 = Savings, 4 = Foreign, 5 = Company

The number of layers and the fuzzy logic system/s for each layer is determined by genetic algorithms. In order to do so, a number is allocated to each fuzzy logic system. Genetic algorithms randomly encode each fuzzy logic system into a number ranging from 1 to 5 for all possible combinations of the fuzzy logic systems. The level in the hierarchy in which a fuzzy logic system is allocated to, is also encoded each string. A string is encoded this way can be represented as



Each individual string is then decoded into a hierarchical fuzzy logic system that defines the fuzzy logic system/s for each level of the hierarchical fuzzy logic system. This string, once decoded, will provide a hierarchical fuzzy logic system, as shown in Figure 3. The set of hierarchical fuzzy logic systems, thus developed, are evaluated, and a fitness value is given to each string. At the end of each generation, (two or more), copies of the best performing string from the parent generation are included in the next generation to ensure that the best performing strings are not lost. Genetic algorithms then performs the process of selection, crossover, and mutation on the rest of the individual strings. Crossover and mutation take place based on the probability of crossover and mutation, respectively. Mutation operator is changed to suit this problem. The process of selection, crossover, and mutation are repeated for a number of generations till a satisfactory hierarchical fuzzy logic system is obtained. We define a satisfactory hierarchical fuzzy logic system as one whose fitness value (predicated interest rate) differs from the desired output of the system (in this case the actual interest rate) by a very small value. We calculate the average error of the system for the training set and tests sets using the following formula (Mohammadian & Kingham, 1997):

$$E = \frac{\sum_{i=1}^{n} abs(Pi - Ai)}{n} \tag{3}$$

where E is the average error, *Pi* is the predicted interest rate at time period *i*, *Ai* is the actual interest rate for the quarter, and *n* is the number of quarters predicted. By using genetic algorithms to design and develop hierarchical fuzzy logic system, better results were obtained. The hierarchical fuzzy logic systems developed using genetic algorithms perform predict the interest rate to different degree of accuracy. It is, however, interesting to see that genetic algorithms is capable of providing different hierarchical fuzzy logic system for predicting the interest rate. It is now possible to choose the best hierarchical fuzzy logic system among those suggested by genetic algorithms. The result of the top performing five hierarchical fuzzy logic systems designed by genetic algorithms is given in Table 1. Comparison of average errors of these five best hierarchical fuzzy logic systems designed and developed using genetic algorithms is also shown in Table 1.

Table 1. Average Errors of hierarchical fuzzy logic (HFL) systems designed and developed using GA and Average Errors of hierarchical neural networks by (Mohammadian & Kingham, 1997; Mohammadian et al., 1998)

	Training Error	Testing Error
Hierarchical fuzzy logic #1	0.356	0.659
Hierarchical fuzzy logic #2	0.343	0.663
Hierarchical fuzzy logic #3	0.289	0.494
Hierarchical fuzzy logic #4	0.274	0.441
Hierarchical fuzzy logic #5	0.291	0.398
Hierarchical neural network	0.354	0.607

COMPARISON OF HIERARCHICAL FUZZY LOGIC SYSTEM WITH NEURAL NETWORK SYSTEM FOR PREDICTION OF INTEREST RATE

Mohammadian and Kingham (1997) reported the use of a hierarchical neural network system using the same data inputs as described for the hierarchical fuzzy logic system. Using these economic indicators, a neural network system was created for each five groups (Country Group, Employment Group, Savings Group, Company Group, and Foreign Group). Each neural network system was trained using back-propagation algorithms. A back-propagation neural network was used with two hidden layers, each consisting of 20 neurons, output layer consists of one node. Sigmoid learning was used to predict the following quarters interest rate. The error tolerance was set to 0.0001, the Learning Parameter (Beta) was set to 0.6, momentum (alpha), and Noise Factor were both set to 0. The neural network was trained for 10,000 cycles (Mohammadian & Kingham, 1997, Mohammadian et al., 1998). After training each neural network system for each group, all neural network systems were combined to form a hierarchical neural network system with the same structure as shown in Figure 2. The final neural network system then was trained. It used the prediction of all five neural networks for each group to predict the quarterly interest rate, as its output. Table 1 shows the comparison of the average errors of hierarchical fuzzy logic systems designed and developed using GA and average errors of hierarchical neural networks by Mohammadian and Kingham (1997).

CONCLUSION AND FURTHER INVESTIGATIONS

In this chapter, an innovative method is used to design and develop hierarchical fuzzy logic systems. Genetic algorithms are used as an adaptive learning method to design a hierarchical fuzzy logic systems to predict the quarterly interest rate in Australia. Using a hierarchical fuzzy logic system, the number of fuzzy rules in the fuzzy knowledge base is reduced dramatically, hence, computational times are decreased resulting in a more efficient system. Genetic algorithms are also used to obtain the fuzzy rules for each fuzzy logic system of a hierarchical fuzzy logic system.

From simulation results, it was found that the hierarchical fuzzy logic system is capable of making accurate predictions of the following quarter's interest rate. The prediction result of the top five hierarchical fuzzy logic systems were compared to a hierarchical neural network. It was found that most of the top five hierarchical fuzzy logic system designed by genetic algorithms performed better than the hierarchical neural network. It should be noted that hierarchical neural network was designed based on the intuition (Mohammadian & Kingham, 1997; Mohammadian et al., 1998) and it may be possible to obtain better prediction results using an automated system using genetic algorithms to automatically design the hierarchical neural network system. The research work performed in this chapter is unique in the way the hierarchical fuzzy logic systems are developed. The application of this method to several industrial problems, such as robotic control and collision avoidance of multirobot systems, is currently under consideration. Research is also currently being performed to automatically design a hierarchical neural network system for modeling and prediction.

INTRODUCTION

In our daily life no one questions the necessity of privacy protection. Nevertheless, our privacy is often put at risk. The first problem has to do with the fact that privacy itself is a concept difficult to define. As a matter of fact, in many countries the concept has been confused with data protection, which interprets privacy in terms of the management of personal information. Nowadays, the term *privacy* is extended to territorial and communications protection.

We will focus on the privacy of electronic communications. When referring to this type of communication, the first aspect we think about is security. In fact, this concept is widely discussed, and nowadays we often hear about threats and attacks to networks.

Security attacks are usually split into active and passive attacks. We consider that an active attack takes place when an attacker injects or modifies traffic in the network with different purposes, such as denial of service or gaining unauthorized access. Unlike active attacks, a passive attack takes place whenever the attacker merely inspects the network by listening to packets, never injecting any packet. Malicious nodes hope to be 'invisible' in order to collect as much network information as possible just by using timing analysis and eavesdropping routing information. A way to avoid this type of attack is to anonymize both data and routing traffic. In this manner we can hide the identities of communicating nodes and avoid data flow traceability.

Various scenarios can be devised where anonymity is desirable. In a commercial transactions context, if we think about an off-line purchase, we accept that some users prefer to use cash when buying some goods and services, because anonymity makes them more comfortable with the transaction. Offering anonymity to online commerce would increase the number of transactions.

Military communications are another typical example where not only privacy but also anonymity are crucial for the success of the corresponding mission.

Finally, if we attend a meeting where some delicate matter is being voted on, it could be necessary for the identities to remain hidden. Again, in this case, anonymity is required.

BACKGROUND

In order to talk about anonymity, first we have to establish the terminology to be used. An important work on this issue is Pfitzmann and Hansen (2000); based on this work, we can establish a classification of anonymity degrees: A node is considered exposed when its identity information is known. If its identity is not the real one, the node is pseudonymous. Furthermore, if it is unlinkable to some kind of relevant information, we achieve anonymity with respect to that information; as an example we can consider the relationship between end-to-end peers or the peers themselves. Finally, when the communication is not perceived, we can say that it is undetectable; and if it is undetectable for any external node and also anonymous for every participant, the communication is unobservable.

In the literature, there are various works based on different networks topologies as the Dining Cryptographers (Chaum, 1988) or MIXes (Chaum, 1981) in order to provide anonymous communications in fixed networks.

PEER ANONYMITY

In this article we will discuss the different degrees of anonymity provided by means of different proposals found in the literature, emphasizing those issues that are still unsolved.

General Approaches

Anonymity has been treated differently depending on the network characteristics and goals. We believe that the two most relevant generic proposals are the Dining Cryptographers network and the MIX network.

Dining Cryptographers Network

The Dining Cryptographers network (DC-net) (Chaum, 1988) achieves sender anonymity in the following way: some pairs of participants share a secret bit. Each participant calculates the sum of all the bits that he shares, and if he wants to transmit, he inverts that result. All the nodes send the result of the sum or the inverted one (if necessary). If no one (or an even number of participants) transmits, the sum of all these transmissions is zero. In cases where one participant (or an odd number of them) transmits, the sum will be one. Each participant could share a key of n bits with another participant, one bit per round. So, the ith bit of each such key will be used in the ith round.

However, this approach is restricted to small networks since only one node can transmit in each round. In large networks the probability of having more than one node wishing to transmit in a specific round increases, and so collisions will render this mechanism impractical.

Furthermore, the anonymous bandwidth of a DC-net is limited by the slowest participant. Overall, DC-nets provide strong anonymity elegantly, but suffer from efficiency and scalability problems.

Herbivore (Goel, Robson, Polte, & Sirer, 2003) is a protocol based on DC-nets that tries to solve the scalability problem by splitting the network into sub-groups (called cliques), but it requires global topology control. In terms of efficiency, results are actually quite poor.

MIXes Network

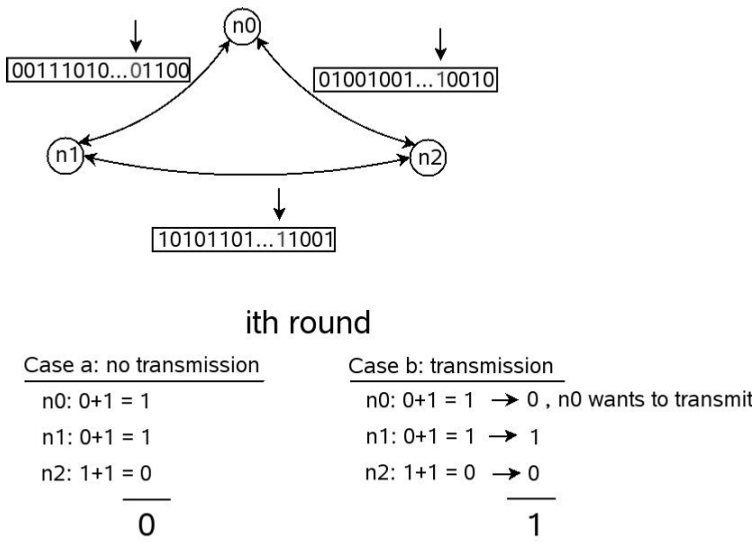
In 1981, Chaum proposed the use of MIXes to anonymize electronic mail users and messages. The main goal for a single MIX is to hide the correlation between incoming and outgoing messages within a large group of messages by delaying or reordering them. In order to do this, encryption and padding mechanisms are applied.

There are several MIX variants:

- A pool MIX only sends part of the incoming messages, keeping the other parts for later rounds. Hence, it uses the reordering technique. It is called a "timed MIX" if the event that triggers the flushing is the expiration of a timeout. In cases where the trigger is the arrival of a message, the MIX will be referred to as a "threshold MIX."
- A stop-and-go MIX (or continuous MIX) delays messages according to an exponential distribution, which does not depend on traffic. Hence, if the number of users is low, the degree of anonymity is also low.

A MIX network can consist of a set of predefined routes, called cascades, or free route networks, where routes are selected by users. Berthold, Pfitzmann, and Standtke (2001) establish that this last type of networks is flexible, scalable, and extendable. However, it is less secure due to the intersection of different anonymity sender/recipient groups,

Figure 1. Example of DC-net



making it easier to reveal participants' identities. Danezis (2003) provides an intermediate solution: Each MIX can only choose routes included in a predetermined graph. The conclusion is that this network is more scalable than a cascade and more resistant to intersection attack than the free route alternative.

In general we can say that MIX-nets always provide relationship anonymity and sometimes also recipient anonymity if their identity remains hidden. However, sender anonymity is more difficult to achieve.

Based on Chaum's MIXes, Tarzan (Freedman & Morris, 2002) provides both sender and recipient anonymity, and therefore relationship anonymity, by using a restricted topology for packet routing. Packets can be routed only between special IP tunnels. Anonymity should be transparent to both client applications and servers.

Tarzan operates at the IP layer and relies on layered encryption: each leg of the tunnel removes or adds a layer of encryption. The tunnels are static and any relay failure requires the formation of a new tunnel, thus increasing both delay and computation overheads.

Instead of single-node MIXes, Cashmere (Zhuang, Zhou, Zhao, & Rowstron, 2005) selects regions (relay groups) as MIXes, providing sender and relationship anonymity. At the same time, any node in a region can act as a MIX, hence reducing the probability of a MIX failure. Each group requires a public/private key pair, which is generated and distributed using an off-line certificate authority (CA). The source randomly selects and orders the relay groups to conceal the destination relay group. It then encrypts the forwarding path in multiple layers using the public keys associated with each relay group. An intermediate node decrypts the message received, forwards it to the next relay group, and broadcasts the decrypted contents to all other members of its own group. The bandwidth cost is higher for this solution than for a node-based relay approach.

Other Protocols

In addition to the solutions already discussed, proposals such as Crowds, Hordes, P5, Tor, and HIP are also relevant in this field of research.

With Crowds (Reiter & Rubin, 1998), the authors provide sender anonymity following this strategy: The source node does not choose the path to be used; instead, it sends the message directly to the Internet with probability p, or forwards the message to another randomly selected user with probability 1-p. The rest of nodes in the network behave in the same way. Therefore, the initiator is indistinguishable from a member that simply forwards a request from another. Once a path is chosen, it remains static for that source-destination pair until the server sends a special message that forces all the established paths to change in order to avoid certain types of attacks. Connections between users are encrypted with the keys distributed by the server.

Shields and Levine (2000) describe the Hordes protocol, which uses a similar strategy to anonymously send a packet from the initiator to the responder. However, it uses multicast communications in the reverse path to reduce the amount of work required from participants and to improve data delivery latency and link utilization. This proposal assumes that shortest path multicast routing trees are available.

The Peer-to-Peer Personal Privacy Protocol (P5) (Sherwood, Bhattacharjee, & Srinivasan, 2002) is another protocol targeting anonymous communications that provides sender and recipient anonymity. It is designed to be implemented in addition to the current Internet protocols without any special infrastructure support. Since it is based on broadcast transmissions, it creates a broadcast hierarchy to avoid scalability problems. This solution has a cost in terms of efficiency; moreover, in mobile environments it would require group management algorithms in order to keep the hierarchy updated. Every node acts as a MIX, scrambling received packets before forwarding them and using hop-by-hop encryption. Also, it maintains a fixed communication rate, sending signal or noise packets only if necessary.

In Dingledine, Mathewson, and Syverson (2004), Tor is proposed as the second-generation onion router. It works on the Internet, and is designed to make TCP-based applications (like Web browsing or instant messaging) anonymous. Clients choose a path through the network and build a circuit, in which each node knows its predecessor and successor, but no other nodes along the path. The length of packets is fixed, and each node unwraps them using a symmetric key. Each onion router maintains a long-term identity key to sign certificates, directories, and the router's descriptor, along with a short-term onion key to decrypt requests from the users to set up a circuit and to negotiate ephemeral keys.

The Host Identity Protocol (HIP) (Moskowitz, Nikander, Jokela, & Henderson, 2007) aims to separate the identifier and locator roles of IP addresses. The base HIP protocol ("base exchange") is used between hosts to establish an IP-layer communications context (called HIP association) prior to communications. This process is based on a Sigma-compliant Diffie-Hellman key exchange (Diffie & Hellman, 1976) with public key identifiers for mutual peer authentication.

The public key of an asymmetric key pair is used as the identifier, named the host identifier (HI). However, a hashed encoding of the HI, usually referred to as the host identity tag (HIT), represents the host identity in protocols due to its short and fixed length (128 bits) and the following three properties: (1) it has the same length as an IPv6 address, and so can be used in address-sized fields in APIs and protocols; (2) it is self-certifying (i.e., given a HIT, it is computationally hard to find a host identity key that matches the HIT); and (3) the probability of HIT collision between two hosts is very low.

Indeed, these properties provide the following advantages: first, its fixed length simplifies the protocol coding and reduces the cost of this technology in terms of packet size. Second, it presents a consistent format to the protocol irrespective of the underlying identity technology used.

Undetectability and Unobservability

The highest degrees of anonymity are undetectability and unobservability.

Referring again to the definitions presented in Pfitzmann and Hansen (2000), and according to the authors: "A mechanism to achieve some kind of anonymity appropriately combined with dummy traffic yields the corresponding kind of unobservability." So we could say, for example, that:

DC-nets + dummy traffic = sender unobservability
MIX-nets + dummy traffic = relationship unobservability

The other two most popular mechanisms used to provide undetectability are steganography and spread spectrum techniques.

The use of power control can also help to reduce the probability of being heard since the attacker must be located very close to the transmitter node. If directional antennas are used, the attacker not only has to stay close, but also inside the corresponding sector to which the antenna is directed.

General approaches to achieve undetectability and unobservability can be found in the literature. In this section we briefly explain some of them that are based on two popular techniques: steganography and dummy traffic.

We focus firstly on the studies related to steganography. The typical approach is based on images where it is easy to introduce hidden information due to the redundancy that this type of message presents, but without forgetting the possibility of compression that would eliminate redundancy and also all the hidden information.

Sender unobservability is provided in Heydt-Benjamin, Serjantov, and Defend (2006) using steganography in a high-latency MIX network, achieving sender/receiver unlinkability as achieved by other MIX networks, while improving sender unobservability. In it, users steganographically embed messages in images which they then post to the most popular Usenet newsgroups. The majority of images in Usenet will not contain stegotext and will serve as cover traffic.

The schema presented in Bo, Jia-zhen, and De-yun (2007) uses the identification field of the IPv4 header to conceal data. According to this proposal the first eight bits of that field will contain data and the next eight bits the order of the packet. Due to the small amount of information transmitted in each packet, several are required to send the whole message. In order to give this field a random appearance, a fourth-order Chebyshev chaotic system is used to generate a sequence from an initial given value. This chaotic sequence is then converted to a binary sequence. Also, a key is shared between source and destination. The message is encrypted with this key. Afterwards the k different encrypted blocks are included in k packets and they are sent to the destination. To ensure the success of the proposal packet, fragmentation along the path must be avoided. To achieve this, the path maximum transfer unit discovery (PMTUD) is enabled. Obviously, the schema is only practical for very short messages.

Ahsan and Kundur (2002) use two strategies to hide information: IPv4 header manipulation (fragment bit and identification field) and packet sorting using the sequence number fields in IPSec (AH or ESP headers).

In the former case they propose the use of the second bit—the DF (Do not Fragment) bit—in the Flags field. In order to send secret information using this bit, both the source and destination have to know the MTU of their network and always build packets that are a smaller size than this MTU to avoid packet fragmentation (that would corrupt the DF bit). The identification field is another possible header field manipulated to hide data. Ahsan and Kundur (2002) use it through chaotic MIXing (toral automorphism systems) to provide a random appearance to the field. The only limitation is that the identification field is unique for a specific source-destination pair as long as the datagram is alive. With regards to the packet sorting, the authors consider that the order of the packets sent is of no concern. So, if there are *n* packets to send, they will have *n!* ways of sending them and the selection of one combination can be interpreted as *log2(n!)* concealed bits. Estimation of hidden information is done using a look-up table to match the stored sequence to the corresponding sequence of packets received, and mapping this sequence to the hidden information. Also, the transmission process is modeled as a non-ideal channel characterized by the position error. The latter is imposed by the network's behavior since the network cannot guarantee sequencing in packet delivery.

With regards to dummy traffic, Diaz and Preneel (2004a) introduced this topic and pointed out the necessity of establishing an appropriate amount of dummy packets depending on the cost of inserting them. Also, the number of dummy packets should depend (or not) on the amount of real traffic. The frequency of generation and the most appropriate route length for these dummy messages are still open questions.

Research presented in Diaz and Preneel (2004b, 2004c) focuses on MIXes networks by trying to determine the best strategy for the insertion of dummy traffic. Such traffic is inserted and removed by MIXes, not users, and two different ways of inserting it are proposed: into the output link at the time of flushing or into the pool of the MIX. In both cases the generation of dummy messages follows a probability distribution independent of the traffic of real messages. With regards to the type of MIXes, the authors compare deterministic and binomial MIXes using random or deterministic dummy policies. They conclude that binomial MIXes,

together with a random dummy policy, provide the greatest level of anonymity. Likewise, in terms of anonymity, it is better to insert dummy traffic at the output link, although latency also increases.

FUTURE TRENDS

In recent times, wireless networks have become important in our daily communications, and so it is necessary to provide them with security mechanisms, and anonymous ones in particular. The proposals for wired networks are not suitable for wireless and mobile communications. Hence, most of the last works for anonymous communications have been specifically designed for MANETs (Kong & Hong, 2003; Zhang, Liu, Lou, & Fang, 2006). However, their performance needs to improve if we want those protocols to be useful and practical.

CONCLUSION

In this article we have analyzed a wide variety of proposals for anonymous communications in wired networks. We believe that the field of anonymous communications is still open to improvements, and no author has yet integrated the different anonymity mechanisms described throughout this article in a consistent and efficient manner. Performance issues also remain largely untackled, and they require more scrutiny before actual deployment can take place.

KEY TERMS

Anonymity: State of being not identifiable among other items belonging to a set. This set is called *anonymity set*.

Dummy Traffic: Randomly generated packets injected in the network to make the perception of real traffic difficult.

Item of the System: Any participating subject, object, or action: node, user, message, sending, and so forth.

Spread-Spectrum Techniques: Methods by which energy generated with a certain bandwidth is deliberately spread in the frequency domain, resulting in a signal with a wider bandwidth.

Steganography: The art and science of writing hidden messages in such a way that no one apart from the sender and the intended recipient even realizes that there is a hidden message.

Undetectability: Incapability of observing an established communication. Thus, undetectability prevents that third parties can observe when a packet is being sent through the network.

Unlinkability: Incapability of stating the relation between two observed items of the system. For example, recipient unlinkability ensures that the sending of a packet and the corresponding recipient cannot be linked by others.

Unobservability: Undetectability by external attackers plus anonymity for internal attackers.

Untraceability: Property of maintaining routes unknown to either external or internal attackers.

Ant Colony Algorithms for Data Classification

Alex A. Freitas

INTRODUCTION

Ant colony optimization (ACO) is a relatively new computational intelligence paradigm inspired by the behavior of natural ants (Dorigo & Stutzle, 2004). Ants often find the shortest path between a food source and the nest of the colony without using visual information. In order to exchange information about which path should be followed, ants communicate with each other by means of a chemical substance called pheromone. As ants move, a certain amount of pheromone is dropped on the ground, creating a pheromone trail. The more ants that follow a given trail, the more attractive that trail becomes to be followed by other ants. This process involves a loop of positive feedback, in which the probability that an ant chooses a path is proportional to the number of ants that have already passed by that path.

Hence, individual ants, following very simple rules, interact to produce an intelligent behavior at the higher level of the ant colony. In other words, intelligence is an emergent phenomenon.

In this article we present an overview of Ant-Miner, an ACO algorithm for discovering classification rules in data mining (Parpinelli, Lopes, & Freitas, 2002a, 2002b), as well as a review of several Ant-Miner variations and related ACO algorithms.

All the algorithms reviewed in this article address the classification task of data mining. In this task each case (record) of the data being mined consists of two parts: a goal attribute, whose value is to be predicted, and a set of predictor attributes. The aim is to predict the value of the goal attribute for a case, given the values of the predictor attributes for that case (Fayyad, Piatetsky-Shapiro, & Smyth, 1996).

BACKGROUND

An ACO algorithm is essentially a computational system inspired by the behavior of natural ants and designed to solve real-world optimization problems. The basic ideas of ACO algorithms are as follows (Dorigo & Stutzle, 2004):

- Each ant incrementally constructs a candidate solution to a given optimization problem. That candidate solution is associated with a path in a graph representing the search space.
- When an ant follows a path, the amount of pheromone deposited on that path is proportional to the quality of the corresponding candidate solution.
- At each step during the incremental construction of a candidate solution, an ant typically has to choose which solution component should be added to the current partial solution (i.e., how to extend the current path), among several solution components. In general the probability of a given component being chosen is proportional to the product of two terms: (a) the amount of pheromone associated with that component; and (b) the value of a (problem-dependent) heuristic function for that component.

As a result, due to a continuous increase of the pheromone associated with the components of the best candidate solutions considered by the algorithm, the ants usually converge to the optimum or near-optimum solution for the target problem.

The motivation for applying ACO algorithms to the discovery of classification rules and related data mining tasks is as follows. Many projects in the field of data mining proposed deterministic rule induction algorithms. These algorithms typically are greedy, and so they are susceptible to find only locally optimal (rather than globally optimal) classification rules. By contrast, ACO algorithms try to mitigate this drawback using a combination of two basic ideas. First, these algorithms have a stochastic aspect, which helps them to explore a larger area of the search space. Second, they use an iterative adaptation procedure based on positive feedback (the gradual increase of the pheromone associated with the best solution components) to continuously improve candidate rules. Combining these basic ideas, in general ACO algorithms perform a more global search in the space of candidate rules than typical deterministic rule induction algorithms, which makes the former an interesting alternative to be considered in rule induction.

The first ACO algorithm proposed for discovering classification rules was Ant-Miner (Parpinelli et al., 2002a). In Ant-Miner each artificial path constructed by an ant represents a candidate classification rule of the form:

IF <*term1* AND *term2* AND … > THEN < *class* >.

Each term is a triple <*attribute, operator, value*>, where *value* is one of the values belonging to the domain of *attribute*. An example of a term is: <*Sex = female*>. *Class* is the value of the goal attribute predicted by the rule for any case that satisfies all the terms of the rule antecedent. An example of a rule is:

IF <*Salary = high*> AND <*Mortgage = No*> THEN <*Credit = good*>.

In the original version of Ant-Miner, the *operator* is always "=" so that Ant-Miner can cope only with categorical (discrete) attributes. Continuous attributes would have to be discretized in a preprocessing step.

The pseudo code of Ant-Miner is described, at a very high level of abstraction, in Algorithm 1. Ant-Miner starts by initializing the training set to the set of all training cases, and initializing the discovered rule list to an empty list. Then it performs an outer loop where each iteration discovers a classification rule.

The first step of this outer loop is to initialize all trails with the same amount of pheromone, which means that all terms have the same probability of being chosen—by an ant—to incrementally construct a rule. This is done by an inner loop, consisting of three steps. First, an ant starts with an empty rule and incrementally constructs a classification rule by adding one term at a time to the current rule. In this step a $term_{ij}$—representing a triple $<Attribute_i = Value_j>$—is chosen to be added to the current rule with probability proportional to the product of $\eta_{ij} \times \tau_{ij}(t)$, where η_{ij} is the value of a problem-dependent heuristic function for $term_{ij}$ and $\tau_{ij}(t)$ is the amount of pheromone associated with $term_{ij}$ at iteration (time index) t. More precisely, η_{ij} is essentially the information gain associated with $term_{ij}$ (see Cover & Thomas, 1991, for a comprehensive discussion on information gain). The higher the value of η_{ij}, the more relevant for classification $term_{ij}$ is and so the higher its probability of being chosen. $\tau_{ij}(t)$ corresponds to the amount of pheromone currently available in the position i,j of the trail being followed by the current ant. The better the quality of the rule constructed by an ant, the higher the amount of pheromone added to the trail positions ("terms") visited ("used") by the ant. Therefore, as time goes by, the best trail positions to be followed—that is, the best terms to be added to a rule—will have greater and greater amounts of pheromone, increasing their probability of being chosen.

The second step of the inner loop consists of pruning the just-constructed rule—that is, removing irrelevant terms. This is done by using the same rule-quality measure used to update the pheromones of the trails, as defined later. In essence, a term is removed from a rule if this operation does not decrease the quality of the rule.

Algorithm 1. High-Level Pseudo Code of Ant-Miner

```
TrainingSet = {all training cases};
DiscoveredRuleList = []; /* initialized with empty list */
REPEAT
  Initialize all trails with the same amount of pheromone;
  REPEAT
    An ant incrementally constructs a classification rule;
    Prune the just-constructed rule;
    Update the pheromone of all trails;
  UNTIL (stopping criteria)
  Choose the best rule out of all constructed rules;
  Add the chosen rule to DiscoveredRuleList;
  TrainingSet = TrainingSet – {cases correctly covered by
  the chosen rule};
UNTIL (stopping criteria)
```

The third step of the inner loop consists of updating the pheromone of all trails by increasing the pheromone in the trail followed by the ant, proportionally to the quality of the rule. In other words, the higher the quality of the rule, the higher the increase in the pheromone of the terms occurring in the rule antecedent. The quality (Q) of a rule is measured by the equation:

$$Q = \text{Sensitivity} \times \text{Specificity},$$

where $Sensitivity = TP / (TP + FN)$ and $Specificity = TN / (TN + FP)$. The acronyms TP, FN, TN, and FP stand for the number of true positives, false negatives, true negatives, and false positives, respectively (Parpinelli et al., 2002a).

The inner loop is performed until some stopping criterion is satisfied, for example, until a maximum number of candidate rules has been constructed.

Once the inner loop is over, the algorithm chooses the highest-quality rule out of all the rules constructed by all the ants in the inner loop, and then it adds the chosen rule to the discovered rule list. Next, the algorithm removes from the training set all the cases correctly covered by the rule—that is, all cases that satisfy the rule antecedent and have the same class as predicted by the rule consequent. Hence, the next iteration of the outer loop starts with a smaller training set, consisting only of cases which have not been correctly covered by any rule discovered in previous iterations. The outer loop is performed until some stopping criterion is satisfied, for example, until the number of uncovered cases is smaller than a user-specified threshold.

Hence, the output of Ant-Miner is the list of classification rules contained in the discovered rule list.

Parpinelli et al. (2002a, 2002b) have performed computational experiments comparing Ant-Miner with two well-known rule induction algorithms, namely CN2 (Clark & Niblett, 1989) and C4.5 (Quinlan, 1993), in several public-domain data sets. In a nutshell, the results showed that Ant-Miner is competitive with both C4.5 and CN2 concerning predictive accuracy on the test set. However, Ant-Miner discovered rule lists much simpler (i.e., smaller) than the rule sets discovered by C4.5 and the rule lists discovered by CN2. This is an advantage in the context of data mining, where discovered knowledge is supposed to be comprehensible to the user in order to support the user's intelligent decision making (Fayyad et al., 1996).

ANT-MINER VARIATIONS AND RELATED ALGORITHMS

(a) Fixing in Advance the Class Predicted by a Rule

In Ant-Miner, each ant first constructs a rule antecedent. Next, the majority class among all cases covered by the rule is assigned to the rule consequent. The fact that the class predicted by a rule is not known during rule construction has two important consequences. First, the heuristic function is based on reducing the entropy associated with the entire class distribution, rather than using a heuristic function specific to the class to be predicted by the rule. Second, the pheromone associated with each term represents the relevance of that term with respect to the overall discrimination between all classes, rather than with respect to a specific class.

In order to make the heuristic function and pheromone values have a more focused relevance, variations of Ant-Miner have been proposed where all the ants in the population construct rules predicting the same class, so that the class to be assigned to a rule is known during rule construction (Chen, Chen, & He, 2006; Galea & Shen, 2006; Martens, De Backer, M., Haesen, Baesens, & Holvoet, 2006; Smaldon & Freitas, 2006). This naturally leads to new heuristic functions and new pheromone update methods, as discussed in the next two subsections.

(b) New Class-Specific Heuristic Functions

Several Ant-Miner variations have replaced the entropy reduction heuristic function by a simpler heuristic function whose value is specific for each class (Chen et al., 2006; Liu, Abbass, & McKay, 2004; Martens et al., 2006; Oakes, 2004; Smaldon & Freitas, 2006; Wang & Feng, 2004). Typically, in these Ant-Miner variations, the value of the heuristic function for a $term_{ij}$ is based on the relative frequency of the class predicted by the rule among all the cases that have the $term_{ij}$. This modification is particularly recommended when the class predicted by a rule is fixed in advance before rule construction, unlike the situation in the original Ant-Miner, as discussed above.

It has also been argued that a simpler heuristic function based on the relative frequency of the rule's predicted class has the advantage of being computationally more efficient without sacrificing the predictive accuracy of the discovered rules, since hopefully the use of pheromones should compensate for the less accurate estimate of the simpler heuristic function. Note, however, that there is no guarantee that the use of pheromones would completely compensate the use of a less effective heuristic function. A more important issue seems to be whether or not the rule's predicted class is known during rule construction, as discussed earlier. In addition, note that in Ant-Miner the heuristic function values are computed just once in the initialization of the algorithm, and in principle the heuristic function values for all terms can be computed in linear time with respect to the number of cases and attributes (Parpinelli et al., 2002a). Hence, the time complexity of the heuristic function of Ant-Miner does not seem a significant problem in the context of the entire algorithm.

(c) Using the Pseudorandom Proportional Transition Rule

As explained earlier, Ant-Miner adds a $term_{ij}$ to a rule with a probability proportional to the product $\eta_{ij} \times \tau_{ij}(t)$. This kind of transition rule is called the random proportional transition rule (Dorigo & Stutzle, 2004). Several variants of Ant-Miner instead use a pseudorandom proportional transition rule (Chen et al., 2006; Liu et al., 2004; Wang & Feng, 2004). In this transition rule, in essence, there is a probability q_0 that the term to be added to the current partial rule will be deterministically chosen as the $term_{ij}$ with the greatest value of the product of $\eta_{ij} \times \tau_{ij}(t)$; and there is a probability $1 - q_0$ that the term to be added to the rule will be probabilistically chosen by the random proportional rule. This transition rule has the advantage that it allows the user to have explicit control over the exploitation vs. exploration trade-off (Dorigo & Stutzle, 2004), which of course comes with the need to choose a good value for the parameter q_0—normally chosen in an empirical way.

(d) New Rule Quality Measures

Ant-Miner's rule quality is based on the product of sensitivity and specificity. Chen et al. (2006) and Martens et al. (2006) proposed to replace Ant-Miner's rule quality measure with

measures that are essentially based on the confidence and coverage of a rule. Coverage is equivalent to sensitivity, so the main idea introduced in these Ant-Miner variations is to replace specificity by confidence in the rule quality measure. Given the importance of rule quality—on which pheromone updating is based—it would be interesting to perform extensive experiments comparing the effectiveness of these two kinds of rule quality measures—something missing in the literature.

(e) New Pheromone Updating Procedures

Several variants of Ant-Miner use an explicit pheromone evaporation rate—this is a predefined parameter in Liu et al. (2004) and Martens et al. (2006) and a self-adaptive parameter in Wang and Feng (2004). Note that this new parameter is not necessary in the original Ant-Miner, where pheromone evaporation is implicitly performed by normalizing all pheromone values after increasing the pheromone of the terms used in the just-constructed rule.

In addition, Liu et al. (2004), Wang and Feng (2004), and Smaldon and Freitas (2006) proposed different equations or procedures to update pheromone as a function of rule quality. These new approaches address the issue that Ant-Miner's original equation for pheromone updating does not work well when the quality of a rule is close to zero. Note, however, that in the original Ant-Miner, the value of the rule quality measure will be close to zero only in rare situations. This is due to the fact that the best possible class for the current rule is always chosen to be added to the rule consequent after the rule antecedent has been fully constructed, which should result in a rule of at least reasonable quality in most cases. On the other hand, in Ant-Miner variants—where the class of all constructed rules is predetermined (see the discussion in the first subsection above) rules with very low quality will be less rare, especially in early iterations of the algorithm, before the pheromone of good terms has been significantly increased. In such Ant-Miner variants, it is indeed important to change the original Ant-Miner equation to update pheromone in order to cope better with low-quality rules.

(f) Coping with Categorical Attributes Having Ordered Values

Ant-Miner copes only with categorical (nominal or discrete) attributes. Hence, continuous (real-valued) attributes have to be discretized in a preprocessing step. Some categorical attributes have unordered values (e.g., the attribute "gender" can take the values "male" or "female"), while other categorical attributes have ordered values (e.g., the attribute "number of children" could take the values "0", "1", "2", "3", or "more than 3"). Ant-Miner does not recognize this distinction. It produces only terms (rule conditions) of the form "attribute = value" using the "=" operator.

Both Oakes (2004) and Martens et al. (2006) proposed Ant-Miner variants that can cope with ordered values of categorical (but not continuous) attributes. These variants can discover rules containing terms of the form "attribute op value" where *op* can be a relational comparison operator such as "<", ">", "≤", or "≥". This allows the discovery of simpler (smaller) rule sets. For instance, a single condition like "number of children < 3" is shorter than the disjunction of conditions: "number of children = 0" or "number of children = 1" or "number of children = 2."

(g) Dropping the Rule Pruning Procedure

Martens et al. (2006) proposed an Ant-Miner variant (Ant-Miner+) that does not perform rule pruning. In order to mitigate the need for pruning, the domain of each attribute was extended with a dummy value, hereafter called the "any" value. Hence, for each attribute i with k values, there is a set of k+1 terms that can be chosen to be added to the current partial rule, where the $term_{i,k+1}$ is the "any" value for attribute i. Adding an "any" value term to a rule means that the attribute in question can have any value when the rule is evaluated, which effectively means that attribute is not present in the rule antecedent. The authors argue that, using this approach, pruning is superfluous because the dummy values already lead to shorter rules. The removal of pruning has the advantage of making Ant-Miner+ significantly faster than Ant-Miner, since rule pruning tends to be the most computational expensive and least scalable part of Ant-Miner (Parpinelli et al., 2002a).

On the other hand, from the point of view of predictive accuracy of the discovered rules, it is not very clear if rule pruning is really superfluous due to the use of dummy "any" values to make rules shorter. In the original Ant-Miner, rule pruning is performed by a deterministic procedure that iteratively removes one term at a time from the rule as long as rule quality is improved. This kind of local search not only reduces the discovered rules' size, but also tends to improve the predictive accuracy of those rules (Parpinelli et al., 2002a). It would be interesting to evaluate if, despite the relatively short size of the rules discovered by Ant-Miner+, the predictive accuracy of those rules could be increased by the use of a deterministic rule pruning procedure driven by rule quality.

(h) Discovering Fuzzy Classification Rules

Galea and Shen (2006) proposed a new ACO algorithm—called FRANTIC-SRL (Fuzzy Rules from ANT-Inspired Computation-Simultaneous Rule Learning)—that discovers

fuzzy classification rules, rather than the crisp rules discovered by Ant-Miner. FRANTIC-SRL maintains multiple populations of ants, where each population is in charge of discovering rules predicting a different class. Hence, the class predicted by a rule is fixed in advance for all ants in each of the populations — see item (a).

Each ant constructs a fuzzy rule by adding one linguistic term (a fuzzy condition) at a time to the current partial rule. This involved replacing the heuristic function of Ant-Miner by a function based on fuzzy systems' theory. The new function is class-specific—that is, the heuristic function of a term depends on the class predicted by the rule– see item (b). At each iteration, instead of evaluating each candidate rule separately, FRANTIC-SRL evaluates each candidate rule set containing one rule from each of the ant colony populations—that is, each candidate rule set containing one rule for each class. Hence, at each iteration the number of evaluated rule sets is $numAnts^{numClasses}$, where *numAnts* is the number of ants in each population and *numClasses* is the number of classes. To speed up this step, the number of evaluated rule sets could be reduced by considering only combinations of the best rules (rather than all rules) from each population, as pointed out by the authors.

(i) Discovering Rules for MultiLabel Classification

Multilabel classification involves the simultaneous prediction of the value of two or more class attributes, rather than just one class attribute as in conventional classification. Chan and Freitas (2006) proposed a major extension of Ant-Miner to cope with multi-label classification, called MuLAM (Multilabel Ant-Miner). In MuLAM, each ant constructs a set of rules—rather than a single rule—where different rules predict different class attributes. A rule can predict a single class attribute or multiple class attributes, depending on which option will lead to better rules for the data being mined. MuLAM uses a pheromone matrix for each of the class attributes. Hence, when a rule is built, the terms in its antecedent are used to update only the pheromone matrix(ces) of the class attribute(s) predicted by that rule.

FUTURE TRENDS

In the last few years, there has been increasing interest in specialized types of classification problems, which tend to be particularly challenging, such as: multi-label classification, where a single rule can predict multiple classes; hierarchical classification, where the classes to be predicted are arranged in a hierarchy; and the discovery of fuzzy classification rules. Recently, the first variations of Ant-Miner for some of these challenging classification problems have been proposed, as discussed earlier, and it seems that a future trend could be the development of more sophisticated Ant-Miner variations or related algorithms for these types of problems.

CONCLUSION

This article has reviewed Ant-Miner, the first ant colony algorithm for discovering classification rules in data mining, as well as a number of variations of the original algorithm. Some of the proposed variations were relatively simple, in the sense that they did not affect the type of classification rules discovered by the algorithm. However, some variations were proposed to cope with attributes having ordered categorical values, somewhat improving the flexibility of the rule representation language. Even more significant variations were also proposed. In particular, Ant-Miner variations have been proposed to discover multi-label classification rules and to discover fuzzy classification rules. The problem of extending Ant-Miner to cope with continuous attributes on-the-fly, during the run of the algorithm (rather than requiring continuous attributes to be discretized in a preprocessing phase), remains an open problem and an interesting future research direction.

A

KEY TERMS

Classification Rule: A rule of the form *IF (conditions) THEN (class)*, meaning that if a case (record) satisfies the rule conditions, it is predicted to have the class specified in the rule.

Data Mining: A research field where the goal is to discover accurate, comprehensible knowledge (or patterns) in data.

Rule List: An ordered list of IF-THEN classification rules discovered by the algorithm during training. When the rules are applied to classify a testing case, they are applied in order, so that the first rule matching the testing case is used to classify that case.

Test Set: A set of cases unseen during the training of the algorithm. The test set is used to measure the predictive accuracy (generalization ability) of the rules discovered during training.

Testing Case: Each of the cases (records) of the test set.

Training Case: Each of the cases (records) of the training set.

Training Set: A set of cases used by the algorithm to discover classification rules.

Antecedents of Trust in Online Communities

Catherine M. Ridings
Lehigh University, USA

David Gefen
Drexel University, USA

INTRODUCTION

Online virtual communities have existed on the Internet since the early 1980s as Usenet newsgroups. With the advent of the World Wide Web and emphasis on Web site interactivity, these communities and accompanying research have grown rapidly (Horrigan, Rainie, & Fox, 2001; Lee, Vogel, & Limayem, 2003; Petersen, 1999). Virtual communities arise as a natural consequence of people coming together to discuss a common hobby, medical affliction, or other similar interest, such as coin collecting, a devotion to a rock group, or living with a disease such as lupus. Virtual communities can be defined as groups of people with common interests and practices that communicate regularly and for some duration in an organized way over the Internet through a common location or site (Ridings, Gefen, & Arinze, 2002). The location is the "place" where the community meets, and it can be supported technologically by e-mail listservs, newsgroups, bulletin boards, or chat rooms, for example. The technology helps to organize the community's conversation, which is the essence of the community. For example, messages in a community supported by a listserv are organized in e-mails, sometimes even grouping together several messages into an e-mail digest. In bulletin board communities, the conversation is organized into message threads consisting of questions or comments posted by members and associated replies to the messages.

Virtual community members form personal relationships with strong norms and expectations (Sproull & Faraj, 1997; Sproull & Kiesler, 1991), sometimes developing deep attachments to the communities (Hiltz, 1984; Hiltz & Wellman, 1997). These developments are interesting, because the members of virtual communities are typically strangers to one another and may never meet face to face. Additionally, the nature of computer-mediated communication is such that nonverbal cues that aid in the interpretation of communication, such as inflections in the voice, gestures, dress, tone, physical personal attributes, and posture, are missing (Sproull & Kiesler, 1991), making the communication open to multiple interpretations (Korenman & Wyatt, 1996). Yet, despite these limitations, many virtual communities flourish by exchanging messages and building their conversation base. A key ingredient in sustaining the conversation in the community is the existence of trust between the members. Trust has a downstream effect on the members' intentions to give and get information through the virtual community (Ridings et al., 2002).

This chapter examines emergent virtual communities, that is, those arising without direction or mandate from an organization, government, or other entity for an expressed economic or academic purpose. For example, a discussion board for a strategic partnership work group between two companies or a chat room for a class taking a college course would not be considered emergent virtual communities. However, an online forum established by the Breast Cancer Young Survivors Coalition so that women could discuss their battles with the disease would be considered an emergent virtual community.

BACKGROUND

Trust is an essential ingredient in social relationships (Blau, 1964; Luhmann, 1979), and understanding and defining trust are dependent upon the situation in which they are considered. In communities, in general, trust is an integral part of interpersonal relations among members and defines an individual's expectations and behavior (Luhmann, 1979; Rotter, 1971). Trust has many definitions. It has been defined as a willingness to take a risk associated with the behavior of others (Mayer, Davis, & Schoorman, 1995) and, more generally, as a method of reducing social uncertainty (Gefen, Karahanna, & Straub, 2003; Luhmann, 1979). In this sense, trust is used in the virtual community to reduce social complexity associated with the behavior of other members, and as a way of reducing the fear that the trusted party will take advantage by engaging in opportunistic behavior (Gefen et al., 2003), much as it does in communities in general (Fukuyama, 1995).

Participating in a virtual community entails exposure to risk. Opportunistic behaviors could include selling personal information that was confidentially provided, adopting a fictitious persona, deliberately and stealthily marketing products and services when this is prohibited, flaming or spamming, making unfair practical jokes at members, providing false information, and, in general, behaving in a dysfunctional

manner that ruins the community. Such behavior also applies to other types of communities, except that in the case of an online community, the anonymity provided by the Internet makes such behavior much easier to accomplish by the perpetrator and much harder to notice by the victim.

Scholarly research on trust has shown that trust is a multidimensional concept consisting of beliefs in ability, benevolence, and integrity (Blau, 1964; Butler, 1991; Giffin, 1967; Mayer et al., 1995; McKnight, Choudhury, & Kacmar, 2002). Ability deals with beliefs about the skills or expertise that another (i.e., trusted parties) has in a certain area. Ability relates to the belief that the other person knows what he or she is talking about. Because virtual communities are almost always focused on a specific topic, concerns about the abilities of others with respect to this topic are important. Benevolence is the expectation that others will have a positive orientation or a desire to do good to the trustee, typically by reciprocating with appropriate advice, help, discussion, and so on, such as contributing to the ongoing discussion with the intent to help, support, and care for others. Benevolence is important in virtual communities, because without positive reciprocation, the community would not exist. Integrity is the expectation that another will act in accordance with socially accepted standards of honesty or a set of principles, such as not telling a lie and providing reasonably verified information. Integrity applies in the virtual community context, because it is the existence of norms of reciprocity, closely linked with benevolence, that allow the community to properly function.

Research based upon surveying members of virtual communities has found that integrity and benevolence are united in this context, because the expected mode of behavior in many of the virtual communities is one of benevolence (Ridings et al., 2002). Hence, adhering to this expected mode of conduct, integrity, should overlap with actually behaving so, namely, with benevolence. Conformance to socially acceptable behavior or standards (integrity) and a desire to do "good" to others (benevolent intentions) are synonymous in the virtual community environment.

THE ANTECENDENTS OF TRUST

Trust in a virtual community is built through several mechanisms that are germane to the online context. As in personal contacts where successful interpersonal interaction builds trust (Blau, 1964; Gefen, 2000a; Luhmann, 1979), the responsiveness of other community members is necessary for trust to develop (Ridings et al., 2002). This can be shown through adherence to the social norms of the community (benevolence and integrity) and competency in the topic (ability). Members who post messages most often expect responses, and when these responses are absent, late, or lacking in number, there is no successful interpersonal interaction, and that hinders the development of trust. Responsiveness is also evident by members indicating gratitude for timely help. Trust is also built by reading what others post. If others post personal information about themselves, they appear less as strangers and more as acquaintances or friends. Divulging gender, age, name, e-mail address, or a personal problem may also add to the credibility of the member (ability) as well as make it easier for other members to shape beliefs regarding adherence to the community's standards and principles (integrity and benevolence). Personal information can also be provided in site profiles. Thus, the confiding of personal information also builds trust in other members of a virtual community (Ridings et al., 2002). Finally, humans have some degree of a general willingness to depend on others, known as disposition to trust (McKnight, Cummings, & Chervany, 1998), and this has been found to be stable across situations (Mayer et al., 1995). In the virtual community where people are unfamiliar with one another, disposition to trust, at least initially before extensive interactions take place, is also an important factor leading to the development of trust in others. Disposition to trust has been empirically found to be directly related to trust in virtual settings (Gefen, 2000a; Jarvenpaa, Knoll, & Leidner, 1998) and in virtual communities, in particular (Ridings et al., 2002).

Because virtual communities lack an enforceable legal system to ensure appropriate behavior online, the actual membership in the community and the feeling of being part of a community, even if a virtual one, may provide a possible way to enforce honest behavior. Virtual communities enhance honest behavior through creating what Ba (Ba, 2001; Ba, Whinston, & Zhang, 2003) called a trusted third party (TTP) certification mechanism. Considering the problems with the three current trust-building mechanisms in online markets (feedback, insurance or guarantee, and escrow), as pointed out theoretically by Ba and with some empirical support by Pavlou and Gefen (2004), extralegal mechanisms might be especially useful in virtual communities. Extralegal mechanisms, such as gossip, reproach, and community appreciation, and the praise and sanctions they bring, may serve to create trust just as they do in regular community settings.

Another way virtual communities may be applied to build trust, according to Ba, is through the sense of community, that, as we know from economics, is crucial when there is a separation in time between the quid and the pro (Ba, 2001). Moreover, if the members of the community are held responsible for the actions of an offender, there will be more social pressure to adhere to the rules. This might only work with online groups with a strong sense of community, but many virtual communities are precisely that.

Trust also has implications with regard to user privacy. Many virtual communities center on personal topics, such as medical conditions, legal issues, or occupations. Participants may care to be anonymous when communicating in such

communities. However, the economic viability of virtual communities may depend on the sale of advertising space or products to users. To accommodate this action, reliance is placed on the provision of user demographics, e-mail addresses, and traffic statistics, information somewhat at odds with the protection of user privacy. It may be possible for virtual communities to incorporate concepts of procedural fairness, where the provision and collection of personal information is perceived as conducted fairly. Procedural fairness has been found to address privacy concerns of customers. Culnan and Armstrong found that procedural fairness builds trust that customers have for an organization using personal information for marketing purposes (Culnan & Armstrong, 1999). Such procedural fairness policies could also be applied in the virtual community context.

FUTURE TRENDS

There are many directions to be investigated from the basic understanding of trust in virtual communities. It may be that trust develops differently in different kinds of communities. For example, trust in medical-based communities may be based more heavily on certain attributes than trust in communities organized for fans of a particular sports team. The level of trust for an individual may be related to the use of the community. Demographic variables such as gender, race, and culture may also influence trust and its development (Gefen, 2000b). Longitudinal studies of virtual communities may yield more information about the development of trust over time.

CONCLUSION

Virtual communities are a key resource on the Internet for individuals looking to exchange information with others as well as Web site sponsors desiring to provide interactivity to their sites. For virtual communities to survive, they must have conversation, and for the conversation to grow and flourish, there must exist trust between the virtual community members. Trust in the other members' abilities and benevolence and integrity is necessary, and this trust has been found to be built by the responsiveness of others, the confiding of personal information, and the member's general disposition to trust.

KEY TERMS

Disposition to Trust: A tendency to believe in the goodness of others based on lifelong socialization.

Reciprocity: Returning favors, which is a major way of building trust.

Trust: A willingness to take for granted that another person will behave as expected in a socially constructive manner. Trust generally reduces the perceived risk that another person will behave in an opportunistic manner.

Trust in Ability: The belief that a person has subject matter expertise in a certain area.

Trust in Benevolence: The belief that a person has a positive orientation or a desire to do good to others.

Trust in Integrity: The belief that a person will act in accordance with socially accepted standards of honesty or a set of principles.

Virtual Community: A group of people with common interests and practices that communicates regularly and for some duration in an organized way over the Internet through a common location or site.

Anytime, Anywhere Mobility

Mikael Wiberg
Umea University, Sweden

INTRODUCTION

Just a couple of years ago several mobile phone operators and others (e.g., Helal, 1999; Galambos, 2002; Ilderem, 2005) pushed forward "anytime, anywhere" as a goal or vision for future mobile services and mobile IT-use. In this article we set out to explore if "anytime, anywhere" mobility is in fact a paradox.

Kleinrock (1996, 1998) claims advanced wireless technologies, the Internet, global positioning systems, portable and distributed computing, and so forth, will realize the vision of "anytime, anywhere." We can today see the first signs of this vision. For example, telework is now possible, remote organizations can be engaged in close cooperation, and people can communicate, collaborate, share digital media, and form communities on the Internet. The world has become a global village, some claim (Preece, 1994, Castells, 1996), where you can interact with anybody independent of time and space.

The vision of "anytime, anywhere" describes a situation where people can do tasks wherever they want and without any consideration of time. Related to the vision is the 2x2 matrix often used in the field of computer supported cooperative work (CSCW) to denote different kinds of computer supported collaboration (e.g., Johansen, 1988; Baecker et al., 1993). This model has the dimensions of time and place, where each can be the same or different. The model is shown in Figure 1.

The vision of "anytime, anywhere" is tasks that can be done independent of time and place (i.e., in any of the four scenarios). This does not say anything about where or when the tasks should be done, only that these dimensions should not restrict them.

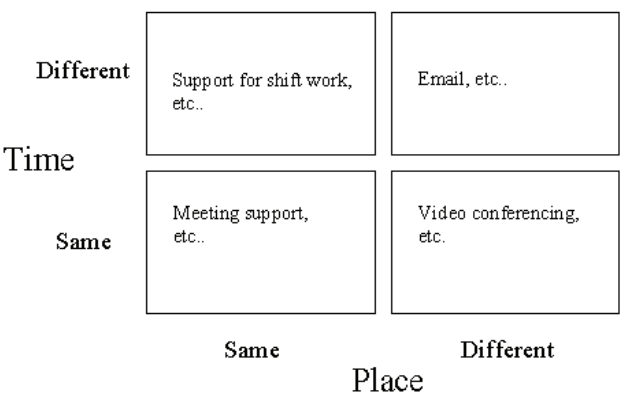
It is interesting to notice that the model does not take into consideration *mobility*. It assumes that people are either in the same place, or in a different place, and whether or not they are mobile does not seem to make a difference.

BACKGROUND

In the past, people traveled because they had no choice. If you wanted to do business or talk to remote friends you had to meet them face-to-face. However, transportation costs prohibited certain meetings and activities. A long series of technological developments (including the pony express, railroads, automobiles, and the telephone) have aimed at lowering the costs associated with transaction and conversation. Computer-mediated communications are the most recent development in that progression. Even so, people still travel and still meet in person.

To summarize: The adoption of Internet technologies, mobile phones, and so forth, have increased and in a sense made the world smaller. Compared to ten years ago, today it is much easier to communicate with remotes sites, and the frequency of communication in many organizations

Figure 1. The model shows different scenarios for groupware (Ellis et al., 1991)



has increased accordingly. Some people have even talked about "the global village" (Preece, 1994). A parallel trend is that people travel more than they used to do. According to predictions, this trend will sustain, and even increase. For example, the national road agency of Sweden reports the number of flights will increase by a factor of four in the next ten years. How can it be that the global village is so mobile? If people can interact and work independent of time and space, why then do they spend more and more time traveling? Is that not a paradox?

Reviewing the literature on the topic, we find no research that has explored this apparent paradox. Authors are either concerned with *remote interaction* (e.g., Ellis et al., 1991; Brave, Ishii & Dahley, 1998; McDaniel, 1996; Kuzuoka, 1992; and Tang & Minneman, 1991) *mobility* (e.g., Luff & Heath, 1998; Bejerano & Cidon, 1998; and Porta et al., 1996) or *mobility as anytime, anywhere work* (e.g., Dix et al, 2000; Perry et al., 2001; Davis, 2002; Ilderem, 2005). Furthermore, research on mobility has mainly dealt with technology issues, (e.g., limited battery life, unreliable network connections, varying channel coding and characteristics, volatile access points, risk of data loss, portability and location discovery) (e.g., Bhagwat, Satish, & Tripathi, 1994; Dearl, 1998; Francis, 1997; and Varshney, 1999). Accordingly, no research so far has explored the relation between, on one hand "the global village," with its idea that distance plays no role, and on the other hand the trend of increased mobility. How do the two trends hang together?

EXPLORING THE "ANYTIME, ANYWHERE" MOBILITY PARADOX

In order to investigate this seemingly paradox we conducted an empirical study of mobile telecommunication engineers in a Swedish company (Wiberg & Ljungberg, 2000). Using qualitative research methods, we studied to what extent the work tasks they do are dependent on time and place. We analyzed the data using a 2x2 matrix, with the two axis "time" and "space," which both have the categories "dependent" and "independent." One of the four situations is "anytime, any where," while the other three are dependent on time, place, or booth (see figure 2).

We found instances of work in all four categories. Some traveling seems very difficult to escape, simply because there are places that staff need to visit physically to do their job. For example, to repair a telephone pole you need to go there. We also found there are time frames that staff cannot escape. For example, rebooting parts of the telephone network has to be done at night. Lastly, there are work tasks that seem pretty much independent of time and space (e.g., scheduling and rescheduling of activities).

As observed during this empirical study there were just tiny parts of service work possible to perform "anytime, anywhere". Most of the work is dependent on spatial factors such as location of breakdown in the telephone network system, the location of the client, etc., or time related dependencies such as fixing problems within 24 hours or coordinate schedules to cooperate around larger problems. For a more throughout description of the empirical material see Wiberg & Ljungberg (2000). Overall, we found there are:

- *Traveling* that seems difficult to remove, thus places that people have to visit physically (e.g., telephone poles, customers houses, not all customers are mobile, network routers, locations where new cables needs to be drawn, etc.)
- *Time frames* which seem very difficult for staff not to do certain tasks within, e.g., customer service within 24 hours, rebooting parts of the telephone network has to be done at night, etc.

Figure 2. The theoretical framework of the study

		Place	
		Independent	**Dependent**
Time	**Independent**	**1. Anytime, anywhere**: Tasks that can be done independent of time and place; they can be done anytime, anywhere	**2. Anytime, particular place**: Tasks that need to be done in a particular place but can be done anytime
	Dependent	**3. Particular time, any place**: Tasks that can be done independent of place but at a certain time or in a certain order	**4. Particular time, particular place**: Tasks that must be done in a particular place within a particular time

- *Tasks* that do not seem to be restricted by time and place (e.g. scheduling and rescheduling of the activities over the day, co-ordinations of activities between the technicians, experiences and knowledge sharing among the technicians, etc.) although important for them since they are alone in their cars most of the day.

Accordingly, the vision of "anytime, anywhere" is not easy to realize in the case of the mobile workers we studied.

FUTURE TRENDS

Both work and leisure activities are becoming increasingly mobile. To describe the mobile worker, new concepts have been coined. Some examples are "road warriors" and "nomads" (Dahlbom, 1998), thus distinguishes mobile workers as moving from terms as distributed work, telework, and co-located work. One reason for this increased mobility is the emergence of service work as the dominating profession in the post-industrial society. Service work very often takes place at the client site, and therefore it is often mobile. Another reason is the increased importance of cooperation in and between organizations. Some cooperation can take place remotely, but people also need to meet physically. A third important reason for increased mobility is the extensive adoption of mobile phones. Mobile phones enable people to be mobile and yet accessible (Wiberg & Whittaker, 2005). As people have become accessible independent of place, new ways of working and new work rhythms have emerged in many organizations (Nilsson & Hertzum, 2005). So, for future development within this prominent area of mobile IT and mobility it is important to have a good understanding of mobile contexts (Tamminen et al., 2004) and keep in mind this "anytime, anywhere" paradox of the mobility vision.

CONCLUSION

This article has shown some limitations to the vision of "anytime, anywhere" in the context of mobile work. Time and place are indeed very old ways for understanding context and it seams like they are useful even for bringing light on the phenomena of the two parallel trends of the global village and mobility.

The article has shown that work has moments (e.g., *time frames*, which are not negotiable so the work is dependent upon those). The article has also shown that work has *places* of non negotiable importance (e.g., you cannot reframe the earth by putting away distance nor go backwards in time, although computers are often described as being able to bridge those gaps in time and space). As seen above, there is not much service work possible to perform "anytime, anywhere" since service work is not only about moving around (i.e., mobility) but also about taking actions at various sites at specific times.

Kleinrock (1998) has argued the vision of mobility as being able to work "anytime, anywhere." However, from the analysis of the empirical study presented above, we argue that there are several limits to that vision. In fact, this article has argued that the concept of "anytime, anywhere" belongs to another trend (i.e., the trend towards a global village, which is something altogether different from the trend of mobility). However, as the analysis has shown above those to trends comes together in practice.

So, finally we conclude this article arguing that the practical limitations of "anytime, anywhere" make it impossible for the mobile service engineers to conduct work "anytime, anywhere."

KEY TERMS

"Anytime, Anywhere" Work: Describes a situation where people can do tasks wherever they want and without any consideration of time (i.e. they can be done anytime, anywhere).

Co-Located Work: Collaborative work carried out by several persons at the same geographical location.

Distributed Work: Collaborative work carried out by several persons at different geographical location.

Global Village: As computers all over the world become interconnected via the Internet and the frequency of communication in and between organizations, countries, cultures, societies etc. has increased accordingly via these networks we can now, on a daily basis and quite easily, maintain contact with anybody independent of time and space, that is. to be able to interact "anytime, anywhere."

Mobile Work: The ability to carry out work while geographically moving around.

"Particular Time, Particular Place" Work: Tasks that must be done in a particular place within a particular time.

Remote Interaction: Information technology mediated human-to-human communication over a distance.

Telework: The ability to carry out work from a distance. For example, sitting at home and doing office work. Telework does not imply that the worker is mobile (i.e., in motion) in any sense even though the concept of telework is sometimes used as a synonym for mobile work.

A

Application of Cognitive Map in Knowledge Management

Ali Reza Montazemi
McMaster University, Canada

Akbar Esfahanipour
Amirkabir University of Technology, Iran

INTRODUCTION

Cognitive map methodologies consist of a set of procedures to capture perceived relationships of attributes related to ill-structured decision problems that decision makers have to face. This article provides an overview of the application of cognitive maps (CMs) in the design and development of intelligent information systems. Here, CM is used as a set of techniques to identify subjective beliefs and to portray those beliefs externally as follows:

- Causal mapping is used to investigate the cognition of decision-makers. A causal map represents a set of causal relationships (i.e., cause and effect relationships) among constructs within a system. For example, Figure 1 shows that better sanitation facilities, causing an initial improvement in health, led to an increase in the city's population. This growth led to more garbage, more bacteria, and therefore more disease. Causal map aids: 1) in identification of irrelevant data, 2) to evaluate the factors that affect a given class of decisions, and 3) enhances the overall understanding of a decision maker's environment, particularly when it is ill-structured.
- Semantic mapping, also known as *idea mapping*, is used to explore an idea without the constraints of a superimposed structure. A semantic map visually organizes related concepts around a main concept with tree-like branches. Figure 2 depicts different types of transportation, organized in three categories: land, water, and air. This technique facilitates communication between end-users and system analysts in support of information requirements analysis.
- Concept mapping is a useful tool for organizing and representing concepts (events or objects) and their interrelationships in a particular domain. Each concept is designated with a label. The relationship between two concepts in a concept map is referred to as a proposition; propositions connect concepts to form a meaningful statement. Relationships between concepts are associative. For example, in Figure 3, two concepts of "plants" and "flowers" are associated via "may have" that form the proposition of "plants may have flowers." Describing complex structures with simple propositions improve quality of conceptual modeling in the development of information systems.

BACKGROUND

Cognitive Map (CM) has been employed to capture, store and retrieve expert knowledge in support of the design and development of intelligent information systems. CM is a representation of the relationships that are perceived to exist among the elements of a given environment. Taking any two of these elements, the concern is whether the state or movement of the one is perceived to have an influence on the state or movement of the other (both static and dynamic relationships can be considered) (Montazemi & Conrath, 1986). CMs have been used to describe experts' tacit knowledge about a certain problem, particularly in ill-structured decision problems (Axelrod, 1976; Montazemi & Chan, 1990). Tacit knowledge is personal knowledge, shared and exchanged through direct and face-to-face contact among actors (Eden, 1988).

There are different perspectives of knowledge within organizations (Nonaka, 1994). Thus, it seems appropriate to use knowledge management categories to identify different applications of cognitive map in the design and development of intelligent information systems. Alavi and Leidner (2001) provide a framework that is grounded in the sociology of knowledge and is based on the view of organizations as social collectives and "knowledge systems." They contend that organizations as knowledge systems consist of four sets of socially enacted "knowledge processes" as follows:

- **Knowledge application:** Those activities concerned with deploying knowledge in order to produce goods and services. Information technology can enhance knowledge application by facilitating capture, updating and accessibility of organizational directives.
- **Knowledge storage/retrieval:** This is also referred to as *organizational memory*, which includes knowledge residing in various component forms, including written documentation, structured information stored in electronic databases, codified human knowledge stored in expert systems, and tacit knowledge acquired by individuals.
- **Knowledge transfer:** Transfer of knowledge to locations where it is needed and can be used. This can occur at various levels: transfer of knowledge between individuals, from individuals to explicit sources, from individuals to groups, between groups, across groups, and from groups to the organization.
- **Knowledge creation:** Developing new content or replacing existing content within the organization's tacit and explicit knowledge. Through social and collaborative processes as well as through the cognitive processes of the individual, knowledge is created, shared, amplified, enlarged and justified in organizational settings.

A literature search shows that application of CMs in intelligent information systems can be found in support of the above four categories of knowledge processes, as depicted in the Appendix. A brief description of each of the above four categories within the context of CMs is presented next.

KNOWLEDGE PROCESSING THROUGH CMs

Knowledge Application

CM techniques (e.g., causal mapping, semantic mapping and concept mapping) have been used to improve the processes of the design and development of information systems. They

include improvement of conceptual modeling (Siau & Tan, 2005a), user–database interaction (Siau & Tan, 2006) and applicability of the resulting information systems (Siau & Tan, 2005b). Siau and Tan (2006) proposed a framework of user-database interaction in support of knowledge application. According to this framework, user-database interaction has three dimensions: content, structure and style. The content (i.e., semantics) dimension is determined by the user's data needs. The structure dimension is determined by both the user's perceived data model (constituent structure) and by the query language (syntactic structure). The style dimension is dictated by user-database interface.

According to this framework, to begin with we need to decide what elements and operations of the database schema (constituent structure) are relevant in order to translate the data needs (content) into a database query. Next, the query is written using the syntax structure as dictated by the query language. Finally, the query is entered into the system in a style offered by the user-database interface. The possible styles include command languages, menu selection, and form fill-in. In this framework, the user's knowledge is critical to an understanding of the data needs, to the formation of a correct and appropriate database schema, and to a proper application of the syntax of the query language. The resulting CMs are suitable materials for user's guides and online help.

Knowledge Storage/Retrieval

Cognitive mapping techniques have been also applied to acquire a decision maker's tacit knowledge when faced with ill-structured decision problems such as the extraction of expert knowledge to forecast stock prices (Montazemi & Chan, 1990), the building of expert systems to control electronic data interchange (Lee & Lee, 2007), for negotiation in a B2B system (Lee & Kwon, 2006) and for analysis of firms with regard to their creditworthiness (Noh, Lee, Kim, Lee, & Kim, 2000). CMs have been used to develop a specific method to analyze complex problems. For example, Satur and Liu (1999) developed an inference method in support of geographic information systems and Kwon, Im, and Van de Walle (2002) proposed a structural analysis method for a DSS in support of urban planning. Noh et al. (2000) adopted CMs to formalize tacit knowledge and proposed case-based reasoning as a tool for storage/retrieval of CM-driven tacit knowledge in the form of frame-typed cases.

Knowledge Transfer

Cognitive maps have been applied in group decision making for the exchange of ideas and opinions between group members in regard to a specific problem. For instance, Caliskan (2006) used the CM approach to facilitate the evaluation of transport investment alternatives using a group of experts. Sengupta and Te'eni (1993) studied the impact of cognitive feedback on group decision making at three levels: individual, interpersonal and collective. They contend that for the development of a group decision support system (GDSS), cognitive feedback should be considered as an integral part at every level, and that a human-computer interaction should be designed as an effective transition across the components of feedback at all levels.

Fuzzy cognitive map (FCM) also has been applied in group decision making to create a new FCM representing the views of a number of experts in a unified manner. For example, Khan and Quaddus (2004) presented a methodology for the development and analysis of FCM as a useful GDSS tool. This methodology consists of two phases: development and application. In the development phase, an FCM is created for each group member and these are then merged to produce a group FCM. The application phase consists of static analysis of concepts and causal relationships, and dynamic analysis of the simulated system over time.

FCMs have been also used to develop a fuzzy cognitive agent to provide personalized recommendations to online customers (Miao, Yang, Fang, & Goh, 2007). The agent learns users' preferences from the most recent cases and helps customers to make inferences and decisions. Xirogiannis and Glykas (2007) proposed the application of the fuzzy causal characteristics of FCMs as the underlying methodology in order to generate a hierarchical and dynamic network of interconnected maturity indicators in e-business strategy formulation exercises. A brief description of this model follows.

In business strategy formulation, maturity metrics are defined by managers at different organizational levels in a hierarchical manner. Top management sets the overall performance targets (strategic maturity). These targets are exemplified further to action plan performance metrics (tactical maturity) and then to operational performance indicators (operational maturity). This model represents inherent relationships between these metrics utilizing FCMs to interpret:

- E-business maturity metrics as concepts
- Decision weights as relationship weights
- Decision variables as maturity concept values
- Hierarchical decomposition of maturity metrics as a hierarchy of FCMs.

This approach allows the stakeholders to reason about the qualitative states of e-business maturity metrics using fuzzy linguistic.

Knowledge Creation

Cognitive mapping techniques have been applied for knowledge creation. Nonaka (1994) defines the four "modes" of

knowledge creation as 1) socialization: conversion of tacit knowledge to new tacit knowledge through interaction of individuals, sharing ideas and experiences and learning from each other; 2) externalization: conversion of tacit knowledge to new explicit knowledge such as articulation of best practices or lessons learned; 3) combination: conversion of explicit knowledge to new explicit knowledge by merging, categorizing, reclassifying and synthesizing existing explicit knowledge; 4) internalization: conversion of explicit knowledge to new tacit knowledge that could be achieved through the learning and understanding that result from reading about a specific topic.

Given that tacit knowledge is difficult to formalize and communicate (Polanyi, 1966), socialization, which occurs through conversion of such tacit knowledge to a new form of tacit knowledge, is a complex task to model. As a result, CMs have not been applied directly to model socialization mode of knowledge creation. However, the four aforementioned knowledge creation modes are interdependent and intertwined so that each mode relies on, contributes to, and benefits from the other modes (Alavi & Leidner, 2001). Hence, it is possible to use one or more intermediate conversion steps to model socialization using CMs. That is, conversion of tacit knowledge to a new explicit knowledge (i.e., externalization) and then converting the obtained explicit knowledge to a new tacit knowledge (i.e., internalization). We may need to use a combination mode before internalization, however.

Cognitive mapping allows modeling of mental models of decision makers, and it leads to clarification and structuring of the experts' thought processes when faced in ill-structured problems (Rodhain, 1999). Thus, CMs can be used as a means of externalization. For example, Rodhain (1999) uses CMs to extract business strategy mental models of managers for determining a portfolio of projects. Other pertinent applications include application of CMs to extract experts' tacit knowledge in order to forecast stock prices (Montazemi & Chan, 1990) and to analyze information requirements (Montazemi & Conrath, 1986).

FCM has been used in group decision making to construct a causal knowledge base in stock investment analysis (Lee & Kim, 1997) and in electronic data interchange (EDI) controls (Lee & Lee, 2007) as a means of externalization, so that the resulting CMs could be transferred, managed and stored as explicit knowledge.

Individuals' CMs could be different in a specific domain because perceived attributes or perceived causal relationships of CMs may be different from one person to another. These differences between CMs, which are called *content difference* (Langfield-Smith & Wirth, 1992) exist because of different levels of individual experience and expertise. Langfield-Smith and Wirth (1992) propose quantitative measures for analyzing content difference between two or more CMs. These measures would assist in providing a more objective basis for qualitative analysis. Eden (2004) discusses the use of CMs as a qualitative method for structuring ill-structure decision problems. Wang (1996) uses neural network as a quantitative method to measure differences between CMs of individuals over time. The comparisons of CMs provide useful information for a decision maker when considering individual points of view. Providing such information can be considered as combination, and analyzing of this information by decision makers to get an insight into a given problem can be considered as the internalization mode of knowledge creation.

Learning methods have been used to improve knowledge represented by means of FCMs. These learning methods include the nonlinear Hebbian learning rule (Papageorgiou, Stylios, & Groumpos, 2003) and unsupervised learning technique (Papageorgiou, Stylios, & Groumpos, 2006). Stach, Kurgan, Pedrycz, and Reformat (2005) propose a genetic learning method to generate FCMs from historical data. Improving the embedded knowledge of CMs through machine learning methods can be considered as combination mode of knowledge creation that can improve the user's tacit knowledge (i.e., internalization).

For example, Lee, Kim, Chung, and Kwon (2002) propose a three-phased Web-mining inference amplification (WEMIA) based on inference logic of FCM. The first phase is used to extract association rules. Because association rules are similar to causal knowledge in which a condition clause triggers a conclusion clause, and then in the second phase, corresponding FCMs are developed. The advantages of causal knowledge over association rules are that it can provide a more refined inference mechanism than can the association rules (Lee et al., 2002). The final phase is used to apply inference amplification procedures to the causal knowledge: to eliminate rule redundancy, to search for the directly and indirectly chained rules, and to amplify inferences about the logical relationships between rules. In this case, knowledge is created thanks to the conversion of some explicit knowledge (i.e., association rules) to another form of explicit knowledge (i.e., FCM), which is referred to as *knowledge combination*. Here, knowledge is improved by the use of inference methods to derive rich semantics which are suitable for and understandable by the decision maker. This is referred to as the *internalization mode of knowledge creation*.

Thus, cognitive mapping techniques can be applied directly toward externalization and combination modes of knowledge creation and can contribute indirectly toward internalization and eventually to the socialization mode of knowledge creation.

FUTURE TRENDS

This literature review shows diverse use of CM in the varied domain of decision making processes. We expect increased

sophistication in capturing CM and its application in support of knowledge management. In particular, CM can play a major role in realizing the usefulness of the Semantic Web, which is the outgrowth of many diverse desires and influences, all aimed at making better use of the Web as it stands. The Semantic Web is portrayed as: 1) a universal library, to be readily accessed and used by humans in a variety of information use contexts; 2) the backdrop for the work of computational agents completing sophisticated activities on behalf of their human counterparts; and 3) a method for federating particular knowledge bases and databases to perform anticipated tasks for humans and their agents (Marshal & Shipman, 2003). Intelligent agents can use the CM of users to filter information from the Semantic Web, making it possible to manage organizational knowledge using the Intranet and the vast resources available from the Internet.

CONCLUSION

Cognitive mapping techniques have been applied in design and development of intelligent information systems as a means of acquiring knowledge from domain experts, manipulating knowledge to create new contents, storing/retrieving knowledge for later use, and sharing knowledge between group members to deal with ill-structured decision problems. Successful applications of cognitive mapping methodologies reveal the efficiency and flexibility of these techniques, which can be potentially utilized by developers of intelligent information systems as follows:

- Providing a rich picture of ill-structured problems for decision makers,
- Facilitating group decision making through clear exchange of ideas and information,
- Modeling dynamic systems in uncertain environments using fuzzy cognitive maps,
- Providing cognitive feedbacks to improve decision makers' decision processes when faced with ill-structured decision problems,
- Improving the quality of conceptual modeling of systems, user-system interactions and usability of the resulting systems, and
- Better identifying end-users' information requirements and improving user-developer communications.

KEY TERMS

Cognitive Map: A representation of the relationships which are perceived to exist among the elements of a given environment.

Explicit Knowledge: Codified knowledge which refers to knowledge that is transmittable in formal and systematic language.

Fuzzy Cognitive Map: An extended and fuzzified version of the cognitive map that enables causal relationships to have fuzzy weights.

Knowledge Application: Those activities concerned with deploying knowledge in order to produce goods and services.

Knowledge Creation: Creation of new content based on the organizational tacit and explicit knowledge.

Knowledge Transfer: Transfer of organizational knowledge from one entity to another entity within/between organizations.

Tacit Knowledge: Personal knowledge which could be shared and exchanged through face-to-face contact among actors.

Application of Fuzzy Logic to Fraud Detection

Mary Jane Lenard
University of North Carolina – Greensboro, USA

Pervaiz Alam
Kent State University, USA

INTRODUCTION

In light of recent reporting of the failures of some of the major publicly-held companies in the U.S. (e.g., Enron & WorldCom), it has become increasingly important that management, auditors, analysts, and regulators be able to assess and identify fraudulent financial reporting. The Enron and WorldCom failures illustrate that financial reporting fraud could have disastrous consequences both for stockholders and employees. These recent failures have not only adversely affected the U.S. accounting profession but have also raised serious questions about the credibility of financial statements. KPMG (2003) reports seven broad categories of fraud experienced by U.S. businesses and governments: employee fraud (60%), consumer fraud (32%), third-party fraud (25%), computer crime (18%), misconduct (15%), medical/insurance fraud (12%), and financial reporting fraud (7%). Even though it occurred with least frequency, the average cost of financial reporting fraud was the highest, at $257 million, followed by the cost of medical/insurance fraud (average cost of $33.7 million).

Statistical methods, expert reasoning, and data mining may be used to achieve the objective of identifying financial reporting fraud. One way that a company can justify its financial health is by developing a database of financial and non-financial variables to evaluate the risk of fraud. These variables may help determine if the company has reached a stress level susceptible to fraud, or the variables may identify fraud indicators. There are a number of methods of analysis that may be used in fraud determination. Fuzzy logic is one method of analyzing financial and non-financial statement data. When applied to fraud detection, a fuzzy logic program clusters the information into various fraud risk categories. The clusters identify variables that are used as input in a statistical model. Expert reasoning is then applied to interpret the responses to questions about financial and non-financial conditions that may indicate fraud. The responses provide information for variables that can be developed continuously over the life of the company. This article summarizes the specifics of fraud detection modeling and presents the features and critical issues of fuzzy logic when applied for that purpose.

BACKGROUND

Fraud Detection

The problem of fraudulent financial reporting is not limited to the U.S. In 2002, the Dutch retailer, Ahold, disclosed losses of $500 million related to accounting at its U.S. subsidiary (Arnold, 2003). Recently, Parmalat, an Italian firm, declared insolvency as a result of fraudulent financial reporting. The CEO of Parmalat has been accused of mishandling $10 billion and of hiding losses in offshore funds and bank accounts. The scandal at Parmalat could also have serious consequences for the company's auditor (Gallani & Trofimov, 2004).

The auditor's responsibility for fraud detection in the U.S. has been defined in Statement on Auditing Standards No. 99, *Fraud Detection in a GAAS Audit* (AICPA, 2002). This statement has four key provisions (Lanza, 2002): (1) increased emphasis on professional skepticism, (2) frequent discussion among audit team personnel regarding the risk of misstatement due to fraud, (3) random audit testing of locations, accounts, and balances, and (4) procedures to test for management override of controls. Auditors are discouraged from placing too much reliance on client representation and are required to maintain a skeptical attitude throughout the audit. The standard encourages auditors to engage in frequent discussion among engagement personnel regarding the risk of material misstatement due to fraud. SAS 99 also requires auditors to inquire of management and others not directly involved with fraud, perform analytical procedures, and conduct necessary tests to assess management override of controls. Finally, auditors are advised to evaluate the risk of fraud and steps taken by the client to mitigate the risk of fraud.

The U.S. Congress in 2002 passed the Sarbanes-Oxley Act, which spells out a number of steps firms must take to minimize fraudulent financial reporting. This legislation requires the principal executive officer and the principal financial officer of publicly traded companies to certify the appropriateness of the financial statements and disclosures in each quarterly and annual report that their company issues. These officers are also responsible for establishing and maintaining internal controls within the company. Further, they must disclose to auditors and the audit committee of

the board of directors any fraud, whether or not material, involving management or employees who have a significant role in defining or implementing internal controls. As this law goes into effect, evaluation and reporting of a company's internal controls and financial statements in order to detect fraud becomes even more critical, and must be on-going.

Prior research shows that various kinds of decision aids may be used to assist the auditor in detecting financial reporting fraud. Bell, Szykowny, and Willingham (1993) used bivariate and cascaded logit to assess the likelihood of management fraud. Their model achieved within-sample correct classification of 97% on the fraud observations and 75% on the non-fraud observations. Hansen, McDonald, Messier, and Bell (1996) used a generalized qualitative response model to predict management fraud. They reported 89.3% predictive accuracy over 20 trials. Bell and Carcello (2000) developed a logistic regression model as a decision aid to assist in the auditor's fraud decision. Auditors may also use an expert system as a decision aid to assist in fraud determination. Eining, Jones, and Loebbecke (1997) examined the effect that the use of an expert system has on auditor decision-making ability in detecting fraud. Their research showed that in allowing the interaction between the auditor and the system, the expert systems that have been used to assist auditors in complex decision processes often give results that are more accurate and consistent. Similarly, Whitecotton and Butler (1998) found that allowing decision makers to select information for the decision aid increases decision aid reliance. Fuzzy clustering may also be used as a decision aid for an auditor to detect fraudulent financial reporting (Lenard & Alam, 2004).

Fuzzy Clustering

When available data does not suggest a clear answer, decision makers often look for patterns or groups in the underlying data to make a decision (Alam, Booth, Lee, & Thordarson, 2000). While discriminant analysis and logistic regression assign observations to groups that were defined in advance, cluster analysis is the art of finding groups in data (Kaufman & Rousseeuw, 1990). Fuzzy set theory, introduced by Zadeh (1965), attempts to classify subjective reasoning (e.g., a human description of "good", "very good", or "not so good") and assigns degrees of possibility in reaching conclusions (Lenard, Alam, & Booth, 2000). As opposed to hard clustering, where there is a clear-cut decision for each object, fuzzy clustering allows for ambiguity in the data by showing where a solution is not clearly represented in any one category or cluster. Fuzzy clustering shows the degree to which (in terms of a percentage) an item "belongs" to a cluster of data. In other words, a data item may belong "partially" in each of several categories. The strength of fuzzy analysis is this ability to model partial categorizations.

Lau, Wong, and Pun (1999) used neural networks and fuzzy modeling to control a plastic injection-molding machine. They suggested that the neural network and fuzzy technology complement each other and offset the pitfalls of computationally intelligent technologies. Alam et al. (2000) used a combination of fuzzy clustering and self-organizing neural networks, and were successful in identifying potentially failing banks. Ahn, Cho, and Kim (2000) reported results using these technologies to predict business failure, and stressed the importance of these predictions as useful in aiding decision makers. Lenard et al. (2000) used fuzzy clustering to identify two different categories of bankruptcy. Companies placed in the second bankrupt category exhibited more extreme values in terms of the financial ratios used in the study. Companies either showed much better results (such as a high current ratio) than would be expected for a company facing bankruptcy, or the companies showed very poor results, such as a much higher debt ratio than any of the other bankrupt companies in the data sample. Lenard and Alam (2004) operationalized a fuzzy logic model for fraud detection in an Excel spreadsheet. By using the fuzzy logic model to develop clusters for different statements representing red flags in the detection of fraud, non-financial data was included with financial statement variables for the analysis. The overall prediction accuracy for the model was 86.7%.

Nolan (1998) used expert fuzzy classification and found that fuzzy technology enables one to perform approximate reasoning, as when a student assignment is graded as "very good", or "not so good", and improves performance in three ways. First, performance is improved through efficient numerical representation of vague terms, because the fuzzy technology can numerically show representation of a data item in a particular category. The second way performance is enhanced is through increased range of operation in ill-defined environments, which is the way that fuzzy methodology can show partial membership of data elements in one or more categories that may not be clearly defined in traditional analysis. Finally, performance is increased because the fuzzy technology has decreased sensitivity to "noisy" data, or outliers. Ammar, Wright, and Selden (2000) used a multilevel fuzzy rule-based system to rank state financial management. The authors used fuzzy set theory to represent imprecision in evaluated information and judgments. Pathak, Viyarthi, and Summers (2003) developed a fuzzy logic based system for auditors to identify fraud in settled claimed insurance. They believe that their system was able to cut costs by detecting fraudulent filings.

CRITICAL ISSUES OF FUZZY LOGIC

The fuzzy clustering procedure used by Lenard et al. (2000) and Lenard and Alam (2004) is called FANNY (Kaufman & Rousseeuw, 1990). The program FANNY uses "fuzzi-

ness" to partition objects by avoiding "hard" decisions, or clustering into fixed, definite categories. For each item in the dataset, the algorithm provides k+1 pieces of information, where k is the number of clusters that are used in the clustering algorithm. The k+1 pieces of information are: U_{iv}, the membership coefficient of item i in cluster v, v = 1 ... k, and S_i, the silhouette coefficient of item i. A higher value of U_{iv} indicates a stronger association of item i and cluster v. The silhouette coefficients satisfy the constraints $-1 \le S_i \le 1$ and indicate how a well-clustered object uses average distances from its own cluster to the closest neighboring clusters. The closer S_i is to 1 the better the clustering of an individual item. A value of S_i close to -1 indicates that an item may be assigned to more than one cluster (Alam et al., 2000). The Euclidean distance measure is used to compute distances between objects and to quantify the degree of similarity for each object. The degree of similarity for each objects *i* and *j* is computed as follows (Kaufman & Rousseeuw, 1990)

$$d(i,j) = \sqrt{(x_{i1} - x_{j1})^2 + (x_{i2} - x_{j2})^2 + ... + (x_p - x_p)^2} \quad (1)$$

where the p^{th} measurement of the i^{th} object is given by x_{ip} and *d(i,j)* is the actual distance between objects *i* and *j*.

Several authors have expanded upon the fuzzy clustering algorithms. Van den Bergh and van den Berg (2000) developed a competitive learning algorithm using fuzzy frequency distributions. They emphasized that sometimes the discovery of exceptions is more important than the main rules. For example, profit opportunities often seem to appear randomly and infrequently, so the agent should concentrate on detecting the unusual, abnormal states, or exceptions, rather than the average normal states (van den Bergh & van den Berg, 2000). Their algorithm seeks to find a mapping from an *M*-dimensional input space X into an *N*-dimensional output space *Y*, given a representative data set *S*. The set *S* contains *P* data pairs (x_p; y_p). The final formula for the mapping is depicted as

$$y_b = \sum_{c=1}^{C_y} \overline{y_c} \; X \overline{u}_c^{Y} \mid \overline{u}_b^{X} \quad (2)$$

Thus, the sum of output cluster centroids y_c is weighted by the "local" membership values $\overline{u}_c^{Y} \mid \overline{u}_b^{X}$.

Fuzzy clustering algorithms have also been extended by the work of Kaymak and Setnes (2000), who proposed fuzzy clustering algorithms with volume prototypes and similarity based cluster merging. These extensions reduce sensitivity of the clustering algorithms to bias in data distribution, and help determine the number of clusters automatically.

Finally, Mashor (2001) proposed a clustering algorithm called adaptive fuzzy *c*-means clustering. In this method, each data sample is assigned a membership grade to indicate the degree of belonging to each center rather than assigning the data sample to one center as in "hard" clustering algorithms like the *k*-means clustering. In addition, the clustering program is not as sensitive to initial centers and gives better performance. The algorithm only requires the data to be presented once, instead of requiring multiple presentations, and as such reduces the computational load.

Identifying the number of clusters in fuzzy clustering is a challenging task. The optimal clustering should consider both fuzzy compactness and separation. The current state of the art does not provide a theoretical basis for an optimal choice of clusters. The objective function based fuzzy clustering algorithms are often used to divide the data into a predetermined number of clusters. The fuzzy *c*-means algorithm is one of the most popular objective functions used for fuzzy clustering. It uses the similarity between objects to measure the distances between clusters. The validity of the clusters is often assessed after the clusters have been formed. Validity Measures typically address the issues of the compactness of the clusters and the distances between them (e.g., Pal & Bezdek, 1995; Xie & Beni, 1991). Gath and Geva (1989) proposed a validity measure, which is a ratio between fuzzy compactness and separation. Bensaid et al. (1996) argued that combining the validity guided clustering algorithm with the fuzzy *c*-means considerably improves the partitions generated by fuzzy *c*-means alone. Various other studies have addressed the issue of the number of clusters, but there is no generally accepted approach of a priori selecting the appropriate number of clusters. Cluster validity tests are the only means available to decide whether the number of clusters used captures the underlying characteristics of the data. Investigating and resolving these issues is crucial in the analysis of financial statement data. The assignment to a particular cluster would determine whether or not the data being analyzed is a high "red flag" indicator of fraud.

FUTURE TRENDS

In addition to fraud determination, there are also other decisions that accounting and financial personnel make that affect financial reporting. Specifically, in the field of auditing, there is the auditor's decision reflected in the audit report about whether the company can continue as a going concern. The auditor uses financial statement and non-financial statement data, and a framework of questions to make the going concern judgment. The auditor also applies judgment in the consideration of materiality. Materiality judgment is closely linked to the analysis of fraud because the auditor must decide the extent to which a discrepancy affects the credibility of financial statements. These decisions may be enhanced by the use of statistical models, expert reasoning,

data mining tools, and now fuzzy logic, to provide support for the auditor's judgment.

CONCLUSION

Financial statement information is used by management, employees, outside analysts, investors and creditors to assess the health of publicly traded companies. Just as this information is now readily available through the Internet and online financial services, so should tools that help in the analysis of that information be readily available or easily obtained. As the different methods of fuzzy analysis become more prevalent, there will be additional opportunities for using fuzzy logic in various other applications.

KEY TERMS

Cluster Analysis: Defining groups based on the "degree" to which an item belongs in a category. The degree may be determined by indicating a percentage amount.

Data Mining: Using powerful data collection methods to analyze a company's database or data stores and select information that supports a specific objective.

Expert Reasoning: Implementing rules or procedures, often programmed to occur automatically, in order to make a decision. Background and heuristics that identify how to reach a conclusion are based on the knowledge of human experts in that field.

Fraudulent Financial Reporting: Intentional or reckless conduct, whether by act or omission, that results in materially misleading financial statements.

Fuzzy Logic: A mathematical technique that classifies subjective reasoning and assigns data to a particular group, or cluster, based on the degree of possibility the data has of being in that group.

Internal Controls: Procedures applied by a business organization that ensure information is safeguarded, that it is accurate and reliable, and that it is processed efficiently and in accordance with management's prescribed policies.

Management Fraud: A situation in which management misrepresents the financial condition of their firm. They may do so for personal financial gain or to disguise the financial results of their company.

Application Service Provision for Intelligent Enterprises

Matthew W. Guah
Warwick University, UK

Wendy L. Currie
Warwick University, UK

ROAD TO ASP

Several historical shifts in information systems (IS) involved strategies from a mainframe to a client server, and now to application service provision (ASP) for intelligent enterprises. Just as the steam, electric, and gasoline engines became the driving forces behind the industrial revolution of the early 1900s, so the Internet and high-speed telecommunications infrastructure are making ASP a reality today. The current problem with the ASP model involves redefining success in the business environment of the 21st century. Central to this discussion is the idea of adding value at each stage of the IS life cycle. The challenge for business professionals is to find ways to improve business processes by using Web services.

It took mainframe computers a decade or two to become central to most firms. When IBM marketed its first mainframe computer, it estimated that 20 of these machines would fulfil the world's need for computation! Minicomputers moved into companies and schools a little faster than mainframes, but at considerably less costs. When the first computers were applied to business problems in the 1950s, there were so few users that they had almost total influence over their systems. That situation changed during the 1960s and 1970s as the number of users grew. During the 1980s the situation became even tighter when a new player entered the picture—the enterprise (McLeord, 1993). In the 21st century, information systems are developed in an enterprise environment (see Diagram 1).

Beniger (1986) puts forth a seemingly influential argument that the origin of the information society may be found in the advancing industrialisation of the late nineteenth century. The Internet is simply a global network of networks that has become a necessity in the way people in enterprises access information, communicate with others, and do business in the 21st century. The initial stage of e-commerce ensured that all large enterprises have computer-to-computer connections with their suppliers via electronic data interchange (EDI), thereby facilitating orders completed by the click of a mouse. Unfortunately, most small companies still cannot afford such direct connections. ASPs ensure access to this service costing little, and usually having a standard PC is sufficient to enter this marketplace.

The emergence of the ASP model suggested an answer to prevailing question: Why should small businesses and non-IT organisations spend substantial resources on continuously upgrading their IT? Many scholars believed that outsourcing might be the solution to information needs for 21st century enterprises (Hagel, 2002; Kern, Lacity & Willcocks, 2002; Kakabadse & Kakabadse, 2002). In particular, the emergence of the ASP model provided a viable strategy to surmount the economic obstacles and facilitate various EPR systems adoption (Guah & Currie, 2004). Application service provision—or application service provider—represents a business model of supplying and consuming software-based services over computer networks. An ASP assumes responsibility of buying, hosting, and maintaining a software application on its own facilities; publishes its user interfaces over the networks; and provides its clients with shared access to the published interfaces. The customer only has to subscribe and receive the application services through an Internet or dedicated intranet connection as an alternative to hosting the same application in-house (Guah & Currie, 2004). ASP is an IT-enabled change, a different and recent form of organisational change, evidenced by the specific information systems area (Orlikowski & Tyre, 1994). ASP has its foundations in the organisational behaviour and analysis area (Kern et al., 2002).

The initial attempt—by the ASP industry to take over the business world—was fuelled by the belief that utility computing offered a new business model to customers, similar to electricity, gas, and water. The commercialization of the Internet meant that, as network traffic increased in a firm's data centre, IT architecture would trigger other resources into action, including idle servers, applications, or pools of network storage. The firm would pay only for the amount of time it used the services. Thus, the concept of 'software-as-a-service' was created (Kakabadse & Kakabadse, 2002). Accessing IT resources in this way would result in reduced up-front investment and expenditure, enabling firms to buy services on a variable-price basis (Dewire, 2000). This fuelled opportunities in the late 1990s for service provid-

ers to offer software applications and IT infrastructure on a rental, pay-as-you-go pricing model (Bennet & Timbrell, 2000). An ASP could be a commercial entity, providing a paid service to customers (Dussauge, Hart & Ramanantsoa, 1994) or, conversely, a not-for-profit organisation supporting end users (Currie, Desai & Khan, 2003).

ASP AREAS OF CONCERN

As evidence relating to the reality and basic features of the ASP market continues to grow, there begins to be less concern about confirming that any structural economic shift has continued historically, and more concern about understanding how the ASP industry is performing, and its impacts on productivity, investment, corporate capital formation, labour force composition, and competition.

The ASP business model is premised on the formation of strategic alliances and partnerships with technology and service providers (Ferergul, 2002). Telecommunications firms entering the ASP market with large IT infrastructures needed to partner with ISVs and hardware manufacturers. One of the significant strategic alliances was between Cable & Wireless (IT infrastructure), Compaq (hardware manufacturer), and Microsoft (ISV). Pure-play ASPs without a large investment in IT infrastructure needed to form strategic alliances with data centre and co-locator firms (telcos) and ISVs. Some of the major reasons for businesses to implement an ASP business model are list in Table 1.

The ASP model was highly volatile, dynamic, and immature. A recent review of the ASP industry concluded that technological factors like scalability, the managerial aspects of speed and focus, and the behavioural aspects of price and flexibility were the key drivers of the model. The inhibitors of the model were poor connectivity, lack of trust in the model, reluctance to be locked into long-term contracts with suppliers, lack of customisation, poor choice and suitability of software applications from ASPs, and few opportunities to integrate disparate applications across technology platforms and business environments. These factors and others led Hagel (2002, p. 43) to conclude:

"ASPs in many respects represented a false start in the efforts to break out of the enterprise straitjacket. In particular, few of them adopted Web services architectures as their technology platform. Instead, they attempted to build businesses on the Internet using traditional technology architectures…this proved to be a significant flaw in the early ASP model and explains many difficulties these businesses experienced."

The business environment for intelligent enterprises (see Diagram 1) includes the enterprise itself and everything else that affects its success, such as competitors; suppliers; customers; regulatory agencies; and demographic, social, and economic conditions (Guah & Currie, 2004). As a strategic resource, ASP helps the flow of various resources from the elements to the enterprise, and through the enterprise and back to the elements.

THE FUTURE OF THE ASP MODEL

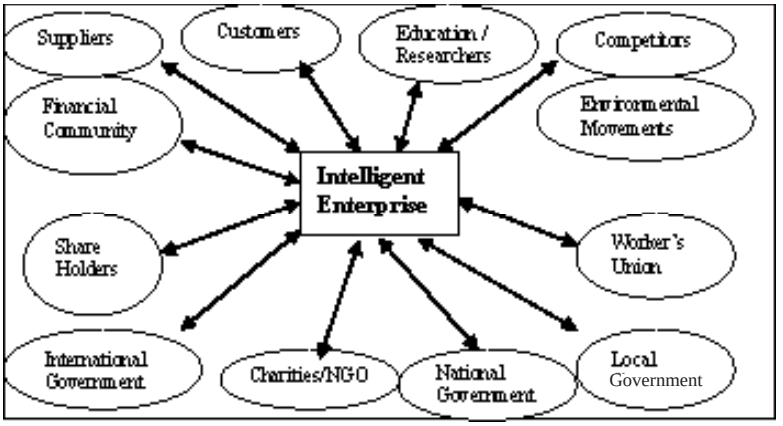
According to Forester Research, the proportion of ASP business in the outsourcing market peaked at about $800 million in 2000 and was projecting for $25 billion by 2005. However, it actually declined by the year 2002 (due partly to the effect of stock market collapse) and currently is being projected at $15 billion by 2006. The overall business interests in the ASP model will continue to rise, with proportionally higher rates of investment by vendors versus traditional outsourcing. We attribute this optimistic forecast to four trends:

- continuing improvements in capabilities and cost-performance characteristics of Remote Support Services by vendors,
- improvements in capabilities and cost-performance characteristics of the technology at the system or application level,

Table 1. A list of motivational factors to implement an ASP strategy

• To take maximise the capabilities of the Internet's latest technology
• To increase sales of products and services
• To reach a highly desirable demographic market
• To stay on top of competition
• To make changing information available quickly
• To test new products and services on the market
• To boast morale among staff and customers
• To experiment with an Internet model to business IT outsourcing

Diagram 1. A tool for controlling influences in a complex environment



- continual development of the telecommunications infrastructure to support ASP performance, and
- gradual reduction of institutional and social barriers to the introduction of the ASP model as a viable business strategy.

There are numerous papers warning that such accelerated Web service evolution increases the difficulty that other competitors have in adapting to ASP (Gottchalk, Graham, Kreger & Snell, 2002; Hondo, Nagaratnam & Nadalin, 2002; Stencil Group, 2002). By modifying the nature and the relative importance of the key factors for success in the ASP industry, Web service technological changes that are introduced by one or more of the vendors can lead to favourable changes in the competitive environment. In an industry built upon high volume, new technologies that are introduced by some of the competitors that nullify or minimise the impact of scale can significantly alter the nature of the competitive environment by making size a drawback rather than an advantage.

Diagram 2 shows that the holistic approach to technology always seems to work better than the piece-meal approach to information systems solution. Early stages of Web services are represented by a two-legged table. The current version of Web services being practiced by vendors after the dot.com crash is represented by the three-legged table in Diagram 2. But an even more successful model of Web services would be a properly architecture four-legged table, represented above. The analogy here is that a two-legged table is less stable than a three-legged table, while a four-legged table is even firmer.

CONCLUSION

We can safely conclude that policy makers in all fields, not just in IS, are forced into ill-considered conclusions and recommendations because they still view their management strategies in pre-Internet terms. Moreover, they are still constrained by statistical calculations based on outmoded and obsolete classification approaches, as well as on invalid assumptions about the fundamental sources of profit and capital formation—without full consideration for business environment.

Rethinking your business in terms of Internet economy, formulating new strategies for gaining competitive advantage, and raising the level of awareness of people throughout your enterprise to the notion that information itself can and should be looked upon as a strategic corporate asset¾these are great steps, but only the first steps for success in the 21st century. In addition, both structural and procedural changes must take place for an intelligent enterprise to put its convictions into operation. Could ASP provide you with such a necessary tool thereby directing your focus into the reality of a 21st century intelligent organisation?

Table 3.Summary of areas affecting the growth of the ASP market

Widespread model ignorance and perceptions among small and medium businesses. Lack of adequate understanding of the ASP business model and its understanding.

IS infrastructure raises a broad range of economic, social, and technical issues. Who should pay for infrastructure? Who should have access to/control over them and at what cost? Which technology should it include? Where ASP is involved, the economic question often puts telephone companies against cable companies, both of whom can provide similar capabilities for major parts of the telecommunications system.

Telecommunications facilitates ASP emancipation. Telecommunications has become virtually inseparable from computer with a paired value that is vital for integrating enterprises. As an e-commerce phenomenon, a few of the essentials of an ASP infrastructure are Common Carriers, Value-Added Networks, Private Line, and Private Networks.

Issues of security. As a program executed upon accessing a Web page, ASP carries a security risk because users end up running programs they don't know and/or trust. The latest solution is encryption, but does any mathematical encryption guarantee absolute security? No. Just as a physical lock cannot provide absolute safety, encryption cannot guarantee privacy—if a third party uses enough computers and enough time, they will be able to break the code and read the message. The encryption system only guarantees that the time required to break the code is so long that the security provided is sufficient. When someone asserts that an encryption scheme guarantees security, what they actually mean is that although the code can be broken, the effort and time required is great. Thus, an encryption scheme that requires a longer time to break than another scheme is said to be 'more secure'.

Overcoming organisational obstacles to a commercial future. The issue of organisation is based on the way ASP has evolved. The ASP industry lacks the type of clear organisation that would make it easy to use as a reliable and profitable business model.

ASP as competitive investment. Not so much return on investment for ASP, rather what is the cost of not investing? Will an enterprise lose customers and market share because it does not have a particular technology in place? Can you enter a new line of business without investing in the technology that competitors have adopted? What kinds of services do customers expect? These are competitive investment issues raised by ASP.

Change is also an opportunity. One stimulus for ASP solution implementation is its intention to transform the enterprise. In this sense, the investment in ASP is part of a larger change programme that is meant to enable intelligent enterprises' virtual and multiple-team structures. The resulting contributions can be described as part of the outcome of a general change effort.

Social-technical issues. The social objectives refer to the expectations of major stakeholders (i.e., employees). An ASP business model that provides information and tools for employees increases involvement because they reinforce the employee's authority and responsibility for work. Those that provide information to managers or quality inspectors but do not support employees can reduce involvement by reinforcing the suspicion that the employee is not really responsible.

Tangible and intangible benefits. The tangible benefits of an ASP solution can be measured directly to evaluate system performance. Examples include reduction in the time for completion of transaction, improvement in response time, reduction in the cost of assets, and reduction in the error rate. Intangible benefits affect performance but are difficult to measure because they refer to comparatively vague concepts. A few intangible benefits of a solution are: better coordination; better supervision; better morale; better information for decision making; ability to evaluate more alternatives; ability to respond quickly to unexpected situations; and organisational learning. Although hard to quantify, intangible benefits are important and shouldn't be ignored, as many IS benefits to organisations are intangible.

The role of government. Modernisation of the machinery and process of government will accommodate many Internet strategies like ASP. This will involve reform of intellectual property law to accommodate access to and exploitation of works via the Internet. It will include administration of Internet domain names on an international basis. Finally, the facilitation of e-commerce development will include national and international initiatives and measures to protect both suppliers and consumers operating within this global electronic marketplace.

Blurring in-house IT and ASP services. As the industry evolves and becomes more complex, the need for new services and specialisation in the division of labour continues to increase. In-house migrates into strategic management and monitoring of IT standard, while ASP migrates into value-added services so that 'business IT becomes a service in a package form'. As the boundaries between in-house and ASP become more blurred through the use of improved communications technologies, the opportunities for entrepreneurs continue to increase.

KEY TERMS

ASP: A third-party service firm that deploys, manages, and remotely hosts software applications through centrally located services in a rental or lease agreement (ASP Consortium, 2000). Such application deliveries are done to multiple entities from data centres across a wide area network (WAN) as a service rather than a product, priced according to a license fee and maintenance contract set by the vendor. An ASP is considered by many to be the new form of IT outsourcing, usually referred to as application outsourcing.

ASP Aggregator: The ASP aggregator model is based on the premise that the rapid proliferation of firms offering ASP services has created an overly complex market for medium-sized enterprises to deal with when investigating application outsourcing options.

Agent-Based Approach to ASP: This approach to ASP is well equipped to address the challenges of multi-market package to e-procurement. Service agents within the ASP model are the system's gateway to external sources of goods and services. These agents are usually aware of the source's market model and of the protocols it uses (Zhang et al., 2000). Service agents are not only able to determine which requests it can service, but also proactively read these requests and try to find an acceptable solution.

Common Carriers: Companies that are licensed, usually by a national government, to provide telecommunications services to the public, facilitating the transmission of voice and data messages.

Infrastructure: An emerging class of companies have opted to approach the ASP market by providing infrastructure management and outsourcing services to ASPs, freeing up their resources to focus more directly on application management issues (telco, data centre, networking).

Internet Service Providers (ISP): Provides access to the Internet via different communications channels such as traditional telephone lines or a high-speed fibre optics channel.

Pure-Play ASP: Those with non-specific industry-required product or service, except Internet/Web-enabled software applications (e-mail/security/disaster recovery). Firms offering this service suffer from the sales of unprofitable commodity applications and therefore have greater reliance on venture capitalist funding as they operate in a rather unstable, volatile, and dynamic market.

Vertical Service Provider (VSP): Vertically focused ASPs offering industry-specific applications are also emerging. Their basic premise is that each industry (health, finance, transportation) has its own unique set of characteristics that can best be served by companies that focus exclusively on the given industry.

Virus: A malicious code added to an e-mail program or other downloadable file that is loaded onto a computer without the user's knowledge and which runs often without the user's consent. Computer viruses can often copy themselves and spread themselves to a user's e-mail address book or other computers on a network.

Web Services: Web Services technology is one of the most important foundations for ASP new-game strategies. Thus, by accelerating the pace of Web services in the industry, a competitor with good capability in the technology reinforces its own competitive position.

Applications for Data Mining Techniques in Customer Relationship Management

INTRODUCTION

With the explosion in the amount of data produced in commercial environments, organizations are faced with the challenge of how to collect, analyze, and manage such large volumes of data. As a consequence, they have to rely upon new technologies to efficiently and automatically manage this process. Data mining is an example of one such technology, which can help to discover hidden knowledge from an organization's databases with a view to making better business decisions (Changchien & Lu, 2001).

Data mining, or knowledge discovery from databases (KDD), is the search for valuable information within large volumes of data (Hand, Mannila & Smyth, 2001), which can then be used to predict, model or identify interrelationships within the data (Urtubia, Perez-Correa, Soto & Pszczolkowski, 2007). By utilizing data mining techniques, organizations can gain the ability to predict future trends in both the markets and customer behaviors. By providing detailed analyses of current markets and customers, data mining gives organizations the opportunity to better meet the needs of its customers.

With such significance in mind, this chapter aims to investigate how data mining techniques can be applied in customer relationship management (CRM). This chapter is organized as follows. Firstly, an overview of the main functionalities data mining technologies can provide is given. The following section presents application examples where data mining is commonly applied within the domain, with supporting evidence as to how each enhances CRM processes. Finally, current issues and future research trends are discussed before the main conclusions are presented.

BACKGROUND

Data mining methods can generally be grouped into four categories: classification, clustering, association rules and information visualization. The following subsections will describe these in further detail.

Classification

Databases are full of hidden information that can help to make important business decisions. Classification involves using an algorithm to find a model that describes a data class or concept (Han & Kamber, 2006). By identifying a series of predefined labels, items can be categorized into classes according to its attributes (e.g., age or income). Thus, it is a useful technique for identifying the characteristics of a new item. For example, in the case of a bank loan clerk, classification is useful for predicting whether loan applicants are a "safe" or "risky" investment for the bank based on the class that they belong to. Popular classification techniques include Decision Trees and Bayesian Networks.

Clustering

Where classification is thought of as a supervised learning technique because it uses a set of predefined class labels, clustering is an unsupervised learning technique. Because no assumptions are made about the structure of the data, clustering can uncover previously hidden and unexpected trends or patterns. Clustering involves grouping items into "natural" clusters based on their similarities (Hand et al., 2001). Each item in a cluster is similar to those within its cluster, but dissimilar to those items in other clusters. In this way, clustering is commonly used to identify customer affinity groups with the aim of targeting with specialized marketing promotions (section 3.2.2). Common clustering techniques include K-means and Kohonen Networks.

Association Rules

Association rules are mainly used to find relationships between two or more items in a database. Association rules are

expressed in the form (X→Y), where X and Y are both items. In a set of transactions, this means that those containing the items X, tend to contain the items Y. Such an association rule is usually measured by *support* and *confidence*, where the *support* is the percentage of both X and Y contained in all transactions and the *confidence* is calculated by dividing the number of transactions supporting the rule by the number of transactions supporting the rule body (Zhang, Gong & Kawamura, 2004). For example, this technique is commonly used to identify which items are regularly purchased together or to identify the navigational paths of users through an online store. The discovery of such relationships can help in many business decisions, such as customer shopping behavior analysis, recommendations, and catalog design (Han & Kamber, 2006).

Information Visualization

Information visualization is based on an assumption that human beings are very good at perceiving structure in visual forms. The basic idea is to present the data with some graphics, for example, 2D graphics and 3D graphics, allowing the human to gain insight from the data, draw conclusions, and directly interact with the data (Ankerst, 2001). Since the user is directly involved in the exploration process, shifting and adjusting the exploration goals is automatically done if necessary (Lopez, Kreuseler & Schumann, 2002). This approach is especially useful when little is known about the data and the exploration goals are vague, for example, analyzing the path of customers through an online store.

Data Mining and Its Applications in CRM

Customer relationship management (CRM) is thought to be an increasingly important success factor for e-business. CRM is the process of managing interactions between a company and its customers. Initially, this involves segmenting the market to identify customers with high-profit potential, from which marketing strategies are designed to favorably impact the behavior of customers in these segments (Berson, Smith & Thearling, 2000).

Customer Analysis

Customer Segmentation

Customer segmentation is the process of splitting customers into homogeneous groups based on their common attributes (Böttcher, Spott, Nauck & Kruse, 2007). More specifically, clustering algorithms are used to discover groups of customers based on such attributes. By doing so, each cluster contains customers who share similar attribute values. Benefits of clustering in this way include a deeper understanding of the needs and behaviors of individual customer groups, allowing the implementation of systems for the purpose of personalized recommendations (section 3.2.1) and targeted marketing (section 3.2.2). For example, Vellido, Lisboa, and Meehan (1999) segmented customers from the data gathered in an online survey. Initially, they conducted a factor analysis of the observable data and then the factor scores were clustered by using the Self Organizing Maps. Five clusters were discovered: cost conscious, complexity avoiders, unconvinced, convinced and security conscious. These clusters allowed researchers to identify which groups of customers frequently used online shopping and those that would be more open to specific marketing campaigns.

However, even though customers can be easily segmented into groups in such a manner, today's fluctuating markets mean that segmentation often becomes obsolete very quickly. Ha (2007) overcame this by providing a method that monitors constantly changing customer needs. After performing Kohonen Network clustering to divide the customers into four dominant clusters, the author focused on keeping track of customer shifts among the segments to monitor the changes over time. Behavior patterns of customers in each of the segments were then predicted through the use of transition paths.

In addition, Böttcher et al. (2007) present a system for customer segmentation which accounts for the dynamic nature of a market based on "interestingness". Their system focuses on the discovery of frequent item-sets and the analysis of their change over time, which provides detailed knowledge about how customer behavior evolves over time. They successfully applied their system to two problem domains in a telecommunications company: customer analytics and network usage. The former aimed to identify the factors likely to drive customer satisfaction in the future, whereas the latter aimed to understand the drivers of change in customer behavior whilst using the services.

Click Stream Analysis

In addition to grouping the types of users through transaction or personal data, click streams, the paths visitors take through a website, also provide valuable information. Analyzing click stream data can show retailers how visitors navigate their way around an online shop, which is useful towards understanding the effectiveness of marketing efforts, that is, how customers find the online store, what products they view and what they purchase (Lee, Podlaseck, Schonberg & Hoch, 2001).

Lee et al. (2001) conducted a study to analyze click streams with a view to evaluating the effectiveness of online merchandising tactics. By using an interactive visualization system, they were able to break down the click streams into individual customer shopping steps to highlight potential

problems with their merchandising. For example, if a product has a high click-to-basket rate, this indicates that the product page is effective. However, if the product has a low basket-to-buy rate, it could mean that although the product is attractive, the customer is turned off because of its high price. Such knowledge would then allow the retailer to focus on marketing the product in a more persuasive way.

Lee, Lee, and Park (2007) used a different method to conduct click stream analysis to investigate the key considerations of customers and how these affect the success of online shopping at a much higher level. In their study, users were classified through the use of decision trees into two categories: those who rarely used online shopping and those who frequently used online shopping. For those who rarely used online shopping facilities, the findings suggest that the time and urgency of the purchase are the most important factors that need to be considered. On the other hand, for those who shop online frequently, price, and human resources were highlighted as the key considerations. Such findings allow organizations to understand their customers and better provide for their needs and preferences.

Customer Profitability

Although segmentation and click stream analysis can provide detailed information about a company's customers, data mining can also be used to predict customer profitability (Shen, Xing & Peng, 2007). In other words, a company can identify its most valuable customers and can concentrate their marketing efforts around them. Wang and Hong (2006) used data mining techniques to develop a Customer Profitability Management system which would lead customers into more profitable behavior. Applying their system to customer data from a telecommunications company, neural networks were used to classify customers into distinct groups with regards to their susceptibility to marketing promotions: profitable, resistant, and unpredictable. This allowed the company to target the latter two groups and, with the aid of additional telephone interviews and surveys, enabled them to develop specific marketing strategies and increase their customer profitability levels by 12%.

Marketing Strategies

Making Recommendations

Due to the high degree of variety in services and products offered on the Web, it is sometimes difficult for customers to select those which are the most appropriate to their needs. In other words, the online consumer is faced with a multitude of choice. To address this issue, personalized recommendation systems can be used to predict and identify the preferences and interests of a particular user based on the behaviors of similar users (Karypis, 2001).

Liu, Ke, Lee, and Lee (2008) used clustering and association rule mining techniques to provide recommendations. Initially, the K-Means algorithm was applied to usage data of composite e-services, which are packages offered by a number of e-service providers, to separate customers into user interest groups. Association rule mining was then applied to each of the groups. This resulted in the discovery of similarities in the buying and browsing habits between members in the groups, which then enabled the use of group-based recommendations. For example, if a customer selected "Programming in Microsoft SQL Server 2000 Database", the association rules would highlight that other customers in the interest group had previously selected "Programming with C#" and "Programming with VB.Net". This provided customers with a set of related recommendations to help them effectively utilize composite e-services.

In a similar vein, Lazcorreta, Botella, and Fernández-Caballero (2007) also proposed a solution for recommendations, but only used association rules. Association rule mining may work effectively for smaller data sets, but limitations, such as the amount of time taken to generate the rules or the number of irrelevant associations identified, have been known to arise when larger data sets are involved. To address this problem, they developed a modified version of the Apriori algorithm for a much larger collection of data. Their modified algorithm included four steps: (1) discovering existing association rules in the original repository of transactions; (2) rewriting the original transactions to reflect all association rules that verify each one of them; (3) analyzing differences existing between both sets of transactions by means of statistical analysis; and, (4) discovering and using the existing relations between rules discovered in step 1 in order to automatically divide the set of transaction rules obtained in step 2. They found that the time and effectiveness of the rules were improved by analyzing the behavior of a single user in accordance with other users.

Targeted Marketing

Once classification has been used to identify a series of key factors that can influence a customer's decision to shop online, clustering techniques can be used to identify customer groups with similar online shopping habits. This data can then be used to target specific groups for marketing promotions or predict the behavior of new customers. Liao and Chen (2004) mined customer, product, and transaction data to generate cross-selling rules for the design of an electronic catalogue. Customers were segmented into groups and association rule mining was used to find frequently purchased item sets. Marketers were then able to use this knowledge to create a personalized online catalog for their targeted customers.

Similarly, Lin and Ong (2008) also analyzed customer behavior to aid in the design of an electronic catalog for a stationery mall. Association rules were used to identify links

between customer profiles and products purchased. In this way, collections of target customers, products, brands and discount prices were designed and emailed to customers in specific segmentation groups in the form of an electronic catalog. A review of sales of the stationery company showed an increase in sales over the six month period that this system was implemented.

Additionally, Yang & Lai (2006) compared the analyses based on three different types of data: (1) order data, (2) browsing data and (3) browsing and shopping cart data. Association rule mining was then used to extract frequent item sets so that product bundles could be created. These bundles proved to be more accurate when both browsing and shopping cart data was used, in comparison to the other two types of data analyzed.

FUTURE TRENDS

It is clear from the aforementioned applications that data mining techniques are very useful tools in customer relationship management. However, with more information becoming accessible via the Web, there are increasing concerns that data mining may pose a threat to individuals' privacy and data security. In general, data mining is used for analyzing transaction data, instead of personal data, but it is likely that privacy-sensitive information is revealed so they should be designed with caution. For example, actions can be taken to remove key fields to ensure privacy is still kept in place. Precautions such as these can help to ensure the integrity of data mining techniques, but essentially the future relies upon the cooperation of all researchers and developers to implement these techniques in a way that preserves privacy (Han & Kamber, 2006).

As well as dealing with such issues, limitations have been highlighted that should be addressed in future research.

- **Specific Application Development:** A study by Anderson, Jolly, and Fairhurst (2007) highlighted that data mining is not utilized evenly across all CRM strategies. For example, of the five strategies identified (improving marketing effectiveness, enhance loyalty by improving customer service, customer analysis, customer acquisition and retention and grow or drive business), customer analysis and marketing were found to have had the most research concentrated previously. Data mining has added value to these two strategies, so further research should concentrate on looking at other strategies.
- **Manageable methods:** The amount of data stored and collected in the business world is rapidly increasing. Therefore, care has to be taken to ensure that data mining algorithms remain efficient and manageable. The idea of introducing constraints into data mining algorithms, that is, constraint-based mining, allows the user some additional control over the efficiency of the process. For example, when using association rules to mine for frequent item sets, statistical methods can be used to restrict the search space to only that which is interesting, therefore resulting in more relevant patterns being identified (e.g., Bonchi & Lucchese, 2007).

CONCLUSION

In summary, data mining can be used to discover novel and interesting relationships from large business databases. These can then be used to enhance an organization's productivity by supporting their CRM functions. This paper provides a background to data mining and has given some examples of how data mining supports CRM, especially focusing customer analysis and marketing strategies. By exploiting the full potential of data mining techniques, organizations can meet their customers' needs in the best possible way.

KEY TERMS

Apriori Algorithm: An iterative association rule-mining algorithm that uses prior knowledge to identify frequent item sets in order to predict future events.

Bayesian Classification: A type of classification algorithm, based on the statistical probability of a class and the features associated with that class.

Decision Tree: A visual representation of a decision problem that forms tree-like predictive models with the aim of helping people to make better decisions.

K-Means: A nonhierarchical clustering technique which splits data sets into K (a given number) subsets in a way that each subset is maximally compact.

Kohonen Networks: A type of unsupervised neural network used for finding patterns in input data without human intervention, consisting of Vector Quantization, Self-Organizing Map, and Learning Vector Quantization.

Neural Network: A computational approach inspired by simple models of the brain, consisting of nodes or neurons connected together in some sort of network.

Self Organizing Map (SOM): An unsupervised neural network algorithm that results in a clustered neuron structure, where neurons with similar properties (values) are arranged in related areas on the map.

INTRODUCTION

The evolution of ICT and the influence over educational areas has been very significant in recent years, changing conception of learning environments, communications and interactions forms, and educational material. Researchers, like Buzon and Barragán (2004), have expressed the need to create new learning (online) environments that allow teaching and learning without the time and space restrictions of residential courses, and ensures continual (**virtual**) **communication** between students and professors, or the need to find new material courses, learning strategies that allow the efficient use of new systems and educational resources emerged from technical advances (Wai-Chung and Li, 2007; Weert, 2006).

On the other hand, among the conclusions reached at the Second Virtual Congress, "Education through Internet and Internet in Education" (2004), was the need for all technological research to take into account the pedagogical, economic, and social aspects, so that a coherent integration between technology and education can be achieved.

Nevertheless, it is still difficult to incorporate the use of tools like chat, electronic mail, text editors, and forums, in other activities that involve no more than the simple exchange of information; this limits their potential and benefits. According to Friendals and Pauls (2005), the majority of Professors still depend on well-established, primitive teaching aids, like, for example, chalk and board. Their analysis revealed that the need for teaching aids in classrooms, which include educational integrative mini-applications, should be one of teaching's main priorities.

Based on these criteria, that is, the need to effectively incorporate ICTs to make changes in the educational field, this research has focused in submitting a proposal of a collaborative teaching strategy, empirical education collaborative **teaching strategy**, shortening EE-Col, like first link to develop later on, a collaborative educational model. EE–CoL's validation will enable to lay down the basis for the design of an exclusive model in **distributed environments** where the generated learning elements are interoperable and reusable, using shared and coordinated resources.

BACKGROUND SECTION

There have been numerous positive experiences in higher education, where **collaborative learning** has been supported by the use of electronic mail and discussion forums (Murillo, 2000; Romero, Osuna, Sheremetov, Chi, & Villa, 2003); collaborative editing systems to support groups that edit, simultaneously, from different places (Ignat & Norrie, 2004; Stavroula, Ignat, Ester, & Norrie, 2006); or experiences that show interest in the design and application of collaborative environments with use of diverse learning technique (Gonzalez, 2006; Lucero, Chiarani, & Pianucci, 2003; Roman, 2003). Similarly, there were solutions that used the Web for collaborative work (Klein, 2004; Thao, 2002). These investigations have evidenced excellent and satisfactory results when utilizing technological elements like auxiliary tools in educational processes

In investigations of **computer assisted collaborative learning,** CSCL, of Rubia, Jarrín and Bote (2003); Martinez, Gomez, Martinez, and Mora (2004); Hansson and Van Heuten (2006), among others, the use of BSCW (*basic support for cooperative work)* for education programs between two institutions, computer simulation tools use for synchronous and asynchronous communication showed their effectiveness to resolve punctual problems of collaborative learning and communications.

The analysis of theses researches confirmed the benefits obtained by students in collaborative learning and advantages offered by ICT for working with distributed environments. Additionally, it helped confirm that most research is directed towards the satisfaction of specific needs, like distance-learning applications, to promote group integration in the acquisition of knowledge, or increase the use of groupware

tools in the educational process in order to improve academic achievement, social **interaction,** and communication. In general, the projects checked were focused on these objectives, while proposals of **teaching strategy** or educational models that allow the incorporation, integration, and systematization of new tools as a fundamental component in teaching processes were not found.

EE-CoL Teaching Strategy

EE-Col, based in the integration of constructivism, negotiation and social integration, cognitive conflict, and collaborative-cooperative work principles, (concepts explained by Fernández & Melero, 1995; Martinez, 2001; Panitz & Panitz,1998=), has, as a premise to reach a consensus through the cooperation of group members, shared authority and acceptance of responsibility of action as a group, applying techniques and methodologies of **collaborative learning** to activate critical thought and autonomous learning.

EE-CoL's fundamental motor is to be applied through the collaborative tools offered by computer technology applications, like electronic mail, videoconferences, chats, discussion and application groups, which allow the strategy to support synchronous and asynchronous interaction to have, at its disposal, the multiple advantages relating to space-time that the tools offer. Such characteristics make the new EE-Col unique, as it results from the combination of pedagogic and collaborative principles, information-technology tools, and emerging technologies of communications and applicable to **blended learning.**

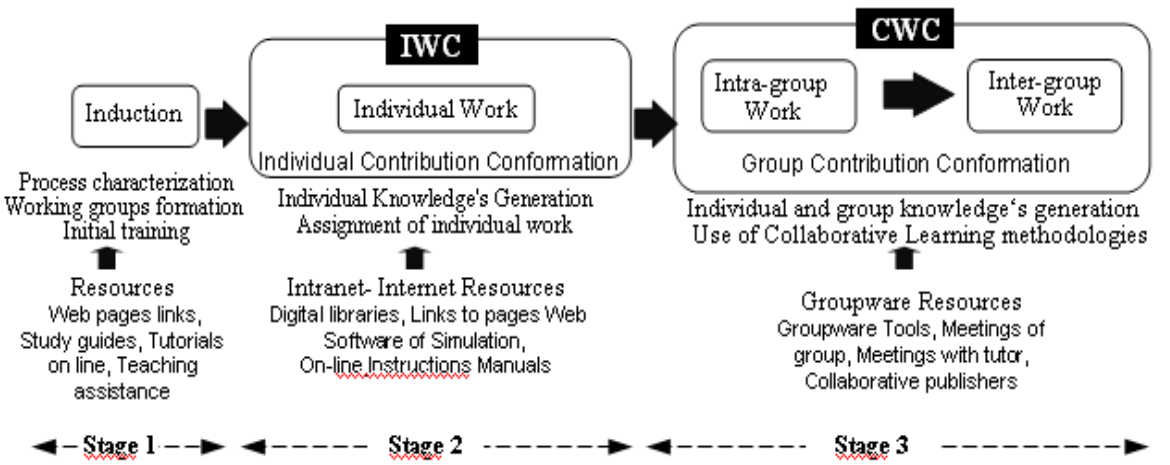
EE-CoL Stages

EE-CoL develops in three consecutive stages, *induction stage*, *individual work stage*, and *group work stage*, that complement each other, in order to achieve acquisition and accumulation of individual and collective knowledge. Figure 1 shows EE-CoL development stages.

Individual work component (IWC). IWC gives each individual the preliminary preparation to achieve certain balance between knowledge and abilities for more effective **interaction** during subsequent group discussions. It is essential for IWC to be focused on two key points: student's needs and student's motivations. In consequence, the professor must carefully select the **teaching methodology** or required activities, schedules, basic material, and online or face-to-face consultation sessions; identify the core concepts and the information available, always bearing in mind the knowledge that the students must acquire during this stage. EE-CoL proposes to use the *introductory focal activity* that specifically seeks to attract the students' attention towards a specific aspect.

***Cooperative work component (CWC*).** The CWC's essence is the knowledge generated by **interaction** and group work through two components. The *cooperative intragroup work* organizes students in order that they can achieve their goals with an active and positive interaction accomplished through synchronous and asynchronous discussions that generate information exchange *between group members* and a global synthesis of the team's work. Intragroup interaction is activated through collaborative work strategies: *jigsaw*

Figure 1. EE-CoL stages



or puzzle, research groups *co-op co-op or kagan* (Diaz & Hernández, 2005), selected according to student numbers, topic, objectives, subject (theoretical or practical), and degree level (undergraduate or postgraduate).

C*ooperative intergroup work* is subsequent stage to interchange of information *between groups,* always through discussion sessions lead by a teacher where each group's results are analyzed and learned by all students. These discussions, which activate productive **interaction,** can take place on the Internet, in virtual classrooms, in videoconferences, in discussion forums, or in person. This subcomponent allows complementing the knowledge acquired within each group.

EE-CoL Implementation

EE-CoL was developed in two sections of Analog Electronics Laboratory Course of the Electrical Engineering School at Universidad Nacional Experimental Politécnica, Venezuela. In these courses, 10 experiences were executed, and the research subjects were the 24 students registered for the course (sections A and B); in each section, three work groups of four students per group were formed.

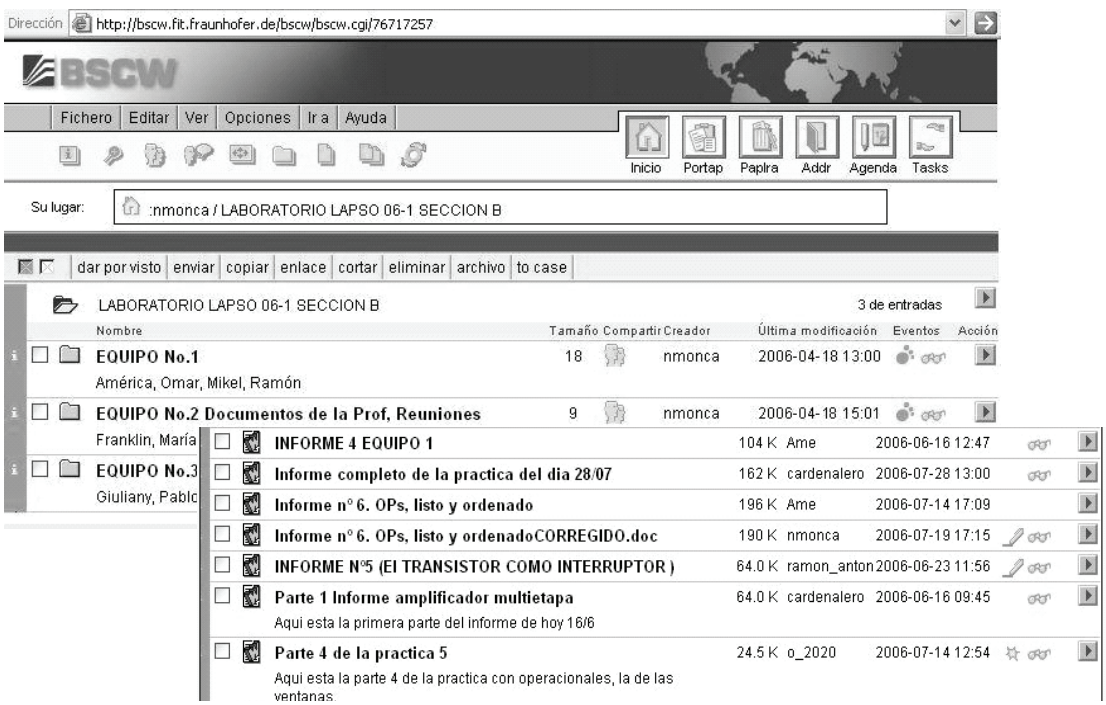
Both strategies, traditional and EE-CoL, were applied to each group of students. The traditional strategy was applied to the first five lab sessions, with traditional methods and work booklet; the subsequent five sessions were developed with the EE-Col strategy, using a new assessment plan and new support material to carry out each stage of strategy

In new support material, each practical session had two parts: *prior preparation,* which should have been prepared individually by each member of the group and it was constituted by questions over procedures explications, components, and equipment operating; and *laboratory experience,* whose processes are closely related with prior preparation. One BSCW space was set for each section to be used by its students as a shared space.

During the *induction stage*, the methods of working, assessment to be followed during the experiment, and the fundamental aspects of the strategy were explained, and the basic processes of **BSCW** (edit documents, add and erase notes, files or folders, and carry out discussions forums) were practiced. For each group, the instructor assigned three basics roles with specific functions: group leader, material organizer, and the editor. It was suggested that for each session, the roles were rotated in accordance with the members' criteria so that they all had the chance of performing each role at least once.

Through the *individual contribution* approval stage, each student had to individually research the questions

Figure 2. Folder's distribution with one use sample of group folder



asked in the previous preparation, operational basis for EE-CoL's *individual work component*, and "upload," on to the shared space, his individual answers that had been supervised by the professor.

The *intragroup contribution* was generated by online discussions, preparation of final documents, pre- and post-laboratory, and experimental works sessions. In order to elaborate the final report, all members of the group checked each other's individual contributions to select the best answers, correct mistakes, add suggestions, so that the final report could be prepared by editor of group. The **BSCW** space was used for these purposes. (See space sample in Figure 2) A chronogram for these activities was suggested by the teacher.

The *intergroup contribution* was made up of face-to-face discussions, led by the instructor, that took place among all students during the first 20 minutes of each laboratory session.

Results of EE-CoL Evaluation

As EE-CoL is a teaching strategy that utilizes electronic tools and collaborative principles, the goal was to somehow measure its basic principles by observing the interaction between students, individual responsibility, active participation in discussions, and academic achievement and performance during the lab session. The active participation in the joint preparation of reports was one parameter considered to measure **interaction** between students. They were able to create, read, and modify the documents being produced by all group members in order to assemble the final document. Graphs in Figure 3 show noticeable activity to produce pre- and postlaboratory reports.

Likewise, use of discussion forums and insertion of comments next to the documents were observed. These were used in order to communicate any doubts, explanations, agreements, or approvals to the modifications made by any of the students. Figure 4 shows the interactions from each group during report creation using the **BSCW** tool.

In order to evaluate the acceptance of the new strategy, and the use of its tools, a survey-type measuring instrument to evaluate the new work material and the group work was used. The following results were obtained:

A high degree of satisfaction was obtained with the incorporation of previous preparations; 72.7% answered that they allowed a better disposition to the understanding and development of the experiments, and a more effective learning process

In reference to group work, 100% agreed on the need for adequate distribution of members and roles within the group in order to obtain better results when working as a team; 80% admitted that the work performed in their roles allowed them to determine weaknesses and strengths in their performance and group work. In the same manner, a high percentage, over 90% were of the opinion that the group work was beneficial and that they felt the interrelation between members.

The groupware tools and the use of BSCW cyberspace was highly accepted within the surveyed groups since they could intervene from any place and at any time; a positive opinion was detected by benefits when group discussions took place, and values over 80% confirmed that discussions, report creation were facilitated.

Figure 3. Distribution of asynchronous interactions (document creation, reading, and modification for reports elaboration (pre–post laboratory)

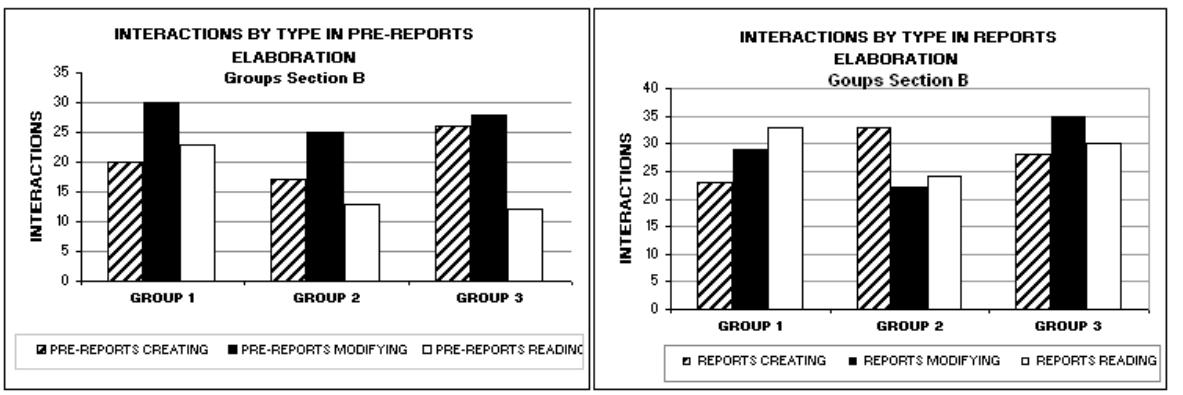


Figure 4. Interactions for reports elaboration of section B groups

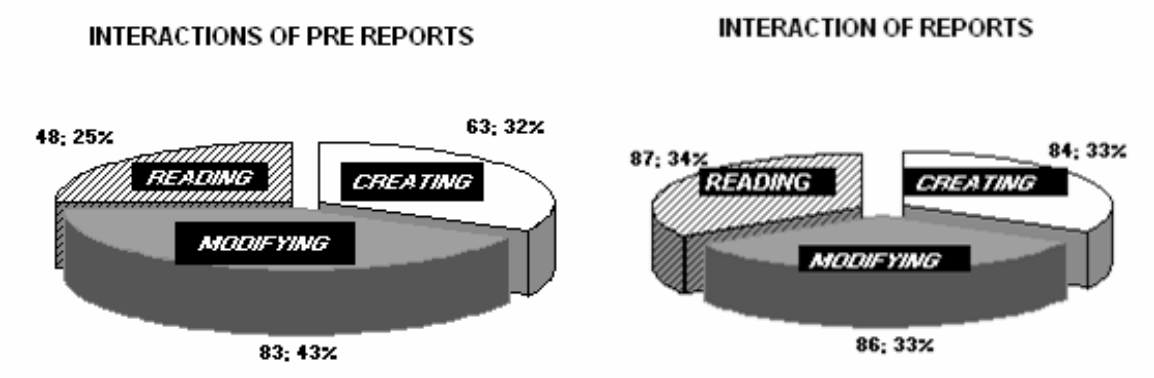

Figure 5. Student performed according to used strategy for both section

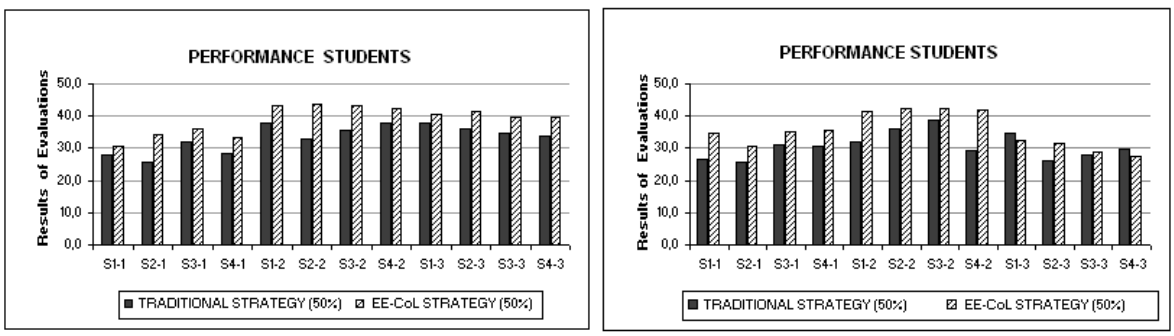

As an important additional element, the students' academic performance in both phases was considered. When comparing the academic performance, 83.3% of students performed better when the proposed strategy was applied. Figure 5 shows a bar chart with students' performance according to the used strategy.

The students' performance level when using EE-CoL was better because there was more active and significant participation in discussions and better disposition to complete the assigned tasks. Furthermore, when using EE-CoL, a more favorable effect is evident in the socio-affective relations of the students, and a higher **interaction** and collaboration between students was achieved, because the student had the possibility to program his own work and to have a better coordination of activities from any place and at any time.

As a collaborative strategy, EE-CoL achieved participation of students in the planned activities, using the different tools made available for collaborative work. In the same manner, group goals were achieved by distributing responsibilities through the roles performed by the students within their group.

The main difficulty observed during the application of the strategy was represented by two factors: lack of skill in the use of computers and electronic tools in some students and

the difficulty to access the different resources and information made available for the work at any specific time, due to the lack of Internet connection outside the campus.

FUTURE TRENDS

Group interactive work plays an important role in the success of the proposed model. Therefore, it is of interest to specify and optimize mechanisms that could boost ***interaction*** and the use of *collaborative tools.* All this implicates the need to initiate further research that will allow the transference of experiences to other educational domains with diverse pedagogical contexts. At the moment, the application of EE-CoL to a master's degree subject is being planned. With this, the usability of the different types of interaction and informatics tools proposed in the strategy could be analyzed and the applicability could be validated.

The use of other technologies that facilitate collaborative work and resources sharing, like grid technology, already existing in several campuses, would allow EE-CoL implementation with better results. With analysis of this alternative, it would then be possible to perform a study to propose a collaborative educational model in grid environments involving both innovations

CONCLUSIONS

This chapter has presented EE-Col, a teaching strategy based on the collaborative work principles and the use of its informatics tools in **distributed environments**. The results have shown significant evidence on effectiveness and efficacy of EE-CoL, when the users achieved their objectives with precision and with relatively few resources; the high degree of satisfaction was also verified by positive attitude of the students towards its use. In addition, the application of this strategy gave satisfactory results with respect to promoting **interaction** and communication, verification of the simplicity of the groupware tools and of the presence of the basic principles of collaborative work.

EE-CoL constitutes an alternative for complementing traditional education or promoting **interaction** and communication in courses whose participants, teacher and students, do not have a continuous contact, like at the postgraduate or training courses. Results allow establishing the link to formulate a new collaborative educational model for **distributed environments**.

KEY TERMS

Asynchronous Communications: Computer-based exchanges of messages for which the participants need not be available or online at the same time, but, rather, read and respond as their schedules (and desires) permit. Examples: e-mail, discussion boards, text messaging over cell phones.

Blended Learning (B-Learning): Learning that combines different modes of delivery, such as online and traditional face-to face learning.

BSCW System: Provides facilities for collaboration over the Internet. It is based on the "shared workspace" metaphor: an object store for group work, with some simple awareness functionality that allows users to keep an overview of what is happening in the workspace.

Focal Introductory Activity: A set of activities that try to fix the students' attention to stimulate the knowledge previously acquired and to create an appropriate motivational initial situation that will be used for any posterior activity. Hypothetical situations, examples, case studies, or a group of approaches or questions are activities that could be utilized.

Groupware: Refers to computer applications designed to help people work together collectively while located remotely from each other. Groupware services can include the sharing of calendars, collective writing, e-mail handling, shared database access, electronic meetings with each person able to see and display information to others, and other activities.

Jigsaw or Puzzle: Technique used in collaborative learning that proposes dividing the academic material in as many sections as the number of group members. All groups learn the same topic but, inside the groups, each member learns their assigned section, making him an "expert" on his "piece of the puzzle" or knowledge section. Later, the members of diverse groups that have researched the same topic meet in the so called "expert groups" to discuss their findings, obtain new knowledge and then, return to their original group to share and teach this topic to the rest of the group.

Kagan Technique: Or co-op co-op technique for collaborative learning. Each work group freely chooses the topics to be divided into subtopics. These subtopics will be assigned to, and developed by, each member. Later, each member will impart the knowledge acquired to the rest of the colleagues, so that at the end, each group presents their work globally.

Synchronous Communication: *Or* direct communication, where all parties involved in the communication are present at the same time. Examples: telephone conversations and instant messaging.

Applying Evaluation to Information Science and Technology

David Dwayne Williams
Brigham Young University, USA

INTRODUCTION

As indicated by the wide range of topics addressed by this Encyclopedia, the fields of information science and technology have grown exponentially. Likewise, the field of evaluation has evolved and become increasingly integral to learning and improving upon principles and practices associated with all fields the Encyclopedia explores.

The field of evaluation is the formal transdiscipline of gathering information about the performance or nature of objects of evaluation and comparing the objects' performance to criteria to help participants make evaluative judgments (Scriven, 2004). Evaluation includes several elements: negotiation with multiple participants regarding their values and criteria, using many different kinds of processes to document and judge the performance of various objects of evaluation, formative and summative purposes, measurement and assessment techniques, and use of quantitative and qualitative data gathering and analysis processes.

This chapter documents the development of evaluation as a field; presents a framework for thinking about evaluation that is theoretically sound and practical to use; and explores ways to apply the framework to facilitate learning, improvement, decision-making, and judgment in all sub-fields of information science and technology.

BACKGROUND

After reviewing several approaches to achieving different evaluation purposes, the relationship between evaluation, measurement, and assessment is explored and the use of quantitative and qualitative data to facilitate evaluation is clarified.

EVALUATION THEORIES OR APPROACHES

For the last few decades, many approaches to evaluation have been evolving. In the 1960's several social scientists, psychometricians, and others responded to government challenges to evaluate funded programs by identifying approaches that have been debated and expanded for years. Many of these approaches are summarized and discussed by Fitzpatrick, Sanders, and Worthen (2004) and Alkin (2004).

For example, one influential thinker, Daniel Stufflebeam (2004a), introduced the CIPP (context, input, process, product) approach in the early 1970's. He elaborated the idea of meta-evaluation and guided the Joint Committee on Evaluation Standards to generate meta-evaluation standards (Stufflebeam, 2004b) for judging evaluations of programs, personnel, and students.

Patton (2004), recognizing that many evaluations, using social science research approaches, were ignored by the stakeholders that they were supposed to serve, he therefore created utilization-focused evaluation. It promotes practical ways to ascertain and target stakeholders' criteria to raise chances of results use.

Lincoln and Guba (2004) questioned the dominant evaluation paradigms and proposed fourth generation evaluation. Its hermeneutic dialectic methods of working with stakeholders seeks to negotiate their often conflicting values to better identify criteria, standards, and questions for guiding evaluations.

Robert Stake's (2003) responsive approach proposed radical changes to his earlier countenance approach by acknowledging that evaluation is only one of many factors that communities of stakeholders consider when negotiating with one another about evaluating objects they care about together.

Cousins, Goh, Clark, and Lee (2004) noted that evaluation is part of most organizations and something all stakeholders are doing constantly. They reviewed ways to encourage stakeholders to collaborate in various participatory approaches to formal evaluation.

Fetterman and Wandersman (2005) have proposed an approach to evaluation that some argue is more a form of social activism than evaluation. Empowerment evaluation seeks to encourage professional evaluators to coach various stakeholder groups, but particularly those that traditionally have less voice in their social and political communities, to conduct their own evaluations.

Formative and Summative Purposes

Scriven (2004) has critiqued other approaches and proposed others, such as goal-free evaluation and the key evaluation

checklist. He also distinguished summative from formative evaluation, to not only test how well evaluands achieve their purposes but also to seek formative feedback to improve evaluands.

Measurement and Assessment Techniques

Another important distinction in the literature is the relationship between evaluation, measurement, and assessment, which are often used synonymously. In the *Encyclopedia of Evaluation* (Mathison, 2005) three authors note: "Measurement may be defined as the set of rules for transforming behaviors into categories or numbers" (Petrosko, 2005, p. 247). "Roughly synonymous with testing and evaluation in lay terms, assessment has become the term of choice in education for determining the quality of student work for purposes of identifying the student's level of achievement" (Mabry, 2005, p. 22). "Evaluation is an applied inquiry process for collecting and synthesizing evidence that culminates in conclusions about the state of affairs, value, merit, worth, significance, or quality of a program, product, person, policy, proposal, or plan. Conclusions made in evaluations encompass both an empirical aspect (that something is the case) and a normative aspect (judgment about the value of something)" (Fournier, 2005, pp. 139-140).

One implication of these quotes is that thinking about the evaluation task in terms that include measurement and assessment as subsets of the broader evaluation concept should help anyone using evaluation to explore its wider ranging concerns and thus enhance whatever they are evaluating as well.

Quantitative and Qualitative

A final concern raised by the approaches to evaluation asks whether quantitative, qualitative, or a mixture of methods are better for evaluation. Although explored extensively in social science literature, this debate continues in evaluation literature as well. To many, some evaluation questions demand qualitative answers while others seem best answered through quantitative data collection and analysis. Lately, mixing methods has been the answer many evaluation theorists give regarding method issues. However, as Yanchar and Williams (2006) have argued, mixing methods without taking into account the assumptions those methods are built upon does not make those assumptions meaningless or of no influence. All evaluators should examine and build upon assumptions they can support and trust when selecting methodologies and associated techniques of data collection and analysis.

Summary

The field of evaluation has developed through efforts of theorists and practitioners from many fields for several years. Although many issues remain unresolved, evaluation scholars and professionals identify several variables to account for in creating evaluations that help stakeholders. Many such variables are addressed in the evaluation framework described below.

AN EVALUATION FRAMEWORK

A framework for applying the lessons learned by the field of evaluation to the many fields associated with information science and technology includes the elements presented in Table 1 and explained thereafter.

IDENTIFYING STAKEHOLDERS

Who are the stakeholders interested in evaluation of information science and technology programs, projects, products, and so forth? This question should be addressed first according to most of the approaches to evaluation cited earlier. Some questions to clarify who the stakeholders are include: Who asked for the evaluation and why? Who is served by the evaluand or should be? Who is likely to use the evaluation results to do something helpful? Who does not usually have a voice in matters associated with the evaluand but has a stake in it?

Table 1. Elements of an evaluation framework guiding what evaluators should do

1. Identify stakeholders and objects of evaluation (evaluands) they care about.
2. Clarify background, literature, values, issues, criteria, standards, and guiding questions reflecting stakeholders' beliefs about "what should be" regarding the evaluands.
3. Use data collection and analysis to document "what is" regarding evaluands.
4. Compare "what should be" to "what is" to generate results and recommendations.
5. Meta-evaluate before, during, and after conducting an evaluation.

Evaluators are Attuned to Stakeholders' Values

They may be internal to an organization or external consultants; but evaluators encourage all stakeholders to speak up and voice their value perspectives. When value conflicts arise among stakeholders, evaluators encourage dialogue, empathic understanding of alternative views, consensus-building, and otherwise involve stakeholders in understanding each others' perspectives. Evaluators believe if stakeholders' preferences and definitions are not identified and built systematically into the evaluation, they may ignore, counter, or misuse the results.

Clearly, the subfields associated with information science and technology are of interest to many potential stakeholders with variegated concerns for how various components of the field are performing. Designers who want to use technologies to create and sell products, potential and actual users of technology innovations, funders of projects and programs all have unique perspectives on what matters most to them and what they look for in terms of quality.

Clarifying Objects of Evaluation (Evaluands) Stakeholders Care About

Evaluators should involve multiple stakeholders in deciding what evaluands to focus the evaluation on. Questions to clarify the evaluand include: What do you want to judge or improve? What are its objectives? What is its "program logic?"

In information science and technology, the evaluator may begin by studying an evaluand such as a computer or a computer program only to discover that the stakeholders are really interested in the implementation of that program or a distributed system of computers or database management technologies more generally. Often stakeholders are not sure what to focus the evaluation on because they have not thought about their evaluands in this way or because they have conflicting purposes in contrast with their colleagues. The evaluator has the task of inviting stakeholders to not only reflect on their values associated with various potential evaluands but to also narrow their consensus focus to particular aspects of the evaluands that might be improved or that need to be summatively judged.

Some potential evaluands associated with information science and technology could include accounting information systems, computers, database management systems, decision support systems and related technologies, distance education teaching methods, learning applications, Web-based course and curriculum development tools, and electronic commerce applications.

Helping Stakeholders Focus Their Inquiry on Particular Criteria

Once the stakeholders associated with a particular evaluand have been clarified, the evaluator should continue working with these stakeholders to identify the background context, literature, questions, values criteria, and standards that need to be understood.

Questions evaluators should help stakeholders answer to focus the evaluation on particular criteria include: What does the literature associated with the evaluand say are the key issues? Why is an evaluation appropriate now? Is the focus on gathering summative or formative information? Is the study best done as an internal or external evaluation? Will the evaluation focus on needs assessment, implementation fidelity, or on outcomes? What concerns do they have about the evaluand? What criteria do they have for judging the evaluand? What do they think the evaluand should be accomplishing? What standards do they have or how completely do they hope the evaluand will meet the criteria? How will they know when the evaluand is successful to their satisfaction?

Examples of criteria and standards this process might yield in the various fields of information science and technology include: There should be a new technological intervention to address several needs identified by the literature and key stakeholders. One of several alternative technological solutions identified should be most worth pursuing and developing according to stakeholders' educated points of view. This new program should be at least 90% implemented in at least 80% of the target locations in terms of the design specifications by next fall. This new product should raise performance levels by 50% during its first year once it is fully implemented in the targeted market.

Identifying Questions to Guide the Evaluation

All the activities described to this point have been focused on helping the evaluators and stakeholders clarify "what should be" regarding the prioritized evaluands they are most interested in evaluating. Once these are identified and agreed upon by stakeholders, particular evaluation questions based on the criteria should be articulated for use in guiding the gathering of "what is" information to compare to the "what should be" criteria in making actual evaluation decisions.

Prioritizing the many questions so the study can be focused on the most important ones is another challenge evaluators face and usually involves more discussion and negotiation with multiple stakeholders to make sure they are in agreement and willing to invest time and energy in

obtaining answers to these questions and using the results to take evaluative action.

Examples of evaluation questions associated with information science and technology might include: Is there a need for a new technological intervention? Which of these alternative technological solution ideas is most worth pursuing and developing? How well is this new program being implemented in terms of the design specifications? What is the estimated impact of this new product in this targeted market during its first year?

The evaluation questions provide the focus for all the remaining components of the evaluation framework presented here. The questions are familiar to social scientists and others because they are similar to research questions that demand particular kinds of information be gathered and interpreted in order to answer them. But the evaluator continues to remind stakeholders and other audiences that evaluation questions are based on values, criteria, and evaluand definitions "owned" by particular stakeholders; so the answers to these questions will be used to ascertain how well those criteria and standards are being met. Evaluation decisions are different than research results in this way.

DESIGNING DATA COLLECTION AND ANALYSIS PROCEDURES

In contrast with the questions asked above, the key issues for evaluators associated with data collection and analysis are very similar to those addressed by researchers. They include: What information from what sources will be collected, using what data collection procedures, by whom, and on what schedule? Also, how will each collection procedure be refined to ensure validity, reliability, credibility, trustworthiness, generalizability, transferability, or whatever other methods standards apply? Analysis questions focus on clarifying how quantitative and qualitative data will be summarized, analyzed, displayed, and represented to best reflect the information gathered.

It is during this phase of the evaluation process that measurement issues become very important. Evaluators have to ask how to most appropriately measure success or progress associated with the various criteria and standards valued by the stakeholders. These measures may be qualitative (such as qualitative descriptions of participants' behaviors, dispositions, attitudes, and interactions) or quantitative (such as performance on tests, surveys, observation protocols, and work records), or some combination of these data. Sometimes these measures will be assembled into assessment systems that are administered and collected regularly to feed continual information into databases for consideration by the evaluating stakeholders. At other times the measures will be periodic and idiosyncratic for particular decisions that need to be made only once in awhile.

Examples of data collection procedures for information science and technology might include surveys of stakeholders' perceptions of the need for a potential innovation, observations of how well a computer lab is being used by trainees compared to how it was designed to be used, or performance assessments of students' skills after using a new software program. Analysis procedures should be tailored for each kind of data collected to allow nuanced interpretation of evidence and presentation in terms of charts, tables, figures, statistics, thick qualitative descriptions, and theme analyses. All these analyses should be focused on answering the evaluation questions but unanticipated findings should also be identified to allow balanced reporting.

DEVELOPING RESULTS AND RECOMMENDATIONS

Finally, once the data regarding "what is" are collected and analyzed, evaluators and stakeholders search for ways to share results in reporting displays and formats that are helpful, timely, and accessible. Oral, written, or mediated formats may form interim and final reports which thoughtfully compare "what is" as learned through evaluation activities to "what should be" as identified through dialogue with stakeholders so evaluation questions can be answered and stakeholders can decide how well the evaluand is meeting their criteria.

Whatever the results, the stakeholders should help decide what to do about them. The evaluator should collaborate with stakeholders to identify realistic recommendations, such as continuing to fund initiatives, modifying processes, refining designs, and otherwise making formative and summative decisions. Unless they are very well informed internal evaluators, most consultants do not adequately understand extenuating circumstances to make realistic recommendations. The best policy is to involve the stakeholders in making their own evaluation and recommendation decisions.

METAEVALUATION

Although listed at the end of this framework, metaevaluation should infuse every other step and concept involved in planning, implementing, and critiquing a final evaluation study. It should be done internally by those who are doing the evaluation and externally by experts who can see the issues from different angles.

The main questions asked during a metaevaluation include: How does this study (as planned, carried out, and reported) hold up against metaevaluation standards such as

those based on the Joint Committee standards (Stufflebeam, 2004b) which address four groups of standards: utility, feasibility, propriety, and accuracy. An internal metaevaluation should explain how the evaluation has been conducted to meet each standard and/or why particular standards are not relevant in that case. An external meta-evaluation should certify whether the evaluation should be trusted or not.

FUTURE TRENDS

What will be done with this framework to improve information science and technology innovations? A major premise of this chapter has been that using the framework, which is based solidly on the formal evaluation literature, will enhance evaluation and associated improvements in various subfields of information science and technology. This process will thereby improve performance of the continually evolving innovations in these areas, if the evaluations are done with sensitivity to the values and needs of the participants who could use the results to make such improvements. To the extent that evaluation is viewed as a helpful way to gain insight into information science and technology innovations and not something to be feared or avoided, the future is bright for both evaluation and growth through feedback.

This future trend can be most effectively achieved by building evaluation more systematically into the strategic operations of organizations and their associated stakeholders. If readers use the framework described earlier to identify evaluation needs and activities before, during, and after implementation of various activities and policies, they will identify ways to improve and judge the evaluands they care the most about. If they collaborate to use the resulting evaluation information to jointly recommend actions to take, "what is" will become more and more like "what should be" and the goals of information science and technology will be more readily achieved. That is the future this article was written to encourage. If evaluation and the ideas in this framework are avoided or enfeebled, the future of the field will be jeopardized.

CONCLUSION

This chapter has argued that evaluation should not be an isolated or esoteric concept, to be avoided out of fear or lack of understanding. Rather, by following the straightforward steps provided in the framework, organizational leaders and members, and consumers of information science and technology products can more effectively make the many evaluative decisions they are already trying to make and will continue having to make anyway. Building systematic and disciplined evaluation into this field is not only possible and necessary but should be integral to all that information science and technology subfields are pursuing.

KEY TERMS

Criteria: Ideals against which evaluands should be compared.

Evaluand: A thing or person being evaluated.

Evaluation: Judging merit or worth by comparing what is to what should be.

Formative Decision: Evaluation results suggesting ways to improve an evaluand.

Measurement: Process of identifying the existence of entities by categorizing or enumerating their qualities.

Stakeholders: People who have an interest in an evaluand and its evaluation and who must be involved in the evaluation so they will value and use the results.

Standard: Level on a criterion to which an evaluand is expected to reach.

Summative Decision: Evaluation results leading to decisions to continue or discontinue an evaluand.

INTRODUCTION

The article presents an approach to optimize the multicast transport protocols. The main constraint of this procedure is the orthogonality (linear independence) of protocol parameters. Protocol parameters are variables defined for protocol classes, where the possible values of each parameter are protocol mechanisms, which serve the same goal in the multicast transport protocol. A multi-dimensional hyperspace of protocol parameters is stated, as a mathematical model of the optimization process where every transport protocol is represented as an individual point. A multicast transport *Sim*ulator for multi*Cast* (*SimCast*) has been developed to describe the performance of the transport protocols and to simulate the operation of these protocols for reliable multicasting. The simulator supports the protocol analysis in the hyperspace of protocol parameters.

BACKGROUND

Reliability is one of the most important features of all multimedia applications. This requirement may be especially critical in case of multicast, where the timely correction or resending of lost data is even more difficult because of the large volume of data to be transferred. Multimedia applications make multicast an active area of research. Multicasting is the one-to-many group communication way. For this purpose the IP-multicast transport is the preferred mechanism (Hosszú, 2005).

Since most of the multicast applications are media-related software, for example, media conference, voice distribution, shared whiteboard, and various collaborative media tools, they need more reliability than the best-effort delivery of Internet protocol (Adamson & Macker, 2001; Luby, & Goyal, 2004). In order to increase the reliability of multicast applications additional *multicast transport protocols* are used to achieve the required level of reliability (Whetten & Taskale, 2000). Such a protocol is the *NORM*: *N*ACK-*O*riented *R*eliable *M*ulticast Protocol (Adamson, Bormann, Handley & Macker, 2004a, 2004b).

It is hard to compare the various protocol mechanisms implemented in different protocols. Therefore, the modularly structured simulator *SimCast* (*Sim*ulator for multi*Cast*) is developed for traffic analysis of unicast (one-to-one) and multicast (one-to-many) streams (Orosz & Tegze, 2001). To carry out the necessary analysis of the unicast and multicast traffic, a well usable simulation program should be applied in order to present statistically correct results for multicast data transfer. The reason of developing a new, custom simulator instead of using a standard framework like *ns* (Breslau, Estrin, Fall, Floyd, Heidemann, Helmy, Huang, McCanne, Varadhan, Xu, and Yu, 2000) is that the architecture of the *SimCast* simulator is optimized for transport layer modeling and, due to its modular design, it is relatively easy to integrate new protocol mechanisms in it.

DECOMPOSITION OF THE MULTICAST TRANSPORT PROTOCOLS

Multicast transport protocols have many different properties for data delivery. These attributes can be represented by the previously mentioned *protocol parameters* (Hosszú, 2005). Each protocol parameter specifies different reliability mechanisms for the same delivery attribute. Such a protocol parameter is, for instance, the repair method, which can have the values like "retransmission", "forward-error correction", "interleaving", or different ways of "local receiver-based repairs" (Luby & Vicisano, 2004). Another parameter is the

acknowledgement type, which could hold the possible values "tree-based", "ring-based" or a "simple direct form".

Various applications have different reliability requirements and, therefore, these protocol parameters should be optimized in order to determinate the best-suited multicast transport protocol for a given application. However, to use any mathematical optimization method for the selection of the protocol parameters, a linearly independent (in other words *orthogonal*) set of parameters should be applied. For this purpose, a hyperspace of protocol parameters is created where each individual transport protocol corresponds to a point of this multi-dimensional space. The optimization procedure finds the most appropriate point in this space to provide the best performance for multicast content delivery. The possible values of the protocol parameters (which are classes of various mechanisms) are the realizations of specific protocol functionalities. A *quasi-orthogonal* subset of the protocol parameters and their possible values are presented in *Table 1*. These parameters represent the well-known reliability mechanisms of transport protocols.

To carry out a correct optimization procedure on the appropriately selected protocol parameters, a well usable simulation program should be applied in order to obtain statistically accurate results for multicast data transfer. Using a convenient simulator, the optimized transport protocol can be *synthesized* for a given media application, satisfying the requirements. This means that by means of a suitable mathematical method, an optimal point in the hyperspace of the protocol parameters can be found.

The optimization process should deal with the dependencies between protocol parameters. Most dependencies should be taken into account, but some of them can be omitted. An example of a negligible dependency is the relation between the protocol parameter *Feedback control* and the protocol parameter *Feedback addressee*, where modifying the actual value of the *Feedback control* from *Structure-based* to *Timer-based* could change the *optimal* value of *Feedback addressee* from *Intermediate host* to *Every member*, however, its influence may practically be ignored.

The developed simulator became a helpful tool for the analysis of multicast transport protocol mechanisms (Orosz & Tegze, 2001). By means of this simulator an optimized transport protocol can be synthesized, satisfying the requirements of certain type of media applications.

SIMULATING THE MULTICAST TRANSMISSION

The multicasting capabilities of the software are demonstrated by a distance vector based multicast protocol implemented in the simulator, which is very much like the existing DVMRP protocol (Distance Vector Multicast Routing Protocol). The concept of this protocol is similar to that of RIP (Routing Information Protocol) unicast routing protocol, which is one of the most common interior gateway protocols. This DVMRP like protocol determinates the multicast routing table by means of a flooding algorithm. Routers send *advertising packets* to the neighbor routers periodically to propagate routing information about them. Receiving such a packet, a router forwards the packet through all of its interfaces to the next router, except the receiving interface, and increments the hop counter field in the packet header. If the hop counter and source address of the received packet indicates a new route or a route better than the previous one, then the router adds it to its multicast routing table or modifies an existing table entry. To avoid infinite circulation of advertising packets, a TTL (Time To Live) like mechanism is used. This means that the source of the packet sets the TTL field of the packet to a positive integer. Each time the packet gets forwarded, this

Table 1. The selected set of the protocol parameters

Protocol parameter	Values
Flow control	Window-based, Rate-based, Multigroup multicast, Receiver give-up, None
Data accuracy	Reliable, Atomic, Non-reliable
Feedback addressee	Original source, Intermediate host, Every member, None
State control	Sender-based, Receiver-based, Shared, None
Feedback control	Structure-based, Timer-based, Representatives-based, Rate-based, None
Way of sending repair	Unicast, Multicast, None
Scope of repair	Global, Global to secondary group, Global to individual members, Local, None
Session membership control	Explicit, Implicit, None

counter is decremented. If this value reaches zero, the packet gets dropped. The implemented protocol can optimize the multicast distribution tree both for hop count and delay.

The administration of group membership in the local subnetwork between the local router and the hosts is performed via the IGMP (Internet Group Management Protocol). The IGMP implementation of *SimCast* is very much like the IGMP v1 (Deering, 1989). The combination of these two protocols makes it possible to carry out comprehensive simulations of multicast data delivery.

THE ARCHITECTURE OF THE SIMULATOR

Figure 1 shows the schematic of the network topology and the state messages generated by the simulator (in the grey box). The presented network topology is composed of 8 routers, and some hosts in their subnets. The routers are denoted by character "R" and their network layer addresses.

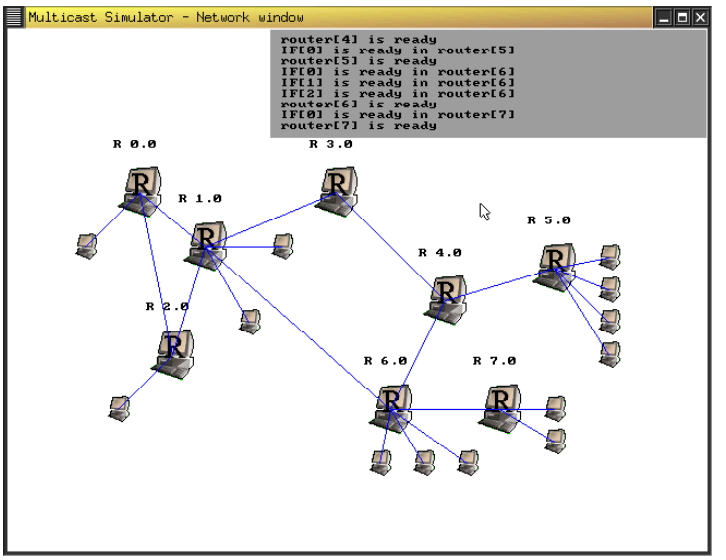
Simulations were carried out using various configurations of data traffic and network parameters. Depending on the packet queue sizes of the routers interfaces, the sending rate and the delay of the network links various congested situations can be simulated.

In simulator programs, basically two kinds of scheduling systems are used: *preemptive* and *non-preemptive* ones. In case of *preemptive* scheduling the *Scheduler* shares the real time among the scheduled objects and it is able to take control away from the scheduled objects after expiring the portioned time slice. Such solutions are applied in real-time and time-sharing systems, where, theoretically, the *Scheduler* can withdraw the right for running after any instruction. Therefore, the synchronization and the mutual exclusion problems must be eliminated during the simulation. In case of preemptive scheduling the states of the running objects must be saved by the *Scheduler*. This solution is not applicable in our case, since the simulated objects must step one simulation time unit in each simulation cycle. Active objects are scheduled with a predefined periodicity, which can be specified in the configuration.

In the case of *non-preemptive* systems, the *Scheduler* cannot take away the control from the scheduled objects, but they have to give it up themselves. In such systems the active objects are implementing a method "execute the next step". The Scheduler calls these methods periodically. After an object executed the necessary activity in the given time period, it saves its actual state in order to continue the run at the next activation according to these states.

In this manner the simulator sends a "go one time-step" message to the objects competing for run-time. Receiving such a message, an object recovers its running activity state based on its inner state attributes and after performing its tasks for the current time period, it updates the state attributes and gives the control back to the *Scheduler*. In such a way, non-preemptively scheduled objects return the control to the *Scheduler*.

Figure 1. The graphical output of the simulation



It is practical to describe the behavior of the simulated objects by state-space model. This model defines finite number of states with some state variables. The simulated protocol entities are deterministic, which means that the next state of an entity depends only on the inputs and the current state. Each of these objects implements the "execute the next step" method. These methods manage the state transitions and other activities of a particular object.

At the design phase the fact should be taken into account that the objects could wait for some event to occur longer than the length of the simulation time slice. In such situations waiting must be realized as cyclic polling. The method "execute the next step" should be implemented in such way that it cuts up the cycles of the state-space graph.

In the *SimCast* simulator scheduling of the simulation time among the routers, hosts and the Transmitter is non-preemptive. The preemptive scheduling is not applicable in the realization of the simulator, since it is important, that active objects should proceed exactly one fixed length time step. This is not guaranteed in the case of preemptive scheduling, since the *Scheduler* can interrupt the run anytime.

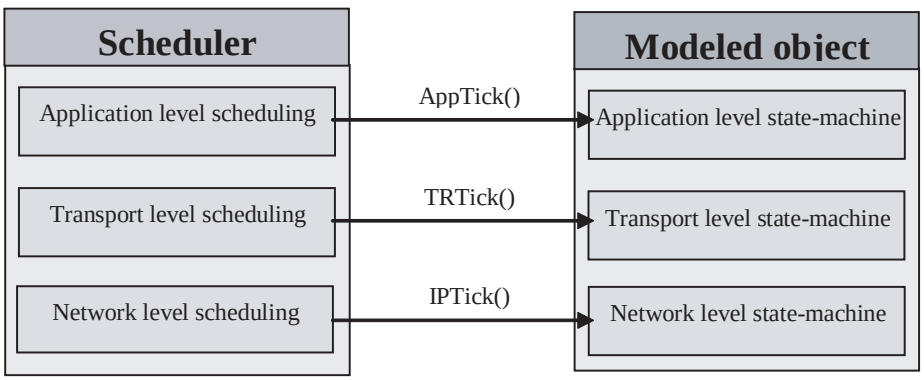
The simulated protocol entities activated with a preconfigured frequency, which is characteristic for the simulated protocol layer. The activation of protocol objects is performed in a *round robin* fashion within a protocol layer. In this way, *SimCast* implements a multi level scheduling system. The levels of the scheduling reflect the modeled protocol layers: network layer, transport layer (transport protocol entities) and application layer, as *Figure 2* shows.

The appropriate protocol entities are generated dynamically in run time according to the load-in configuration. The scheduler cannot make the difference between the various protocol entities, because the scheduling is implemented using abstract methods. Since the scheduling interfaces are realized with abstract methods, additional protocol entities can be built into the system without the modification of the core system, if the new protocol entities implement the scheduling interface defined by existing abstract protocol classes. This object oriented design results in very modular simulator system.

The simulator implements the *Manager* object, which is responsible for loading configuration data, as well as the creation and initialization of other simulation objects. After system initialization *Manager* gives control to the *Scheduler* object. Descendant classes of the abstract Sender object model the sender protocols. At transport layer the *Sender* actuates a repair buffer. The size of this buffer is controlled by some inner state variables of the simulated transport layer entities. This buffer is also known as *congestion window.* It is also the task of the *Sender* entities to handle the retransmission timers, which are needed to detect packet losses. On the receiver side the transport layer, receiver protocol reassembles the data stream sent by the sender side. The receiver application can access this stream through the *Receiver Socket* object. It is also the task of the receiver side transport layer entity to generate acknowledgement packets. *SimCast* adopts various acknowledgement methods depending on the simulated transport protocol. Receiver also handles negative or positive acknowledgements. When one uses positive acknowledgement, delayed or normal acknowledgement can be chosen as a further parameter. It is also the liability of the transport layer protocol to assemble and disassemble data stream from sent and received segments together with the multiplexing and demultiplexing of data between the communicating sockets based on the port numbers.

Socket objects make contact between application layer protocols and transport layer entities. In case of connection oriented transport protocols like TCP and TFRC entities, ap-

Figure 2. Canonical model of the simulation



plication layer senders and receivers are handling data sent to and received from sockets as data streams. The functions required to exchange data with sockets are very similar to standard file system read and write functions.

Descendants of the abstract *ProNetwork* class implement the model of network layer. Network interfaces incorporate input and output buffers also known as FIFO objects, which have limited capacity. As an input FIFO reaches its full capacity further incoming packets are lost. This behavior models the *drop-tail* property of existing network routers. The capacity of the FIFOs are given in packets.

Host, *Router*, *Interface* and *Wire* objects realize the model of physical layer. The bandwidth and bit error rate are typical attributes of this layer. The maximal sending rate is limited by the properties of *Interface* and *Wire* objects. *SimCast* gives us the opportunity to change these attributes in run-time. Therefore, we can run simulations with predefined, variable network conditions. In this way, we have the possibility to perform simulations based on network conditions measured in real world networks or imported from other network simulators.

The *Logger* subsystem is activated in each time slice, which ensures that all relevant data of the simulation is stored. The post-processing phase of the analysis extracts several useful network statistics based on this data.

The *SimCast* software is written in object-oriented C++ and it is compiled by GNU C++ under Linux operating system and runs on the Xwindow graphical user interface. The simulator uses the Allegro platform independent graphical framework. The simulator is portable to the following operating systems: Linux, MS Windows, DOS, BeOs.

FUTURE TRENDS

The importance of the network simulation is obvious. The larger the communication network is, the harder to estimate its behavior. Analytic models are useful for a coarse level of examination, but the number of problems they can tractably solve is limited (Nicol & Liu, 2005). Detailed discrete-event simulations remain a useful tool for examining computer networks.

In case of IP-multicast, the difficulty of the problem regarding network simulation is more dramatic, due to the possible large number of participants. Because of the complexity of the problem, developing a specially designed simulator seemed to be more efficient than using a more general product, which may not be suitable for the multicast transport protocol optimization.

It is an important advantage of the *SimCast* simulator, that the latest congestion control mechanisms are also implemented in it. In this way, the cooperation among different multicast transport protocols and the widely used TCP protocol entities or various other unicast transport level protocols can be examined (Yaun, Bhutada, Carothers, Yuksel, and Kalyanaraman, 2003).

Based upon the performed experiments, it became clear that the special purpose simulator is an appropriate way to examine multicast transport protocols. However, to model the operation of the transport protocols on the Internet realistically, a more sophisticated network model should be built.

CONCLUSION

The simulation results showed that the presented multicast simulator can simulate the various multicast transport protocol mechanisms and the obtained simulation results are suitable for further processing. The simulator serves as a testbed for multicast transport protocol synthesis. It implements a simplified model of the network layer and a detailed model of the multicast transport. Furthermore, it can accept the statistical network attributes obtained from other, specific network simulators. Therefore, it can be considered as a valuable tool for multicast traffic analysis and protocol optimization.

The IP-Multicast itself is a smooth extension of the basic IP-unicast paradigm to mass-communication. However, the already elaborated sophisticated procedures and methods should be configured precisely in order to achieve the required efficiency in their performance. That is why the simulation tools give special advantages in the field of the reliable multicast communication research.

KEY TERMS

Congestion Window Size: This is the maximal allowed amount of unacknowledged data to be sent to the network.

FIFO: This is the way packets stored in a queue are processed. Each packet in the queue is stored in a queue data structure. The first data to be added to the queue will be the first data to be removed, then processing proceeds sequentially in the same order.

Hyperspace of Protocol Parameters: This abstract space is composed of the possible values of each property of the multicast transport protocols. The values represent various protocol mechanisms.

IP-Multicast: Network-level multicast technology, which uses the special class-D IP-address range. It requires multicast routing protocols in the network routers. Its other name: *Network-level Multicast (NLM).*

Multicast Routing Protocol: In order to forward the multicast packets, the routers have to create multicast routing tables using multicast routing protocols.

Multicast Transport Protocol: To improve the reliability of the multicast delivery special transport protocols are used in addition to the unreliable *U*ser *D*atagram *P*rotocol (*UDP*).

Pre-Emptive Scheduling: In case of this scheduling method scheduler can take away execution right from an active object at any time.

Socket: A socket is an abstraction, designed to provide a standard application programming interface for sending and receiving data across a computer network. Sockets are designed to accommodate virtually any networking protocol.

TTL: *Time-to-live,* a field in the IP packet header. Its value is the allowed hop-count, the number of routers, which can forward the packet before delivery or dropping out.

Unicast Transport Protocol: They handle the ports in each computer, or improve the reliability of the unicast communication. As examples, the *U*ser *D*atagram *P*rotocol **(***UDP***)** is a simple unicast transport protocol mainly for the port-handling, and the *T*ransmission *C*ontrol *P*rotocol (*TCP*) is intended for the reliable file transfer.

Approaches to Telemedicine

José Aurelio Medina-Garrido
Cadiz University, Spain

María José Crisóstomo-Acevedo
Jerez Hospital, Spain

INTRODUCTION

Information technologies have become essential for most businesses, including those in the healthcare industry (Chau & Hu, 2004; Rodger & Pendharkar, 2000). Information technologies can improve both the delivery of the healthcare service and certain aspects of healthcare centers' administration.

There has been a proliferation of *information systems applied to the health sector*, such as hospital information systems, medical decision-support systems, systems for interpreting medical tests and images, expert systems based on the handling of medical knowledge, or telemedicine (Rao, 2001).

Etymologically, the term *telemedicine* means medicine from a distance. This concept can include something as simple as two healthcare professionals debating the case of a patient by telephone, or as complex as conducting the diagnosis of a patient remotely using videoconference.

Telemedicine implies that there is an exchange of information, without personal contact, between two physicians or between a physician and a patient. Thanks to telecommunications technologies, telemedicine enables the provision of healthcare services or the exchange of healthcare information across geographic, temporal, social, and cultural barriers (Chau & Hu, 2004). Telemedicine makes use of a wide range of technologies to overcome distances, such as radio, analog landlines, e-mail, the Internet, ISDN, satellites,telesensors, and so forth, for the transmission of medical information, (data, voice, and video) and provision of medical services from a distance.

With regard to the *transmission of medical information*, this includes the digital handling of patient information (for example, from their *electronic medical records*), or the transfer of images (such as radiographs, high-resolution medical images, computer tomography scans, magnetic resonance imaging pictures, ultrasound images, electrocardiograms or echocardiograms, video images of endoscopic cameras, etc.) or sounds (for example, from electronic stethoscopes) (Rao, 2001).

With regard to the provision of remote medical services, specialist physicians can see their patients in consultation, conduct medical examinations, arrive at a diagnosis and prescribe treatment, all without needing to be in actual physical contact with them.

The essence of *telemedicine* is to move the medical knowledge and experience rather than move the patient physically. For this, telemedicine involves rather more than just taking medical services to where they did not exist before. It has also become a practice of transmitting and handling knowledge. It enables medical practitioners to exchange their knowledge (Robinson, Savage & Campbell, 2003) so that others can apply it in specific situations.

We should not confuse telemedicine with e-health (or tele-health). Telemedicine only refers to the provision of medical services. *E-health*, on the other hand, refers to both medical services and any other type of service, as long as it has something to do with health and employs information technology. In this respect, e-health would also include healthcare educational activities, research in the health sciences, the handling of electronic files in the healthcare system, and any other use of information technologies in the healthcare system.

The rest of this article is organized as follows. The second section discusses the antecedents of telemedicine, and proposes two taxonomies, one in function of the temporal synchronization of the individuals using it, and the other in function of the medical specialty for which it is employed. The third section tries to identify the obstacles in the way of an adequate acceptance and development of telemedicine. Before the conclusions section, section four suggests some future trends, including what technologies are most in use at present and which ones are promising for the future.

BACKGROUND

The concept of *telemedicine* does not actually require the use of information technologies. Indeed, it was common in the past to exchange medical opinions and prescribe treatments using mail, the radio, or even visual signals. People living in remote areas of Australia at the beginning of the 20th century used radio to communicate with the Royal Flying Doctor Service of Australia. At this time, physicians

on dry land also used the radio to communicate with ships suffering from medical emergencies (Wootton, 2001). Some African villages used smoke signals to warn outsiders not to approach the village during an epidemic. Similarly, ships used flags to warn that they were in quarantine (Darkins & Cary, 2000).

Nevertheless, modern IT has given new meaning to the practice of *telemedicine* (Bladwin, Clarke & Jones, 2002). The majority of projects have shown that technology enables the exchange of medical information both in urban and rural areas (Thames, 2003). The University of Nebraska was one of the pioneers, in 1959, when its scientists transmitted neurological examinations within the campus, and again in 1964, when it ran a telemedicine project with a distant mental hospital. NASA's activities in telemedicine are more familiar. In the 1960s the space agency used a satellite as part of a telemedicine project in the Appalachian and Rocky Mountain regions and Alaska. In the same decade, NASA monitored the pulse and blood pressure of the first astronauts remotely while they were in space (Rao, 2001). In the 1970s, telemedicine evolved further thanks to satellite technology, which, for example, enabled isolated villages in Alaska and Canada to be connected with distant hospitals (Rao, 2001).

A first taxonomy can differentiate between two types of practice in *telemedicine and* in function of the temporal synchronization of the users. In this respect, we can identify synchronous (or real-time) telemedicine and asynchronous telemedicine.

Synchronous telemedicine can range from a simple telephone conversation to a robot-assisted surgical operation. Videoconference is very often combined with devices for monitoring and diagnosing patients remotely.

Asynchronous telemedicine involves previously storing medical information and then transmitting it to the appropriate medical specialist. As we can see, the two parties need not coincide at the same time.

Telemedicine can also be classified in function of the specialties to which it is applied. In this respect, we might mention the following specialties (Tachakra, 2003):

- *Telenursing*. Nurses tend to use telemedicine in two ways. They can process patient data in a database in order to monitor patients undergoing medical treatment and refer them to the appropriate medical services. Another possibility is to monitor patients remotely, for example, in their own homes, using electronic medical devices, and interactive video applications. Nurses prompt the patients to take their medicine, blood pressure, temperature, and so forth.
- *Teleradiology*. This telemedicine specialty involves sending electronic radiology images such as X-rays, computerized axial tomography scans, or magnetic resonance images.
- *Telepathology*. This specialty involves transmitting high-resolution images of microscope slides, photographs of lesions or smears, and so forth.
- *Teledermatology*. This involves transmitting images of the skin using a dermascope.
- *Telecardiology*. Transmitting information relating to electrocardiograms, echocardiograms, angioplasty, and cardiac pacemaker monitoring.
- *Telesurgery*. The surgeon operates on the patient remotely using robotics and audio/video devices.
- *Video teleconferencing.* Videoconference allows physicians to attend to their patients, conduct diagnoses, and offer treatments remotely.

OBSTACLES TO THE ADOPTION AND USE OF *TELEMEDICINE*

There is no doubt that telemedicine offers considerable advantages to the population in general, and to certain patients in particular (the chronically ill, elderly, population of rural areas, etc.). Physicians can also gain by accessing digital information that can help them in their diagnoses and treatments, as well as allowing them to exchange opinions with expert colleagues. Nevertheless, the use of telemedicine is advancing only slowly, and healthcare professionals have shown some reluctance to embrace it (Audet, Doty, Peugh, Shamasdin, Zapert, & Schoenbaum, 2004; Parente, 2000; Sands, 2004; Wilson, 2005). This section analyzes the main factors that may explain this slow development and practitioners' resistance to accept these technologies.

The most important obstacles to the development of telemedicine are as follows (Adams, 2001; Kirsch, 2002; Lumpkin, 2000; Miller & Derse, 2002; Parente, 2000; Rao, 2001): the difficulty in making money from it; lack of technological infrastructure; lack of standardization; unequal access to the Internet; insufficient legislation; reprisals from traditional healthcare organizations; and cultural barriers.

It has been argued that telemedicine will offer important business opportunities (Parente, 2000). But the healthcare sector is having difficulties making money from it (Kirsch, 2002), due to: government intervention in financing and regulating the healthcare system; physicians' reluctance to pay for information services; the lack of incentives for healthcare professionals to improve their productivity and the quality of their work; and the fact that patients are often captives of public health systems with traditional procedures.

Another problem is the lack of the necessary technological infrastructure. The healthcare sector has been characteristically slower to adopt new information technologies than other service-sector industries (Parente, 2000). In general, the different healthcare centers are rarely interconnected digitally (Rao, 2001).

The lack of standardization of *clinical data* has been identified by some authors as one of the main technical obstacles to telemedicine (Lumpkin, 2000). The information contained in medical records, consultations, diagnoses, treatments, and administrative aspects of the healthcare sector is rarely recorded digitally, and, when it is recorded, independent, fragmented, and unintegrated information systems tend to be used, employing different, incompatible formats. There is also a lack of standards for the digital transmission of clinical images (Rao, 2001) and for the electronic exchange of clinical data. With regard to this last point, the lack of standards for exchanging clinical data, two types of behaviors are evident in organizations. On the one hand, we find pioneers and innovators that invest large sums and commit themselves to a particular standard. On the other, a large number of organizations make no such investments; they simply wait for the market to decide which standard will predominate. These organizations act as free riders, holding back technological development in telemedicine as a whole.

Another technical obstacle is the unequal access to the Internet. The Internet is widely available, but it is not used everywhere. The use of information and communications technologies promises to reduce the disparities in the population – caused by demographic and socio-economic factors – in access to healthcare services (Ahern, Kreslake & Phalen, 2006; Cashen, Dykes & Gerber, 2004; Gibbons, 2005). But it is precisely the most deprived individuals who have least access to these technologies.

Another threat to the development of telemedical practice is the absence of global legislation for the provision of what can be a global service. In this digital environment, some patients may obtain diagnoses, treatments, or prescriptions for drugs from physicians who may not have a valid medical license in the state or country where the patient lives. The lack of a well-designed public policy, along with market incentives and consumer demand, could lead to a telemedical practice that undermines patients' well-being, the quality of the healthcare service, the nature of the patient-physician relationship, and the integrity of the medical profession (Miller & Derse, 2002).

A legal problem with the implementation of telemedicine concerns the protection of patients' privacy (Adams, 2001; Lumpkin, 2000; Miller & Derse, 2002). Consumer privacy laws could restrict firms' handling of *patients' clinical data*, or even prevent it altogether, either because this information could be consulted illegally or because the firm could pass it on to third parties without the patient's authorization. With regard to illegal access to the data, the Internet has advanced sufficiently to store information securely using encryption methods. With regard to making the information available to third parties, there is some protection, but there is a legal vacuum since most countries are applying the existing legislation, which was conceived with the old health economy in mind.

From the perspective of competitive strategy we must bear in mind that traditional healthcare organizations lacking a presence in the new virtual economy may retaliate against their new rivals. While some big business successes on the Internet had no traditional competitors in the market, the healthcare sector of the old economy is a mature, concentrated sector, and it could fight back against this virtual threat. For this reason, it is perhaps more feasible for these traditional organizations to gradually increase their presence on the Internet, offering patients and healthcare professionals the right balance between the virtual and the physical. Nevertheless, and as we have mentioned, the technological progress of the old healthcare economy is proving slow.

Finally, a number of cultural barriers and misconceptions, among both physicians and patients, hinder the adoption of telemedicine. Patients do not have sufficient confidence to deposit and update their *clinical data* on the Internet. This undoubtedly requires efforts to raise patient confidence, involving the right legal and technological protection, and a cultural change. This latter point may perhaps be the most difficult of all, but the increasing use of credit cards for online purchases shows that change is possible. Physicians, in turn, often argue that they do not have time to attend to patients remotely, as they are too busy with the consultations and medical services they provide to the patients who see them in person. This is a shortsighted view from the strategic perspective, since they would be able to attend to more patients if they automated medical services wherever possible, for example in prescribing drugs for the chronically ill.

FUTURE TRENDS

Despite the barriers to the adoption of telemedicine discussed in the previous section, the application of information and communications technologies to health is growing gradually. Thus, telemedicine is now being used, for example, to attend to patients' calls from *medical call centers*, for remote consultations and prescriptions of treatments, or to send microscope images to colleagues (Eckhardt, Roulet, Schneeberger, Stauffacher, & Stump, 2004).

However, some telemedicine applications are still incipient or insufficiently employed. This is the case of remote monitoring, or telemonitoring. *Telemonitoring* is fundamentally used to control and treat chronic patients (Eckhardt, et al., 2004).

Another incipient trend is that of online healthcare advice and drug prescription. But prescribing drugs on the Internet can be extremely controversial (Coile, 2000).

Although e-mail is being increasingly used in the workplace and privately, it is still rare in communications between patients and their physicians, having grown only modestly

in recent years (Audet, et al., 2004; Sands, 2004). The use of e-mail in the physician-patient relationship is recognized as a useful tool for improving communication between both (Car & Sheikh, 2004; Patt, Houston, Jenckes, Sands, & Ford, 2003; Moyer, Stern, Dobias, Cox, & Katz, 2002). E-mail use in physician-patient communications is likely to increase in the future, just as this technology is increasingly used in communications between firms and private individuals (Brooks & Menachemi, 2006).

Citizens are very accepting of electronic communication, including e-mail, voicemail and instant messaging, and its use may provide opportunities to improve patient monitoring and education. The Internet and short message services (SMS), it has been suggested, may be potentially useful tools for improving self-monitoring of asthma or diabetes, and outbreak management.

Classical mobile telemedicine means using portable mobile computer sets with medical equipment and satellite links. But the new conception of mobile telemedicine means quick, easy, and useful access to telemedical technologies. The telemedicine tools should be in the doctor's pocket, alongside the stethoscope, pencil, or scalpel. The development and improvement of mobile technologies (PDAs, cell phones with digital cameras or videocameras, cell phones with message services (MMS/SMS), GPRS Internet, etc.) allows medical doctors to be online 24 hours a day.

Nevertheless, the most promising application of telemedicine is in the provision of medical services to people living in geographically-isolated areas (Rao, 2001) or developing countries (O'Neill, 2001) who lack access to healthcare services. Paradoxically, however, although developing countries have the most to benefit from telemedicine, they are the ones that can least afford it (Jarudi, 2000), and they also have the poorest telecommunications infrastructures.

CONCLUSION

Thanks to telemedicine some patients can now access medical services and experience that would otherwise not be available to them. This is particularly important for people in rural areas (Thames, 2003), in prison, on board ship (Rao, 2001; Wootton, 2001), in a war zone (Rodger & Pendharkar, 2000), or in any other situation that prevents them from accessing healthcare services normally (O'Neill, 2001). It will be equally valuable for patients suffering from rare diseases (Miller & Derse, 2002), or people wanting a second medical opinion who need to look for a particular specialist some distance away.

There are undoubtedly obstacles to the adoption of telemedicine activities. These obstacles are hindering the rapid development that this activity could and should be enjoying. They include, most notably, the difficulty in making money from telemedicine, the lack of technological infrastructure, the lack of standardization in the data, files and images being exchanged electronically, unequal access to the Internet among the population, insufficient legislation for the accredited practice of telemedicine, or to protect patients' privacy, competitive retaliation from the traditional healthcare organizations, and cultural barriers among patients and physicians.

Nevertheless, these barriers are similar to those that have already been overcome in other industries outside healthcare. Healthcare organizations are increasingly running telemedicine projects. The advantages of using telemedicine and other e-health applications, together with the unstoppable development of information and communications technologies, make it likely that these technologies will grow considerably in the medium to long term.

KEY TERMS

Computerized Axial Tomography Scans: A medical imaging method used to generate a three-dimensional image of the internals of an object from a large series of two-dimensional X-ray images.

E-Health: The provision of any healthcare service that is supported by electronic processes and communications.

Electronic Medical Records: Computer-based patient medical records. Patient medical records are a systematic documentation of a patient's medical history and care.

Telecardiology: The digital transmission between healthcare professionals of information relating to electrocardiograms, echocardiograms, angioplasty, and cardiac pacemaker monitoring.

Teledermatology: The digital transmission between healthcare professionals of images of the skin using a dermascope.

Teleendoscopy: The digital transmission between healthcare professionals of the results of endoscopic examinations.

Telemedicine: The use of information and communications technologies to exchange information between practitioners, or to deliver medical services to a patient remotely.

Telemonitoring: The remote monitoring of patients' state of health. It is fundamentally used to control and treat chronic patients.

Telenursing: Healthcare services provided by nurses remotely, such as monitoring patients in their homes, or referring patients to the appropriate medical services through the processing of patient data.

Telepathology: The digital transmission between healthcare professionals of high-resolution images of, for example, microscope slides, photographs of injuries or smears, etc.

Teleradiology: The digital transmission between healthcare professionals of electronic radiology images such as

X-rays, computerized axial tomography scans, or magnetic resonance images.

Telesurgery: Remote surgery using robotics and audio/video devices.

Architecture Methods and Frameworks Overview

CTS Inc., USA

INTRODUCTION

The e-business models in today's globalized business world demand ever-increasing flexibility, responsiveness, and agility of information technology (IT) solutions. It is compulsory for the IT group to provide higher levels of services at a lower cost for the business to compete and succeed. The reality to IT is that there is no choice other than to build more complex, flexible, scalable, extensible, innovative, and forward-thinking technical solutions, to satisfy the growing business needs.

In large organizations like worldwide financial institutions, virtually thousands, if not millions, of IT applications and systems have been constructed or purchased to provide electronic services for external customers and internal employees in the past years, utilizing heterogeneous technologies and architectures to meet diverse functional requirements from different lines of business. In the banking industry, as an example, the business process generally contains different business sectors in consumer, commercial, small business, wealth management, and capital management. In particular, services are delivered to different channels such as automated teller machines (ATMs), Web browsers, interactive voice response, agent assistance, e-mails, mobile devices, and so on. To effectively manage the architecture assets and rationalize the architecture designs in such a diverse environment, a multi-disciplinary engineering approach is of crucial importance to abstract concerns, divide responsibilities, mitigate risks, encapsulate the complexity, reverse-engineer existing applications, identify reengineering opportunities, and conduct objective technology assessments, which leads to in-depth technical recommendations and rationalization action plans.

BACKGROUND

The computing environment has gone through a number of generations of evolution in the last few decades, ranging from monolithic, client/server, multi-tier, object-oriented, component-based, service-oriented, event-driven, to social computing models. The overall solution architecture has become increasingly complicated and thus hardly manageable through a traditional waterfall process. Previous studies (DoD, 1997; IEAD, 2004; Kruchten, 2003; OMG, 2007; Putman, 2001; The Open Group, 2007; Zachman, 1987) in the past have strived to address the issue of architecture design complexity, which has grown exponentially as the computing space is transformed to a service-oriented architecture paradigm.

The architecture methods and frameworks are the general or proven approaches to designing/developing architecture of information systems. They have progressively undergone an evolutionary growth in the last 20 years. The prominent architecture methods and frameworks developed and proposed so far are listed as follows:

- **Zachman Framework**
- **E2AF:** Extended Enterprise Architecture Framework
- **TOGAF:** The Open Group Architecture Framework
- **RUP:** Rational Unified Process, evolved to Enterprise Unified Process and OpenUP
- **MDA:** Model-Driven Architecture
- **Microsoft Solutions Framework (MSF)**, and **Microsoft Systems Architecture (MSA)**
- **C4ISR:** Command, Control, Computers, Communications (C4), Intelligence, Surveillance, and Reconnaissance (ISR).
- **FEA:** Federal Enterprise Architecture Framework
- **TEAF:** Treasury Enterprise Architecture Framework
- **PERA:** Purdue Enterprise Reference Architecture
- **RM-ODP:** Reference Model for Open Distributed Processing
- **ATAM:** Architecture Tradeoff Analysis Method
- **SAAM:** Software Architecture Analysis Method
- **IDEF:** Integrated Definition Methods
- **MODAF:** Ministry of Defense Architectural Framework

The design principles for the development of architecture methods and frameworks are specified in the following section, with detailed articulations on each method/framework provided in the subsequent section. A comparison matrix is presented afterwards, whereas future trends and recommendations are elaborated next, followed by the conclusions.

DESIGN PHILOSOPHY

The following design principles have been generally applied in developing architecture methods and frameworks:

- Information processing activities comply with applicable laws, orders, and regulations.
- Business objectives are well defined before initiating information technology solutions.
- Total business value is the primary objective when making information technology decisions.
- Architectural selections maximize the interoperability and reusability.
- Architecture methods take advantage of standardization to fulfill common customer requirements and to provide common functions.
- Information technology groups collaborate to share information, data, services, components, and infrastructure required by the business units.
- Business and information technology requirements adopt matured commercial off-the-shelf (COTS) technology where appropriate rather than customized or in-house solutions.
- Information, services, applications, systems, and infrastructure are vital assets that must be managed, controlled, and secured in a holistic manner.
- Enterprise architecture (EA) is consistent with the guidance and strategic goals at the divisional levels.

METHODS AND FRAMEWORKS

The major architecture methods and frameworks are discussed in greater detail in this section.

Zachman Framework

The Zachman Framework (Zachman, 1987) is a logical structure used to categorize and organize the descriptive representations of an enterprise IT environment, which are significant to the organization management and the development of the enterprise's information systems. It takes the form of the two-dimensional matrix, and has achieved a level of penetration in the domain of business and information systems architecture and modeling. It is mainly used as a planning or problem-solving tool. However, it tends to implicitly align with the data-driven approach and process-decomposition methods, and it operates above and across the individual project level.

E2AF

Extended Enterprise Architecture Framework (E2AF) (IEAD, 2004) takes a very similar approach to the Zachman Framework. Its scope contains business, information, system, and infrastructure in a 2-D matrix. E2AF is more technology-oriented. Both Zachman Framework and E2AF approaches are heavyweight methodologies, which necessitate a fairly steep learning curve to get started in an organization.

TOGAF

Another heavyweight approach, The Open Group Architectural Framework (TOGAF) (The Open Group, 2007), is a detailed framework with a set of supporting tools for developing an enterprise architecture to meet the business and information technology needs of an organization. The three core parts of TOGAF are *architecture development method*, *enterprise architecture continuum*, and *TOGAF resource base*. The scope of TOGAF covers *business process architecture*, *applications architecture*, *data architecture*, and *technology architecture*. The focal point of TOGAF is at the enterprise architecture level, rather than the individual application architecture level.

RUP

Rational unified process (RUP) (Kruchten, 2003) attempted to overcome the shortcomings in the heavyweight methods by applying the unified modeling language (UML) in a use-case driven, object-oriented, and component-based approach. The concept of 4+1 views interprets the overall system structure from multiple perspectives. RUP is characterized by process orientation and is generally a waterfall approach. RUP barely addresses the phases of software maintenance and operations, and lacks a broad coverage on physical topology and development/testing tools. It mainly operates at an individual project level. RUP has recently been expanded to enterprise unified process (EUP), and was partially open sourced—OpenUP. RUP is now part of the IBM Rational Method Composer (RMC) product, enabling the process customization.

MDA

Model-driven architecture (MDA) (OMG, 2007) takes a different approach. MDA aims to separate business logic or application logic from the underlying platform technology.

It provides an open, vendor-neutral approach in UML to the challenge of business and technology change. The core of MDA is comprised of the platform-independent model (PIM) and platform-specific model (PSM), which provide greater portability and interoperability as well as enhanced productivity and maintenance. Platform-independent models of an application or integrated system's business functionality and behavior can be implemented via the MDA on practically any open or proprietary platforms. MDA is primarily for the software modeling part in the development lifecycle process.

MSF/MSA

Microsoft Solutions Framework (MSF) (Microsoft, 2007) is a comprehensive set of software engineering principles, processes, and proven practices that are specified to enable developers to achieve success in the software development lifecycle (SDLC). MSF is equipped with an adaptable guidance, based upon experiences and best practices from inside and outside of Microsoft, to enhance the chance of successful delivery of information technology solutions to clients by working fast, reducing the headcounts on the project team, mitigating risks, while not sacrificing high quality in the results.

The Microsoft Systems Architecture (MSA) is a program developed by Microsoft with the objectives of defining, designing, verifying, and documenting a set of IT infrastructure architectures, which comprise software, hardware machines, storage, connectivity, networking infrastructure, data center, and other tools/products.

C4ISR

The C4ISR Architecture Framework (DoD, 1997) provides comprehensive architectural guidance for the various commands, services, and agencies within the United States (U.S.) Department of Defense, to guarantee the interoperability and cost-effectiveness in the military systems. The framework consists of the guidance, policies, and product descriptions for defining and developing architecture descriptions that guarantee a common denominator for understanding, comparing, and integrating architectures.

FEA

The Federal Enterprise Architecture (FEA) framework (Federal Office, 2007) specifies direction and guidance to U.S. federal agencies for structuring enterprise architecture. The FEA is a group of reference models with a common taxonomy and ontology developed to describe IT resources, comprising the *performance reference model*, *business reference model*, *technical reference model*, *data reference model*, and *service component reference model*.

The *performance reference model* is a standardized construct to quantify the performance of key IT spendings and their impact on overall program performance. The *business reference model* specifies a function-centric structure to depict the agency-independent business operations in the public sector. The model provides an organized, hierarchical framework describing the daily business operations of the U.S. government via a functionally driven method. The *technical reference model* defines a component-based technical structure to classify the specifications, standards, guidelines, and solutions, which enable and support the delivery of service capabilities and components. The *data reference model* describes the data and information at an aggregate level, which support government programs and line-of-business operations. It empowers agencies to specify the types of interaction and exchanges that occur between citizens and the U.S. government. Finally, the *service component reference model* defines a business and performance-centered, functional structure that categorizes service components regarding how they support business and/or performance goals.

TEAF

The Treasury Enterprise Architecture Framework (TEAF) (Treasury Department, 2000) is to guide the planning and development of enterprise architectures in all bureaus and offices of the Treasury Department. It provides a framework for producing an EA, guidance for developing and using an EA, and guidance for managing EA activities. The framework subdivides an EA by views, perspectives, and work products.

PERA

The Purdue Enterprise Reference Architecture (PERA) (Purdue University, 2007) is aligned to computer integrated manufacturing. The PERA generic enterprise model consists of three basic elements: *product facilities*, *people/organization*, and *control and information systems*. The most basic way to structure the enterprise model in PERA is by "phase". Various diagrams are used in each phase of the enterprise to reflect the developing detail, ranging from initial definition to operations phase, to dissolution.

RM-ODP

The ISO Reference Model for Open Distributed Processing (RM-ODP) (Putman, 2001) is a coordinating framework for the standardization of open distributed processing in heterogeneous environments. It creates an architecture model that integrates the support of distribution, interworking and portability, using five "viewpoints"—*enterprise*, *informa-*

tion, *computational*, *engineering*, and *technology*—and eight "transparencies"—*access*, *location*, *relocation*, *migration*, *persistence*, *failure*, *replication*, and *transaction*. RM-ODP was adopted as ISO Standard 10746 in late 1990s, composed of four fundamental elements: *an object modeling approach*, *system specification*, *system infrastructure definition*, and *system conformance assessment framework*.

ATAM

In software engineering, Architecture Tradeoff Analysis Method (ATAM) (SEI, 2007) is a risk-mitigation process used early in the software development lifecycle. ATAM was developed by the Software Engineering Institute at the Carnegie Mellon University. Its purpose is to help choose a suitable architecture for a software system by discovering trade-offs and sensitivity points.

ATAM is most beneficial when used in the early stage of the software development lifecycle, in which the cost of changing architectures is minimal. The ATAM process consists of gathering stakeholders together to analyze business drivers and from these drivers extract quality attributes that are used to create scenarios. These scenarios are then used in conjunction with architectural approaches and architectural decisions to conduct an analysis of trade-offs, sensitivity points, and risks (or non-risks). This analysis can be converted to risk themes and their impacts whereupon the process can be repeated.

SAAM

Scenario-based Architecture Analysis Method (SAAM) (SEI, 2007a) is an evaluation method of software architecture. As one of the first documented software architecture analysis methods, it was developed to analyze a system for modifiability but is useful for testing any nonfunctional aspect. Architecture models are examined via scenarios in SAAM with regard to achieving quality attributes. SAAM can be used to assess existing systems, evaluate planned systems, or compare old and new systems. As a low-cost method, SAAM's results may not be precise. In spite of inaccurate results, the main value of SAAM is in the way that it focuses on investigation, stimulates discussions among the stakeholders, and helps build consensus among the parties involved.

IDEF

Integrated Definition Methods (IDEF) (IDEF, 2007) forms a structured approach to enterprise modeling and analysis. IDEF was produced by the integrated computer-aided manufacturing (ICAM) initiative of the U.S. Air Force. More specifically, the integrated information support system (IISS) project priorities 6201, 6202, and 6203 fathered IDEF. IISS was an effort to build an information processing environment running on heterogeneous physical computing systems. The purpose was to build "generic subsystems" that can be reused by a large number of collaborating enterprises, such as U.S. Defense contractors and the armed forces of alliance nations.

IDEF consists of 16 methods, covering a wide range of uses—*function*, *information*, *data*, *simulation*, *process description capture*, *object-oriented design*, *ontology description capture*, *design rationale capture*, *information system auditing*, *user interface*, *scenario-driven information system design*, *implementation architecture*, *information artifact*, *organization*, *schema mapping*, and *network design*.

MODAF

The UK Ministry of Defense Architectural Framework (MODAF) (UK, 2007) defines a standardized way of modeling an enterprise. The purpose of MODAF is to ensure a consistent approach to enterprise architecture development. It defines architectural views covering the strategic goals of the enterprise as well as the people, processes, and systems that deliver those goals. It also includes capability management (lines of development, doctrine, organization, training, material, leadership & education, personnel, and facilities) and programmatic aspects such as project dependencies. A MODAF model is organized into six viewpoints: *operational*, *system*, *strategic*, *technical*, *acquisition*, and *all viewpoints*.

COMPARISON MATRIX

Most of today's architecture design practices are still ad hoc, manual, and error-prone, which inevitably leads to chaotic outcomes and failures in the execution. According to surveys (Standish Group, 2007), a vast majority of information systems projects are routinely behind schedule, over budget, or canceled. A lack of a systematic approach to objectively assessing and validating the architecture design methods is indirectly attributed to the overwhelming failure.

As discussed in the preceding section, most of the existing methods and frameworks reveal the architectural aspects of a software application to some extent from a specific perspective. The necessity of a comprehensive comparison to evaluate various architecture frameworks becomes more and more evident, demanding a systematic disciplined head-to-head assessment. A highly structured comparison matrix is thus constructed to provide a side-by-side comparison and contrast. Table 1 shows a comprehensive chart of the comparative study.

Table 1. Comparison matrix of architecture methods and frameworks

Method / Framework	Description	Scope	Strengths	Weaknesses	Focus	Reference

FUTURE TRENDS

A plethora of architecture methods and frameworks have emerged and evolved in the last couple of decades. Some of them have matured while some have merged or been transformed to other structures. The others have simply retired. However, most of the prominent architecture methods and frameworks have distinctive design goals with a focus on different domains of dissimilar scope and structures based on different principles and approaches. Consequently, it becomes difficult in the real world to directly apply these methods and frameworks in a particular domain. Generally speaking, there are five approaches to leveraging these existing methods and frameworks to the maximum extent: *direct use*, *adaption*, *best-of-breed*, *aggregation*, and *build*. The most straightforward way is via *direct use*, in which a method/framework is adopted without any modification. The general-purpose methods and frameworks are good candidates to be picked in this situation. The second approach is *adaption*, which customizes a selected method or framework for the needs in a specific segment. In this approach, typically a heavyweight method or framework in the same business sector is chosen as the baseline, and is subsequently streamlined and customized to adapt to an individual domain. The third way is *best-of-breed*, in which desired features from several methods and frameworks are extracted to form an optimal solution. The constituents in various methods and frameworks are selectively united to formulate a compound stack. The fourth approach is *aggregation*, which combines capabilities from various methods and frameworks, and further augments these features to establish a composite method. This usually results in a hybrid approach in the real-world application, benefitting from multi-disciplines, richer features, and better user friendliness as a result of aggregation. The other alternative is *build*, in which an organization creates its own framework from scratch for the unique requirements in the environment. This usually is the least cost-effective option. Nevertheless, a number of artifacts and fundamentals in the well-established methods and framework can still be directly or indirectly utilized in this approach, such as principles, techniques, patterns, and structures.

In general, there is no one-size-fits-all in this area. Some of the existing architecture methods and frameworks will continue to grow and mature, incorporating forthcoming innovations and adapting to the latest advance in the field. Convergence is expected to take place to unite the methods and frameworks with similar capabilities and contexts. Hybrid methods and frameworks demonstrate a stronger potential for widespread adoption, exploiting the promising benefits of both heavyweight and agile approaches. Fewer brand-new but more holistic methods and frameworks tend to emerge from the ground up to satisfy the new needs in the architecture paradigm. It can be foreseen that notations will be unified and tooling will be standardized, with more advanced round-trip engineering practices to fully automate the architecture design process.

CONCLUSION

This article provides an overview of the predominant architecture methods and frameworks used in enterprise architecture planning, development, management, and governance. The design principles of architecture methods are evaluated. The major methods and frameworks discussed in this paper include Zachman Framework, E2AF, TOGAF, RUP/EUP/Open-UP, MDA, MSF/MSA, C4ISR, FEA, TEAF, PERA, RM-ODP, ATAM, SAAM, IDEF, and MODAF. The key characteristics and capabilities are detailed in the articulation. A comparison matrix is constructed to provide a head-to-head comparison of the strengths and weaknesses of each individual model. The scope and selection guidelines are also included in the chart. Future trends and recommendations are elaborated in the context.

KEY TERMS

ATAM: Architecture tradeoff analysis method, a risk-mitigation process used early in the software development lifecycle.

E2AF: Extended enterprise architecture framework, covering business, information, system and infrastructure in a 2-D matrix.

IDEF: Integrated definition methods, a structured approach to enterprise modeling and analysis, consisting of 16 methods.

MDA: Model-driven architecture, an agile approach. MDA aims to separate business logic or application logic from the underlying platform technology.

Microsoft Solution Framework: A comprehensive set of software engineering principles, processes, and proven practices that are specified to enable developers to achieve success in the software development lifecycle.

MODAF: Ministry of Defense architectural framework, a standardized way of modeling an enterprise, with six viewpoints ranging from people to processes and systems.

RM-ODP: Reference model for open distributed processing, a coordinating framework for the standardization of open distributed processing in heterogeneous environments, with five viewpoints and eight transparencies.

RUP: Rational unified process, a use-case driven, object-oriented and component-based approach.

SAAM: Scenario-based architecture analysis method, an evaluation method examining architectures via scenarios with regard to achieving quality attributes.

TOGAF: The Open Group architectural framework, a detailed framework with a set of supporting tools for developing an enterprise architecture, composed of architecture development method, enterprise architecture continuum, and TOGAF resource base.

Zachman Framework: A logical structure used to categorize and organize the descriptive representations of an enterprise IT environment, designed by John Zachman.

Architectures for Rich Internet Real-Time Games

Matthias Häsel
University of Duisburg-Essen, Germany

INTRODUCTION

Many researchers regard multiplayer online games as the future of the interactive entertainment industry (Brun, Safaei, & Boustead, 2006; El Rhalibi & Merabti, 2005; Sharp & Rowe, 2006). In particular, due to advances in game design and the availability of broadband Internet access to the end-user, multiplayer online games with real-time interaction have come into wide use (Aggarwal, Banavar, Mukherjee, & Rangarajan, 2005; Claypool & Claypool, 2006; Yasui, Yutaka, & Ikedo, 2005). The majority of these games are made up by classic software titles that need to be installed on the players' machines (El Rhalibi & Merabti, 2005). Browser-based multiplayer games, on the contrary, can be run instantly from a Web site, but have, due to technical limitations, long been round-based, strategy-focused games. However, with the ongoing evolvement of Rich Internet Application (RIA) technology (Allaire, 2002) such as Adobe Flash and Java, browser-based online game development has reached a point where also *real-time* games can be produced and distributed to a large audience quickly and easily. Browser-based games can be utilized in conjunction with e-business offers in a very simple way and hold a number of exciting possibilities for new online business models, new markets, and new growth (Kollmann & Häsel, 2006; Sharp & Rowe, 2006). However, as the browser is a very different operating environment and interactive experience from that of classical game software, browser-based multiplayer real-time games involve gaming architectures that are distinct from their classical counterparts. A major challenge when designing and implementing such architectures is that multiplayer online games are highly vulnerable to propagation delays resulting from redundant communication, bottlenecks, single points of failure and poor reactivity to changing network conditions (Ramakrishna, Robinson, Eustice, & Reiher, 2006). As latency from input of information to its output determines gameplay and fairness (Brun et al., 2006), the game architecture has to be designed in a way that it mitigates latency effects and meets the expectations of the players (Claypool & Claypool, 2006). Elaborating on the example of an online tabletop soccer game with two remote players, this article discusses two architectural models that can be applied to implement browser-based multiplayer real-time games using RIA technology.

BACKGROUND

Online games that give the player the ability to compete against other players over a network emerged strongly in the middle of the last decade. Traditionally, multiplayer online games have been implemented using client-server architectures (GauthierDickey, Zappala, Lo, & Marr, 2004). Thereby, a copy of the software is installed on each player's machine, which connects directly to a central authoritative server designed to handle game logic (Claypool & Claypool, 2006; El Rhalibi & Merabti, 2005; Guo, Mukherjee, Kangarajan, & Paul, 2003). The server deals out information individually to each client as it is requested and keeps all the players up to date with the current state of the game (El Rhalibi & Merabti, 2005). Whenever a client performs an action (such as firing a gun or kicking a ball), the data is sent to the server, which calculates the effects of that action and sends the updated game state to the clients (El Rhalibi & Merabti, 2005). Client-server architectures have the advantage that a *single* decision point orders the clients' actions, resolves conflicts between these actions and holds the global game state (GauthierDickey et al., 2004). Unfortunately, they also have several disadvantages. The most obvious one is that client-server architectures introduce delay because messages between players are always forwarded through the server (GauthierDickey et al., 2004). This adds additional latency over the minimum cost of sending commands directly to other clients (Cronin, Kurc, Filstrup, & Jamin, 2004). Moreover, traffic and CPU load at the server increases with the number of players, creating localized congestion and limiting the architecture by the computational power of the server (GauthierDickey et al., 2004).

To address the problems associated with client-server architectures, many authors and game designers have developed fully distributed peer-to-peer architectures for multiplayer games (El Rhalibi & Merabti, 2005; GauthierDickey et al., 2004). In a peer-to-peer architecture, players send their actions to each other and react on the received action (Guo et al., 2003). Each peer acts as a decision point that has exactly the same responsibilities as every other peer (El Rhalibi & Merabti, 2005). Peer-to-peer architectures have a lot of advantages. Firstly, there is neither a single point of failure nor an expensive server infrastructure. Moreover, the amount of bandwidth required is reduced dramatically as there is a

direct communication between two peers. This also reduces latency on the network, as the bottleneck caused by a server is eliminated (El Rhalibi & Merabti, 2005). However, unlike games using a client-server architecture, where there is a single authoritative copy of the game state kept at a central server, peer-to-peer architectures require an up-to-date copy of the entire game state to be kept at each peer. Consequently, these architectures require some form of distributed agreement protocols between the peers that prevents the peers' game states from diverging over time and becoming inconsistent (Cronin et al., 2004; Guo et al., 2003).

Although most online games have low bit-rate requirements sending frequent but small packets typically well within the capacity of broadband connections (Brun et al., 2006), deploying these applications over a large-scale infrastructure presents a significant technological challenge. In both client-server and peer-to-peer architectures, an increase in the geographical distances among participating clients or servers results in an unavoidable end-to-end delay that may render the game "unresponsive and sluggish even when abundant processing and network resources are available" (Brun et al., 2006, p. 46). Moreover, differences in game responsiveness to user input may give some players an unfair advantage (Brun et al., 2006; Aggarwal et al., 2005). If the latency between a client and the server (or between two peers) is large enough, the responsiveness of the game to a player's action decreases, and the player's performance is likely to degrade (Claypool & Claypool, 2006). A game can be regarded as playable if the players find its performance acceptable in terms of the perceptual effect of its inevitable inconsistencies, whereas fairness is concerned with relative playability among all players (Brun et al., 2006).

ARCHITECTURE DESIGN AND IMPLEMENTATION

After reviewing existing literature on architectural concepts and issues of multiplayer online games, the remainder of this article will examine to what extent these concepts and issues hold for *browser-based* multiplayer real-time games. As a matter of simplification, the focus will be on games featuring concurrent, pairwise real-time interactions between two remote players, such as it the case for the online tabletop soccer game that is depicted in Figure 1.

For the player-side RIA, Adobe Flash is assumed to be the best-suited technology since Flash, due to its common runtime environment across operating systems, browsers and chip architectures, enables easy deployment on multiple platforms and devices (Allaire, 2002). In contrast to Java as a possible alternative, Flash has a much higher diffusion rate and can be updated by the player in a very easy way. Moreover, Flash is very efficient in rendering

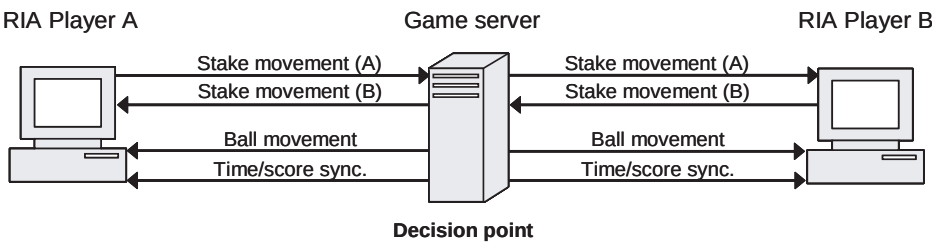
Figure 1. An online tabletop soccer game with two remote players

vector graphics and thus provides an optimal runtime for fast-paced browser-based games. With respect to real-time and multiplayer functionality, Flash applications are able to integrate socket-based, two-way communications and to keep live connections to servers for building applications with persistent connectivity (Allaire, 2002). However, a major limitation of Flash is the fact that these live connections are inevitably based on TCP. At first sight, this seems to be fairly advantageous, because TCP enables an error-free, ordered data transfer and a retransmission of lost packets, rendering built-in mechanisms to deal with message loss unnecessary (Pantel & Wolf, 2002). In the context of real-time games, however, TCP connections are unfortunate because a client cannot receive the packets coming after a lost packet until the retransmitted copy of the lost packet is received (Pantel & Wolf, 2002). In fact, for real-time clients it would be more useful to get most of the data in a timely fashion (as it would be the case for UDP) than it is to get all of the data in succession, as the resulting effects of packet loss can be mitigated by frequent game-state updates and techniques such as dead-reckoning vectors (Guo et al., 2003; Aggarwal et al., 2005) and client-side prediction (Brun et al., 2006). Though packet loss and latency resulting from applied packet loss mitigation techniques is zero, latency in connection with TCP results from the data transmission itself. For instance, as the difference in network latency between two tabletop soccer players becomes larger, the position of the ball displayed at one player diverges more largely from that at the other, bringing inconsistency among the two players (Yasui et al., 2005). In particular, there are two kinds of inconsistencies that may occur (Brun et al., 2006): First, the increased response time, that is, the delay between the time of a player's input and the rendering of the respective results on a player's screen, may frustrate players and make the game unplayable. Second, a presentation inconsistency may occur due to the fact that the game-state update reaching a RIA is already outdated to some degree because the real game state may have varied while the update packet was on its way. This would mean, for instance, that the player's perception of the current ball position is slightly inconsistent with the real ball position at the server, respectively, the opponent's RIA. Such inconsistencies may prevent a player from responding effectively or appropriately, and thus can lead to player frustration, especially in highly competitive game environments such as an online soccer league (Guo et al., 2003).

Latency, however, is not the only limitation with respect to RIAs, including both Flash applications and Java applets. Due to the sandbox principle of these technologies, a direct data exchange (i.e., peer-to-peer communication) between two client-side game applications is not possible. Consequently, browser-based multiplayer games must inevitably be based on physical client-server architectures. With respect to their logical nature, however, there are two alternatives: client-server and hybrid peer-to-peer. The main difference between these two approaches lies within the distribution of the game's decision points. In the former approach, the current game state is calculated by the server, whereas in the latter approach, the calculation of the game states is performed by the clients, while the game server is simply relaying peer-to-peer communication. In the following, these two approaches will be discussed in more detail, including the advantages and drawbacks resulting from each alternative.

In its essence, a browser-based multiplayer real-time game based on a client-server architecture (Figure 2) is very similar to classical multiplayer games where the server acts as a central decision point that calculates and simulates the game states based on the players' actions. Moreover, the server enables players to join the game and assigns opponents to each other. The Flash clients, in contrast, simply render and present the game states to the player and send the players' inputs to the server. In the context of an online tabletop soccer game, each player sends update vectors representing the stakes he controls, including each stake's current position and rotation. The server uses these vectors to calculate an update vector representing the current ball position and trajectory, and sends it to the clients. Clients themselves do not (and cannot) communicate with each other, and neither do they play any active role in deciding the ordering of actions in the game. Moreover, the server sends synchronization updates relating to the current score and time. This is necessary because the timing of a Flash

Figure 2. Client-server architecture for browser-based multiplayer real-time games



client is highly inaccurate, as it depends on the application's frame rate, which again depends on the local CPU speed and type of browser.

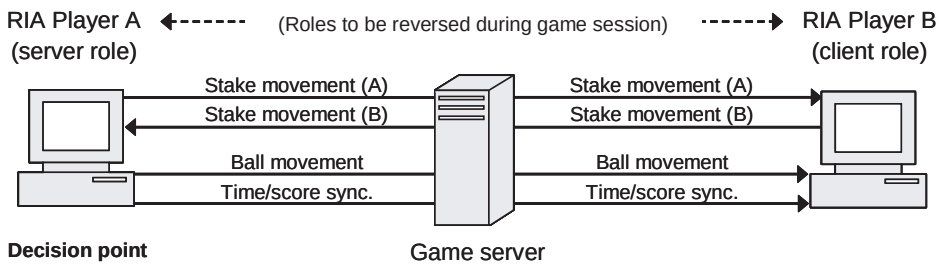
A major drawback of the client-server model is that the game server becomes the main bottleneck for both network traffic and CPU capacity. Moreover, as the network delay from the server to different clients is different, players may receive the same state update at different times. Vice versa, players' action messages can also take different times to reach the game server, and therefore unfairness in processing player action messages can be created at the game server. A player further away from the game server or connected to the server through congested or slower links will experience longer message delay. Because of this, even fast reacting players may not be given credit for their actions, leading to an unfair advantage for players with small message delays (Guo et al., 2003). For instance, a player with a large delay would always see the ball later than the other player and, therefore, this player's action on the ball would be delayed even if the player reacted instantaneously after the ball position was rendered (Aggarwal et al., 2005).

In contrast to a fully distributed peer-to-peer architecture, a hybrid peer-to-peer architecture for browser-based games still needs to be based on a central game server because a direct communication is not possible using current RIA technologies. Consequently, communication between two peers must be relayed via a *nonauthoritative* game server in this model. Besides that, the peers still rely on the server to join the game and to discover their opponents. While the client-server model guarantees event ordering because messages from all the players are only delivered at a central decision point (Guo et al., 2003), peer-to-peer games introduce discrepancies among decision points that can cause some decision points to evaluate events out of order, possibly violating causality and prompting incompatible decisions (Brun et al., 2006). Event consistency in peer-to-peer architectures has been well studied in the online gaming literature devised to guarantee a uniform view of the game state using causality control techniques such as bucket synchronization (Diot & Gautier, 1999; Pantel & Wolf, 2002), trailing state synchronization (Cronin et al., 2004), delta-causality control (Yasui et al., 2005), and time warp synchronization (Mauve, Vogel, Hilt, & Effelsberg, 2004). However, these techniques have been mainly designed for real-time games with high consistency requirements, but *low* latency requirements (Cronin et al., 2004), and thus cannot be used in conjunction with highly fast-paced games such as the tabletop soccer. Moreover, implementing clock-based synchronization in Flash renders extremely difficult, as timing depends on the respective client machines and browsers. These limitations make a topology with multiple decision points unfeasible.

One solution for guaranteeing event consistency despite this limitation is to transfer causality control to one of the RIAs during the game session (Figure 3). This is possible because the game session of browser-based games is relatively short-lived, that is, there is no global game state that needs to be preserved for several hours or days. However, with respect to playability and fairness in fast-paced games generating high bitrates, there are two main drawbacks of this approach: First, the player acting as the decision point is per se in advantage, as for this player, the propagation delay of the game state is zero, while, in comparison to the client-server architecture, the other player's response time has roughly *doubled*. As a fair game gives all users the same level of handicap (Brun et al., 2006), a possibility to re-establish fairness is to switch the decision point between the RIAs during the game session. For the tabletop soccer game, for instance, this could be done after each goal or at halftime. Second, the fact that one of the RIAs takes over server functionality increases the amount of outgoing traffic for that client. As the *upload* speed of high bandwidth lines such as ADSL is relatively low, this introduces an additional bottleneck at the respective decision point.

Whether a browser-based multiplayer real-time gaming architecture is implemented using the client-server or the hybrid peer-to-peer model fairly depends on the type of game. While slower games may be implemented using a hybrid peer-to-peer architecture, a client-server architecture seems to be the better choice with respect to playability and fairness in highly fast-paced browser-based games, as response times are shorter and both clients are treated equally. However, this solution may incur significant cost in the form of more CPU

Figure 3. Hybrid peer-to-peer architecture for browser-based multiplayer real-time games



capacity and server software. In both architectural models, one possibility for implementing the server is using a high-level language such as Java, using its TCP socket API for exchanging real-time data with the Flash clients. Another possibility is to use server-side RIA technology such as Adobe Flash Media Server (Lesser, Guilizzoni, Reinhardt, Lott, & Watkins, 2005), which provides a framework with a number of ready-made server-side components for building Flash-based client-server applications with real-time capabilities. Yet, with respect to games that are generating high bitrates, technologies such as these are cost-intensive because license fees typically depend on bandwidth requirements.

FUTURE TRENDS

From a practical point of view, it will be interesting to see which architectural model and what kinds of technology will prevail in the realm of browser-based real-time multiplayer games. Although current RIA technology still entails some limitations with respect to real-time communication, this is likely to change in the future. From a theoretical point of view, likewise, researchers will have to explore what combination of gaming architecture and technology is best-suited for what kind of browser-based game. In this regard, it also has to be explored to what extent the two architectural models presented in this article can be applied to implement browser-based real-time games featuring *more* than two opposing players in a single game session.

Moreover, with respect to online gaming portals with several thousand concurrent players, the architectural concepts presented in this article have to be enhanced. A single server cannot be expected to suffice to deal with thousands of players synchronously. This suggests implementing the authoritative game server as cluster of machines with dedicated responsibilities. Also, such approaches need to consider intelligent methods for choosing the best-suited server for groups of geographically dispersed players. Future research has to explore how such concepts can be realized in connection with RIA technology.

CONCLUSION

With the advent of RIA technology, browser-based multiplayer gaming has finally reached a point that deserves the attention of serious game designers, programmers and online gaming researchers. The vast possibilities connected with technologies such as Adobe Flash and Java include producing many engaging and sought-after types of games. When implementing real-time multiplayer games, the main challenge lies within guaranteeing playability and fairness despite synchronization issues that are connected with the current best-effort Internet. These issues need to be solved by designing appropriate game architectures and trading off inconsistencies between players depending on their perceptual impact. This article introduced two architectural models that can be used to implement browser-based real-time multiplayer games. Both models rely on a central server, as a direct peer-to-peer communication cannot be realized with current RIA technology. However, this server can either form a global decision point that is calculating the current game state (client-server architecture) or simply relay game data between the clients, while one of the clients takes over decision point functionality (hybrid peer-to-peer architecture). While the former approach makes the game server a major bottleneck with respect to CPU capacity, the latter approach has major drawbacks resulting from the two different roles that clients can play. The choice of architecture certainly depends on the type of game to be implemented. Future research has to further elaborate on the architectures and technologies that are best-suited for browser-based real-time applications.

KEY TERMS

Browser-Based Game: An online game that is accessed with a Web browser over the World Wide Web. Unlike classical game software, browser-based games can be played instantly and do not require a prior installation on the player's machine. Browser-based games may be implemented using standard hypertext mark-up or Rich Internet Application technologies.

Client-Server: A network architecture that separates several clients from a server. A client is an application that sends requests to the server and is often responsible for rendering the user interface. The server passively waits for the clients' requests, processes them and sends appropriate responses to the clients.

Latency: A time delay between the moment something is initiated, and the moment one of its effects begins. With respect to packet-switched networks such as the Internet, latency (also referred to as *lag*) refers to the time taken for a packet of data from the sending application to the receiving application.

Multi-Player Game: A game that is played by multiple people at the same time. In contrast to single-player games that feature artificial opponents, players in multiplayer games compete against each other or team up to achieve a common goal. Modern multiplayer games connect geographically dispersed players by using Internet technologies and allow them to play together.

Peer-to-Peer: A network architecture that does not have the notion of clients or servers, but only equal peer nodes that simultaneously function as both clients and servers to each other. If a peer-to-peer network has a central server that keeps information on peers and responds to requests for that information, this network is often referred to as *hybrid* peer-to-peer.

Real-Time Game: A multiplayer game featuring real-time interaction between the players, that is, when a player performs an action, other players are made aware of the consequences of that action within an operational deadline. As a discrepancy in the perceptions of the players may lead to undesirable outcomes, such games entail increased constraints on responsiveness and consistency.

Rich Internet Application: A browser-based application that has the features and functionality of a traditional desktop application. Rich Internet Applications (RIAs) introduce an intermediate layer of code between the user and the server that acts as an extension of the browser. They are typically run in a secure "sandbox" environment and can be implemented using technologies such as Flash, Java or Ajax.

Archival Issues Related to Digital Creations

Mark Kieler
Carnegie Mellon University, USA

Michael J. West
Carnegie Mellon University, USA

INTRODUCTION

The authors define "intellectual creations" as human expressions embodied in text, music, or other forms of art. Increasingly, we encode these creations in digital formats that have extremely short life cycles. Eventually, backward compatibility is lost. Thus, after very little time, a digital encoding format becomes obsolete, and intellectual works encoded in the format may become irretrievable. In contrast, the cultural worth of an intellectual creation may not be realized for generations. Additionally, future generations must access artifacts, including intellectual creations, to understand a culture in historical context. We contend that technology – intensive storage and manipulation of data may result in an inability to gain this access. Technology creators have some responsibility to facilitate future retrieval through careful documentation, and by selective maintenance of hardware that may be required to access archival media.

BACKGROUND

Cultural artifacts nearly always outlive the technologies that made them possible, which is particularly obvious with digital technology. Imagine the discovery hundreds of years from now of a floppy diskette containing a document written in WordStar®. Once a code has been lost, have all texts written in that code been lost as well?

At some point, supporting a technology is no longer economically viable if it is abandoned by enough people. It ceases to exist except in archival form. Currently, home videocassettes are being replaced by the DVD (Digital Video Disc), which subsequently will also be superceded.

Linguists stress the organic nature of language, which it is in constant evolution. Grammars are codifications constructed of "snapshot images" of spoken and written language usage. Despite the fact that both are considered examples of English, speakers of the vernacular of Shakespeare and the vernacular of rap music would find each other incomprehensible. With technology, as with language and culture, timing is everything, and context plays an important role in shaping how we interact with each other and with technology.

HOW DO WE KNOW ABOUT PAST CULTURES?

In engineering, Shannon (1948) described elements of a communications system: An information source generate data. A transmitter encodes information to travel over a channel through distance and time. At the other end, a receiver decodes the signal for the destination, which is the person or thing for which the message is intended. Since we are worried about humans, we consider them to be the source and destination. While parts of the transmission system have changed greatly over time, one could certainly argue that technology has caused the other portions of the system to change more rapidly than the human elements. Linguists, beginning with Ferdinand de Saussure, established semiotics as a science of signs, which likewise focuses on the sender and the receiver of a message. Semiotics also posited the arbitrary nature of the sign and looked at the ways human languages encode and transmit messages. (Saussure, 1974).

Physical artifacts that survive from the distant past reveal much about a culture, depending on their purpose and the quality of materials from which they are made. Our record from ancient civilizations is far from perfect, but archaeologists can construct some details about them from these clues.

Significant events have often been recorded in the living embodiment of a storyteller, and oral traditions still form an important part of many cultures. The historical record has often been related by language, as well as by performance (e.g., a ritual dance). Some of these oral histories survived long enough to be recorded in other more permanent media. However, not only have many oral traditions died with the last generation of storyteller, others have assumed inaccuracies and exaggerations as a result of being passed serially through generations.

As languages evolved and became standardized, it became possible to encode events in written form. Because writing has traditionally been the province of the learned few, written documents were recorded on long-lived media, and special care was accorded to their storage. Fortunately, many ancient documents have survived, albeit, with significant degradation. Given the constant change in a living language, when a culture dies, the language often dies with it. Language experts

attempt to reconstruct meaning by looking for patterns that may establish types of words and contexts and similarities to more modern languages.

In addition to printed text, human expression is also accomplished through artistic means such as music, painting, and dance. While we only have been able to preserve musical and dance performances for a relatively recent portion of human history, for centuries we have had a written procedure for recreating music, using notes, measures, and time definitions. The methods for recording dance instructions are much less standardized and rely on interpretations and tradition.

Art works degrade over time, depending on the types of inks, paints, or dyes used, the media on which they are deposited, and overall interaction with the environment. Even sculpture is subject to environmental degradation, such as damage from acid rain.

THE INTRODUCTION OF TECHNOLOGY

The invention of the printing press made wide distribution of printed information possible, and wood pulp-based paper made it affordable for the general public. However, unlike expensive fiber-based paper, pulp-based paper has usually been manufactured through an acid-based process, and residual acid in the paper eventually destroys it. Thus, paradoxically, fiber-based books from the 19th century are often more legible than their 20th century wood pulp counterparts.

Text

Text was the first means of expression to be converted into electrical form. In fact, text went "direct to digital." Morse code is a duration-encoded digital signal, unrecognizable to anyone who does not understand it. Initially, storage was primitive, used mainly to "buffer" the information until a human could reconvert it to text. Thus, long-term storage and archiving of Morse code traffic was not an issue.

The first modern bit encoding of text occurred in 1874. Emile Baudot, a French telegraph engineer, devised a 5-bit code for each letter of the alphabet. Unlike Morse code, each symbol had a fixed length representation, dependent only on the presence or absence of electrical current. The Baudot code was durable, used by news service teletypewriters throughout the 1970s (Freed, 1995). Crude paper tape punches were often utilized for storage. The digital code could be read, albeit slowly, merely by holding the tape up to a light.

ASCII (American Standard Code for Information Interchange) uses 7 bits. The added bits allowed upper and lower case letters, as well as numbers, punctuation, and other special characters. It endures as the "plain text" standard.

The rise of WYSIWYG (what you see is what you get) computer interfaces, and the availability of sophisticated word processing programs, made it possible to digitally encode additional expressions to text. Different art styles of text (fonts) could be used, and these could embody visual variations such as italics, bold, superscripts and subscripts, and underlines. Word processing evolved to encode these variations. This was accomplished by adding bits to the original text data, or by software commands that controlled a section of ASCII text. These techniques represent a deviation from international standards into conventions of the word processing software. As the level of sophistication increases, we become increasingly unable to understand an encoded section of text without the software used to create it. In fact, the actual text becomes only a tiny portion of the code. If the page is graphically encoded, as occurs in programs such as Adobe Acrobat®, then plain text representations are lost all together (Kieler et al., 2004).

Audio and Visual Technology

Storage of audio and visual data began in the 19th century and progressed in sophistication throughout most of the 20th century. While not strictly correct in each instance, the general paths of progress could be viewed as follows:

- Visual Still and Audio-Only, to Visual Motion, to Visual Motion with Audio
- Mechanical or Chemical-Based Recording, and Storage to Electronic Recording and Storage
- Mechanical Reproduction to Electronic Reproduction
- Analog Encoding to Digital Encoding

The most significant impediments to easy retrieval of an intellectual creation involve electronic encoding and storage, and digital conversion.

Electronic encoding of visual information marks the historical point where the original signal cannot be recovered merely by converting stored data directly into light or motion. The visual image is stored as a series of lines, and voltage references signal new lines or new collections of lines (*frames*). Thus, one must be able to properly decode the various electronic levels and pulses unique to the method, and understand how the lines are ordered and encoded in order to correctly reconstruct the scanned image. Incompatible formats include PAL (Phase Alternating Line), NTSC (National Television Standards Committee) and SECAM (Systéme Electronique Couleur Avec Mémorie) (Abbott, 1994).

With the advent of magnetic storage, one could no longer directly "see" the information on the storage medium without a great deal of technological aid. As an example, by the late 1920s, light modulation of audio onto motion picture film was possible (Hochheiser, 1992), and both audio and video information are clearly visible on the film. In contrast, the

advent of practical magnetic video recording in 1956 (Shima, 1984) resulted in a signal which can only be observed using microscope techniques (Chinn, 1957).

Finally, digital data types in streams of 1s and 0s are indistinguishable without the reverse algorithm to retrieve the original information. The significance is that in addition to the physical details of how the data was encoded, we also need mathematical processing information on how the data was changed after its conversion. Data protection techniques, including public and private key cryptography, hashing algorithms, and other methods (Wayner, 1997), added on top of the conversion technique, have deliberate obscuration of data as their intent. Thus, the data is not readable, even when the encoding techniques are known, unless the proper decrypting information is available.

Lossy Encoding

An additional dilemma is that digital conversions result in massive amounts of data. Compact disc audio, for instance, necessitates a bit rate of 4.32 million bits per second (Carrasso et al., 1982). Efficient storage and transmission virtually require data reduction. We must actually throw away some of the original information (hence the term *lossy*) to make any real progress in storage efficiency. We discard information based on redundancies in the retained data, or upon deeming it insignificant through models of human perceptual limitations. For instance, Moving Picture Experts Group Layer 3 audio (MPEG 3 or MP3) achieves a better than 10 to 1 savings (Jack, 1996). However, the encoded audio bit stream now represents a set of mathematical manipulations on top of the interleaving, control, data, and error correction algorithms of the storage format. It has become impossible to reconstruct the data without complete knowledge of each of these transformations.

IMPACT ON LONG-TERM DATA AVAILABILITY

If intellectual creations are stored in formats that require an exact knowledge of the encoding transforms, the issue for society is whether any of these techniques will be available, or even remembered, in the distant future.

In the short term, there is no problem, as new formats usually incorporate backward compatibility and conversion. Eventually, however, the overhead needed to retain compatibility hampers the effectiveness of a system. As demand collapses, the resources that support an obsolete format must be utilized for other purposes.

The digital revolution has compressed the time scale. Tremendous gains in hardware and software capability have resulted in unprecedented rates of obsolescence. For example, in both popular personal computing formats, operating systems have migrated to 32-bit code, abandoning the previous 16-bit systems. In doing so, they have shed much backward compatibility with the previous systems (White, 2002.) This transition has occurred in a mere 20 years. Thus, the ability to retrieve data created with a 16-bit program may well be lost once the last 16-bit compatible system is "upgraded."

New generations of artists and creative personalities use electronic and especially digital formats as freely as their predecessors used physical media. While most popular culture intellectual creations have little lasting value, a few will be significant enough to be studied and preserved far into the future. The problem is that human society does not always immediately recognize an intellectual work's significance, and it may fall into obscurity for decades or even centuries. A cursory encyclopedia search (Compton's, 1994) reveals examples from many fields. For example, painter Sandro Botticelli's works remained obscure from the late 1400s until the 19th century.

While not individually significant, ordinary popular culture creations collectively can reveal a great deal about a period in society. However objective evaluation often requires the passage of at least several decades. Even then, critiques and judgments may go through many modifications and revisions before any consensus is reached.

MINDSETS: CREATORS OF TECHNOLOGY VERSUS CREATORS OF IDEAS

Technology creators derive value from innovation. Profits and employment fall once a particular technology generation "matures" and a "shakeout" era ensues, where only the most efficient producers prevail. Software and digital data can be infinitely replicated with no degradation. Thus, barring legal impediments, there is virtually no value in creating additional copies. Even with legal protections against duplication, others may create software that operates differently but accomplishes the same goal. These characteristics shape the mindset of technology creators into a "cult of the new." Obsolescence is the fuel for continued employment and profitability.

With intellectual creations, there is also a progress-oriented motivation. Artists do not merely rest on past achievements. However, since these creations embody a combination of knowledge, ideas, and interpretation, their value is not necessarily superceded by later works. While only a few will have lasting value to society, there is no way to know when this value will finally be appreciated. The finest intellectual works must prove their value repeatedly through decades and centuries of cultural change.

The issue is that these works are increasingly created through a technological process that need only prove itself until the next "better" innovation comes along. The potentially tremendous but unpredictable future value of key intellectual works may never be realized if they are embodied in a technical process that has zero value five years later. While future societal worth is of little present economic value to the creation of intellectual work, the encoding technology creator derives nothing beyond the initial sale of the software.

Certainly, the same could be said of those who produce physical creative media such as paint or canvas. However, the medium usually survives regardless of the intentions of its original manufacturer. Deterioration is directly observable, and can often be repaired to foster preservation. With modern technology, however, the "medium" is a combination of the physical storage object and the encoding software/hardware systems. Even if the storage object can last centuries, the ability to retrieve it is governed by entities that have, if anything, a *dis*incentive to ensure continued long-term accessibility. This leaves society with no way to rediscover and realize the benefits of important intellectual creations in the distant future.

FUTURE TRENDS

While it is unfair to lay all responsibility for long-term accessibility on technology creators, it is clear that the nature of digital innovation fosters the problem. Among engineering ethicists, there is general agreement that those who create technology have a unique insight into potential side effects. Harris, Pritchard, and Rabins (1992) discuss the need for "preventive ethics" in engineering. Shinzinger and Martin (2000) describe engineering as social experimentation. This implies a responsibility for technology creators to envision possible social consequences and, at the very least, take steps to inform others of their existence and nature. This is especially true where the complexity of the technology is transparent to the end-user.

Thus, while digital technology creators may not solely be responsible for ensuring future accessibility of works expressed through their technology, one could argue that they have a responsibility to enter into dialogues about preserving accessibility, and to design their encoding technology to foster preservation.

Currently, preservation awareness is coming, not from the technology developers, but rather from the software archivists. Pennavaria (2003) details a number of concerns and efforts of groups such as the American Library Association and the American Film Institute. Although technologists are involved in these efforts, they tend to deal only with existing analog and digital formats. Also, they tend to concentrate largely on the deterioration mechanisms of the physical media, as opposed to preserving the availability of playback hardware and decoding software.

Some hardware, such as silicon chips, could last for centuries. Conversely, other pieces of machinery clearly have a limited shelf life due to physical deterioration and wear. It is the "soft" items, such as encoding and decoding software and the underlying algorithms and manipulations, that have the greatest chance to be lost, owing to their short lifetimes. Only the creators of these artifacts can take steps to ensure their survival. This implies a responsibility that the technologists cannot ignore. The broader culture must also realize the problem and work with the technologists to foster preservation. Otherwise, much of our current culture will disappear in less than a century.

CONCLUSION

The attractiveness and availability of digital processing has resulted in its use by creators of intellectual content. The rapid turnover of digital applications may make access to these creations impossible within a very short period, compared to the time it takes for society to determine their ultimate worth. Technology creators must work with society leaders to ensure that intellectual creations are not lost forever.

KEY TERMS

Analog: Encoding a physical phenomenon by a direct, perceptually continuous variation of a physical property such as electromagnetic intensity (recording tape), mechanical displacement (Vinyl disk), or opaqueness (photographic film).

ASCII: American Standard Code for Information Interchange. A standard method of encoding upper and lower case text and other symbols with a 7-bit code.

Baudot: A 5-bit standard encoding method for uppercase letters, Invented by Emilie Baudot in 1874.

Intellectual Creation: Any work of creation, such as authorship, visual arts, performing arts, or music.

Lossy Encoding: Removal of data that represents redundant information, or differences presumed imperceptible to humans, in order to reduce stored or transmitted quantities of digital data.

Masking: In psychoacoustic models, the ability of a loud tone to block the perception of sounds or noise occurring in nearby frequencies.

Psychoacoustic Models: Models of human aural perception, especially with regard to the ability or inability to perceive signals that are masked by other signals.

Semiotics: A theory of signs and the use of signs in languages. Semiotics posits the arbitrary nature of the sign and looks at how human languages encode and transmit messages.

Wood Pulp: An inexpensive paper stock. Acid, used as part of the production process, frequently remains in the paper and causes its destruction. This destruction is rapid compared to paper made from fiber.

WYSIWYG: "What you See is What you Get." A user display that shows text and graphical information exactly as it will appear in print or other subsequent distribution. This includes expressional and artistic variations of text fonts, such as italics, bold, and underlined text.

Artificial Intelligence and Investing

Roy Rada
University of Maryland, Baltimore County, USA

INTRODUCTION

The techniques of artificial intelligence include knowledge-based, machine learning, and natural language processing techniques. The discipline of investing requires data identification, asset valuation, and risk management. Artificial intelligence techniques apply to many aspects of financial investing, and published work has shown an emphasis on the application of knowledge-based techniques for credit risk assessment and machine learning techniques for stock valuation. However, in the future, knowledge-based, machine learning, and natural language processing techniques will be integrated into systems that simultaneously address data identification, asset valuation, and risk management.

WHAT IS ARTIFICIAL INTELLIGENCE?

Computers play a role in many aspects of investing. For example, program trading is computer-driven, automatically executed trading of large volumes of shares, and has become increasingly prominent on stock exchanges. Artificial intelligence is a technique of computing that is perpetually on the cutting edge of what can be done with computers. Artificial intelligence could apply to program trading, but also other aspects of investing.

In the early days of computing, a typical task for a computer program was a numerical computation, such as computing the trajectory of a bullet. In modern days, a typical task for a computer program may involve supporting many people in important decisions, backed by a massive database across a global network. As the tasks that computers typically perform have become more complex and more closely intertwined with the daily decisions of people, the behavior of the computer programs increasingly assumes characteristics that people associate with intelligence. When, exactly, a program earns the label of "artificial intelligence" is unclear. The classic test for whether a program is intelligent is that a person would not be able to distinguish a response from an intelligent program from the response of a person. This famous Turing Test is dependent on factors not easily standardized, such as what person is making the assessment under what conditions.

A range of computer programming techniques that are currently, popularly considered artificial intelligence techniques includes (Rada 2008):

- Knowledge-based techniques, such as in expert systems.
- Machine learning techniques, such as genetic algorithms and neural networks.
- Sensory or motor techniques, such as natural language processing and image processing.

These methods may apply to investing. For instance, expert systems have been used to predict whether a company will go bankrupt. Neural networks have been used to generate buy and sell decisions on stock exchange indices. Natural language processing programs have been used to analyze corporate news releases, and to suggest a buy or sell signal for the corporate stock.

While artificial intelligence (AI) could apply to many areas of investing, much of what happens in computer-supported investing comes from non-AI areas. For instance, computational techniques not considered primarily AI techniques include numerical analyses, operations research, and probabilistic analyses. These non-AI techniques are routinely used in investing.

INVESTING AND DATA

The process of investing has three stages of:

- Data identification,
- Asset valuation, and
- Risk management.

AI has been most often applied to asset valuation, but is also applicable to data identification and risk management.

Two, high-level types of data used in financial investing are technical data and fundamental data. The price of an asset across time is technical data, and lends itself to various computations, such as the moving average or the standard deviation (volatility). Fundamental data should support cause-and-effect relationships between an asset and its price. For instance, the quality of management of a company should influence the profitability of a company and thus, the price of its stock.

The universe of fundamental data is infinite. Many streams of data that might be relevant, such as corporate earnings or corporate debt, might also be related to one another. Various

non-AI tools, such as linear regression analysis and principal components analysis, might be used in identifying what sets of data are more likely to be useful than what other sets. Such non-AI, computational techniques can be combined with AI techniques in experimenting with various combinations of data and choosing what data to use in asset valuation.

ASSET VALUATION

Different computational techniques might be appropriate for different assets or for different types of data for a particular asset. For instance, both stocks and commodities have price histories that might be tracked by the same time series analysis methods. However, the knowledge bases that would apply to valuing these assets might be significantly different. For example, knowledge about corporate management is less germane to commodity valuation than to stock valuation, while knowledge about weather patterns is more germane to commodity valuation than stock valuation.

Many assets have derivatives, such as options, that are priced and exchanged on markets. The computational characteristic of the Black-Scholes option pricing equation means that option valuation is done with the support of computer programs. Solving the Black-Scholes equation is not an artificial intelligence operation, although adequately handling options valuation could well involve artificial intelligence techniques.

An index is a special kind of asset. For instance, Standard & Poor's 500 Index (S&P500) is a widely traded asset that represents, with a single number, the price of shares of 500 companies. Programs that would be appropriate for evaluating the fair price of the S&P500 would be different from programs designed to evaluate the fair price of a particular company's shares. Among other things, the S&P500 does not have corporate management, per se. Neural networks have been extensively applied to predicting prices of stock indices.

A typical technical approach to a market problem (Chun & Park, 2006) took daily values over 5 years for five attributes of the Korean stock price index: daily high and low values, daily opening and closing values, and daily trading volume. On the other hand, the bond rating work of (Kim & Lee, 1995) looks at fundamental data with an expert system The input data for the bond rating work considers the quality of management and the quality of financial policies. The expert system's approach has a professional interactively answer questions from the system. Through this user interactivity, the system might collect subjective information, such as a company's management quality.

If a bank considers lending money to a company, the bank would be interested in judging the likelihood that the company would go bankrupt. More generally, financial institutions that lend money want to judge the credit worthiness of the entities to which they might lend money. These valuations of credit worthiness are a kind of asset valuation, but the techniques for doing this credit assessment would tend to be different from those for assessing the fair price of a company share. In particular, expert systems are more likely to be used for bankruptcy predictions, and neural networks are more likely to be used for stock price prediction. A bank may take its time in deciding what conditions, if any, to offer for a loan. Once the loan is made, its conditions are not subject to ready change. Investing in stocks or financial derivatives may be a fast-moving activity based on a history of prices. Those prices may be volatile, and entry and exit from the market may occur any time. The speculative financial investing problem is more of a time-series problem than the financial accounting problem and is thus, amenable to a different set of computational tools.

RISK MANAGEMENT

Risk or portfolio management involves choosing the asset classes in which to invest, and modifying the held assets across time, so as to suit the investment objectives. Various mathematical models, such as the Markowitz portfolio selection model, may be used by professional managers to guide the diversification of holdings so as to minimize risk for any specified rate of return. Implementing this kind of portfolio management may rely on numerical computation at one level, but can also benefit from various artificial intelligence techniques.

Lee et al. (Lee, Trippi, Chu, & Kim,1990) have described a knowledge-based system for supporting portfolio management. The system has different agents for different tasks. One agent elicits client goals, another agent implements dynamic hedging strategies, and another suggests market-timing decisions. Lee et al. note that the agents are only successful in narrow domains, and intervention of the human, portfolio manager is regularly necessary. In more recent work, Abdelazim and Wahba (2006) use genetic algorithms and neural networks to modify the parameters suggested by the Markowitz portfolio selection model, and obtain portfolios that earn higher returns at a specified risk level.

AI TRENDS

A multiagent architecture for an integrated system that considers data identification, asset valuation, and risk management has been proposed by researchers at Carnegie Mellon University. The system is called WARREN, which refers to the first name of the famous investor Warren Buffet (Sycara, Decker, Pannu, Williamson, & Zeng, 1996). The WARREN

system design includes components for collecting large amounts of real-time data, both numeric and textual. The data would be preprocessed and then fed to various asset valuation agents that would, in turn, feed their assessments to a portfolio management agent. The portfolio management agent would interact with clients of WARREN. Systems with various features of WARREN are available from commercial vendors, and are developed in-house by large investing companies, but more research is needed on how to develop integrated, AI systems that support investing.

Natural language processing systems may include large bodies of domain knowledge and parse free text, so as to make inferences about the content of the text. However, such natural language processing systems do not seem as popular in investing applications as much simpler natural language processing techniques. The natural language processing work that has been applied to the investing seems to be largely of the sort in which the distribution of word frequencies in a document is used to characterize the document. In this word-frequency way, Thomas (2003) has shown a potential value to processing news stories to help anticipate stock price changes.

As one can see cycles in the value of financial assets, one can also see cycles in the frequency of publication of articles on certain topics. In the field of artificial intelligence, one might identify, roughly speaking, three phases, as follows (Rada, 2008):

1. machine learning, in what was then called perceptron and self-organizing systems research, was popular from 1955 to 1975,
2. knowledge-based, multiagent, or expert systems work was popular from 1975 to 1995, and
3. machine learning research, now called neural networks or genetic algorithms research, returned to dominate the AI research scene from 1995 to the date of this article.

When AI research has been applied to investing, the AI technique used has tended to be the technique popular at the time. This leaves, unaddressed, the question of whether investing is more appropriately addressed with one AI technique or another.

The recent literature is rich with neural network applications to investing, but a new trend is the combining of knowledge-based techniques with neural network and genetic algorithm techniques. For instance, Tsakonas et al. (Tsakonas, Dounias, Doumpos, & Zopounidis, 2006) use "logic" neural nets that can be directly understood by people (traditional neural nets are a "black box" to humans). Genetic programming modifies the architecture of the logic neural net by adding or deleting nodes of the network in a way that preserves the meaning of the neural net to people and to the net itself. Bhattacharyya et al. (Bhattacharyya, Pictet, & Zumbach,2002) have added knowledge-rich constraints to the genetic operators in their application for investing in foreign exchange markets.

A promising research direction is to combine the earlier knowledge-based work on financial accounting with the more recent work on machine learning for stock valuation. For instance, neural logic nets could represent some of the cause-effect knowledge from a bankruptcy system and become part of a learning system for predicting stock prices. Some of the bankruptcy variables are readily available online, such as a company's debt, cash flow, and capital assets.

The financial markets are human markets that evolve over time as opportunities to make profits in this zero-sum game depend on the changing strategies of the opponent. Thus, among other things, what is important in the input may change over time. An AI system should be able to evolve its data selection, asset valuation, and portfolio management components. The future direction for AI in investing is to integrate the three major tools of AI (knowledge-based systems, machine learning, and natural language processing) into a system that simultaneously handles the three stages of investing (data collection, asset valuation, and portfolio management). Such systems will interact with humans so that humans can specify their preferences and make difficult decisions, but in some arenas, such as program trading, these sophisticated AI systems could compete with one another.

KEY TERMS

Artificial Intelligence: The ability of a computer to perform activities normally considered to require human intelligence

Asset Valuation: The process of determining the worth of something

Expert System: A program that uses knowledge and inferences to solve problems in a way that experts might

Investing: The act of committing money to an endeavor with the expectation of obtaining profit.

Neural Networks: Programs that simulate a network of communicating nerve cells to achieve a machine learning objective

Risk Management: The process of managing the uncertainty in investment decision-making.

Artificial Intelligence Applications in Tourism

INTRODUCTION

The tourism industry has become one of the fastest growing industries in the world, with international tourism flows in year 2006 more than doubled since 1980. In terms of direct economic benefits, United Nations World Tourism Organization (UNWTO, 2007) estimated that the industry has generated US $735 billion through tourism in the year of 2006. Through multiplier effects, World Travel and Tourism Council (WTTC, 2007) estimated that tourism will generate economic activities worth of approximately US $5,390 billion in year 2007 (10.4% of world GDP).

Owing to the important economic contribution by the tourism industry, researchers, policy makers, planners, and industrial practitioners have been trying to analyze and forecast tourism demand. The perishable nature of tourism products and services, the information-intensive nature of the tourism industry, and the long lead-time investment planning of equipment and infrastructures all render accurate forecasting of tourism demand necessary (Law, Mok, & Goh, 2007). Past studies have predominantly applied the well-developed econometric techniques to measure and predict the future market performance in terms of the number of tourist arrivals in a specific destination. In this chapter, we aim to present an overview of studies that have adopted artificial intelligence (AI) data-mining techniques in studying tourism demand forecasting. Our objective is to review and trace the evolution of such techniques employed in tourism demand studies since 1999, and based on our observations from the review, a discussion on the future direction of tourism research techniques and methods is then provided. Although the adoption of data mining techniques in tourism demand forecasting is still at its infancy stage, from the review, we identify certain research gaps, draw certain key observations, and discuss possible future research directions.

BACKGROUND

Econometric modeling and forecasting techniques are very much highly exploited to the understanding of international tourism demand. The econometric techniques have evolved and improved in accuracy and sophistication in recent years with the development of stationarity consideration, cointegration, and GARCH and time varying parameter (TVP) models. However, the development of such techniques might have reached a plateau for the time being. It is often expressed that econometric models are expanded at the expense of model comprehensiveness. That is, demand relationship is represented in a complicated system of equations in such models, which policy makers and practitioners find it like a black box that is hard to comprehend.

Besides, the conventional econometric models are founded on strict statistical assumptions and stringent economic theory (e.g., utility theory and consumption behavioral theory). These theories suggest that economic factors, such as income, price, substitute price, and advertising, are the primary influences of demand. However, tourism consumption, particularly if it involves a long-haul trip, is restricted by not only income constraint, but also on time constraint (Cesario & Knetsch, 1970; Morley, 1994), and the *intrinsic* properties of a particular tourism product or service that have not been modeled in the traditional demand framework (Eymann & Ronning, 1992; Morley, 1992; Papatheodorou, 2001; Rugg, 1973; Seddighi & Theocarous, 2002). The noneconomic factors, such as psychological, anthropological, and sociological factors, had not been analyzed in the traditional econometric travel demand studies. It is true that there exists a large amount of tourism literature that studies how these noneconomic factors could affect travel motivation, and how travel motivation affects destination choices (e.g., Edwards, 1979; Gray, 1970; Mayo & Jarvis, 1981; Um & Crompton, 1990), published articles have failed to show how noneconomic factors could affect demand for tourism, however.

Researchers have attributed the reasons for not including many relevant variables to the lack of data availability and difficulty in obtaining exact measures for the determining factors (Gonzelez & Moral, 1995; Kulendran, 1996, Song & Witt, 2000; Song *et al.*, 2000). Perhaps the true reason lies in the expense of the increasing complexity of a model in exchange for the inclusion of more determining factors, as noted in Turner and Witt (2001), Stabler (1990), as well as Faulker & Valerio (2000).

A RETROSPECTIVE VIEW ON DATA MINING IN TOURISM DEMAND ANALYSIS AND FORECASTING

In view of the growing importance of data mining in business applications, we review and analyze the relevant articles that adopt data-mining techniques to forecast tourism demand in tourism research journals. We sorted the 70 research journals in tourism, as mentioned by McKercher, Law, and Lam (2006), for the period between 1980 and early 2007, and the ScienceDirect, and the Hospitality and Tourism Complete index on EBSCOhost Web for the period between mid-2006 and early 2007. We identified 174 papers on tourism demand forecastin,g published in a 28-year span (1980 to early 2007) and among them, only 14 used data-mining techniques, with the first one published in 1999. Nine out of the 14 papers were published in the last 5 years (2003-early 2007).

A variety of neural network (NN) systems was adopted in these 14 studies, and they include supervised feed forward NN, back propagation NN, Elman's NN, multilayer perceptron NN, radial basis function NN, and Bayesian NN. Others have adopted rough sets, support vector regression, group method of data handling, fuzzy time series, and grey forecasting model.

Neural Networks

Traditionally, the term neural network had been used to refer to a network of biological neurons, but it is often refered to as artificial neural networks (ANN) nowadays. ANNs are computer software that mimics the human intelligence to deduce or learn from a dataset. What gives ANNs excellent classification and pattern recognition ability are their capabilities of representing knowledge based on massive parallel processing, and pattern recognition based on past experience. This pattern recognition ability makes ANNs a superb classification and forecasting tool for industrial applications.

Supervised Feed Forward Neural Networks (SFFNN)

The SFFNN was first adopted by Uysal and El Roubi (1999) and Law and Au (1999) in tourism demand studies. Uysal and El Roubi (1999) developed a preliminary neural network that used Canadian tourism expenditures in the United States as dependent variable; whereas per capita income of Canada, consumer price index, lagged expenditure by one period, and seasonal dummy variables were used as independent variables. Their findings showed that the neural network achieved highly accurate results with high-adjusted correlations and low-error terms. Law and Au (1999) used the model to forecast Japanese tourist arrivals to Hong Kong. Using six independent variables, including relative service price, average hotel rate in Hong Kong, foreign exchange rate, population in Japan, marketing expenses by the Hong Kong Tourist Association, and gross domestic expenditure in Japan, the neural network achieved the lowest mean average percentage error (MAPE), and highest acceptance percentage and normalized correlation coefficient compared to four other commonly used econometric models, including multiple regression, naïve I, moving average, and single exponential smoothing.

The SFFNN was adopted by Law (2001) in an attempt to capture turbulent travel behavior as a result of regional financial crisis in Asia in 1997. Law (2001) tested and compared the forecasting accuracy of this model with naïve I, naïve II, moving average, single exponential smoothing, Holt's exponential smoothing, and multiple regression in predicting Japanese demand for travel to Hong Kong. Using the same variables as in Law and Au (1999) and Law (2000), but with updated data, neural network, again, outperformed other techniques in three of the five accuracy measurements, including MAPE, trend change accuracy, and the closeness between actual and estimated values. Law (2001) concluded that no single forecasting method could outperform others in all situations when there was a sudden environmental change, but neural network appeared to perform reasonably well in terms of predicted values. Using tourism demand data of South Africa, Burger *et al.* (Burger, Dohnal, Kathrada, & Law, 2001) also investigated performance and SFFNN with a few benchmark models, such as Naïve I, moving average, decomposition, single exponential smoothing, ARIMA, autoregression, and found that neural networks with 1-month-ahead forecast generated the lowest MAPE values. Radial basis function network, a type of SFFNN, was employed by Kon and Turner (2005), but the forecasting performance falls behind that of multilayer peceptron NN model in all seasonal and deseasonalized series.

Back Propagation Neural Networks (BBNN)

BPNN was found as a core model in Law (2000), and it is used to analyze the nonlinearly separable Taiwanese visitor arrivals to Hong Kong from 1967 to 1996 using similar variables in Law and Au (1999). Their results showed that the calibrated neural network model outperformed all other approaches (commonly used econometric models, including multiple regression, naïve I, moving average, and single exponential smoothing), by attaining the highest forecasting accuracy. Besides, Kon and Turner (2005) also employ BPNN as a type of multilayer perceptron to analyze and forecast tourism demand for Singapore. Their results confirm that correctly structured NN model can outperform basic structural model and other simpler methods, such as Naive I and Holt-Winters model, in the short run. The BPNN was also used in Chen and Wang (2007) as a model for comparison with support vector regression.

Elman's Neural Networks (Elman's NN)

The Elman's NN has the advantageous time series prediction capability because of its memory nodes, as well as local recurrent connections. Cho (2003) established an Elman's NN in its time series analysis to forecast the number of visitors from different origins to Hong Kong. Their findings showed that Elman's neural networks performed the best in five of the six origins, compared with ARIMA model and exponential smoothing.

Bayesian Neural Networks (BNN)

BNN model was tested together with multilayer perceptron neural network (MLP) and radial basis function neural network (RBF) in Kon and Turner (2005) on both deseasonalized and nondeseasonalized data series. The BNN model did not forecast accurately on the sample data.

Rough Sets (RS)

RS algorithms can handle both numeric and nonnumeric data. As such, the noneconomic factors, along with economic factors, can be analyzed without having to bear the problem of insufficient degree of freedom and loss of information from transforming the nonnumeric factors into numeric ones.

There were two regression papers that incorporated the RS theory to tourism demand forecasting. In the first paper, Goh and Law (2003) built an RS-based model using independent variables of real gross domestic product, relative consumer price index, population, trade volume, and foreign exchange rate to form six decision rules for forecasting tourist arrivals. Their findings achieved 87.2% accuracy rate in six samples. High classification capability of the RS model was also demonstrated in Law, Goh, and Pine (2004). The empirical findings showed that the RS-based model correctly classified 86.5% of the testing data.

Goh, Law, and Mok, (forthcoming), for the first time, have introduced a leisure time index and a climate index into the rough sets forecasting framework.

Support Vector Regression (SVR)

The model was tested by Pai and Hong (2005) on arrival data in Barbados. SVRs are normally used to avoid the over- or the under-fitting of data series. In SVR models, parameter values of structural error range (ε), the flatness (C), and the curvature (σ) could be adjusted through a dynamic shift procedure. In this study, genetic algorithms (Holland, 1975) were employed to select the optimal parameter for the three SVR model parameters. The results indicated that support vector machines with genetic algorithms (SVMG) outperform ARIMA model and accurately forecast arrivals in Barbados, and can predict the increasing tendency of arrivals properly. The dynamic shift procedure easily captures the data patterns, and the genetic algorithms provide a proper procedure to determine SVR parameters, hence the whole process could minimize the structural risk. For these reasons, SVMG is particularly suitable to forecast tourist arrivals that tend to exhibit profound structural change in the series.

Group Method of Data Handling: Genetic Regression (GMDH)

The GMDH has an inductive nature that automatically finds interrelations in data and selects the optimal model structure by sorting out possible variants. This automatic sorting of different solutions in the GMDH networks minimizes the researcher's manipulation on the results of modeling. Burger *et al*. (2001) used this model alongside with eight other models, including SFFNN, to forecast travel demand of American for Durban. However, the model was found to perform poorly owing to the fact that GMDH algorithm needs to reserve a large set of data for validation and hence, leaving a relatively small data set for model fitting. It was believed that the model performance should improve with a larger overall data set, however.

Fuzzy Time Series (FTS)

The main assumption of FTS model is that the variation of this year is related to the variation of previous years and the model is, therefore, appropriate for analyzing tourism data

that exhibits habit persistence. As FTS model is designed to forecast processes with linguistic value observation, in Wang's (2004) and Yu and Schwartz's (2006) studies, the numerical value of tourism demand was translated into a linguistic value, and then the predicted variation value is translated back into a numeric value. In Wang (2004), two AI models, FTS, hybrid grey theory and a Markov modification model were used to forecast arrivals to Taiwan from Hong Kong, United States, and Germany. The empirical results indicate that FTS model leads the others only on forecasting tourism demand of Hong Kong to Taiwan. Yu and Schwartz (2006) also established FTS forecasting model and grey-theory-based model for tourist arrivals to the United States from eight origins, and compared them with two benchmarking models, double exponential smoothing and double moving average model. Different from Wang (2004), experimental findings indicated that the sophisticated data-mining technique did not produce more accurate forecasting results. The authors thus cautioned that tourism researchers should proceed with care when dealing with innovative data-mining techniques.

Grey Forecasting Model (GFM)

Similar to FTS model, GFM is particularly suitable for forecasting with few available past observations, such as one for tourism. In Wang (2004), the study revealed that GFM performed well when sample data showed a stable increasing trend while Markov modification model performs better when there is significant fluctuation in the series.

KEY OBSERVATIONS AND ANALYSIS

We derive a few observations from this review on tourism demand studies that adopted data-mining techniques. These articles were predominantly published in first-tier and second-tier research journals in tourism. According to a recent survey with worldwide scholars, two of these journals were rated at 3.6 and 3.8, and the other journals were all rated above 4 on a 5-point Likert scale (McKercher, Law, & Lam, 2006).

Both time series and regression approaches were used in the reviewed studies. Although six studies were to investigate tourism demand relationship, their results were either not compared with econometric models, or the comparisons were done with simple regression models. Other than Uysal and El Roubi's (1999) study, other studies only analyzed annual data under which seasonality, an important phenomenon in tourism, was basically neglected in these studies.

One interesting observation for tourism demand forecasting studies using data mining is the dominance of artificial neural network approach. For example, Burger *et al*. (2001), Law and Au (1999); Law (2001), and Uysal and El Roubi (1999) all applied SFFNN. Later, researchers extended the applicability of neural networks by incorporating back-propagation learning process into nonlinearly separable tourism demand data (Chen & Wang, 2007; Law, 2000). Elman's concurrent network was also used to fit time series tourism data (Cho, 2003). In a more comprehensive approach, Kon and Turner (2005) fitted the tourism time series data with three different network architectures, including the multilayer perceptron (MLP), radial basis function network (RBF), and BNN, and compared the models' performance with a number of time series econometric models.

We also observe that the data-mining techniques adopted in tourism demand forecasting studies were mainly used to analyze tourist arrivals to a specific destination from either one specific origin (Burger *et al*.., 2001; Law & Au, 1999; Law, 2000; Law, 2001; Law *et al*.. 2004; Uysal & El Roubi, 1999), a number of selected origins (Chen & Wang, 2007; Pai & Hong, 2005; Palmer, ., Montaño, & Sesé, 2006), or from an aggregate total of certain countries (Cho, 2003; Goh & Law, 2003; Kon & Turner, 2005).

FUTURE TREND

The review reveals several research gaps. It is observed that the forecasting accuracy of the adopted data-mining techniques was often compared with the traditional and less sophisticated forecasting techniques; thus it remains largely unknown whether data-mining techniques are able to outperform the advanced econometric techniques, such as nonstationary regression approaches, system of equation techniques, and the time varying parameter (TVP) models. The comparison between forecasting quality of data-mining techniques and advanced econometric techniques is crucial for tourism data-mining researchers to be confident of their research findings.

Another noticeable gap is the effective nonexistence of examining noneconomic variables in the published data-mining articles. With the exception of Goh, Law, and Mok, (2008), who have introduced a leisure time index and a climate index into the rough sets forecasting framework, none of the reviewed articles has investigated the impact of noneconomic factors on tourism demand. Given the fact that strict statistical assumptions are not required in data-mining techniques, as they are in econometric models, noneconomic variables, which are found in many tourism studies (Decrop, 1999; Galarza *et al.*, 2003, Heung, Qu, & Chu, 2001; Um & Crompton, 1990) that may affect tourists' decision making could also be investigated using data-mining techniques.

Apparently, prior studies on tourism demand forecasting using data-mining techniques largely followed the variables that have long been used by economists. This is manifested by the same variables of demand measurements instead of

innovative variables. Moreover, hybrid data-mining systems, such as fuzzy neural networks, were still unpopular in tourism demand studies. The last observable gap related to the use of data for model calibration and model testing. Virtually all prior studies on data mining in tourism demand forecasting relied on regional instead of truly international data.

CONCLUSION

The interest in adopting data mining into tourism demand forecasting is evident by the fact that ever since the initial attempt in 1999, articles on data mining and tourism demand forecasting have been regularly published in leading tourism journals. Nevertheless, comparing to the traditional econometric modeling techniques, data mining is still at its infancy stage. What are needed in the future are the endeavors to integrate different data-mining approaches into a commonly agreeable process that can be applied to the tourism industry at large. In the meantime, the introduction of more rigorously developed data-mining techniques with sufficient tests on both primary and secondary data (instead of purely using secondary data) is needed. As right now, most of the published tourism-demand forecasting articles offered only general suggestions, it would be desirable to generate more applicable business solutions calibrated with industrial experts using qualitative approaches, such as jury of executive opinion and Delphi method.

The coverage of this review is limited by the selection channels and the number of published papers. As such, future research efforts can certainly go beyond this limitation in order to have a more comprehensive review of related literature. The research gaps that have been discussed also deserve further investigations by researchers in data mining and tourism forecasting.

KEY TERMS

Cointegration: An econometric property of time series variables. If two or more series are themselves nonstationary, but a linear combination of them is stationary, then the series are said to be cointegrated.

Econometrics: It is concerned with the tasks of developing and applying quantitative or statistical methods to the study and elucidation of economic principles. It combines

economic theory with statistics to analyze and test economic relationships.

Multiplier Effect: In economics, it refers to the idea that an initial spending rise can lead to even greater increase in national income

Nonstationary: A condition where value of the time series changes over time, usually because there is some trend in the series so that the mean value is either rising or falling over time.

Perishable Tourism Product: Tourism services are perishable, and cannot be stored for sale at a later date. This affects the distribution of tourism services, as they must be marketed in a way that minimizes lost capacities.

Statistical Assumptions: Statistical assumptions are general assumptions about statistical populations. In order to generate interesting conclusions about real statistical populations, it is usually required to make some appropriate background assumptions in order to generate valid and accurate conclusions.

Assessing Critical Success Factors of ERP Implementation

Leopoldo Colmenares
Simon Bolivar University, Venezuela

INTRODUCTION

An enterprise resource planning (ERP) system is an integrated set of programs that provides support for core organizational activities. ERP is a software infrastructure embedded with "best practices," or best ways to do business based on common business practices or academic theory. The aim is to improve the cooperation and interaction between all the organizations' departments, such as the products planning, manufacturing, purchasing, marketing and customer service department. ERP systems is a fine expression of the inseparability of IT and business. As an enabling key technology as well as an effective managerial tool, ERP systems allow companies to integrate at all levels and utilize important ERP systems applications, such as supply-chain management, financials and accounting applications, human resource management and customer relationship management (Boubekri, 2001). ERP systems hold the promise of improving processes and decreasing costs. Furthermore, two important new frontiers for ERP systems are electronic business (e-business) and supply-chain management (Wang and Nah, 2001). The systems can connect with suppliers, distributors, and customers, facilitating the flow, the product and information.

ERP systems implementation is costly and complex. In many cases, an ERP system is the largest single investment in any corporate-wide project. The software is expensive, and the consulting costs even more. Meta Group found that the average ERP systems implementation takes 23 months with total owners' cost of $12 million (Stewart, 2000). The ERP systems implementation is the process where business process and ERP system match each other. Usually the firm has to change the business process per ERP systems. Sometimes most positions have to be redesigned according to the ERP systems. Thus the difficulties and high failure rate in implementing ERP systems have been widely cited in the literature (Davenport, 1998; Kim, Lee, & Gosain, 2005)). The failure percentage of ERP systems was determined by one study as ranging from 40 to 60% and from another study as between 60 and 90% (Langernwalter, 2000; Ptak and Schragenheim, 2000; Yingjie, 2005).

Although the failure rates of these ERP implementations have been highly publicized, this has not distracted companies from investing large sums of money on ERP systems (Somers & Nelson, 2004). ERP systems provide companies with the means of integrating their business functions into a unified and integrated business process. As companies implement more enterprise based systems throughout their organizations, the need for integration of these systems becomes even more paramount. Expanding from the functional areas of accounting, human resources, and shop floor control to an enterprise-wide system has become a format for producing full organization integration.

Over the past few years, limited research has been conducted about ERP implementation issues: mainly case studies in individual organizations have been reported. That is a motivation toward conducting empirical studies to explore critical factors that affect ERP systems implementation.

This study presents the results of an empirical study that surveyed managers from seven corporations, who were identified as having a key role in ERP systems implementation, in order to assess empirically which CSFs are critical in leading a successful implementation of ERP systems. A factor analysis solution was used to derive factors affecting successful ERP implementation. These factors are: ERP implementation management, users aptitudes and communication and technical knowledge. The study reveals that about 81.5 % of the variances in ERP systems implementation were explained by the critical factors identified in the study.

The remainder of this article is organized in four sections. First ERP-related literature is reviewed. The next section introduces the research methodology, followed by the presentation of the results. The paper ends with the conclusions and implications for future research and practice.

BACKGROUND

Implementing an ERP system is not an easy task (Tsai et al., 2005). It can cause dramatic changes that need to be carefully administered if the potential advantages of an ERP systems solution (Al-Mudimigh, Zairi, & Al-Mashari, 2001) are to be gained. In some well-documented cases, spectacular results have been achieved (Johnston, 2002). There is on the other hand a relatively high failure rate: it was reported that three-quarters of ERP systems projects were judged to be unsuccessful by the ERP systems implementing firms (Kyung & Young, 2002). What is more, failures are much less extensively documented. As a result, pitfalls to be avoided tend to be less well known.

A recent summary of ERP systems literature states that research of critical success factors (CSFs) in ERP systems implementation is rare and fragmented (Nah, Lau, & Kuang, 2001). Identifying CSFs relevant to local companies is one way to increase the chances of a successful local implementation (Sum, Ang & Yeo, 1997). The idea of identifying CSFs as a basis for determining the information needs of managers was popularized by Rockart (1979). CSFs are those factors that are critical to the success of any organization, in the sense that, if objectives associated with the factors are not achieved, the organization will fail—perhaps catastrophically (Rockart, 1979). In the context of ERP systems project implementation, CSFs represent the essential ingredients without which a project stands little chance of success. (Colmenares, 2005)

A literature review was conducted to understand the CSFs in successful ERP implementations. So we find that in a study on ERP implementation in China, the authors posit strong considerations for national cultural issues, since critical success factors may vary significantly, depending on the country in which an implementation is carried out (Shanks & Parr, 2000). ERP implementations have also been investigated through case studies with varying degrees to describe critical success factors. These include the impact of ERP on job characteristics (Perez & Rojas, 1999), strategic options open to firms beyond the implementation of common business systems (Upton & McAfree, 1997), means to avoid ERP project failures (Scott, 1999), issues of business alignment (Smethurst & Kawalek, 1999; Volkoff, 1999) business process reengineering (BPR) (Slooten & Yap, 2000), and change management (Klaus, Rosemann, & Gable, 2000). Others studies have assessed the ambiguous role of large systems as both catalysts and inhibitors to change (Pawlowski & Boudreau, 1999) analyze the special challenges of ERP implementations outside the business world (Sieber & Nah, 1999), and describe global supply chain (Chatfield & Andersen,1998). Implementing ERP with or without BPR has been surveyed and analyzed (Bernroider & Koch, 1999). Theoretical considerations have focused on global business processes (Basu & Palvia, 1999) and IT architecture options (Chan, 1999), as well as on enhancement of process engineering and development methodologies (Sato, 2000).

The critical challenge in ERP implementation has been to first identify the gaps between the ERP generic functionality and the specific organizational requirements (Soh, Kien, & Tay-Yap, 2000). Too often, ERP adopting companies fail to understand the business requirements which the ERP systems are expected to solve. The congruence between

Business process reengineering
Project management
Effective communications
Presence of a champion
Interdepartmental cooperation and communication
Management of expectations
Vendor/customer partnership

ERP systems and organizational culture is the prerequisite to successful ERP implementation (Hong & Kim, 2002). The implementation of an integrated system such as ERP requires that the basic business practices embedded in the ERP system be adapted to the organizational processes and culture. Others authors have developed studies that list the CSFs, but these lists are generally based on experience or casual observation, not controlled research. See for example Bingi, Sharma, and Godla (1999), Esteves and Pastor (2001), Falkowski et al. (1998), Holland and Light (1999), Nah, Lau, and Kuang (2001), Rosario (2000), Stefanou (1999), Sumner (1999) and Wee (2000).

Therefore we can conclude that the literature varies according to the variables required for implementation success, so there is not a general consensus as to the factors that are key to success in ERP implementation. It is probably a combination of factors that are important in explaining ERP implementation success (Zhang et al., 2003). However, from the review, twenty factors emerged frequently mentioned as critical to the successful implementation of ERP systems. They were obtained after careful analysis and grouping of related sub-factors. Table 1 shows these CSFs.

RESEARCH METHODOLOGY

The target of the study was the organizations that have implemented ERP systems successfully. The key informant method was used for collecting information in a social setting by surveying (or interviewing) a selected number of participants. Seven firms that proclaimed having succeeded in implementing ERP systems were identified from newspapers and computing magazines. We contacted the ERP project managers of each company in charge of ERP implementation. About one hundred questionnaires were sent to the ERP project managers of each firm, who forwarded the questionnaires to the project team members in charge of individual processes. A total of 86 questionnaires were returned, of which 84 were valid. The questionnaire consisted of two main parts: the company background and the CSFs. The first part was designed to determine characteristics such as size of the company, type of industry, location of company, etc. The second part consisted of twenty statements about the success factors of ERP systems implementation, derived from the literature review. The language used in the survey was Spanish. Translation was rather easy because Venezuelans used original English terms for many technical and management concepts and especially for management, information systems and computing concepts.

Participants were requested to rate the importance of each CSF using a five-point Likert scale, where a score of 5 indicated "extremely critical" and a score of 1 indicated "not critical." This method was employed on the grounds that a rating method avoids the problems of having to consider twenty CSFs simultaneously in order to rank them. The data collected was then analyzed by using SPSS. Based on the responses, descriptive statistics, factor analysis and reliability tests were carried out to identify the CSFs for the successful implementation of ERP systems and data validity respectively.

RESULTS

Ranking

The importance rating of the twenty CSFs is listed in Table 2.

The individual mean value of the Likert rating scale is the popular usage indicator for measuring an item's importance, without regard to the other items: so the higher the value the more important the factor. Most items are rated above the 3.0 scale (mid-point). The three most important factors, in order of declining importance, are: top management support, presence of a champion, and project management, with a mean value ranging from 4.80 to 4.64. Just as the literature argues, these are key items for ERP implementation management (Johnston, 2002). Conversely, use of steering committee, business process reengineering, and use of vendor's development tools, are the three items lowest in the list, with a mean value ranging from 2.95 to 2.06.

Factor Analysis

Exploratory factor analysis was used to analyze the managers' responses. The main reason for using the exploratory factor analysis was to reduce the dimensionality of the attribute data and uncover a smaller number of underlying factors that account for a major amount of the variance in the original measures [39]. Factor analysis is a data reduction technique that uses correlations between data variables. The underlying assumption of factor analysis is that a number of factors exist to explain the correlations or inter-relationships among observed variables (Chatfield & Collins, 1992). For the present study, factor analysis was performed on all twenty variables using principal components extraction (Tabachnick & Fidell, 1989). The goal of this method is to extract maximum variance from the data set within each factor. It is basically used to reduce a large number of variables down to a smaller number of components. The measure of sampling adequacy for the twenty items was 0.87 indicating that the items were suitable for factoring (Kaiser, 1974).

A three-stage factor analysis was conducted with an orthogonal (varimax) rotation to obtain a stable factor structure (Rai et al., 1996), resulting in easily interpretable factors. Under this three-round factor analysis, items were omitted according to the following two criteria: (1) no loading greater than 0.35, or (2) loading greater than 0.35 on two

Table 2. Ranking of CSFs

Rank	CSF	Mean	Std. Dev.
1	Top management support	4.80	0.62
2	Presence of a champion	4.75	0.85
3	Project management	4.64	0.92
4	Best people full time	4.58	0.60
5	Effective communications	4.51	0.85
6	Interdepartmental cooperation and communication	4.40	0.91
7	Management of expectations	4.36	1.02
8	Technical and business knowledge	4.33	1.21
9	User participation	4.22	0.82
10	Discipline and standardization	4.09	0.85
11	Vendor package selection	4.02	0.61
12	User training	4.01	1.12
13	Implementation approach	4.00	1.20
14	Clear goals, focus and scope	3.89	1.14
15	Use of consultants	3.75	0.85
16	Minimal customization	3.68	1.52
17	Vendor/customer partnership	3.15	0.52
18	Use of steering committee	2.95	0.63
19	Business process reengineering	2.84	0.55
20	Use of vendor's development tools	2.06	0.42

N: 84
Scale: 1-5 (5: "extremely critical"; 1:"not critical")

or more factors (Kim & Mueller, 1978). Table 3 shows the results of this analysis. A first factor analysis was conducted and produced five factors. According to the two criteria, three items were dropped. A second factor analysis on the remaining 17 items resulted in four factors and the dropping of three items. Finally, a three-factor structure was derived which kept a total of 14 items after three iterations. The minimum eigenvalue from a varimax rotation for which a factor was to be retained was set at 1.0 in order to satisfy the minimum eigenvalue criterion (Nunnally, 1978). The goal in labeling each of these factors is to come up with a term that best describes the content domain of the attributes that load highly on each factor. The naming of a particular factor is determined by those response variables that load on the factor. Next the three-factor structure is described:

- Factor 1, named "ERP implementation management," comprises six items relating to implementation management: top management support, presence of a champion, project management, management of expectations, implementation approach, and clear goals, focus and scope.
- Factor 2, named "user aptitudes and communication," comprises four items relating to user participation: effective communication, interdepartmental cooperation and communication, user participation, and user training.
- Factor 3, named "technical knowledge," comprises four items relating to knowledge of business and ERP: best people full time, technical and business knowledge, use of consultants, and discipline and standardization.

Cronbach alpha coefficients were calculated to test the reliability of these CSFs, as shown in the last row of Table 3. The reliability of coefficients obtained ranges from 0.56 (factor 3) to 0.88 (factor 1). Srinivasan (1985) proposed that a coefficient of 0.7 or higher is acceptable, while a coefficient of 0.5 or higher is considered sufficient when dealing with exploratory research combined with invalidated data. Thus, the reliability coefficients in this study are deemed

Table 3. Results of factor analysis

		Factor Loading (Final Factor Structure)		
CSF	**Mean**	**F1**	**F2**	**F3**
Top management support	4.80	0.608		
Presence of a champion	4.75	0.541		
Project management	4.64	0.586		
Best people full time	4.58			0.741
Effective communications	4.51		0.565	
Management of expectations	4.40	0.420		
Interdepartmental cooperation and communication	4.36		0.452	
Technical and business knowledge	4.33			0.584
User participation	4.22		0.562	
Discipline and standardization	4.09			0.387
User training	4.01		0.510	
Implementation approach	4.00	0.478		
Clear goals, focus and scope	3.89	0.411		
Use of consultants	3.75			0.573
Eingenvalue		7.56	2.54	1.20
Percentage of variance		58.50	14.36	8.65
Cumulative percentage of variance		58.50	72.86	81.51
Cronbach alpha coefficient		0.88	0.74	0.56

Scale: 1-5 (5: "extremely critical", 1:"not critical"); F1: ERP implementation management; F2: Users aptitudes and communication; F3: Technical knowledge

acceptable. The strength of factor analysis is that it provides a basis for data reduction. Rather than looking at all twenty items, just three factors can be examined. That simplifies the rankings and clarifies the most important items. Rather than focusing on individual items, practitioners and researchers can focus on the broad set of items represented by the essential factors.

FUTURE TRENDS

Many companies around the world are following the trend toward making large investments in implementing ERP systems. Several approaches and methodologies of ERP project implementation recognize a series of critical factors that must be carefully considered to ensure successful implementation of an ERP system project. In essence, there are dominant critical factors hypothesized to play a more overriding role in the implementation of ERP project and, they should be ongoing throughout all implementation levels. Clearly, the dominant factors are the ones that will shape the overall project culture, and subsequently the organizational culture as ERP is far reaching in nature.

Post-ERP activity seems to follow a clear path. A Deloitte Consulting study of 62 companies segments post-ERP activity into three stages. The first stage entails a three- to nine-month productivity decline, which is overcome by redefining jobs, establishing new procedures, fine-tuning ERP software, and taking charge of the new streams of information created by the platform. The second stage, which lasts from six to 18 months, involves skills development, structural changes, process integration, and add-on technologies that expand ERP functionality. The third stage, of one to two years' duration, is one of transformation, where the synergies of people, processes, and technology reach a peak. Another set of treds in ERP systems are as follows:

a. More ERP systems are going to be browser based, this makes it hardware and operating system independant.

b. ERP systems area turning more towards open source and they are moving to ASP model or hosted solutions.
c. ERP systems prices are coming down so the smaller companies can take advantages of the features and functionality of a integrated ERP solution.

Finally and perhaps most important, ERP forces discipline and organization around processes, making the alignment of IT and business goals more likely in the post-ERP era.

CONCLUSION

Despite the benefits that can be achieved, there is already evidence of failure in projects related to ERP systems implementation (Davenport, 1998). It is therefore important to find out what are the CSFs that drive ERP systems project success.

According to the respondents in this study, the six top CFSs for ERP systems implementation in Venezuelans firms are: top management support, presence of a champion, project management, best people full time, effective communications, and management of expectations.

This research has derived three composite CSFs in ERP systems implementation:

1. ERP implementation management
2. Users aptitudes and communication
3. Technical knowledge

Four of the six top individual items contribute to the composite factor of ERP systems implementation management, which is by far the most important. It is made up of items that are concerned with the management of ERP systems implementation projects.

The results of ranking ERP systems critical success factors in this study are largely consistent with the literature review, though the relative ranking of some factors varies. In the literature, top management support, change management, presence of a champion and management of expectations are the four most often cited critical factors.

A majority of factors—twelve—were rated as critical (rating > 4). Only one factor, business process reengineering, which is rated as critical in most articles reviewed, was not rated as critical in this study (rating < 3.0). Hence, the perceptions on CSFs of Venezuelan managers involved in ERP systems implementation projects are largely consistent with the findings reported in the literature.

There are a number of questions still to be determined. For example, although this paper establishes the relative importance of CSFs in seven firms, it has not established the reasons. Future studies could look at differences by size of firms, by industry type, by number of locations, by number of customers etc.

Finally, it should be noted that all CSFs are based on previous research; the success items can be modified when further research is conducted. For instance, discovery-oriented research through comprehensive interviews with several top-level managers in an attempt to identify new CSFs is an option.

KEY TERMS

Business Process Reengineering (BPR): Any radical change in the way in which an organization performs its business activities. BPR involves a fundamental re-think of the business processes followed by a redesign of business activities to enhance all or most of its critical measures—costs, quality of service, staff dynamics, etc.

Change Management: Change management is the process of developing a planned approach to change in an organization. Typically the objective is to maximize the collective benefits for all people involved in the change and minimize the risk of failure of implementing the change.

Critical Success Factors: (CSF) indicates the few key areas of activity in which favorable results are absolutely necessary for the manager to succeed.

Enterprise Resource Planning System: Business software package for running every aspect of a company including managing orders, inventory, accounting, and logistics. Well known ERP software providers include BAAN, Oracle, PeopleSoft and SAP, collectively known to industry insiders as the "BOPS."

Factor Analysis: Any of several methods for reducing co-relational data to a smaller number of dimensions or factors; beginning with a correlation matrix a small number of components or factors are extracted that are regarded as the basic variable that account for the interrelations observed in the data.

Project Champion: A member of an organization who creates, defines or adopts a new technological innovation and who is willing to risk his or her position and prestige to make possible the innovation's successful implementation.

Project Management: Is the ensemble of activities concerned with successfully achieving a set of goals. This includes planning, scheduling and maintaining progress of the activities that comprise the project.

Software Package: Written programs or procedures or rules and associated documentation pertaining to the operation of a computer system and that are stored in read/write memory.

Systems Implementation: Customization or parameterization and adaptation of the software application according to the needs of the organization.

Assessing ERP Risks and Rewards

Joseph Bradley
University of Idaho, USA

INTRODUCTION

Enterprise resource planning (ERP) systems claim to meet the information needs of organizations. These off-the-shelf software packages replace hard to maintain solutions created by IS departments or older off-the-shelf packages that often provided only piecemeal solutions to an organization's information needs. ERP systems evolved from material requirements planning (MRP) systems and manufacturing resources planning (MRP II) systems. ERP serves the entire enterprise, not just manufacturing and inventory control as with its predecessors. ERP integrates information for the entire organization in a single database. But ERP implementations are often complex and experience serious problems. Failures, abandoned projects, and general dissatisfaction have been well publicized in the business press. ERP systems are "expensive and difficult to implement, often imposing their own logic on a company's strategy and existing culture" (Pozzebon, 2000, p. 1015).

BACKGROUND

Three characteristics distinguish ERP implementations from other IT projects (Somers, Ragowsky, Nelson, & Stern, 2001).

- ERP systems are "profoundly complex pieces of software, and installing them requires large investments of money, time and expertise (Davenport, 1998, p. 122).
- The packages may require changes in business processes and procedure, induce customization, and leave the implementing firm dependent on a vendor for support and updates (Lucas, Walton, & Ginsberg, 1988).
- The adopting firm is usually required to reengineer its business processes. As a result, the project must be managed as a broad program of organizational change rather than a software implementation (Markus & Tanis, 2000; Somers et al., 2001).

Despite these risks, global firms annually spent $10 billion on ERP software and another $10 billion on consultants to implement the systems in the late 1990s (Davenport, 1998). An AMR study estimated 2001 firm spending on ERP systems at $47 billion (Cotteleer, 2002). CIOs identified ERP as a leading application and technology development in a 2005 survey (Luftman, Kempaiah, & Nash, 2006).

This article will discuss the benefits firms expect to realize by adopting ERP systems, why some firms do not adopt these systems, risks associated with ERP implementation, some well-publicized ERP failures, risk management tools, and future trends in ERP implementation.

WHY DO FIRMS ADOPT ERP?

Firms adopt ERP for technical and business reasons. The technical reasons include reducing systems operating costs, solving specific problems such as Y2K, accommodating increased system capacity, and solving maintenance problems with legacy systems. Business reasons may include presenting a single face to the customer, quoting realistic delivery times, accommodating business growth, improvement of business processes, standardization of data, reduction of inventory carrying costs, and elimination of delays in filling orders (Markus & Tanis, 2000).

The rapid growth of the commercial market for ERP is attributed to the following factors (Watson & Schneider, 1999):

- Use of the popular client/server platform
- Can be used as an enabler for reengineering projects
- Y2K compliant
- Marketed to CEOs and CFOs as "strategic solutions" rather than as transaction processing software
- A way to outsource a significant part of the IS function (Watson & Schneider, 1999)

Advantages of ERP systems include (Rashid, Hossain, & Patrick, 2002):

- Reliable information access by using a single database
- Avoiding multiple data entries, reducing cost, and improving accuracy
- Delivery and cycle time reduction minimizing delays in reporting
- Cost reduction including time saving and improved controls
- Easy adaptability with business process options based on best practices easy to adapt

- Improved scalability
- Improved maintenance with long-term vendor contracts
- Global outreach with extensions to modules such as CRM and SCM
- E-commerce and e-business capabilities

An example of a decision to adopt an ERP system is provided by Geneva Pharmaceuticals, a manufacturer of generic drugs. Faced with eroding margins and continuing price pressure, the existing systems were proving inadequate. Data shared across business units had to be re-keyed, resulting in frequent errors. Data were locked in "functional silos" and did not support new processes. Geneva adopted ERP to solve the following problems:

- "implement best practices in business processes,
- integrate data across business units (hence reduce re-keying and maintenance costs),
- enforce data standardization (to reduce software maintenance costs),
- integrate well with new technologies or systems of acquired companies,
- provide scalability with growing product and customer base, and be Y2K (year 2000) compliant." (Bhattacherjee, 2000, p. 12)

A survey of Fortune 1000 firms identified organizational changes following ERP implementations, including (Jones & Young, 2006):

- Greater collaboration among functional areas in divisions
- Reorganization of processes
- Greater integration of processes across the organization
- Reduced silo behavior within divisions of the organization
- Reduced costs of operations
- Reduced silo behaviors across the organization
- Greater collaboration across divisions of the organization
- Greater integration of processes within divisions.

In addition, Jones and Young (2006) found people have a better view of the big picture, utilize more teamwork, and are more receptive to change.

With the identification of the prospective benefits of ERP, why have some firms not adopted ERP?

WHY DO FIRMS NOT ADOPT ERP?

Markus and Tanis (2000) identified three broad categories of reasons why firms that otherwise have all or some of the reasons to adopt ERP systems, do not adopt it, or only adopt ERP in part. These firms may adopt only certain modules and rely on legacy systems or new custom systems for their needs. Other firms may begin an implementation only to discontinue it for a variety of reasons. The reasons are:

1. Lack of feature-function fit
2. Company growth, strategic flexibility, and decentralized decision-making
3. Availability of alternatives to increase systems integration

Lack of feature-function fit may be due to the design of most ERP for discrete manufacturing. Many companies have specialized processes common to their industry, which may not be solved by the best practices embedded in ERP systems. The various modules may not fully support process manufacturing industries such as food processing and paper manufacturing, project industries such as aerospace, or industries that manufacture products with dimensionality such as clothing or footwear (Markus & Tanis, 2000). As the ERP market becomes saturated, vendors are designing packages for industries that were previously viewed as too complex.

Companies concerned with maintaining rapid growth rates, those needing strategic flexibility, and those without a top down decision-making style may be non-adopters or partial adopters of ERP systems. Dell Computer Corp. planned full implementation of SAP R/3 but discontinued the implementation after installing the human resource module. Dell's CIO expressed concern with the software's ability to keep pace with Dell's extraordinary growth rate. Visio, a software company subsequently acquired by Microsoft, expressed concern with the ability of SAP to handle the frequent changes it required to its sales analysis and commission requirements (Markus & Tanis, 2000, p. 29).

The experiences of Dell and Visio focus on the need for efficiency and flexibility in dealing with the external environment and internal processes. In a stable environment, mechanistic structures are appropriate consisting of "high degrees of standardization, formalization, specialization and hierarchy" (Newell, Huang, Galliers, & Pan, 2003). In a dynamic environment, organic structures are needed to enable organizations to be flexible to change products, processes, and structures. In these organizations, low levels of standardization, formalization, specialization, and hierarchy are most appropriate. ERP may maximize organizational efficiency at the cost of flexibility (Newell et al., 2003). The result may be an inability to respond quickly to changes in the environment, reducing the firm's competitiveness.

Organizational culture may also be a factor in non-adoption or partial adoption of ERP systems. Kraft Foods Inc. was highly decentralized but slowly moving to a one-company philosophy. ERP was regarded as culturally inappropriate with this strategy (Markus & Tanis, 2000).

Lean enterprises succeed "as a growth strategy for increasing sales by trimming the company's product delivery system into a competitive weapon" (Bradford & Mayfield, 2001, p. 30). Lean enterprises have difficulty using ERP systems due to the lack of flexibility. "ERP creates many non-value-added transactions by making companies track every activity and material price in the factory. This is counter to Lean philosophy, which aims at speeding up and smoothing production" (Bradford & Mayfield, 2001, p. 30).

Alternatives to ERP systems include data warehousing technologies that integrate data from source systems for query and analysis. These systems, sometimes described as "poor man's ERP," are limited by the quality of the underlying source systems (Markus & Tanis, 2000). In 1993 Great Atlantic & Pacific Tea Company, Inc. completed a supply chain and business process infrastructure based on a "robust data warehousing capacity for category management and other grocery-specific functionality" (Retek, 2003).

Other problems identified with implementation of ERP include time, expense, vendor dependence, and complexity.

RISKS ASSOCIATED WITH ERP IMPLEMENTATION

Implementing ERP can be a risky proposition for firms. Brown and Vessey (2003) observe, "Although failures to deliver projects on time and within budget were an old IT story, enterprise systems held even higher risks—they could be a 'bet-our-company' type of failure" (p. 65)

Markus (2000) propose 10 categories of IT related risks, all of which would apply to ERP systems:

1. Financial risk
2. Technical risk
3. Project risk
4. Political risk
5. Contingency risk
6. Non-use, under use, misuse risk
7. Internal abuse
8. External risk
9. Competitive risk
10. Reputational risks

"IT-related risk includes anything related to IT that could have significant negative effects on the business or its environment from the perspective of an executive investing in IT" (Markus 2000).

Some firms may be averse to the risks an ERP implementation can create. Scott (2003) discusses some of the risks identified by Markus and Tanis (2000). He describes project risks, information systems risks, organizational risks, and external risks in ERP implementations.

Project risks stem from the customization of purchased packages and the difficulty of interfacing with legacy systems. When firms believe their business processes are unique, they may customize ERP software instead of adopting best practices imbedded in a standard implementation. Data conversion can also be a problem when firms do not clean up their data before embarking on a project. After implementing SAP, Halliburton reported that inventory accuracy stood at less than 80% (Anderson, 2003). Project leadership, limiting project scope, avoiding customization, and a phased implementation (rollout) can minimize this risk (Scott, 2003).

Information systems risks arise from system performance problems. ERP systems may be poorly configured, or the hardware may need upgrading. Another risk arises when the use of multiple vendors creates the need for multiple interfaces. Multiple vendors contributed to the problems in the Hershey Food Corporation implementation. Information systems risks can be minimized by avoiding customization, use of data warehousing for reports and queries, and avoiding multivendor implementations (Scott, 2003).

Organizational risks of a bad ERP implementation can impact the firm's operating profits. Customer deliveries can be delayed, putting customer relationships at risk. Impacts can be with customers, financial performance, or internal business objectives. Organizational risks can be minimized with training and strong leadership, which assures that sufficient resources are allocated to the project and inspires employees who may resist the implementation (Scott, 2003).

External risk centers on litigation associated with the implementation. Firms with implementation problems may sue consultants and/or ERP vendors. Over-billing by consultants and use of incompetent trainees have been sources of litigation (Scott, 2003). Gore-Tex claims its consultant promised expert staff and delivered incompetent trainees. Managing consultants by specifying goals and individual competence of consultants can minimize this risk (MacDonald, 1999).

Political risk occurs "if a dominant coalition attempts to use the ERP package as a means by which to impose its views on other functional areas" (O'Gorman, 2004, p. 25). A case study at an international oil supplies company where the ERP implementation was dominated by the financial management of the business left the supply chain management function without the tools they believed they needed (Bradley, 2005).

A survey of members of the Chinese Enterprise Resource Planning Society identified the top 10 ERP risk factors as follows (Huang, Chang, Li, & Lin, 2004):

- Lack of senior management commitment to the project
- Ineffective communication with users
- Insufficient training of end users
- Fail to get user support

- Lack of effective project management methodology
- Attempting to build bridges to legacy applications
- Conflicts between user departments
- The composition of project team members
- Fail to redesign business processes
- Unclear/misunderstanding changing requirements

Competitive Advantage

Another reason for non-adoption may be that a standard software package available to all potential purchasers may reduce a firm's competitive advantage. A resource-based view of the firm assumes that the individual firm's unique collection of resources and capabilities is a potential source of competitive advantage. Capabilities leading to competitive advantage may be embedded in current business processes.

To create competitive advantage, such capabilities must be valuable, rare, costly to imitate, and non-substitutable. "Valuable and rare organizational resource[s] can only be sources of sustained competitive advantage if firms that do not possess these resources cannot readily obtain them" (Barney, 1991, p. 107). An off-the-shelf package may be costly, but would not be rare or costly to imitate. Adoption of ERP packages based on "best practices" may cause the loss of the unique and valuable advantage imbedded in current business processes. A case study showed that:

... the introduction of SAP-specific business routines can threaten established core, enabling and supplemental capabilities and related knowledge sets. The integration of SAP's embedded business routines and reporting functionality contributed to the creation of (a) highly rigid reporting structures; (b) inflexible managerial decision-making routines; and (c) reduced autonomy on the factory floor ... (Butler & Pyke, 2004, pp. 167-168)

WELL-PUBLICIZED FAILURES AND PROBLEMS

Numerous descriptions of ERP failures have appeared in the business press. The experience of serious problems at many well-run, well-financed firms may be enough to discourage some firms from beginning an ERP implementation.

Hershey Foods embarked on an ERP investment in mid-1996 to solve its Y2K problems and improve its ability to perform just-in-time store deliveries to its customers (Severance & Passino, 2002). After spending $112 million on an ERP project, Hershey Foods Corporation was unable to fill Halloween candy orders in October 1999, resulting in a 19% drop in third quarter profits (Stedman, 1999). As a result of Hershey's problems, its stock price fell by a third and the firm lost market share to Mars and Nestle (Severance & Passino, 2002).

A study by the PA Consulting Group found that "92% of companies are dissatisfied with results achieved to date from their ERP implementation and only 8% achieved a positive improvement in their performance" (ERP Implementation Disappoints Companies, 2000).

Davenport (1998) identifies several unsuccessful implementation efforts:

- Fox-Meyer Drug claims that an ERP system led to its bankruptcy.
- Mobil Europe spent hundreds of millions on ERP, but abandoned the project when a merger partner objected.
- Dell found that its ERP system did not support its new decentralized management style.
- Applied Materials gave up on its ERP implementation when it became overwhelmed with the organizational changes it required.

ERP success stories receive much less publicity.

MANAGING RISKS

ERP vendors have tried to overcome the concern of potential clients by developing tools to assess and manage risks associated with ERP implementation. Risk management as a process should (Zafiropoulos, Metaxiotis, & Askounis, 2005):

- Identify the context and criteria of the risk
- Identify the risks
- Determine the significance of each risk
- Identify, select, and implement risk management options
- Monitor and review the corrective options

These risk management systems allow project managers to make more realistic cost and time estimates to help avoid problems during implementation. Zafiropoulos et al. (2005) found that the use of a generic risk management tool they developed provided a structured way to assess risks, better integrated the use of consultants, improved communications between consultants and the project manager, led to more realistic time planning, and reduced the impact of problems when they occurred since the problems were expected and part of the project planning.

FUTURE TRENDS

Recently, the Gartner Group coined the term "ERP II" to describe a shift in ERP from an enterprise information base to moving information across the supply chain (Tak-

ing the Pulse of ERP, 2001). ERP II includes applications such as customer relationship management (CRM), supply chain management (SCM), and e-business. New risks and challenges will be faced by organizations opening up information systems to supply chain partners. Supply chain partners could be potential competitors or pass information to existing competitors. Resolving trust issues will be key to advancement in ERP II. Luftman et al. (2006) expect that the line between ERP, CRM, and SCM will blur as ERP vendors expand the functionality of their products and redefine their packages.

Davenport and Brooks (2004) discuss the need for both infrastructural and strategic capabilities in the organization. ERP or Enterprise Systems provide core functionality but are expensive and time consuming to implement. "These infrastructural capabilities provide very little in the way of real business value" (p. 13). These systems do not provide "short-term cost savings or other competitive advantage" (p. 13). In contrast, SCM applications provide "strategic, competitively-oriented capabilities," (p. 13) which can reduce inventories and improve customer service. Firms beginning to build infrastructure with ERP systems may run out of time and money, neglecting the strategic supply chain management systems (Davenport & Brooks, 2004).

Small and mid-sized enterprises (SME) will become leading adopters of ERP systems as the large company market becomes saturated. Vendors have been developing less expensive versions of their software to appeal to the SME market.

CONCLUSION

ERP implementation projects continue to present risks to adopting organizations. Continuing ERP spending demonstrates that most organizations have concluded that the benefits resulting from such implementations outweigh the substantial risks and cost of ERP systems. Perhaps the risks of not adopting ERP are determined to be greater than the risks faced by adopters. The prospect of extending ERP beyond organizational boundaries to supply chain partners makes ERP even more attractive and possibly more risky. Organizations will continue to adopt ERP as a strategic necessity to remain competitive in their industry, but few, if any, will gain any sustainable competitive advantage by adopting ERP.

KEY TERMS

Enterprise Resource Planning Systems (ERP): An off-the-shelf accounting-oriented information system that meets the information needs of most organizations. A complex and expensive information tool to meet the needs of an organization to procure, process, and deliver customer goods or services in a timely, predictable manner.

ERP II: ERP systems that extend beyond the enterprise level to exchange information with supply chain partners. Examples are CRM, SCM, and e-business.

IT-Related Risk: This risk includes "anything related to IT that could have significant negative effects on the business or its environment from the perspective of an executive investing in IT" (Markus, 2000).

Legacy Systems: Transaction processing systems designed to perform specific tasks. Systems that have become outdated as business needs change and the hardware and software available in the market place improve.

Manufacturing Resources Planning (MRPII): Extends MRP by addressing all resources in addition to inventory. MRPII links material requirements planning with capacity requirements planning avoiding over and under shop loading typical with MRP.

Material Requirements Planning (MRP) Systems: Processes that use bills of materials, inventory data, and a master productions schedule to time phase material requirement, releasing inventory purchases in a manner that reduces inventory investment yet meets customer requirements.

Risk Management: A system designed to avoid "problems during a project, which can lead to deviation from project goals, timetables, and cost estimations" (Zafiropoulos et al., 2005, p. 213).

Risks: "A risk is a future event that may or may not occur. The probability of the future event occurring must be greater than 0% and less than 100%. The consequences of the future event must be unexpected or unplanned for" (Hall & Hulett, 2002, p. 5).

INTRODUCTION

In recent years, we have witnessed an explosive growth in the amount of data generated and stored from practically all possible fields (e.g., science, business, medicine, military just to name a few). However, the ability to store more and more data has not been followed by the same rate of growth in the processing power, and, therefore, much of the data accumulated remains today still unanalyzed. Data mining, which could be defined as the process concerned with applying computational techniques (i.e., algorithms implemented as computer programs) to actually find patterns in the data, tries to bridge this gap. Among others, data mining technologies include association rule discovery, classification, clustering, summarization, regression and sequential pattern discovery (Adrians & Zantige, 1996; Chen, Han, & Yu, 1996; Fayyad, Piatetsky-Shapiro, & Smyth, 1996). This problem has been motivated by applications known as market basket analysis which find items purchased by customers; that is, what kinds of products tend to be purchased together (Agrawal, Imielinski, & Swami, 1993).

BACKGROUND

The goal of the data mining task is to find all frequent itemsets above a user specified threshold (called *support*) and to generate all association rules above another threshold (called *confidence*) using these frequent itemsets as input. This type of information could be used for catalogue design, store layout, product placement, target marketing, and so forth. The prototypical application of this task has been the market basket analysis, but the specific model is not limited to it since it can be applied to many other domains (e.g., text documents [Holt & Chung, 2001], census data, [Brin et al., 1997], telecommunication data and even medical images, etc.). In fact, any data set consisting of "baskets" containing multiple "items" can fit this model. Many solutions have been proposed in the last years using a sequential or a parallel paradigm, experimenting on factors such as memory requirements, I/O scans, dimensionality reduction, and so forth.

The specific problem was first introduced by Agrawal et al. (1993) and an algorithm by the name AIS was proposed for effectively addressing it. Agrawal and Srikant (1994) have introduced a much more efficient solution and two new algorithms by the names Apriori and AprioriTid were proposed. Algorithm Apriori has been and still is the major reference point for all subsequent works. Most algorithms and approaches proposed thereafter (Toivonen, 1996; Brin et al., 1997; Park, Chen, & Yu, 1995; Han, Pei, & Yin, 2000) focus on either decreasing the number of passes made over the data or at improving the efficiency of those passes (i.e., by using additional methods for pruning the number of candidates that have to be counted). Among other things studied in association rule mining are: (1) incremental updating (Cheung, Han, Ng, & Wong, 1996; Lee, Lin &Chen, 2001), (2) mining of generalized and multi-level rules (Han & Fu, 1995; Srikant &Agrawal, 1995), (3) using multiple minimum supports (Liu, Hsu, & Ma, 1999), (4) mining of quantitative rules (Srikant & Agrawal, 1996), (5) parallel algorithms (Agrawal & Shafer, 1996; Park, Chen, & Yu, 1995).

Lately, it has been widely accepted that the model of association rules is either oversimplified or suffers from several omissions that cannot nowadays be considered insignificant especially in a retail environment. For example, treating the items as mere statistical probabilities and neglecting their real significance or handling them as Boolean variables and not taking into consideration their exact number of appearances in every transaction leads to fragmentary and dubious results (Liu, Hsu, & Ma, 1999). In this article we present a collection of works trying to solve all these problems as

well as to address new ones. The main technical contribution of these works is the technically challenging assignment of weight values to different items in a given sell-period independently from other items; we call this process association rules mining since it tries with this careful selection of weights to mine suitable association rules. The focus of all these works is retail data and organizations.

IDENTIFYING THE "HOT" ITEMS WITHOUT GETTING BURNED

The idea behind association rule mining is to search a considerable amount of data collected over a long period and to apply various techniques to discover some more or less unseen knowledge hidden inside the data. However, one of the biggest omissions of the approaches used up to now was that they discovered long existing relations and rather ignored the emerging ones. All approaches up to now followed rather than kept up with the sales or, more generally, the appearances of the itemsets. What we need is an approach that finds emerging trends in the bud along with the long established ones. This situation can be explained better in the example next.

Let's suppose that there exists a product that is sold in a retail store for many years, with moderate sales as compared to all other products and another product that just entered the market (e.g., is on sale about a year) but has tremendous sales. Applying the classical statistical model of association rule mining, where we simply measure the number of appearances of every itemset and if it is above a user specified threshold it is considered as frequent, would unavoidably doom the new product. A product that is on sale for so little can not practically come even near the sales of a product that is on sale for so long. So one must either wait for so long as for the new products to sum enough sales, which could well take months or even years, or find a way to effectively take them into consideration as soon as possible. The same situation can take place with products that were on the market but with very low sales and suddenly begun to present abnormally high sales because they are currently under heavy promotion, they suddenly became in fashion, some external circumstances or factors (e.g., weather conditions) promoted their sales, and so forth. The specific situation is very usual, especially at retail stores where the items on sale present such behaviors. After all, this kind of bursty sales behavior in a retail organization is probably far more interesting than that of high selling but stable products.

Therefore, the notion of "hot" items has been introduced by Kouris, Makris, and Tsakalidis (2004b), where as "hot" is considered any item that presents very high sales in a certain period of time. More formally, for every 1-itemset the, so called, *interest ratio* is calculated, which is defined as the number of sales of an item in the last period of sales (i.e., from the last time the algorithm has run again) divided by the mean number of sales of all items in the same period.

$$\dot{r}_i = \frac{sales_i}{\overline{sales}}$$

Every item that has its interest ratio above a user defined threshold called minimum interest threshold is considered as "hot" for the specific period. Of course, if an item has a number of sales above the support threshold it is treated as a frequent item. In essence, the proposed algorithm searches for items that have sales below the support threshold, but their interest ratio is above the minimum interest threshold. The user has, of course, the option of giving to that threshold any value depending on the desired output.

A logical question could be what happens with an item that was "hot" in the previous period but is no longer "hot" or frequent in the next one. One option would be to treat these items as infrequent items in the new period since they are obviously no longer interesting for the users. Another one could be to give these items a grace period, and treat them as "hot", to see if they will come back to high sales. Either one is possible and acceptable and depends solely on the needs of the data miner. One, though, could claim that such items were wrongly considered as interesting since their subsequent trend showed that they are no longer "hot". Nevertheless, the algorithm managed to immediately identify the period that they became interesting, took them into consideration, and promoted their sales when they were actually very interesting and this was exactly the goal. If, on the other hand, a "hot" item becomes frequent in the next period then the algorithm managed to successfully predict its future performance early enough and to take it into consideration in advance rather than having to wait for it to actually become frequent.

ASSESSING THE IMPORTANCE OF ITEMS IN A RETAIL ORGANIZATION

In contrast to the assumption upon which all association rules approaches work, that is that the correct support value is already known, in practice the correct minimum support value is not known and can only be estimated based on domain knowledge or on previous experience. Also when talking about the "correct" value, this is judged after the completion of the mining process based on the number of discovered frequent itemsets (i.e., too few or too many itemsets as compared to what has been anticipated), or in other words through completely subjective and rather trivial criteria. Consequently, if the support threshold changes, then the mining has to be repeated from the beginning requiring

at least the same number of passes over the database as the previous run (if the new threshold is lower than before), and what's most important without being able to use knowledge from previous runs of the same algorithm. So, the whole process of assigning support values to all the items in a database has to be as accurate as possible in order to avoid unnecessary runs of the same algorithm over the data.

Association rules algorithms are very powerful tools but suffer from the drawback that they take no provision in the business value of items and the associations between them when determining the support of an item (Cabena, Hadjinian, Stadler, Verhess, & Zanasi, 1997), especially in retail organizations. As a consequence, the support assigned does not reflect the real value of the items, which in turn results in the homogenization of all items in any dataset. The specific problem was addressed in Kouris, Makris, and Tsakalidis (2004a), by using an efficient weighting scheme for assigning the correct minimum support values to all the items. The intuition was simple. Every item can have support at maximum: $max\ sup(i)=T_i/T_{total}$, where T_i is the number of transactions that an item appears in and T_{total} denotes the total number of transactions.

The closest the support of an item is set to its maximum support, the more appearances there are needed in order for it to quantify as a frequent and the less important it is considered. So the final support of an item is determined by multiplying the maximum support an item can have with a weight that reflects its importance according to the following formula: $\sup(i)=wf * \max \sup(i)$.

The value of *wf* reflects the answer to the following questions:

1. What are the net profits of an item compared to the average net profits from all itemsets in a dataset?
2. What are the total sales of an item compared to the average total sales from all itemsets?
3. What is the number of transactions an item appears in compared to the average number of transactions all items appear in?

These factors are combined in the following equation:

Equation 1

$$wf = \log_A\left(1+\frac{\overline{T}total}{T_i}+\frac{\overline{S}total}{S_i}+\frac{\overline{N}total}{N_i}\right)$$

where

$$A = \max\left(1+\frac{\overline{T}total}{T_i}+\frac{\overline{S}total}{S_i}+\frac{\overline{N}total}{N_i}\right)$$

where T_i is the number of transactions that an item apears in $\overline{T}_{total}$, is the average number of transactions all items appear in, S_i is the number of times an item appears in general in the database, $\overline{S}_{total}$ is the average number of appearances of all items, N_i is the net profit per item, and N_{total} is the average net profit from all items.

The main characteristic of the specific equation is that it takes into consideration all three factors, and an item must have all three factors small in order to be considered as very important. It is not enough for an item to appear in many transactions, or to appear many times in total, or to have large net profits in order to get a very low support value. It is the combination of all these three factors that make it most important. Also, in Equation 1, one is free to enter a different degree of influence to every factor he decides to. For example, if a company is more interested in increasing its market share (i.e., its actual sales) rather than its net profits, it could boost the effect of the factor

$$\frac{\overline{S}total}{S_i}$$

by multiplying it with a constant positive value below one.

The parameter *A* acts as a normalization factor in order to have the value of *wf* always less than 1 for every item. Note that altering the importance of various items can change the value of *A*, but this is desirable since *wf* estimates the relative importance of an item to the other items and not its absolute importance; hence, changes in other items' importance that could alter this value of *A* should be reflected to changes to the value of *wf*, for each item. Of course, the less important item would have *wf* value equal to 1.

Finally, it should be mentioned that the specific equation allows the introduction of any new factor a user considers important. Of course, the philosophy and the logic of this approach can be used with little modifications in all kinds of businesses and applications.

LOCALLY FREQUENT PRODUCTS

As interesting could be considered any item that should be taken into account when generating association rules, even if it fails to meet the minimum support or any other measure used for generating all frequent itemsets. Examples of criteria for interesting items could be the profit margin, the lifetime, the durability, and so forth. A large percentage of the products that are sold in a retail organization have a significant seasonal or more generally localistic behavior. This kind of products was the focus of the work of Bodon, Kouris, Makris, and Tsakalidis (2005), namely those items that are very frequent if considered in relation to a specific

part of the database, but their total number of appearances fails to exceed the minimum support value in the whole database. This part could correspond to sales made during a specific time period in a specific branch of an enterprise, and so forth. This case is very common and has extreme interest especially at large supermarkets or at retail stores where some products are on sale throughout the year whereas others only at a per season basis. Such products can reach support values of way over 60% at the specific periods with considerable profits, but the rest of the year they are not even at a shelf and, as a consequence, their overall support value becomes very low. So if one is to present a complete view of all rules concerning a dataset that truly reflects reality, these items must certainly be taken into account. This case arises frequently in many other situations too like, for example, with items bought at specific geographical areas only, or due to special circumstances, and so forth.

Essential to the approach is the distinction between the items that are frequent and the items that should be considered frequent in relation to a specific part of our database. An item is said to be locally frequent if its local frequency ratio is above a user specified threshold. As *local frequency ratio* (*LFR*) is defined to be the ratio of the number of occurrences of an item in a specific transactions interval divided by that interval.

LFR = Item interval count / Interval

If this ratio is above a user specified minimum, then this item is considered as a locally frequent item. The specific ratio depends heavily on the interval that is chosen to count the support of the items. In a dataset there may exist locally frequent itemsets of various orders (e.g., 1-itemsets, 2-itemsets, 3-itemsets, and so forth), and the user can define the order of itemsets in which he/she is interested.

FUTURE TRENDS

Concerning future trends, an interesting subject is the further employment of Markov models in the data mining arena (Giudici & Castelo, 2001, 2003). Another very interesting subject in the area right now is data mining for bioinformatics (Wang, Zaki, Toivonen, & Shasha, 2005). In Bioinformatics, data mining refers to finding and predicting motifs in sequences, to discover genetic mechanisms, to summarize clustering rules for multiple DNA or protein sequences and so on. Finally, program comprehension through data mining, is a promising area to most probably become the center of attention in the years to come; representative works can be found in Xiao and Tzerpos (2005), Chen, Tjortjis, and Layzell (2002), and Tjortjis and Layzel (2001).

CONCLUSION

Mining association rules especially from large databases of business data such as transactions records has been and probably will remain for quite a long the "hottest" topic in the area of data mining, mainly due to its large financial interest. In this article we have presented a collection of techniques and methodologies more oriented towards the practical side of the knowledge discovery process and especially for retail organizations and data. The main technical contribution of these techniques was the technically challenging association of weight values to different items; we call this process *association rules mining* since its purpose is to mine suitable association rules. These works manage to solve many ambiguities suffered from all previous methods and also describe and address novel problems in a way that is both efficient and effective.

KEY TERMS

Association Rules Mining: Finding frequent patterns, associations, correlations, or causal structures among sets of items or objects in transaction databases, and other information repositories.

Confidence: A statistical measure of importance that denotes the strength of implication.

Data Clustering: Clustering is the unsupervised classification of patterns (observations, data items, or feature vectors) into groups (clusters).

Data Mining: Analysis of data in a database using tools which look for trends or anomalies without knowledge of the meaning of the data. The nontrivial extraction of implicit, previously unknown, and potentially useful information from data. The science of extracting useful information from large data sets or databases.

"Hot" Itemsets: Itemsets that present abnormally high appearances as compared to the appearances of all other items but mainly as compared to their own previous number appearances.

Itemsets: A collection or a combination of items in a database.

Locally Frequent Itemsets: Itemsets that present a highly localized and condensed appearances behavior as compared to all other itemsets.

Support: A statistical measure of importance that indicates the frequencies of the occurring patterns in a rule.

Attribute Grammars and Their Applications

Krishnaprasad Thirunarayan
Wright State University, USA

INTRODUCTION

Attribute grammars are a framework for defining semantics of programming languages in a syntax-directed fashion. In this chapter, we define attribute grammars, and then illustrate their use for language definition, compiler generation, definite clause grammars, design and specification of algorithms, and so forth. Our goal is to emphasize its role as a tool for design, formal specification and implementation of practical systems, so our presentation is example rich.

BACKGROUND

The lexical structure and syntax of a language is normally defined using regular expressions and context-free grammars respectively (Aho, Lam, Sethi & Ullman et al., 2007,). Knuth (1968) introduced attribute grammars to specify static and dynamic semantics of a programming language in a syntax-directed way.

Let G = (N, T, P, S) be a context-free grammar for a language L (Aho et al., 2007). N is the set of non-terminals. T is the set of terminals. P is the set of productions. Each production is of the form A::= α, where A ∈ N and α ∈ (N U T)*. S ∈ N is the start symbol. An *attribute grammar* AG is a triple (G, A, AR), where G is a context-free grammar for the language, A associates each grammar symbol X ∈ N U T with a set of attributes, and AR associates each production R ∈ P with a set of attribute computation rules (Paakki, 1995). A(X), where X ∈ (N U T), can be further partitioned into two sets: synthesized attributes S(X) and inherited attributes I(X). AR(R), where R ∈ P, contains rules for computing inherited and synthesized attributes associated with the symbols in the production R.

Consider the following attribute grammar that maps bit strings to numbers. CFG = ({N},{0,1},P,N), where P is the left column of productions shown below. The number semantics is formalized by associating a synthesized attribute *val* with N, and providing rules for computing the value of the attribute *val* associated with the left-hand side N (denoted N_l) in terms of the value of the attribute *val* associated with the right-hand side N (denoted N_r), and the terminal.

N ::= 0	N.*val* = 0
N ::= 1	N.*val* = 1
N ::= N0	N_l.*val* = 2 * N_r.*val*
N ::= N1	N_l.*val* = 2 * N_r.*val* + 1

An attribute grammar involving only synthesized attributes is called an *S-attributed grammar*. It is straightforward to parse a binary string using this grammar and then compute the value of the string using a simple top-down left-to-right traversal of the abstract syntax tree.

The above attribute grammar is not unique. One can construct a different S-attributed grammar for the same language and the same semantics as follows.

N ::= 0	N.*val* = 0, N.*len* = 1
N ::= 1	N.*val* = 1, N.*len* = 1
N ::= 0N	N_l.*val* = N_r.*val*; N_l.*len* = N_r.len +1
N ::= 1N	N_l.*val* = 2^ N_r.*len* + N_r.*val*; N_l.*len* = N_r.len +1

Attribute grammars can be devised to specify different semantics associated with the same language. For instance, the bit string can be interpreted as a fraction by associating an inherited attribute *pow* to capture the left context—the length of the bit string between left of a non-terminal and the binary point, to determine the local value or the weight of the bit.

F ::= **.** N	F.*val* = N.*val*, N.*pow* = 1
N ::= 0	N.*val* = 0
N ::= 1	N.*val* = (1 / 2^ N.*pow*)
N ::= 0N	N_l.*val* = N_r.*val*; N_l.*pow* = N_r.pow +1
N ::= 1N	N_l.*val* = (1 / 2^ N.*pow*) + N_r.*val*; N_r.*pow* = N_l.pow +1

Each production is associated with attribute computation rules to compute the synthesized attribute *val* of the left-hand side non-terminal and the inherited attribute *pow* of the right-hand side non-terminal (we leave it as an exercise for the interested reader to devise an S-attributed grammar to capture this semantics).

APPLICATIONS OF ATTRIBUTE GRAMMARS

Attribute grammars provide a *modular framework* for formally specifying the semantics of a language based on its context-free grammar (or in practice, for conciseness, on its Extended Backus Naur formalism representation (Louden, 2003)). By *modular*, we emphasize its role in structuring specification that is incremental with respect to the produc-

tions. That is, it is possible to develop and understand the attribute computation rules one production at a time. By *framework*, we emphasize its role in structuring a specification, rather than conceptualizing the meaning. For instance, denotational semantics, axiomatic semantics, and operational semantics of a language can all be specified using the attribute grammar formalism by appropriately choosing the attributes (Louden, 2003). In practice, different programming languages interpret the same syntax/construct differently, and attribute grammars provide a framework for defining and analyzing subtle semantic differences.

In this section, we illustrate the uses and the subtleties associated with attribute grammars using examples of contemporary interest. Traditionally, attribute grammars have been used to specify various compiler activities formally. We show examples involving (i) type checking/inference (static semantics), (ii) code generation, and (iii) collecting distinct variables in a straight-line program. Attribute grammars can also be used to specify compiler generator activities. We show parser generator examples specifying the computation of (i) nullable non-terminals, (ii) first sets, and (iii) follow sets, in that sequence (Aho et al., 2007). Definite clause grammars enable attribute grammars satisfying certain restrictions to be viewed as executable specifications (Bratko, 2001). We exemplify this in SWI-Prolog. The essence of attribute grammars can be seen to underlie several database algorithms. We substantiate this by discussing the magic sets for optimizing bottom-up query processing engine. We also discuss how attribute grammars can be used for developing and specifying algorithms for information management (Thirunarayan, Berkovich, & Sokol, 2005).

Type Checking, Type Inference, and Code Generation

Consider a simple prefix expression language containing terminals {n, x, +}. The type of variable n is int, and the type of variable x is double. The binary arithmetic operation + returns an int result if both the operands are int, otherwise it returns a double. The type of a prefix expression can be specified as follows.

E ::= n E.*typ* = int
E ::= x E.*typ* = double
E ::= + E E E.*typ* = if E_{r1}.*typ* = E_{r2}.*typ*
then E_{r1}.*typ* else double

The corresponding executable specification in Prolog can be obtained by defining a binary relation 'typ' between prefix expression terms and their types as follows. Observe that each line of specification that ends in a "." is an axiom (first two are Prolog facts, while last two are Prolog rules), E, F, T, T1, and T2 are universally quantified Prolog variables, ":-" stands for *logical if*, and "," stands for *logical and*.

```
typ(i,int).
typ(x,double).
typ(+(E,F),T) :- typ(E,T), typ(F,T).
typ(+(E,F),real) :- typ(E,T1), typ(F,T2),  T1 \= T2.
```

A type checking query '?- typ(+(n,x),int).' verifies if the expression '+(n,x)' is of type int, while a type inference query '?- typ(+(n,x),T).' determines the type of the expression '+(n,x)'.

Attribute grammar specifying the translation of an equivalent expression language containing infix + into Java bytecode in the context of the instance method definition: 'class { double f(int n, double i) { return E;}}' is as follows:

E ::= n E.*code* = [iload_1]
E ::= x E.*code* = [dload_2]
E ::= E + E E.*code* = if E_{r1}.*typ* = int
then if E_{r2}.*typ* = int
then E_{r1}.*code*@E_{r2}.*code*@[iadd]
else E_{r1}.*code*@[i2d]@E_{r2}.*code*@[dadd]
else if E_{r2}.*typ* = int
then E_{r1}.*code*@E_{r2}.*code*@[i2d,dadd]
else E_{r1}.*code*@E_{r2}.*code*@[dadd]

The attribute *typ* has been specified earlier. The attribute *code* is bound to a list of Java bytecode. '@' refers to list append operation. Java compiler maps the formal parameters n and x to register 1, and register pair 2 and 3, respectively. (The double value requires two registers.) iload_1 (dload_2) stands for pushing the value of the int n (double x) on top of the stack; dadd (iadd) stands for popping the top two double (int) values from the stack, adding them, and pushing the result on top of the stack; and i2d stands for coercing an int value into a double value (Lindholm & Yellin, 1999). (Note that + is left associative in Java.) In practice, the code generator has to cater to variations on whether the method is static or instance, whether the formal arguments require 4 or more registers, whether the arguments are of primitive types or reference types, etc, and all this can be made explicit via attribute grammars.

Collecting Distinct Identifiers

We use the example of collecting distinct identifiers in an expression to illustrate the influence of primitive data types available for specifying the semantics on the ease of writing specifications, and the rules of thumb to be used to enable sound and complete attribute computation in one-pass using top-down left-to-right traversal of the abstract syntax tree.

<exp> ::= <var> | <exp> + <exp>

Suppose we have ADT SET available to us as a primitive. We associate synthesized attributes *id* and *ids* with <var> and <exp> respectively, to obtain the following attribute grammar. ('∪' refers to set-union.)

<exp> ::= <var>	<exp>.*ids* = { <var>.*id* }
<exp> ::= <exp> + <exp>	<exp>.*ids* = <exp>.*ids* U <exp>.*ids*

Instead, if we have only ADT LIST available to us, we associate synthesized attribute *envo* and inherited attribute *envi* of type list of symbols with <exp>, to obtain the following attribute grammar.

<exp> ::= <var>	<exp>.*envo* = if <var>.id ∈ <exp>.*envi* then <env>.*envi* else cons(<var>.*id*, <env>.*envi*)
<exp> ::= <exp> + <exp>	$<exp_{r1}>$.*envi* = $<exp_{l}>$.*envi* $<exp_{r2}>$.*envi* = $<exp_{r1}>$.*envo* $<exp_{l}>$.*envo* = $<exp_{r2}>$.*envo*

Observe that, given the definition of the attributes and the production rule, one can *automatically* determine the left-hand sides of the attribute computation rules required. *There is one rule for each synthesized attribute of the left-hand side non-terminal, and one rule for each inherited attribute of the right-hand side symbol (non-terminal).*

<exp>	::=	<exp>	+ <exp>
↓ envi		↓ *envi*	↓ *envi*
↑ *envo*		↑ envo	↑ envo

For the above production, the attributes shown in italics need to be determined using the attributes given in italics. *To enable one-pass top-down left-to-right computation of the attributes, each inherited attribute of the right-hand side symbol can depend on all the attributes associated with preceding right-hand side symbols and the inherited attribute of the left-hand side non-terminal. Similarly, the synthesized attribute of the left-hand side non-terminal can depend on all the attributes associated with all the right-hand side symbols and the inherited attribute of the left-hand side non-terminal.* Effectively, the inherited attribute associated with the left-hand side non-terminal provides context information from the parent and the left siblings, while the synthesized attributes of the right-hand side non-terminals provide information from their descendants.

From modularity perspective, if the attribute computation rules associated with each production satisfies the above constraints, it can be argued using induction principle that all the attributes associated with each node in the abstract syntax tree will be well-defined after one-pass of computation.

In practical compiler construction, a programming language is specified to a parser generator as an S-attributed grammar that transforms a program into its abstract syntax tree. This abstract syntax tree is traversed multiple times for semantic analysis and code generation. The APIs of the meta-language provide primitive functions and data types for defining and implementing semantic actions (attribute computations). For example, bottom-up parser generator Bison is based on C/C++ libraries, top-down parser generator ANTRL is based on Java APIs, and so forth.

Definite Clause Grammars

Prolog's definite clause grammars can be used to execute the set-based and the list-based attribute grammars discussed earlier. Each DCG rule resembles a production with the predicate name corresponding to the non-terminal and the formal arguments corresponding to the attributes. The input string is encoded as a list of symbols (tokens). Upon loading, the DCG rules are automatically translated into ordinary Prolog rules using difference-list implementation (Bratko, 2001). As a result, the predicate exp in the query has two additional arguments than are found in the DCG specification. The semantic action code inside curly braces incorporates calls to SWI-Prolog library functions.

The DCG corresponding to the set-based attribute grammar is as follows.

```
exp(Ids)    →   aexp(Ids).
exp(Ids)    →   aexp(Ids1), ['+'] , exp(Ids2), {union(Ids1,Ids2,Ids)}.
aexp([Id])  →   [Id], {atom(Id)}.

/* ?- exp(Vs, [x, '+', y, '+', z, +, y],[]). */
/* Vs = [x, z, y] ; */
```

The DCG corresponding to the list-based attribute grammar is as follows.

```
exp(Envi,Envo)   → aexp(Envi,Envo).
exp(Envi,Envo)       →      aexp(Envi,EnvT), ['+'] , exp(EnvT,Envo).
aexp(Envi,Envo)      →      [Id], {atom(Id)},
                            {member(Id,Envi) -> Envo = Envi;
                                    Envo = [Id | Envi]}.

/* ?- exp([],Vs, [x, '+', y, '+', z, +, y],[]). */
/* Vs = [z, y, x] ; */
```

The sample queries and the results have been commented out. Refer to (Bratko, 2001) for DCG details.

Specifying Compiler Generator Operations

Attribute grammars can be used to formalize and implement parser generators (Thirunarayan, 1984). For instance, consider the computation of nullable non-terminals, first-sets associated with non-terminals and follow-sets associated with non-terminals. A non-terminal is *nullable* if it can derive a null string. The *first-set* associated with a non-terminal is the set of tokens that can begin a string derivable from the non-terminal. The *follow-set* associated with a non-terminal is the set of tokens that can come after the non-terminal in a sentential form. These can be specified for an expression grammar along the lines indicated below. (Only partial specification has been given.)

S ::= T E
E ::= ε | + S
T ::= x | y

S.*nullable* = T.*nullable* and E.*nullable*
E.*nullable* = true
T.*nullable* = false

S.*first-set* = if T.*nullable* then T.*first-set* ∪ E.*first-set* else T.*first-set*
E.*first-set* = {ε , +}
T.*first-set* = {x , y}

T.*follow-set* = if E.*nullable* then S.*follow-set* ∪ E.*first-set* else E.*first-set*
S.*follow-set* = E.*follow-set*
E.*follow-set* = S.*follow-set*

The dependencies among the various attributes can be exploited to sequence their computation in three phases: compute *nullable* first, followed by *first-sets*, followed by *follow-sets* (Bochmann, 1976). Each phase can potentially require multiple iterations to converge to a fixed-point. The *nullable* is a synthesized attribute and requires multiple bottom-up pass. The *first-set* is also a synthesized attribute computed using multiple bottom-up left-to-right pass. The *follow-set* is an inherited attribute computed using multiple top-down right-to-left pass.

Optimizing Bottom-up Database Query Evaluation

Top-down query evaluation and bottom-up query evaluation are two well-known deductive database query implementation strategies (Ramakrishnan & Sudarshan, 1991). In top-down approach, the query solution tree is grown from the root (goal) to the leaves (data), applying the datalog (function-free Horn-logic or Prolog) rules from left to right. It is potentially incomplete in the presence of left-recursive rules, but it is efficient because the bindings in the queries are propagated to the base relations (data). In bottom-up approach, the query solution tree is grown from the leaves (data) to the root (goal), applying the datalog rules from right to left. It is complete, but can be inefficient because the search is not goal directed. Memoing techniques can be used to improve top-down strategy by making its search complete, while magic predicates can be employed to improve bottom-up strategy by making it more focused and efficient (Beeri & Ramakrishnan, 1987). The ideas underlying the definition of magic predicates and sideways information processing are reminiscent of attribute computation rules involving inherited and synthesized attributes as explained and illustrated in the following.

Consider the definition of the ancestor relation based on the parent relation, and the ancestor query with the first argument bound.

```
ancestor(X,Y) :- parent(X,Y).
ancestor(X,Y) :- parent(X,Z), ancestor(Z,Y).
?- ancestor(john, N).
```

In order to explore only a small fragment of the necessary parent facts to compute the query answers using naïve bottom-up approach, it is important to restrict the "firing" of the second rule. This can be done by transforming the second rule using *magic* predicates so that it is satisfied only for the ancestors of john as follows.

```
magic(john).
magic(Z) :- magic(X), parent(X,Z).
ancestor(X,Y) :- magic(X), parent(X,Y).
ancestor(X,Y) :- magic(X), parent(X,Z), ancestor(Z,Y).
```

The rules for *magic* predicate are analogous to the computation of attributes. The first fact corresponds to the inherited attribute value corresponding to the first argument of ancestor initialized by the top-level query. The second rule corresponds to the computation of additional inherited attribute values corresponding to the first argument of ancestor obtained through sideways information passing of the synthesized attribute from the parent relation. Beeri and Ramakrishnan (1987) provide several additional examples embodying attribute grammars ideas for query optimization.

Specifying Algorithms for Customized Information Extraction

In this section, we discuss an information extraction problem of industrial significance that has benefited from attribute grammar based algorithm specification. We skip the detailed specification *per se* due to space constraints.

A typical materials and process spec (from authoring organizations such as GE, Pratt and Whitney, ASTM, AMS, and so forth) contains requirements for making and testing a variety of alloys. A typical customer order specifies the desired material in terms of the specs it must conform to, and a collection of domain-specific product parameters such as product type, spec class, product dimension and cross-section, etc. A fundamental operation of interest on a spec is the determination of applicable fragments of the spec for a customer order. The goal of coarse-grain extraction is to convert a spec into a form that can be evaluated against the order parameters to determine applicable fragments.

To balance the commercial viability of the extraction task and its tractability, a spec is transformed into a possibly, nested sequence of conditioned notes of the form "If CONDITIONS Then [Note = " ... "]", where the note contains contiguous block of spec text. These extractions are cheap to produce because the detailed requirements are still in text.

In order to formalize conditioned notes, we need to propose a structure for the conditional expression and the note it qualifies. The conditional expression can be formed

using characteristic names (e.g., spec class, alloy, product type, etc.), constants, relational symbols (e.g., `=', `$>$', etc.), and boolean connectives (e.g., `and', `or', etc) in the standard way. The note can be defined in quanta of (sub)-sections and paragraphs. Thus, there are two important technical problems to be solved for carrying out extraction: (1) identification of the values of a characteristic that can appear as a condition, and (2) transformation of the relevant spec text into a sequence of conditioned notes.

The conditioned notes can be specified in terms of the scope rules of applicability of characteristic-value pairs to the spec text fragments. For instance, to associate a spec class with a section or a paragraph, we use the following heuristic: Every (sub-)section is conditioned on all spec classes named in section 'scope.' Explicit spec class references in a paragraph override the default condition. Otherwise, a paragraph inherits the condition from its left sibling (earlier paragraph), or transitively from its parent (enclosing (sub-)section). The rationale behind the heuristic is that, when the conditionals in an extraction are evaluated against the given condition values, it should generate all applicable fragments of the spec.

To abstract the algorithmic details of the extraction, the structure of a spec can be captured using EBNF as:

```
<document> ::= <document-header> <section>+
<section> ::= <sectionNumber> <sectionHeading> <paragraph>+ <section>*
```

and the computation of the conditioned notes involving spec classes can be given using attribute grammars. There are many other qualifiers of interest besides spec classes such as products, product types, alloys, and so forth. (See Thirunarayan et al., 2005 for a detailed attribute grammar specification.)

FUTURE TRENDS

Information flow ideas underlying attribute grammars can provide a general framework for designing and specifying algorithms. For example, Neven (2005), and Neven and Den Bussche (2002) demonstrate the influence of attribute grammars on query languages.

Web technologies such as XML/XSLT that are based on adorned context-free grammars can benefit from techniques developed for attribute grammars (Harold, 2004). Conceptually, an XML document consists of annotations, where each annotation consists of an associated XML-element that reflects the semantic category to which the corresponding text fragment belongs, and the associated XML-attributes that are bound to relevant semantic values. Overlaying domain-specific XML tags on a text document enables abstraction, formalization, and in-place embedding of machine-processable semantics. In the future, we can expect the annotated data to be interpreted by viewing it as a function/procedure call, and defining the XML-element as a function/procedure in a language such as XSLT or Water for associating different collections of behaviors with XML-elements (Thirunarayan, 2005).

CONCLUSION

Historically, attribute grammars were developed in the context of compiler construction. We provided several examples illustrating the application of attribute grammars for static analysis of programs, for program translation, and for specifying certain phases of a parser generator. We also provided general principles for developing attribute grammar specifications for efficient one-pass computation of attributes. We introduced Prolog's definite clause grammars to enable attribute grammars to be viewed as executable specifications. We showed how the information flow ideas implicit in the attribute computation rules can be exploited to optimize bottom-up evaluation of datalog programs. Finally, we discussed the application of attribute grammars for specifying information extraction algorithms, and its future role in XML technologies.

KEY TERMS

A

Attribute Computation Rules: Rules used to compute attributes, usually defined in terms of other attributes and standard primitives.

Attribute Grammar: An attribute grammar is an extension of context-free grammar that enables definition of context-sensitive aspects of a language and its translation.

DCG: A definite clause grammar is a Prolog built-in mechanism for implementing attribute grammars efficiently using difference lists.

EBNF: Extended Backus Naur formalism is an extension of context-free grammar with regular expression operations for defining context-free languages. It provides a more concise syntax specification.

Inherited Attributes: These attributes pass information from root to the leaves of a parse tree, or sideways among siblings.

Machine-Processable Semantics: Metadata added to the documents to enable machines to understand and reason with text or multi-media content.

Synthesized Attributes: These attributes pass information from leaves to the root of a parse tree.

XML/XSLT: Extensible markup l,anguage is a meta-language for creating markup languages. XML is a subset of SGML. XHTML is an instance of XML. Extensible stylesheet language transformations is a language for manipulating XML documents.

Audience-Driven Design Approach for Web Systems

Olga De Troyer
WISE Research Group, Belgium

INTRODUCTION

In the last years, Web systems have evolved from a simple collection of hypertext pages toward applications supporting complex (business) applications, offering (rapidly changing) information and functionality to a highly diversified audience. Although it is still easy to publish a couple of pages, it is now recognized that appropriate Web design methods are needed to develop more complex Web sites and applications (generally called Web systems). In the past, Web systems were created opportunistically without prior planning or analysis, and without any regard for methodology, resulting in Web systems that were lacking consistency in structure, navigation, and presentation, and were not transparent. A lot of these systems were also suffering from the classical maintenance problems and development backlog. In the same period, Web technology evolved at an equally dazzling rate enabling more advanced Web applications, but with the unfavorable consequence that Web development is no longer simple and easy. The latest developments in the field of the Web are related to the vision of the Semantic Web: an extension of the current Web in which information is given well-defined meaning, better enabling computers, and people to work in cooperation (Berners-Lee, Hendler, & Lassila, 2001).

Together with the Web, a new problem unknown in classical information systems emerged: competition for the visitor's attention. Especially for commercial Web systems, it is important to hold the interest of the visitors and to keep them coming back. As stated by usability expert Nielsen (2000, p. 9), "all the competitors in the world are but a mouse click away." Much more than in "classical" software systems, the usability of Web systems is a primary factor for their success.

BACKGROUND

One way to deal with the usability of a Web system is by assessing the usability once the system is built and improving it if necessary. The techniques for accessing the usability of a Web system are mainly the same as those used in usability testing of classical user interfaces, for example, heuristic evaluation, expert-based evaluation, experimental evaluation, interviews, questionnaires, and so forth (Nielsen & Mack, 1994). Also, different tools are developed that support assessing the usability of Web sites (e.g., WebQuilt [Hong, Heer, Waterson, & Landay, 2001; Vanderdonckt, Beirekdar, & Noirhomme-Fraiture, 2004], and the full-featured experimentation environment of Noldus [www.noldus.com]). Another approach to enhance usability (and complementary to the first approach) is to use a Web design method that ensures a higher usability. The first Web design methods, HDM (Garzotto, Paolini, & Schwabe, 1993) and its successors HDM2 (Garzotto, Paolini, & Mainetti, 1993) and OOHDM (Schwabe & Rossi, 1995), and RMM (Isakowitz, Stohr, & Balasubramanian, 1995), were originally designed for hypertext applications or came from the database research community. These methods used database design methods like E-R (Chen, 1976) or OMT (Rumbaugh, Blaha, Premerlani, Eddy, & Lorensen, 1991), and focused on the organization of the data to be presented on the Web. These methods could solve to some extent maintenance problems, but they did not address usability. Essential for achieving a good usability in Web systems is meeting the needs of the (different) visitors. WSDM was one of the first Web design method to recognize this. This method was presented at the WWW7 conference (1998) as a "user-centered" design method for Web sites (De Troyer & Leune, 1998). The starting point in the approach is the set of potential visitors (audiences) of the Web system. The method recognizes that different types of visitors have different needs and that this should drive the design of the Web system rather than the organization of the available data. Later on (De Troyer, 2001), the authors renamed their approach from "user-centered" to "audience-driven," to avoid confusion with the term "user-centered" from the HCI (human-computer interaction) field. In HCI, a user-centered approach refers to a design process in which users are actively involved (by interviews, scenario analysis, prototyping, evaluation, etc.). This explicit involvement is not necessary in WSDM. On the contrary, the individual Web users are unknown during the Web development process; they cannot be interviewed in advance, and they cannot be involved in the development process. In the audience-driven approach as defined by WSDM, the users play a central role, but it is not necessary to involve them actively in the development process.

Since the late 1990s, several Web design methods have been conceived. Some examples are WebML (Ceri, Fraternali, & Bongio, 2000), UWE (Koch & Kraus, 2001), HERA (Houben, Barna, Frasincar, & Vdovjak, 2003), OO-H (Gómez, Cachero, & Pastor, 2003), SHDM (Schwabe, Szundy, de Moura, & Lima, 2004), and Co-Design (Schewe & Thalheim, 2005). Some of these design methods focus on adaptivity or personalization as a way to enhance the usability. These methods use a user model to adapt the Web system to the needs or characteristics of an individual user. This implies that a particular Web system will look different to two different users, or even that the system will look different when the same user revisits it. Although personalization may be undoubtedly a good solution in some situations (e.g., e-learning, e-commerce), in other situations it may be less appropriate (e.g., regular Web systems). In this article, we will not consider personalization as a way to enhance usability.

When designing a Web system, there are two important questions to be answered:

1. What information and services should be provided?
2. How should all this information and services be structured?

To answer these questions, different design approaches can be followed. One of them is the *audience-driven* approach. Other possible approaches are the *data-driven* approach and the *organization-driven* approach.

In a data-driven approach, the data (and services) available in the organization (in databases, brochures, internal documents, etc.) are the design's starting point. Following this approach, the structure of the Web system will reflect the way the data are structured and maintained in the organization, and the content will parallel the internal data. The same applies for services or functionality. Forms available in the organization will be converted into e-forms, and the current way of working will be reflected in the Web system. The advantage is that structuring the information and services is easy and that the maintenance can be done in parallel with the maintenance of the internal data and procedures. However, the disadvantages are: (1) the data are presented and organized the way they are used in the organization. This is not necessarily how people external to the organization need it or perceive it; (2) information or services may be missing because it was not available in the form of a specific document or existing procedure and the designers were not aware of the fact that users may need this; (3) all information and all services are offered to all users. As a consequence, visitors may be drowned in information.

In an organization-driven approach, the internal structure of the organization is the starting point: the structure of the Web system reflects the structure of the organization. This approach is often used for large organizations with a lot of divisions, for example, a university Web system that reflects its internal structure into faculties, departments, and research institutes. As for the data driven approach, it is easy to structure the Web system, and the development and maintenance of the different parts can be assigned to the different divisions of the organization. The disadvantage is that it may be very difficult for visitors not familiar with the internal structure of the organization to know where to look for information or services.

In the audience-driven approach, the information and services needed in the Web system are determined by the needs and requirements of the target audiences (users). Also the main structure of the Web system will be based on the different types of audiences and their requirements. This last point differentiates the audience-driven approach from many so-called user-centered approaches. We illustrate this with an example, a university Web site. Following the audience-driven approach, the university Web site would (at least) contain a part with general information interesting to all visitors; a part with information specific for students and lecturers; and a part containing information for researchers and third parties interested in research. The audience-driven approach gives consideration to the fact that (large) Web systems usually have different types of visitors that may have different needs. Clearly, such Web systems will have a higher usability than the ones structured using a data-driven or organization-driven approach. However, the downsides of the medal are that the effort needed to design the Web system is higher and that the task of maintaining may be spread over the organization (usually, there will be no one-to-one mapping from the structure of the Web system onto the structure of the organization).

THE AUDIENCE-DRIVEN APPROACH

As explained in the introduction, an audience-driven design approach means that the different target audiences (visitors) and their requirements are taken as starting points for the design and that the main structure of the Web system is derived from this. Concretely, this results in a Web system where the homepage contains different navigation paths (called audience tracks), one for each different kind of visitor.

To arrive to such an audience-driven organization of the Web system, the different types of audiences and their needs are identified already in an early stage of the design process (Casteleyn & De Troyer, 2001). One way to identify the different types of audiences is by looking at the activities of the organization relevant for the Web system and the role people play in these activities. These people are the potential users (audiences) of the Web system. For example, the activities of a university are "performing research," "giving courses," and "advising third parties." The people involved are researchers, students, potential students, teaching staff,

and third parties. Next, the people identified, are classified into *audience classes* by collecting their requirements (information-, as well as functional- and usability requirements), that is, we establish what kind of information those people want to find on the Web system (information requirements), what kind of functionality they expect (functional requirements), and which special needs they have from a usability point of view, for example, advanced search functionality (usability requirements). Users with the same information and functional requirements become members of the same audience class. Whenever the information and functional requirements of a set of users differ, a new audience class is defined, or if possible, an audience subclass is introduced. An audience class is a subclass of another audience class if the members of the subclass have all the same information- and functional requirements as the members of the superclass but also some extra requirements. If possible, the activities we started from are decomposed in order to refine the audience classes. This may introduce more audience subclasses. In this way, a hierarchy of audience classes can be constructed. The top of the audience class hierarchy is always the audience class visitor, which represents all target users. The requirements associated with the visitor class are the requirements that are common to all users. The requirements associated with a particular audience class are specific for the members of this audience class.

The audience class hierarchy is the basis for the main structure of the Web system. For each audience class, a separate *audience track* will be created. Such an audience track can be considered as a subsystem containing all and only the information and functionality needed by the members of the associated audience class. To fill in the detailed navigation and content of such a track, the different requirements of the corresponding audience class are considered. This is done as follows. With each requirement formulated for this audience class, a task is provided in the audience track that a user can choose when he or she wants to satisfy this requirement. The task will provide the necessarily information and functionality by means of nodes and links that can be followed. For a simple information requirement, this means that a node will be provided containing the necessarily information. For a functional requirement (i.e., booking a flight), nodes offering the necessary information and functionality will be provided connected by navigational links respecting the workflow of the task. Details on how this can be achieved are given by De Troyer and Casteleyn (2003).

Next to the fact that different types of users (audiences) may have different information and functional requirements, it may be necessary to represent the (same) information or functionality in different ways to different kinds of users. This depends on the characteristics of the users. As an example we again consider the university example. Potential students, especially secondary school students are not familiar with the university jargon and should be addressed in a young and dynamic way. Also, by preference, the information should be offered in the native language. The enrolled students are familiar with the university jargon. They also prefer to have the information in the native language; however, for foreign students (e.g., who follow exchange programs) English should be used as communication language. For researchers, it may be sufficient to use English. This can be taken into consideration by specifying for each audience class identified, the characteristics of its members. Examples of characteristics are level of experience with the Web in general, frequency of use, language issues, education/intellectual abilities, age, income, lifestyle, and so forth. Some of the characteristics may be translated into usability requirements, while others may be used to guide the design of the "look and feel" of the different navigation tracks, for example, choice of colors, fonts, graphics, and so forth.

FUTURE TRENDS

In the last years, many different researchers have recognized the need to take the users into consideration during the Web development process and adopted either the user-centered approach from the HCI field (as in Cato, 2001; Lazar, 2001; McCracken & Wolfe, 2004) or an approach similar to WSDM's audience-driven approach (with respect to the fact that it is necessary to give due attention to the users but not necessary to actively involve them in the design process) (as in Bomsdorf & Szwillus, 2003; Brinck, Gergle, & Wood, 2002; Lengels, 2002; McCracken & Wolfe, 2004). More and more, we see that due consideration is given to usability in general, but also to more specific issues such as accessibility for people with disabilities, localization, personalization, and context-awareness. One approach to the accessibility problem consists of stimulating people to design Web systems with accessibility in mind. In this context design guidelines are developed that Web developers can use to ensure that their Web system is accessible to people with disabilities (see the W3C Web Content Accessibility Guidelines [http://www.w3.org/WAI/]), and software exists that can be used to test if a Web system is conforming to these recommendations (e.g., W3C Markup Validation service [http://validator.w3.org]). Others try to automatically transform existing Web pages into a form more appropriate for disabled persons (e.g., Aurora [Huang & Sundaresan, 2000]), while also work is in progress to approach the problem from a Web engineering approach ensuring that Web systems are inherently accessible (e.g., Plessers et al., 2005). In the context of the Web, localization deals with adapting or preparing Web systems to be able to deal with the requirements of different local communities: different language, different regulations, and different culture (see, i.e., De Troyer et al., 2006, or De Troyer & Casteleyn, 2004). As already mentioned, personalization is used to adapt the content, structure and presentation of a Web system to

the needs of a particular user. This has proven to be useful in, for example, online shops to offer customized services and recommendations to the customer, or in e-learning systems to offer an individualized learning plan. Context-awareness aims at achieving a similar goal, but instead of adapting to the individual user, the system is adapted to the context in which it is used, for example, to the device on which it is used (PDA, mobile phone, etc.), the location, or the available connection. Sometimes, both are combined (such as in Ceri, Daniel, & Matera, 2003).

CONCLUSION

There exist different approaches to elicit and structure the information and services in a Web system. In the audience-driven approach, this is done by taking the different audiences of the Web system as the starting point. This results in Web systems where the information and the services are organized according to the needs of the different audience classes. This may result in higher usability, which is a primary factor for the success of Web systems.

KEY TERMS

Accessibility: People with disabilities can perceive, understand, navigate, and interact with the Web, and they can contribute to the Web.

Audience Class: Group of target visitors of a Web system with the same requirements.

Audience-Driven Web Design: The different audiences and their requirements are taken as the starting point for the design of the Web system. The information and services in the Web system are organized around these different audiences.

Audience Track: Part of the Web system that provides information and services specifically tailored to a particular audience class.

Context-Awareness: Property of devices or systems that have information about the circumstances under which they operate and can react accordingly. Context-aware systems may also try to make assumptions about the user's current situation (also called personalization).

Data-Driven Web Design: The data available in the organization are taken as the starting point for the design of the Web system.

Localization: In Web design and software, localization refers to the adaptation of language, content, and design to reflect local cultural sensitivities.

Organization-Driven Web Design: The structure of the organization is taken as the starting point for the design of the Web system. The structure of the organization is reflected in the Web system.

Usability: The extent to which a product or system can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use.

User-Centered Web Design: The requirements of the users of a Web system play a central role in the design process.

Audio Analysis Applications for Music

Simon Dixon
Austrian Research Institute for Artificial Intelligence, Austria

INTRODUCTION

The last decade has seen a revolution in the use of digital audio: The CD, which one decade earlier had taken over the home audio market, is starting to be replaced by electronic media which are distributed over the Internet and stored on computers or portable devices in compressed formats. The need has arisen for software to manage and manipulate the gigabytes of data in these music collections, and with the continual increase in computer speed, memory and disk storage capacity, the development of many previously infeasible applications has become possible.

This article provides a brief review of automatic analysis of digital audio recordings with musical content, a rapidly expanding research area which finds numerous applications. One application area is the field of music information retrieval, where content-based indexing, classification and retrieval of audio data are needed in order to manage multimedia databases and libraries, as well as being useful in music retailing and commercial information services. Another application area is music software for the home and studio, where automatic beat tracking and transcription of music are much desired goals. In systematic musicology, audio analysis algorithms are being used in the study of expressive interpretation of music. Other emerging applications which make use of audio analysis are music recommender systems, playlist generators, visualisation systems, and software for automatic synchronisation of audio with other media and/or devices.

We illustrate recent developments with three case studies of systems which analyse specific aspects of music (Dixon, 2004). The first system is BeatRoot (Dixon, 2001a, 2001c), a beat tracking system that finds the temporal location of musical beats in an audio recording, analogous to the way that people tap their feet in time to music. The second system is JTranscriber, an interactive automatic transcription system based on (Dixon, 2000a, 2000b), which recognizes musical notes and converts them into MIDI format, displaying the audio data as a spectrogram with the MIDI data overlaid in piano roll notation, and allowing interactive monitoring and correction of the extracted MIDI data. The third system is the Performance Worm (Dixon, Goebl, & Widmer, 2002), a real-time system for visualisation of musical expression, which presents in real time a two dimensional animation of variations in tempo and loudness (Langner & Goebl, 2002, 2003).

Space does not permit the description of the many other music content analysis applications, such as: audio fingerprinting, where recordings can be uniquely identified with a high degree of accuracy, even with poor sound quality and in noisy environments (Wang, 2003); music summarisation, where important parts of songs such as choruses are identified automatically; instrument identification, using machine learning techniques to classify sounds by their source instruments; and melody and bass line extraction, essential components of query-by-example systems, where music databases can be searched by singing or whistling a small part of the desired piece. At the end of the article, we discuss emerging and future trends and research opportunities in audio content analysis.

BACKGROUND

Early research in musical audio analysis is reviewed by Roads (1996). The problems that received the most attention were pitch detection, spectral analysis and rhythm recognition, areas which correspond respectively to the three most important aspects of music: melody, harmony and rhythm.

Pitch detection is the estimation of the fundamental frequency of a signal, usually assuming it to be monophonic. Methods include: time domain algorithms such as counting of zero-crossings and autocorrelation; frequency domain methods such as Fourier analysis and the phase vocoder; and auditory models which combine time and frequency domain information based on an understanding of human auditory processing. Recent work extends these methods to find the predominant pitch (e.g., the melody note) in a polyphonic mixture (Gómez, Klapuri, & Meudic, 2003; Goto & Hayamizu, 1999).

Spectral analysis is a well-understood research area with many algorithms available for analysing various classes of signals, such as the short time Fourier transform, wavelets and other more signal-specific time-frequency distributions. Building upon these methods, the specific application of automatic music transcription has a long research history (Chafe, Jaffe, Kashima, Mont-Reynaud, & Smith, 1985; Dixon, 2000a, 2000b; Kashino, Nakadai, Kinoshita, & Tanaka, 1995; Klapuri, 1998, 2003; Klapuri, Virtanen, & Holm, 2000; Marolt, 1997, 1998, 2001; Martin, 1996; Mont-Reynaud, 1985; Moorer, 1975; Piszczalski & Galler, 1977; Sterian, 1999; Watson, 1985). Certain features are

common to many of these systems: producing a time-frequency representation of the signal, finding peaks in the frequency dimension, tracking these peaks over the time dimension to produce a set of partials, and combining the partials to produce a set of notes. The differences between systems are usually related to the assumptions made about the input signal (e.g., the number of simultaneous notes, types of instruments, fastest notes, or musical style), and the means of decision making (e.g., using heuristics, neural nets or probabilistic reasoning).

The problem of extracting rhythmic content from a musical performance, and in particular finding the rate and temporal location of musical beats, has also attracted considerable interest in recent times (Allen & Dannenberg, 1990; Cemgil, Kappen, Desain, & Honing, 2000; Desain, 1993; Desain & Honing, 1989; Dixon, 2001a; Eck, 2000; Goto & Muraoka, 1995, 1999; Large & Kolen, 1994; Longuet-Higgins, 1987; Rosenthal, 1992; Scheirer, 1998; Schloss, 1985). Previous work had concentrated on rhythmic parsing of musical scores, lacking the tempo and timing variations that are characteristic of performed music, but recent tempo and beat tracking systems work quite successfully on a wide range of performed music.

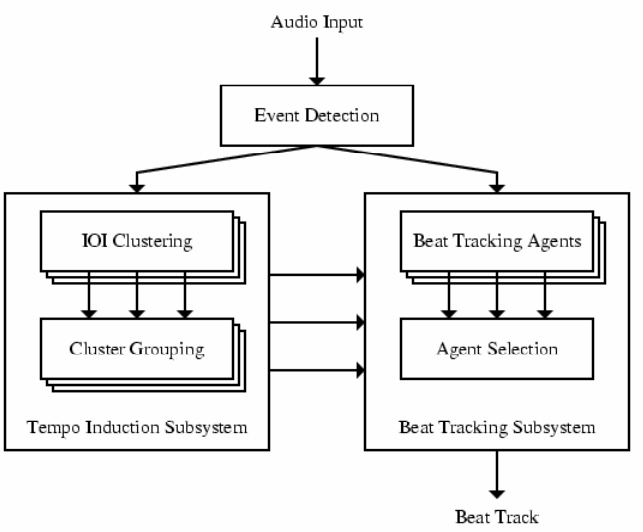
Music performance research is only starting to take advantage of the possibility of audio analysis software, following work such as Scheirer (1995) and Dixon (2000a). Previously, general purpose signal visualisation tools combined with human judgement had been used to extract performance parameters from audio data. The main problem in music signal analysis is the development of algorithms to extract sufficiently high level content, since it requires the type of musical knowledge possessed by a musically literate human listener. Such "musical intelligence" is difficult to encapsulate in rules or algorithms that can be incorporated into computer programs. In the following sections, three systems are presented which take the approach of encoding as much as possible of this intelligence in the software and then presenting the results in an intuitive format which can be edited via a graphical user interface, so that the systems can be used in practical settings even when not 100% correct. This approach has proved to be very successful in performance research (Dixon et al., 2002; Goebl & Dixon, 2001; Widmer, 2002; Widmer, Dixon, Goebl, Pampalk, & Tobudic, 2003).

BEATROOT

Compared with complex cognitive tasks such as playing chess, beat tracking (identifying the basic rhythmic pulse of a piece of music) does not appear to be particularly difficult, as it is performed by people with little or no musical training, who tap their feet, clap their hands or dance in time with music. However, while chess programs compete with world champions, no computer program has been developed which approaches the beat tracking ability of an average musician, although recent systems are approaching this target. In this section, we describe BeatRoot, a system which estimates the rate and times of musical beats in expressively performed music (for a full description, see Dixon, 2001a, 2001c).

BeatRoot models the perception of beat by two interacting processes (see Figure 1): The first finds the rate of

Figure 1. System architecture of BeatRoot



the beats (tempo induction), and the second synchronises a pulse sequence with the music (beat tracking). At any time, there may exist multiple hypotheses regarding each of these processes; these are modelled by a multiple agent architecture in which agents representing each hypothesis compete and cooperate in order to find the best solution. The user interface presents a graphical representation of the music and the extracted beats, and allows the user to edit and recalculate results based on the editing. Input to BeatRoot is either digital audio or symbolic music data such as MIDI. This data is processed off-line to detect salient rhythmic events, using an onset detection algorithm which finds peaks in the slope of the amplitude envelope of the signal (or a set of frequency bands of the signal). The timing of these events is then analysed to generate hypotheses of the tempo at various metrical levels.

First, inter-onset intervals (IOIs), the time differences between pairs of onsets, are calculated, and then a clustering algorithm is used to find groups of similar IOIs which represent the various musical units (e.g., half notes, quarter notes). Information about the clusters is combined by identifying near integer relationships between clusters, in order to produce a ranked list of tempo hypotheses, which is then passed to the beat tracking subsystem.

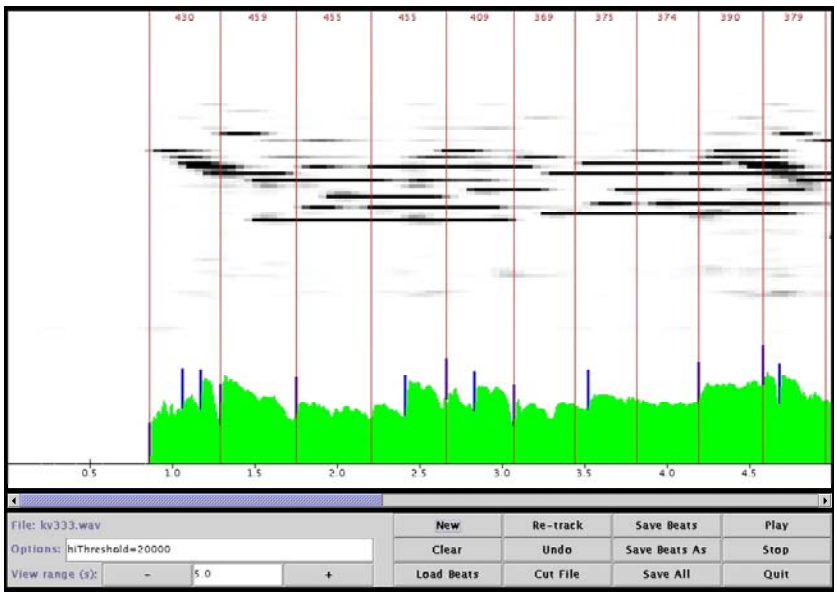
The beat tracking subsystem uses a multiple agent architecture to find sequences of events which match the various tempo hypotheses, and rates each sequence to determine the most likely sequence of beat times. Each agent represents a specific hypothesis about the rate and the timing of the beats, which is updated as the agent matches the detected onsets to predicted beat times. The agent also evaluates its beat tracking, based on how evenly the beat times are spaced, how many predicted beats correspond to actual events, and the salience of the matched events, which is calculated from the signal amplitude at the time of the onset. At the end of processing, the agent with the highest score outputs its sequence of beats as the solution to the beat tracking problem.

BeatRoot is written in Linux/C++, and comprises about 10,000 lines of code, with a graphical user interface consisting of 1,000 lines of Java. The user interface allows playback of the music with the beat times marked by clicks, and provides a graphical display of the signal and the beats with editing functions for correction of errors or selection of alternate metrical levels (Figure 2). BeatRoot is open source software (under the GNU Public License), and is available from:

http://www.oefai.at/~simon/beatroot

The lack of a standard corpus for testing beat tracking creates a difficulty for making an objective evaluation of the system. The automatic beat tracking algorithm has been tested on several sets of data: a set of 13 complete piano sonatas, a large collection of solo piano performances of two Beatles songs and a small set of pop songs. In each case, the system found an average of over 90% of the beats (Dixon, 2001a), and compared favourably to another state of the art

Figure 2. Screen shot of BeatRoot processing the first five seconds of a Mozart piano sonata, showing the inter-beat intervals in ms (top), calculated beat times (long vertical lines), spectrogram (centre), waveform (below) marked with detected onsets (short vertical lines) and the control panel (bottom)



tempo tracker (Dixon, 2001b). Tempo induction results were almost always correct, so the errors were usually related to the phase of the beat, such as choosing as beats onsets half way between the correct beat times. Interested readers are referred to the sound examples at:

http://www.oefai.at/~simon

Presently, BeatRoot is being used in a large scale study of interpretation in piano performance (Widmer, 2002; Widmer et al., 2003), to extract symbolic data from audio CDs for automatic analysis.

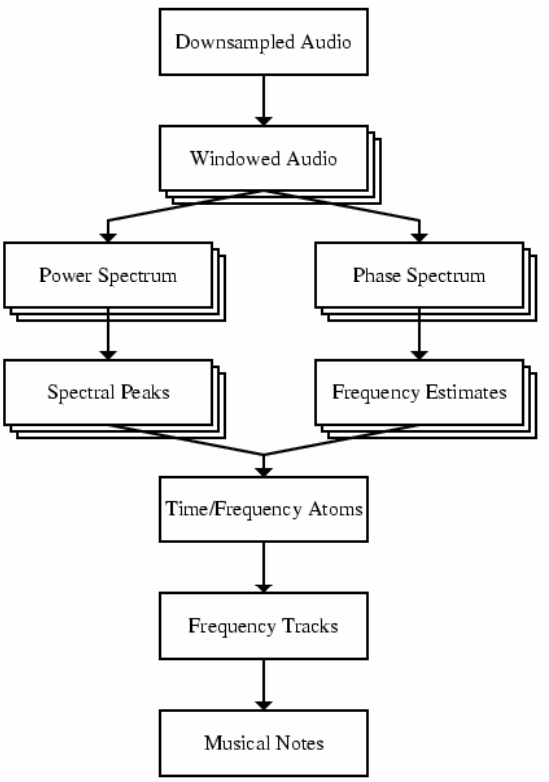
JTRANSCRIBER

The goal of an automatic music transcription system is to create, from an audio recording, some form of symbolic notation (usually common music notation) representing the piece that was played. For classical music, this should be the same as the score from which the performer played the piece. There are several reasons why this goal can never be fully reached, for example, that there is no one-to-one correspondence between scores and performances, and that masking makes it impossible to measure everything that occurs in a musical performance. Recent attempts at transcription report note detection rates around 90% for solo piano music (Dixon, 2000a ; Klapuri, 1998; Marolt, 2001), which is sufficient to be somewhat useful to musicians.

A full transcription system is normally conceptualised in two stages: the signal processing stage, in which the pitch and timing of all notes is detected, producing a symbolic representation (often in MIDI format), and the notation stage, in which the symbolic data is interpreted in musical terms and presented as a score. This second stage involves tasks such as finding the key signature and time signature, following tempo changes, quantising the onset and offset times of the notes, choosing suitable enharmonic spellings for notes, assigning notes to voices in polyphonic passages, and finally laying out the musical symbols on the page. Here, we address only the first stage of the problem, detecting the pitch and timing of all notes, or in more concrete terms, converting audio data to MIDI.

The data is processed according to Figure 3: The audio data is averaged to a single channel and downsampled to increase processing speed. A short time Fourier transform (STFT) is used to create a time-frequency image of the signal, with the user selecting the type, size and spacing of the

Figure 3. Data processing steps in JTranscriber



windows. Using a technique developed for the phase vocoder (Flanagan & Golden, 1966), a more accurate estimate of the sinusoidal energy in each frequency bin can be calculated from the rate of change of phase in each bin.

The next step is to calculate the peaks in the magnitude spectrum, and to combine the frequency estimates to give a set of time-frequency atoms, which represent packets of energy localised in time and frequency. These are then combined with the atoms from neighbouring frames (time slices), to create a set of frequency tracks, representing the partials of musical notes. Frequency tracks are assigned to musical notes by estimating the most likely set of fundamental frequencies that would give rise to the observed tracks, and the pitch, onset time, duration and amplitude of each note are estimated from its constituent partials.

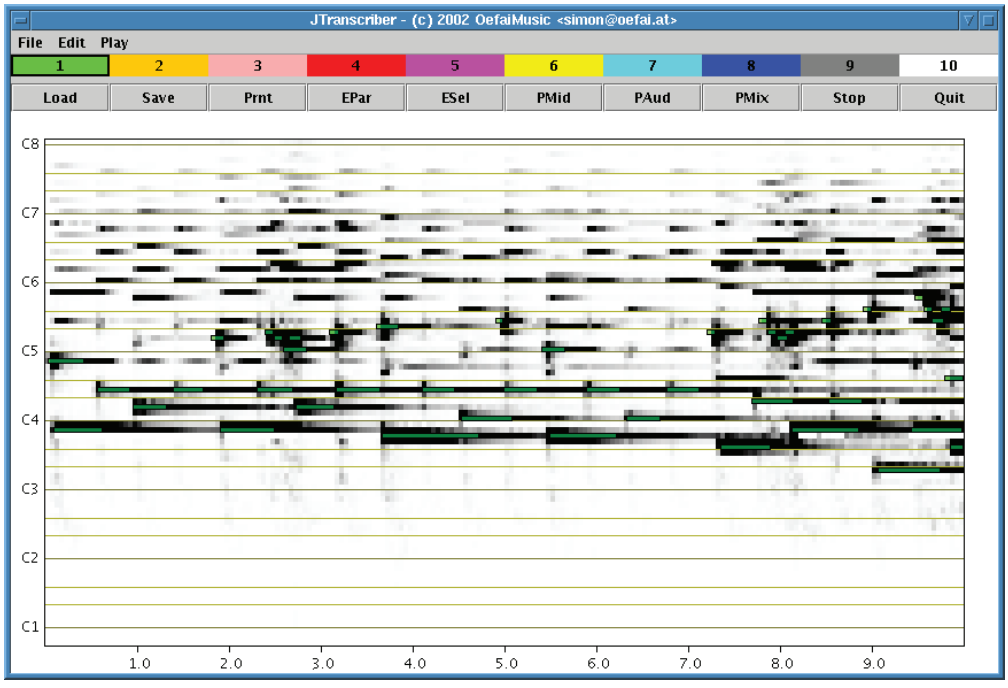
An example of the output is displayed in Figure 4, showing a spectrogram representation of the signal using a logarithmic frequency scale, labelled with the corresponding musical note names, and the transcribed notes superimposed over the spectrogram in piano roll notation. (The piano roll notation is colour and partially transparent, whereas the spectrogram is black and white, which makes the data easily distinguishable on the screen. In the grey-scale diagram, the coloured notes are difficult to see; here they are surrounded by a solid frame to help identify them.) An interactive editing system allows the user to correct any errors made by the automatic transcription system, and also to assign notes to different voices (different colours) and insert high level musical structure information. It is also possible to listen to the original and reconstructed signals (separately or simultaneously) for comparison.

An earlier version of the transcription system was written in C++, however the current version is implemented entirely in Java. The system was tested on a large database of solo piano music consisting of professional performances of 13 Mozart piano sonatas, or around 100,000 notes (Dixon, 2000a), with the results that approximately 10-15% of the notes were missed, and a similar number of the reported notes were false. The most typical errors made by the system are thresholding errors (discarding played notes because they are below the threshold set by the user, or including spurious notes which are above the given threshold) and octave errors (or more generally, where a harmonic of one tone is taken to be the fundamental of another, and vice versa).

THE PERFORMANCE WORM

Skilled musicians communicate high-level information such as musical structure and emotion when they shape the music by the continuous modulation of aspects such as tempo and loudness. That is, artists go beyond what is prescribed in the score, and express their interpretation of the music and their individuality by varying certain musical parameters within

Figure 4. Transcription of the opening 10s of the second movement of Mozart's Piano Sonata K332. The transcribed notes are superimposed over the spectrogram of the audio signal (see text). It is not possible to distinguish fundamental frequencies from harmonics of notes merely by viewing the spectrogram.



acceptable limits. This is referred to as expressive music performance, and is an important part of Western art music, particularly classical music. The Performance Worm (Dixon et al., 2002) is a real-time system for tracking and visualising the tempo and dynamics of a performance in an appealing graphical format which provides insight into the expressive patterns applied by skilled artists. This representation also forms the basis for automatic recognition of performers' style (Widmer, 2002; Widmer et al., 2003).

The system takes input from the sound card (or from a file), and measures the dynamics and tempo, displaying them as a trajectory in a 2-dimensional performance space (Langner & Goebl, 2002, 2003). The measurement of dynamics is straightforward: It can be calculated directly as the RMS energy expressed in decibels, or, by applying a standard psychoacoustic calculation (Zwicker & Fastl, 1999), the perceived loudness can be computed and expressed in sones. The difficulty lies in creating a tempo tracking system which is robust to timing perturbations yet responsive to changes in tempo. This is performed by an adaptation of the tempo induction subsystem of BeatRoot, modified to work in real time. The major difference is the online IOI clustering algorithm, which continuously outputs a tempo estimate based only on the musical data up to the time of processing. The clustering algorithm finds groups of IOIs of similar duration in the most recent eight seconds of music, and calculates a weighted average IOI representing the tempo for each cluster. The tempo estimates are adjusted to accommodate information from musically-related clusters, and then smoothed over time by matching each cluster with previous tempo hypotheses. Figure 5 shows the development over time of the highest ranked tempo hypothesis with the corresponding dynamics.

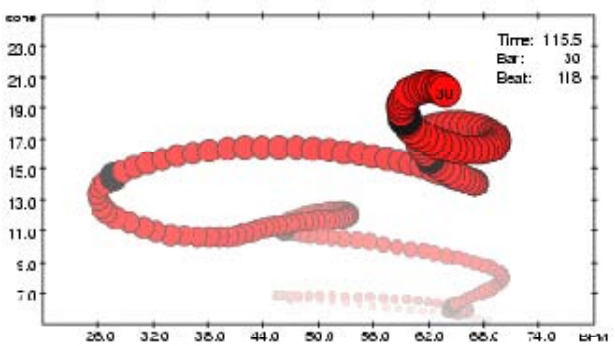
The Performance Worm is implemented in about 4,000 lines of Java, and runs in real time on standard desktop computers. The graphical user interface provides buttons for scaling and translating the axes, selecting the metrical level, setting parameters, loading and saving files, and playing, pausing and stopping the animation.

Apart from the real-time visualisation of performance data, the Worm can also load data from other programs, such as the more accurate beat tracking data produced by BeatRoot. This function enables the accurate comparison of different performers playing the same piece, in order to characterise the individual interpretive style of the performer. Current investigations include the use of AI pattern matching algorithms to learn to recognize performers by the typical trajectories that their playing produces.

FUTURE TRENDS

Research in music content analysis is progressing rapidly, making it difficult to summarise the various branches of investigation. One major initiative addresses the possibility of interacting with music at the semantic level, which involves the automatic generation of metadata, using machine learning and data mining techniques to discover relationships between low-level features and high-level concepts. Another important trend is the automatic computation of

Figure 5. Screen shot of the performance worm showing the trajectory to bar 30 of Rachmaninov's Prelude op.23 no.6 played by Vladimir Ashkenazy. The horizontal axis shows tempo in beats per minute, and the vertical axis shows loudness in sones. The most recent points are largest and darkest; the points shrink and fade into the background as the animation proceeds.



musical similarity for organising and navigating large music collections. For other developments in this area, interested readers are referred to the web site at:

http://www.semanticaudio.org

CONCLUSION

The three systems discussed are research prototypes, whose performance could be improved in several ways, for example, by specialisation to suit music of a particular style or limited complexity, or by the incorporation of high-level knowledge of the piece being analysed.

This is particularly relevant to performance research, where the musical score is usually known. By supplying a beat tracking or performance analysis system with the score, most ambiguities are resolved, giving the possibility of a fully automatic and accurate analysis.

Both dynamic programming and Bayesian approaches have proved successful in score following (e.g., for automatic accompaniment, Raphael, 2001), and it is likely that one of these approaches would also be adequate for our purposes. A more complex alternative would be a learning system which automatically extracts the high-level knowledge required for the system to fine-tune itself to the input data (Dixon, 1996). In any case, the continuing rapid growth in computing power and processing techniques ensures that content-based analysis of music will play an increasingly important role in many areas of human interaction with music.

ACKNOWLEDGMENT

The Austrian Research Institute for Artificial Intelligence ackowledges the financial support of the Austrian Federal Ministry for Education, Science and Culture (BMBWK) and the Austrian Federal Ministry for Transport, Innovation and Technology (BMVIT). This work was supported by the START programme (project Y99-INF) of the BMBWK. Special thanks to the Bösendorfer Company, Vienna, for performance data used in this work.

KEY TERMS

Automatic Transcription: The process of extracting the musical content from an audio signal and representing it in standard music notation.

Beat Tracking: The process of finding the times of musical beats in an audio signal, including following tempo changes, similar to the way that people tap their feet in time to music.

Clustering Algorithm: An algorithm which sorts data into groups of similar items, where the category boundaries are not known in advance.

Frequency Domain: The representation of a signal as a function of frequency, for example as the sum of sinusoidal waves of different amplitudes and frequencies.

Music Content Analysis: The analysis of an audio signal in terms of higher-level (cognitive) properties such as melody, harmony and rhythm, or in terms of a description of the signal's component sounds and the sound sources which generated them.

Music Information Retrieval: The research field concerning the automation of access to music information through the use of digital computers.

Onset Detection: The process of finding the start times of notes in an audio signal.

Time Domain: The representation of a signal, such as the amplitude or pressure of a sound wave, as a function of time.

Authentication Methods for Computer Systems Security

Zippy Erlich
The Open University of Israel, Israel

Moshe Zviran
Tel-Aviv University, Israel

INTRODUCTION

With the rapid growth of networked systems and applications such as e-commerce, the demand for effective computer security is increasing. Most computer systems are protected through a process of user identification and authentication. While identification is usually non-private information provided by users to identify themselves and can be known by system administrators and other system users, authentication provides secret, private user information which can authenticate their identity. There are various authentication approaches and techniques, from passwords to public keys (Smith, 2002).

This article presents the three main authentication approaches, their technology and implementation issues, and the factors to be considered when choosing an authentication method.

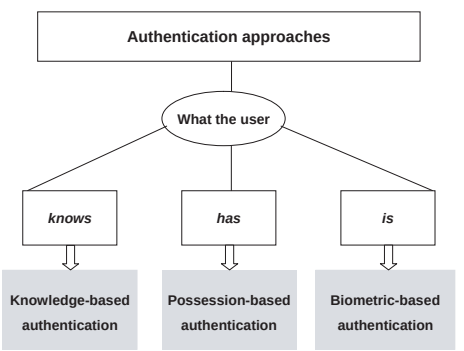
BACKGROUND

Even before computers came along, a variety of distinguishing characteristics were used to authenticate people. Computer systems have applied these characteristics for user authentication. The authentication approaches can be classified into three types according to the distinguishing characteristics they use (Menkus, 1988), as presented in Figure 1:

- What the user *knows*—knowledge-based authentication (e.g., password, PIN, pass code)
- What the user *has*—possession-based authentication (e.g., memory card and smart card tokens)
- What the user *is*—biometric-based authentication: physiological (e.g., fingerprint) or behavioral (e.g., keyboard dynamics) characteristics

As all these authentication types have benefits and drawbacks, trade-offs need to be made among security, ease of use, and ease of administration. Authentication types can be implemented alone or in combination. To strengthen the authentication process, the use of at least two types is recommended. Multiple layers of different types of authentication provide substantially better protection.

Figure 1. Classification of authentication methods

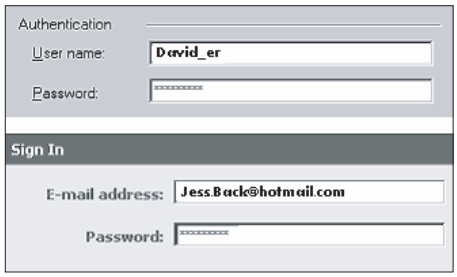


KNOWLEDGE-BASED AUTHENTICATION

The most widely used type of authentication is knowledge-based authentication. Examples of knowledge-based authentication include passwords, pass phrases, or pass sentences (Spector & Ginzberg, 1994), graphical passwords (Thorpe & Van Oorschot, 2004; Wiedenbeck, Waters, Birget, Brodskiy, & Memon, 2005), pass faces (Brostoff & Sasse, 2000) and personal identification numbers (PINs). To verify and authenticate users over an unsecured public network, such as the Internet, digital certificates and digital signatures are used. They are provided using a public key infrastructure (PKI) which consists of a public and a private cryptographic key pair (Adams & Lloyd, 1999).

The traditional, and by far the most widely used, form of authentication based on user knowledge is the password (Zviran & Haga, 1993). Most computer systems are protected through user identification (like user name or user e-mail address) and a password, as shown in Figure 2.

Figure 2. Authentication through user identification and password



A password is conceptually simple for both system designers and end users. It consists of a secret series of characters according to some predefined rules. The user ID and password pair acts as user identification and authentication and serves to block unauthorized access to computing resources. In most systems, it can provide effective protection if used correctly.

However, passwords are known to suffer from a number of pitfalls due to human information processing limitations (Sasse, Brostoff, & Weirich, 2001; Yan, Blackwell, Anderson, & Grant, 2005). First, there is a trade-off between memorability and security. Passwords should be difficult to guess and easy to remember. The fact that difficult-to-guess and difficult-to-crack passwords are difficult to remember and that easy to remember passwords are easy to guess and easy to crack poses a dilemma for the generation of passwords. The most secure password is a random string of characters. Such passwords are difficult to guess by others, but at the same time are difficult to remember and thus compel the users to write them down, which impairs their secrecy. Moreover, most users have multiple passwords for different systems and applications, forcing them to remember several passwords. In order to help them to remember the passwords, they usually choose meaningful strings such as names, nicknames, or initials (Adams & Sasse, 1999), which are easy to remember but also easy to crack. They also tend to duplicate their passwords and thus cause the domino effect of password reuse (Ives, Walsh, & Schneider, 2004); namely, all the systems with the same password are no more secure than the weakest system using this password.

In order to improve password security and protect it from dictionary and brute force attacks, password policy should implement rules for choosing and maintaining passwords (Smith, 2002). The major rules are:

- Non-dictionary and no-name passwords.
- Long enough passwords with mixed types of characters.
- Password ageing and not reusing.
- Complex passwords using acronyms, rhymes, and mnemonic phrases, which are difficult to guess and easy to remember (Carstens, McCauley-Bell, Malone, & DeMara, 2004; Yan et al., 2005).
- Passwords should not be shared and should not be written down.
- The number of unsuccessful authentication attempts should be limited by the system.
- Passwords should never be stored in clear text; they should be encrypted or hashed.

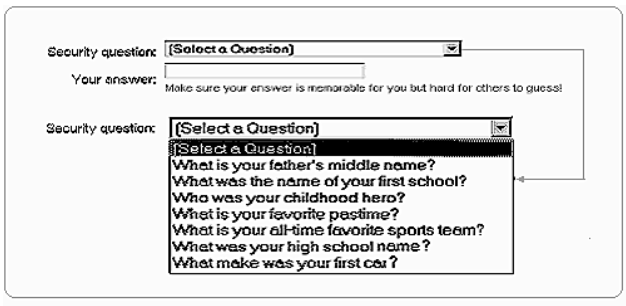
Passwords based on the aforementioned rules are more effective, more difficult to identify and to determine by cracking utilities. To overcome the problem of sniffing passwords when authentication is performed over the Internet, one-time passwords are used. The one-time password can be implemented using smart cards—a kind of possession-based authentication discussed hereafter.

Passwords, used as the first level of authentication, that allow access to information system resources through operating systems are commonly referred to as *primary passwords*. Passwords used as the second level of authentication, for further control and protection of multi-level access to segments of these resources, such as sensitive applications or data files, are commonly referred to as *secondary passwords* (Zviran & Haga, 1993).

In determining primary passwords, the operating system manufacturer uses system-generated passwords or user-generated passwords with predefined rules. User-generated passwords are shown to be easier to remember but less secure than system-generated passwords as they can be easily guessed (Lopez, Oppliger, & Pernul, 2004).

In order to overcome the difficulty of remembering passwords, a *question-and-answer password* method has been suggested (Haga & Zviran, 1991). This method is mainly used for secondary passwords. It involves a dialogue between the user and the system, as shown in Figure 3.

Figure 3. Example of a question-and-answer password



In a typical question-and-answer session, the user is presented with several randomly selected brief questions from a set of questions stored in his or her profile in the operating system. Access to a system or to a particular application is granted only upon a match between the user's answers and those stored in his/her profile.

The two main types of question-and-answer passwords are: *cognitive passwords* and *associative passwords* (Bunnell, Podd, Henderson, Napier, & Kennedy-Moffat, 1997; Haga & Zviran, 1991; Zviran & Haga, 1993). In cognitive passwords, the user must provide the system with answers to personal fact-based or opinion-based questions, such as the user's mother's maiden name (fact-based) or user's favorite type of music (opinion-based).

In associative passwords, the user must provide the system with a set of word associations, consisting of both cues and their unique associated responses.

POSSESSION-BASED AUTHENTICATION

Possession-based authentication, referred to also as token-based authentication, is based on what the user has. It makes use mainly of physical objects that a user possesses, like tokens. Aside from the fact that presentation of a valid token does not prove ownership, as it may have been stolen or duplicated by some sophisticated fraudulent means (Svigals, 1994), there are problems of administration and of the inconvenience to users of having to carry them.

Tokens are usually divided into two main groups: *memory tokens* and *smart tokens*. Memory tokens store information but do not process it. The most common type of memory token is the magnetic card, used mainly for authentication together with a knowledge-based authentication mechanism such as a PIN. Memory tokens are inexpensive to produce. Using them with PINs provides significantly more security than PINs or passwords alone.

Unlike memory tokens, smart tokens incorporate one or more embedded integrated circuits which enable them to process information. Like memory tokens, most smart tokens are used for authentication together with a knowledge-based authentication mechanism such as a PIN. Of the various types of smart tokens, the most widely used are those that house an integrated chip containing a microprocessor. Their portability and cryptographic capacity have led to their wide use in many remote and e-commerce applications (Juang, 2004; Ku & Chen, 2004; Wu & Chieu, 2003). Due to their complexity, smart tokens are more expensive than memory tokens but provide greater flexibility and security and are more difficult to forge. Because of their high security level, smart tokens are also used for one-time passwords for authentication across open networks.

BIOMETRIC-BASED AUTHENTICATION

Biometric-based authentication is based on what the user is, namely, automatic identification using certain anatomical, physiological or behavioral features and characteristics associated with the user (Kim, 1995; Wayman, Jain, Maltoni, & Maio, 2004). Biometric authentications are based on the fact that certain physiological or behavioral characteristics reliably distinguish one person from another. Thus, it is possible to establish an identity based on who the user is, rather than on what the user possesses or knows and remembers. Biometrics involves both the collection and the comparison of these characteristics. A biometric system can be viewed as a pattern recognition system consisting of three main modules: (1) the sensor module, (2) the feature extraction module, and (3) the feature matching module. The users' personal attributes are captured and stored in reference files to be compared for later authentication to determine if a match exists. The accuracy of the different biometric systems can be evaluated by the measurement of two types of errors (Matyas & Stapleton, 2000): (1) erroneous rejection, that is, false non-match (type I error), and (2) erroneous acceptance, that is, false match (type II error). In a biometric system that provides a high level of authentication, the rate of these two errors is low.

Biometric authentications are technically complex and usually expensive as they require special hardware. Although all biometric technologies inherently suffer from some level of false match or false non-match, they have a high level of security. Despite their high security, they do not have a high acceptance rate by users as they are perceived to be intrusive and an encroachment on privacy (Prabhakar, Pankanti, & Jain, 2003) through automated means. They also raise ethical issues of potential misuse of personal biometrics such as for tracking and monitoring productivity (Alterman, 2003). Thus, they are not popular and mainly used in systems with very high levels of security.

The emergence of biometric authentication addressed the problems that plagued traditional verification methods, providing the most effective and accurate identification method with an edge over traditional security methods in that it cannot be easily stolen or shared. Biometric systems also enhance user convenience by alleviating the need to determine and remember passwords. However, while convenient, the digital scan or pattern is vulnerable to network analysis and once stolen, can no longer be used (Ives et al., 2004).

There are various kinds of biometrics (Matyas & Stapleton, 2000) and they are usually divided into two main categories: physiological and behavioral biometrics. Physiological biometrics are based on the user's stable physical attributes. The best known are fingerprints, finger scans, hand geometry, iris scans, retina scans, and facial scans. Fingerprints are the most widely used physiological characteristic in systems that automatically recognize a user's identity (Ratha

& Bolle, 2005; Wayman et al., 2004). An example of one of its up-to-date applications is the use of fingerprint-based identification and authentication to support online, Web-based course examinations (Auernheimer & Tsai, 2005).

Behavioral biometrics are based on users' behavioral attributes that are learned movements (Guven & Sogukpinar, 2003; O'Gorman, 2003; Yu & Cho, 2004). The best known are: keystroke dynamics, signature dynamics, mouse dynamics, and speech or voice verification.

FACTORS IN CHOOSING AN AUTHENTICATION METHOD

In choosing an authentication method a number of factors need to be considered: effectiveness, ease of implementation, ease of use, and user attitude and acceptance (Furnell, Dowland, Illingworth, & Reynolds, 2000). Table 1 shows the ranking of the three authentication types according to these four factors.

The knowledge-based authentication type is inexpensive and easy to implement and change. Unfortunately, it is also the easiest to compromise and is less secure than tokens or biometric-based authentication methods, which are inherently more secure. On the other hand, tokens and biometric-authentication methods are more expensive to implement. User attitudes towards knowledge-based authentication are highly positive, less positive towards possession-based authentication, and negative towards biometric-based authentication (Deane, Barrelle, Henderson, & Mahar, 1995; Prabhakar et al., 2003). As knowledge-based authentication is less effective than the other types, it is recommended that it be used in two-type authentication; for example, a password and a token or a password and a keystroke (Furnell, Papadopoulos, & Dowland, 2004; Yu & Cho, 2004).

Passwords provide the most cost effective solution, they are portable to other applications, easy to deploy and scale to an unlimited number of users. They are integrated into many operating systems and users are familiar with them. Improved security can be achieved with a secondary technique, like a cognitive or associative password.

Possession-based authentication using tokens provides higher security than knowledge-based authentication. Most of the problems associated with tokens relate to their cost, administration, loss, and user dissatisfaction. Because of vulnerability to theft, a token should not be used alone but with another authentication type. When combined with a password, it can provide major advantages as it can store or generate multiple passwords, and the user has to remember only the single password needed to access the token.

Table 1. Ranking of authentication types from 1 (low) to 3 (high)

	Factor			
Authentication type	Security effectiveness	Ease of implementation	Ease of use	User attitude and acceptance
Knowledge-based	1	3	3	3
Possession-based	2	2	2	2
Biometric-based	3	1	1	1

FUTURE TRENDS

Since passwords are comparatively inexpensive, simple to use, and attractive to users, they will probably continue to be the most widely used form of authentication in the foreseeable future. When properly managed and controlled, they can provide effective security. Further research is needed on the three authentication types to improve and enhance their technologies and to enable the design of more usable and effective security systems.

CONCLUSION

Computer systems are protected by three main types of authentication approaches: (1) knowledge-based, (2) possession-based, and (3) biometric-based. Each of these has both benefits and drawbacks. When choosing an authentication method we have to consider the trade-off among security effectiveness, ease of implementation, ease of use, and user attitude and acceptance. In order to strengthen the authentication process, the use of at least two-type authentication is recommended.

Overall, there is no one best solution to the user authentication problems. Multiple layers of protection provide substantially better security.

KEY TERMS

Associate Password: A question-and-answer password in which the user provides the system with associated responses to rotating cues.

Authentication: Verifying the identity of the user. There are three main approaches to user authentication: knowledge-based, possession-based, and biometric-based.

Biometric-Based Authentication: An authentication based on what the user is—unique physiological characteristics such as fingerprints or behavioral characteristics such as keyboard dynamics.

Cognitive Password: A question-and-answer password in which the user provides the system with answers to personal, fact-based questions such as the user's mother's maiden name, or opinion-based questions such as the user's favorite type of music.

Identification: The activity of users who supply information to identify themselves, such as name, user name, and user ID.

Knowledge-Based Authentication: An authentication based on what the user knows, such as password, PIN, and pass code.

Password: Knowledge-based authentication consisting of a secret series of characters according to predefined rules. It is the most widely used mechanism of authentication.

Possession-Based Authentication: An authentication based on what the user has, such as memory cards and smart card tokens. Possession-based authentication is also referred to as token-based authentication.

Question-and-Answer Password: A session in which a user is presented with several randomly selected questions from a set of questions stored in the user's profile in the operating system. The user's answers are compared to match with those stored in the profile. The two main types of question-and-answer passwords are cognitive passwords and associative passwords.

Autognomic Intellisite

Jon Ray Hamann
University at Buffalo, State University of New York, Baird Research Park, USA

INTRODUCTION

The 20th century saw the beginning of the evolution of learning machines from the growth of Boolean computers into Bayesian inference machines (Knuth, 2003). For some this is the crux of Artificial Intelligence (AI); however, AI research generally has yielded a plethora of specifically engineered, but formally unrelated, theories/models with varied levels of applications successes/failures, but without a commonly-explicatable conceptual foundation (i.e., it has left a *theory-glut*). Despite these many approaches to AI, including Automated Neural Nets, Natural Language Processing, Genetic Algorithms, Fuzzy Logic and Fractal Mathematical computational approaches, to identify only a few, AI itself has remained an elusive goal to achieve by means of a systems architecture relying on an implementation based on the systemic computer paradigm.

The 21st century experience is overwhelmingly one of an ever-accelerating, dynamically changing world. Just staying in place seems nearly impossible—getting ahead is becoming increasing unfathomable in a world now characterized by an evolving dominance of Information Science and Technology Development in exponentially tighter (shorter) innovation cycles (IBM, 2008). In business, for example, there is the continuous challenge to ensure that the business's products appear obviously differentiated from the competition, while staying current with the never-ending hot new trends that buffet the industry. A prime case in point is that of staying current with the trends in the computer solutions industry since adapting a computer dependent business (and most are) for the *next big trend* can be expected to be mitigated, if not made completely obsolete, by the *next next big trend* already on the radar screen.

BACKGROUND

It is becoming increasingly evident to a growing number of key decision makers that innovation development and management demands a technological assist (Roco & Bainbridge, 2002). This technology, however, must dramatically Augment Human Intelligence in the near future while moving toward a General Autonomous Artificial Intelligence in the longer term (Singularity Institute for Artificial Intelligence, Inc., 2001). Despite the recognition that meeting the demands of accelerating innovation is only likely through advancing AI, which in turn has the potential to impact every aspect of human life, the problem/dilemma for AI developers is that there is no *standard theory of mind*.

To further accentuate this circumstance, the networking of computers has in turn led to the Web with essentially an unlimited growth of data/information (i.e., an *info-glut*). The industry's response, however, to the info-glut problem, has been an ever-growing abundance of Web-access tools, which to an average user seem ironically as only another "glut" (a *technology-glut* or *tool-glut*).

Proposed theories of the Web, like with AI, are also numerous and without a common foundation on which to build a mutual understanding of *AI and the Web*. There are also a plethora of heuristic technological approaches to *AI and the Web* ranging from Intelligizing™ the Web through Learning/Thinking Webs to the Web as a Global (Super) Brain and Virtual Reality as Social Superorganism [See for instance these topics at Principia Cybernetica Web (2008)]. Basically, however, research on *AI and the Web* is categorizable as to whether the focus is on the preeminence of *brain vs. mind* (Roco & Bainbridge, 2002), as for the Human Cognome Project keyed to reverse engineering the human brain**,** or *mind vs. brain*, via a modular description of a general intelligence capable of open-ended recursive self-enhancement (Singularity Institute for Artificial Intelligence (2001), *General Intelligence and Seed AI*) or, alternatively, on the *co-evolution of mind & brain*, characterized by *Project AutoGnome™/CoGnome™/ CogWeb™*, this being the approach of Ai3inc.

The explication of the Web as a Virtual Reality (a computer-based CyberSpace) which is an *image* (sign, symbol, icon)–*communication* system, that is, a *Semiotic* (Goodwin & Queiroz, J., 2007) Relational System, is also of the essence of *Mind*. Ai3inc's long-term focus is on an approach to Synthetic Mind/Artificial Intelligence via a patented technology known as the AutoGnome. This addresses a uniform solution to all of the foregoing problems of glut by way of an Intellisite™, an *Intelligent Website*. The AutoGnome, as an Automated Inference/Inquiry/Intuition software exploiting Mechanized Semiosis, also provides an optimal approach to a General Theory of an Autonomous Virtual Society (Virtuality)—this being an autonomous semiotic universe of Virtual Minds (WebGnomes™); hence Virtuality is related to (Human) Reality through the Virtual Reality of the Web. It is the provision of the foregoing which implicates a *standard theory of mind* that is the focus of As It Is, Inc.'s current development of "*Semiotic* Relational Systems: The

AutoGnome as Synthetic Mind" and "*AutoGnomics* and Intelligent Systems Development" including the present "*AutoGnomic Intellisite"* (Hamann, 2007a).

Relational Systems Foundations

Generally, a canvassing of human experience has reports thereof falling into two fundamental forms—experience of Systems (objects, things, stuff, matter, etc.) and experience of Relations (connections,interactions, functions, transformations, etc.). Historically, this record has been largely confined to a form in which Relations were assumed to exist only between/among Systems, Systems Related to other Systems (SRS'). Between 1963-1968, work was introduced in which Relations were also taken to logically exist both as Relations between/among Systems and other Relations (SRR') and as Relations between/among Relations and other Relations (RR'R''). Based on the presumption of the foregoing and with certain Systems or Relations taking the place of (i.e., imaging (signifying)) other Systems or Relations (this being the notion of image) and with certain Systems or Relations being part of other Systems or Relations (this being the notion of subsumption), the foundation of a Relational Evolutionary paradigm, Relational Systems (RS), was promulgated. (Hamann, 2007b)

From *Image* and *Subsumption* to Mathematics and Logic

First, a Relational Conjecture is restated to form and substantiate the notion of *image*: It is conjectured that the origin of an *image* (or *sign*) system as a chaotic ordering (emergent) event in the evolution of physical/chemical systems is a necessary and (possibly) sufficient condition for the origin of *Life* (and thus Intelligence/*Mind*) (Hamann & Bianchi, 1970).

Second, beginning with the simplest fundamental derivative of the Presumption of *subsumption,* that is, the notion of *distinction* (Spencer-Brown, 1969; Shoup, 2008) whereby there is formed a *boundary* which generates *twoness,* a mathematics of distinction has been created and grown into a general candidate for an approach to a universal language for formal systems, that is, multiboundary mathematics. Inherent to this Boundary Mathematics is a Boundary Logic (from which Boolean Logic is derivable as a special case), which is leading to a more powerful computer design (Bricken, 2007). Generally, taking a *universal formal system* as an axiom system with the property that any other consistent axiom system can be interpreted within it, the mathematics of distinction implies a mathematics of subsumption which, in turn, implies a membership theory as a first step towards a universal language for mathematics (Etter, 2006).

Theory of Mind and of Virtuality

An approach to understanding the "origin" and nature of "mind" is in development based loosely at this point in the process on the System of Boundary Mathematics. This is interpreted as deriving from the Foundations notions of Relational Systems. A theoretical architecture has been posited regarding the formalization of an order (an instantiation of the Mathematics of Subsumption in terms of a degree of partial subsumption) and its derivative calculus, the latter taken as a formulation of the disorder experientially related to the given order, which also implies a reorder(ing) disorder format. Within a Nonseparable System of order/disorder/reorder Relations, this architecture suggests The Form of a meta-theory of theory formation. The Form, in turn, has been invoked in formulating Theories of Intelligence/Mind and Virtuality.

Assume, in a simple, but common instance of the foregoing, that *ordered* experience is *formally signifiable* as a Boolean Network (lattice, algebra, graph or diagram) composed of *points* (nodes, objects, states or Systems) and *lines* (edges, connections, transitions or Relations). Assume further that experience is not totally ordered and that the *disorder* is *formally signifiable* by extending the Boolean Network to the form of a Bayesian Network via a Coxian theory of the algebra of probable inference/inquiry. (Cox, 1961) And finally, assume that *reordering disorder* is *formally signifiable* via the Cox/Jaynes (Jaynes, 2003) form of maximum entropy (maxent) or its generalized probabilistic optimization principal. This approach to modeling both the Web (as a Virtual Reality) and Mind is warranted by the "natural" Network-of-*Images* view of the Web and by the historical predominance of connectionist theories of Mind, and neural-network analyses of mental processes and states.

The resulting synthesis of the foregoing is an approach to Relational Science of Signs, including *signification* and *communication*, that is, a Theory of *Semiotic* Relational Systems**.** This is the necessary basis upon which is built a Theory of Mind and of Virtuality with technologically engineered applications as Synthetic Intelligence(s)/Synthetic Mind and Virtual Reality. (Hamann, 2007a)

AutoGnomic Technology

Based on the work of Charles Sanders Peirce and his successor, Charles Morris, Gene Pendergraft (Pendergraft, 1993), proposed the architecture of a special kind of system, called the AutoGnome, which would be able to perform mechanized (automated) inference using principles derived from semiotics. A venture for the implementation of such an architecture in software code was begun and has resulted in the building of a first release of an AutoGnome System, AutoGnome 01, being a partial implementation of the General AutoGnome Specifications, but representing only about 10-15% of the

complete Conceptual Specification. This first version is a basically a general purpose *pattern generation/recognition/categorization/prediction* engine.

The *Autognome*

General Characterization

The AutoGnome (AG) by its Specification is a General Purpose System of Automated Inference/Inquiry software exploiting a system of Mechanized Semiosis. Unlike most other forms in the mainstream of Artificial Intelligence developments, the AutoGnome is designed to approximate the known semiotic structure and processes of Human Mind. The AutoGnome, to be a complete Semiotic Inference/Inquiry Engine, must account for *The Form* of experience including:

- Ordred (i.e., determined or certain) experience: a formal algebra/logic of semiosis
- Disordered (indeterminate or uncertain) experience: a theory of probable inference/inquiry
- Reordering Disordered experience: via a generalized probabilistic optimization principal

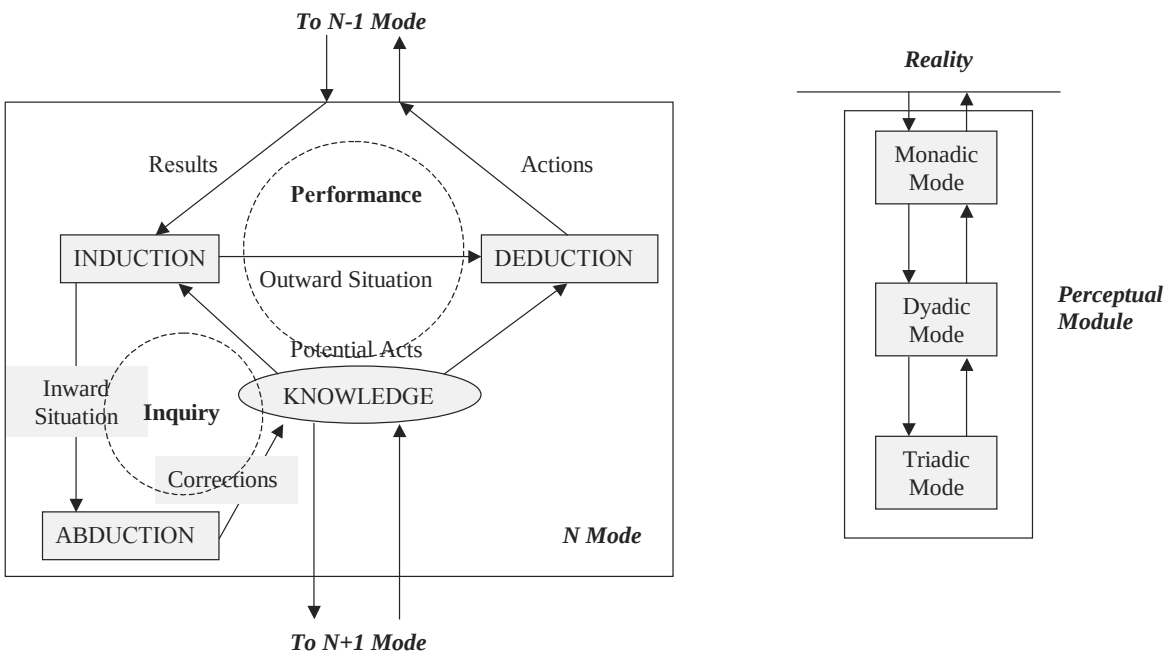
The AutoGnome Architecture

The AutoGnome Architecture (see Figure 1) may be envisioned as multiple modules (perceptual, conceptual, and valuational), each module coding a specific model of the formalisms of semiosis composed of the three modes of semiosis (monadic, dyadic and triadic) and three inferential processes (deduction, induction, and abduction). These recursive inference processes operate on three information stores (an experience store, a knowledge store and a valuation store), gain experience through connective agents (sensors, mediators and effectors (actors)), and function (act) in both an inquiry cycle and a performance cycle.

The probabilistic inference processes integrated formally with the logic of semiosis are the processes of formal representation of the Disorder whereby an AutoGnome identifies and maintains its Identity (Order). The information stores at any particular time are stable states of such probablilistic processes generated by optimizing acts in response to environmental (other system) perturbations of the perceptual module. The form of these optimization procedures for Reordering Disorder are those implementing *Optimum Systemic (subSystemic) Probable Inference* (e.g., MaxEnt).

Note: If the system's ability to perform the Intelligent Act does not depend on the "content" of the inferences (e.g., the three inferential processes do not presuppose what is being reasoned about), then such intelligence can be deemed "generalized". "General Intelligence" is one of the most important design objectives of the AutoGnome and distinguishes it further from other specifically engineered forms of AI.

Figure 1. The AutoGnome – Inference architecture



The Intellisite

The most informative reading of this section is best accomplished while visiting www.truethinker.com which best engenders a realistic sense of an Intellisite

The first application of the AutoGnomic Technology, the Intellisite (an Intelligent WebSite **generically branded as TrueThinker),** is a constructed software environment (a Website) with an embedded form of the AutoGnome known as a WebGnome. MyWebGnome™ then is an intelligent agent residing in this cyberspace environment which, with its continuous adaptive learning from mimicking the user's behavior, will grow into a likeminded replica (*MIND*Clone™) of a user-*self* acting in the Virtual Reality of the Internet with capabilities initially including *knowledge organization* (learning), *knowledge creation* (thinking) and *knowledge applications* (acting) (Hamann, 2007a).

As a homepage "portal to cyberspace", TrueThinker is a premier Knowledge Development Management System.

Intellisite Derivatives

The Intellisite obviously has a broad spectrum of applicability apart from its key functionality as an individual's mirrored Intelligence/Knowledge, in particular as an Autonomous Scientific Intelligence (AScI), a Collective-AutoGnome (CoGnome) and the CogWeb (cognitive network of Intellisites).

AScI

A first generative instantiation of the AutoGnome deriving from its form as a general [meta order(ing)] theory of theory formation is as an Autonomous Scientific Intelligence (AScI) which promises to automate the scientific method (Knuth, 2003).

CoGnome and CogWeb

Assigning a priority MetaQuery/Response status to a selected WebGnome which inter-connects two or more Intellisites in a Network provides a computerized collective intelligence, the CoGnome.

The CogWeb is, by definition, the implementation of the CoGnome for Network Decision-Making by Intellisite-defined groups, organizations, communities, and societies.

While the Intellisite itself was focused on the development of a semiotic engine as an Individual Intelligence, the full potential of individual intellect, be it human or machine, is realized in groups; hence the Automated Community Builder functionality of the Intellisite. This collective creativity, while related to the intelligence of the individual, is actually a feature not only of the Decision Network's inquiry/inference processes (the CoGnome), but more generally of the Network Architecture. Since it is increasingly evident that smart aggregates of humans are frequently more effective decision makers than individuals (Rheingold, 2003), this CogWeb architecture collectively technologically enables cointelligence.

FUTURE TRENDS

In the context of the AutoGnomic approach to Synthetic Mind, the following definitions might be projected to emerge in characterizing the Web:

- Web 1.0 – Syntactic Web (Perceptual; Intelligence) (Lynch, 1996)
- Web 2.0 – Syntactic-based Social Web (Tapscott, 2007)
- Web 3.0 – Semantic Web (Cognitive; Knowledge)
- Web 4.0 – Semantic-based Social Web
- Web 5.0 – Pragmatic Web (Valuational; Wisdom**)**
- Web 6.0 – Pragmatic-based Social Web
- Web 7.0– AutoGnomic (Semiotic) Web; a Semiotic Web holistically incorporates the Syntactic, Semantic and Pragmatic functionalities as well as including its Social Web and anticipates a new computing paradigm realizing Boundary Logic (Bricken, 2007) in a Relational Computer-*PILE* (Krieg, 2007). Hence the uniqueness, novelty and robustness of the AutoGnome. *Q.E.D.*

The current status in this development (Synthetic Mind: Intelligence→Knowledge→Wisdom) is hovering between Web 1.0 and Web 2.0 with forays into Web 3.0. Hence, Synthesizing Knowledge is the present goal with Wisdom (Knowledge processed through a Value filter) still a human interpretive extension. Nevertheless, the mission of AutoGnomics, in contrast to approaches to bring AI into the Web, is to reform the Web as AI; hence, Web 7.0 is a present goal of an approach to both a Synthetic Mind and Virtuality, the AutoGnomic Intellisite.

CONCLUSION

The AutoGnome is at the beginning of its technology cycle now focused on Knowledge Development and has a technical roadmap which will continuously and significantly increase, in contrast to competitors, its differentiation into the future. In particular, its Virtual Nature as an autonomous WebGnome (and CoGnome and CogWeb) in the IntelliSite application will make it stand out as unlike user-dependent web tools. The benefits of applications of the current version

of the AutoGnomic Technology in contrast with other special purpose AI approaches derive from the general purpose Semiotic Nature of its core Automated (Autonomous) Inference/Inquiry Engine whereby this same core engine can be deployed in a broad spectrum of contexts (education, health, business, economic and community development, homeland security, etc.) with only the provision of the "connectors" of the engine to that context, but no re-development of the engine itself. It should be emphasized that the current status in the development of the AutoGnomic Technology is essentially state of the art amongst competing commercial technologies, albeit the claims include significant advancements yet to be commercially introduced.

KEY TERMS

Algebra of Probable Inference/Inquiry: The *Algebra of Probable Inference/Inquiry* is a common sense foundational reformation of the concepts of Probability, by the simple generalization of *implication* among logical statements in the Boolean algebra to *degrees of implication*, and of Entropy, by generalizing a particular function of the question lattice to a valuation called *relevance* which is a measure of the degree to which a statement answers a given question. This effectively establishes probability theory as logic.

AutoGnome: The AutoGnome is a self-knowing general purpose software system of automated (autonomous) inquiry, inference and intuition exploiting a mechanized carrier system for relational semiosis as a virtual (synthetic) mind.

Boundary Mathematics: Boundary Mathematics is a semiotic formalism generated by creating a distinction (a boundary) in nonexistence (of system) thus resulting in a first system. Extended to multiboundaries with a common sense reiterative reduction rule leading either to one distinction or nonexistence, this mathematical form and process is the germ of an approach to the formulation of a universal language of mathematics.

CoGnome: The CoGnome is a selected WebGnome which, inter-connecting two or more Intellisites in a Network of Intellisites, provides a computerized collective intelligence, an automated cointelligence, that is, the Collective-AutoGnome (Auto(Co)Gnome) or simply the CoGnome.

CogWeb: The CogWeb is the Network of Intellisites implemening the CoGnome for Network Decision-Making by autonomously formed Intellisite-defined groups, organizations, communities, and societies.

Intellisite: The Intellisite (an Intelligent Website) is a constructed software environment (a Website) with an embedded form of the AutoGnome known as a WebGnome, an intelligent agent residing in this cyberspace environment which, with its continuous adaptive learning from mimicking the user's behavior, will grow into a likeminded replica (*Mind*Clone) of a user-*self* acting in the Virtual Reality of the Internet with the synthetic mind capabilities of the AutoGnome.

Maximum Entropy (MaxEnt) Principle: MaxEnt is a technique for automatically acquiring probabilistic knowledge from incomplete information without making any unsubstantiated assumptions. Entropy is a mathematical measure of uncertainty or ignorance: greater entropy corresponds to greater ignorance. Hence, the MaxEnt solution is the least biased possible solution given whatever is experimentally known, but assuming nothing else.

Order/DisOrder/ReOrder Form: It is a tenet of Relational Systems that any semiotic act must, of necessity, express the *Form* of experience as the inseparable conjunction of:

- Ordered (i.e., determined or certain) experience: a formal algebra/logic of semiosis
- DisOrdered (indeterminate or uncertain) experience: a theory of probable inference/inquiry
- ReOrdering DisOrdered experience: via a generalized probabilistic optimization principal

That is to say, experience is all at once partially ordered, partially chaotic and partially organizable.

Semiotic Relational Systems: A Semiotic Relational System is a system of relations exhaustively admitting all forms of interrelatedness among systems and/or relations and with certain systems or relations taking the place of (i.e., imaging (signifying)) other systems or relations.

Automation of American Criminal Justice

J. William Holland
Georgia Bureau of Investigation, USA

INTRODUCTION

Criminal Justice has been one of the public sectors in the forefront of the move toward automation and digital government. The effect of computerization on American criminal justice has been profound and it has transformed the criminal justice process in many fundamental ways. Starting with President Lyndon Johnson's government commission, *The Challenge of Crime in a Free Society: A Report by the President's Commission on Law Enforcement and the Administration of Justice*, public and private experts in criminal justice and technology laid out the information needs of the criminal justice system and the computer systems to meet those demands. At a time when computerization was minimal throughout the criminal justice system, these task force members developed the blueprint for today's multilayered automated criminal justice environment (Dallek, 1998, pp. 405-407, 409-411; *Challenge of crime in a free society*, 1967, pp. 268-271).

Among the major recommendations of the commission were the creation of a national directory of offenders' criminal records, what came to be known as Computerized Criminal History (CCH) and the development of similar directories at the state level. The commission also called for federal coordination of standards for criminal justice information and sharing. Finally, the report urged that a study of fingerprint classification techniques be undertaken with a view to automating much of the fingerprint search and identification effort and that work be intensified to create a national linkage of files on wanted persons and stolen vehicles under the name of the National Crime Information Center (NCIC) (*Challenge of crime in a free society*, 1967, pp. 255, 268-271; *Task force report: Science and technology*, 1967, p. 69).

BACKGROUND

One of the earliest responses to this report was the creation of the Law Enforcement Assistance Administration (LEAA) within the United States Department of Justice (DOJ). In 1969, LEAA funded Project SEARCH to create a nationwide computerized criminal history system. From this initial effort, SEARCH quickly evolved into an independent consortium of states with the mission of demonstrating a computerized system for the electronic exchange of criminal history information. On the national level, the United States Attorney General assigned management responsibility for the interstate and national portion of this system to the Federal Bureau of Investigation. The states also formed the National Law Enforcement Telecommunications System (NLETS) electronically linking the states as well as the FBI and the Royal Canadian Mounted Police. By 1976, 26 states had used LEAA funding to create state level central repositories for computerized criminal history information (U.S. Department of Justice, 2001c, p. 26).

It became apparent during the last half of the 1970s, however, that greater decentralization of the nation's criminal history systems was urgently needed. To respond to these issues and concerns, the various states, FBI and SEARCH created the Interstate Identification Index or Triple I (III) concept in 1980 (U.S. Department of Justice, 2001c, pp. 26-27, 76-82, 88). Designed to replace a centralized national criminal history file, III was an index of criminal offenders that pointed to the state or states where detailed criminal history information could be found. There was widespread acceptance of III for criminal justice purposes: By 2001, 43 states participated. Legal restrictions and concerns, however, limited use of III for non-criminal justice use and weakened any effort to achieve a truly decentralized criminal history system. Consequently, the FBI continued to maintain criminal histories on individuals to meet interstate non-criminal justice needs (U.S. Department of Justice, 2001c, pp. 76-82).

Another factor that prevented the decentralization of criminal history information was the vast effort required in the time-consuming fingerprint identification process. A new system called the NCIC classification was implemented in the 1970s. It did little, however, to speed up the overall identification process (*Challenge of crime in a free society*, 1967, p. 255; *Task force report*, 1967, p. 16; Ms. Shirley Andrews, personal communication, September 9, 2002).

During the mid 1980s, new technological solutions for fingerprint identification emerged on the market. These systems, called automated fingerprint identification systems (AFIS), significantly reduced the manual tasks needed to search a fingerprint and made true searching of latent crime scene fingerprints possible. By the close of the 1980s, many states and a few local agencies had purchased these systems. Most were stand alone systems dedicated to the fingerprint input, search, and presentation of potential candidates for human comparison. A few states, however, attempted to expand the capabilities of these systems and link them to

other criminal history processes. When combined with the proven effectiveness of the AFIS latent search capability, the new technology contained the potential to transform criminal justice systems (U.S. Department of Justice, 2001b, pp. 43-44; U.S. Department of Justice, 2001c, pp. 61-63).

In the early 1990s, efforts were made through the National Institute of Standards and Technology (NIST) to devise a national fingerprint transmission standard; an effort spearheaded by the FBI. By 1993, a national standard for the electronic interchange of fingerprint information was approved by NIST and became the basis for the electronic linkage of local jurisdictions to state criminal history bureaus and the FBI. It formed the basis for the emerging national network of real-time identification and criminal history systems (See *Data format for the interchange of fingerprint, facial, and SMT information*, originally issued in 1993, amended in 1997 and further amended in 2000; U.S. Department of Justice, 2001c, pp. 61-63.)

CURRENT AND FUTURE TRENDS IN CRIMINAL JUSTICE AUTOMATION

Building on these past activities in fingerprint and criminal history automation, emphasis within state and national criminal justice circles has shifted to the need to share information, what is known as integrated criminal justice. With the explosion of the Internet and simultaneous cost limitations on criminal justice system development, both federal and state funding entities require that new criminal justice system developments build in the concept of information sharing, realignment of processing functions, and greater involvement of all criminal justice parties in individual systems development. The goal of this new focus is to eliminate duplicate entry of the same information and increase the overall completeness and accuracy of criminal justice information. (U.S. Department of Justice, 2001c, pp. 63-65; Harris, 2000, pp. 7, 14, 18-20, 41; U.S. Department of Justice, 2001b, pp. 47-48, 50; *Planning the integration of justice information systems*, 2002, pp. 2-3.)

Integrated justice efforts, however, have also resurrected older worries about privacy of such information and merged them with new concerns about greater linkage of criminal justice and non-criminal justice information on individuals. Questions about release of integrated information are linked to serious questions about the accuracy of the information released. These fears are intensified as private companies demand access to criminal history information, gathered at public expense, to market to customers for profit. In many jurisdictions, the old line between public and private responsibilities and authority has faded as private companies have assumed many of the traditional criminal justice information systems functions. In addition, the heightened threat of terrorist attacks has led to efforts to gather large amounts of information on individuals into databases to search for terrorist patterns. These efforts have collided with fears about loss of privacy and misuse of such information by the government. Initiatives such as the Total Information Awareness effort and the MATRIX project to correlate private and public data on suspicious individuals have ground to a halt in the face of protest from citizens fearful of the loss of civil liberties. (Ideas that mattered in 2003:9. No future for terror market, 2003; MATRIX Updates, 2003; *Planning the integration of justice information systems*, 2002, p.5; Stanford, 2003; U.S. Department of Justice, 2001a, pp. 8, 12; U.S. Department of Justice, 2001b, pp. 2-3, 27-28, 50).

CONCLUSION

In 1967, a national commission developed *The Challenge of Crime in a Free Society*, the roadmap for today's highly automated but incomplete criminal justice system. This report served the nation well but it is time to move beyond its confining vistas, time to recognize that dramatic developments in computer technology and digital government demand new answers to old questions and the formulation of entirely new questions. The events of September 11, 2001 have raised anew questions about lack of information on potential threats to society and posed new questions on how we as a nation can weave together governmental and private computerized information to detect dangerous individuals intent on mass murder without compromising constitutional safeguards and individual liberties. It is time to convene a new national task force charged with the duty to assess the challenge of crime and terror in a free digital society. Only then can criminal justice automation and digital government move forward in a planned and comprehensive way.

KEY TERMS

Automated Fingerprint Identification System (AFIS): A system that provides computerized fingerprint identification of arrestees, applicants for licensing and employment, and crime scene fingerprints of potential suspects.

Computerized Criminal History (CCH): A system containing offenders and their individual arrests, final disposition of those arrests, and custodial information for those arrests.

Federal Bureau of Investigation (FBI): The federal government's investigative, forensic, and criminal justice information system entity. It is part of the U.S. Department of Justice.

Interstate Identification Index (III): a national index of offenders housed at the FBI that points an inquiring entity to those states that contain detailed criminal histories on the requested individual.

Multistate Anti-Terrorism Information Exchange (MATRIX): A consortium of states attempting to create a database of public and private information on individuals to allow for advanced searches to uncover suspicious criminal and/or terrorist activity.

National Crime Information Center (NCIC): A national center housed at the FBI that provides 24 hour a day, seven day a week, real time access to law enforcement for warrants, stolen vehicles and other articles.

National Institute of Standards and Technology (NIST): A federal government standards setting body housed in the U.S. Department of Commerce.

National Law Enforcement Telecommunications System (NLETS): A state managed national network that provides state to state communications as well as links to the FBI and other large scale criminal justice entities.

SEARCH Group, Inc: A state managed consortium that represents the states as a body on criminal justice information systems issues at the national level.

Total Information Awareness: A discontinued effort by the federal government to create a vast database containing public and private information on individuals to allow for advanced search techniques to uncover suspicious activity or indications of possible terrorist links.

Autopoietic Approach for Information System and Knowledge Management System Development

El-Sayed Abou-Zeid
Concordia University, Canada

INTRODUCTION

In the last decade a new generation of information systems (ISs), such as Web-based information systems and knowledge management support systems, have emerged in response to ever-changing organizational needs. Therefore, the need for new "Information System Design Theories" for the emerging ISs is recognized. According to Walls, Widmeyer, and El-Sawy (1992), an "IS design theory" must have two aspects—one dealing with the description of the system and one dealing with the prescription, that is, the process of developing of the system. The prescription aspect includes a description of procedures and guidelines for system development. In addition, these two aspects must be grounded on theories from natural or social sciences (i.e., kernel theories).

As information systems are socio-technical phenomena in which social and technical factors interweave the ways in which people work, the issue of "how to integrate the work activity and social context of users into the IS which is being designed" becomes one of the principal problems of IS development (Bai & Lindberg, 1999). Therefore, the development of new IS design theories requires a closer look at the system theories that go beyond the traditional system theory that is based, among other things, on Cartesian dualism (i.e., mind/body or cognition/action) and on a model of cognition as the processing of representational information (Mingers, 2001). One of the candidate theories is the theory of autopoiesis, which can be best viewed as a system-grounded way of thinking with biological foundations, together with its extension into social domain.

BACKGROUND

In order to conceive of living systems in terms of the processes that realized them, rather than in terms of their relationships with an environment, Maturana and Varela (1980) coined the word *autopoiesis* (αυτοσ = self, ποιενιν = creation, production) to denote the central feature of their organization, which is "autonomy." The meaning of this word coveys the very nature of living systems as systems that maintain their *identity* through their own operations of continuous self-renewal. Moreover, these systems could only be characterized with *reference to themselve*s and whatever takes place in them, takes place as necessarily and constitutively determined in relation to themselves—that is, *self-referentiality.*

One of the key concepts of autopoiesis is the distinction between organization and structure. On one hand, *organization* is the capability of a system to reproduce its identity by referring constantly to itself, through the alternate reproduction of its components together with the component-producing processes, that is, the capability of a recursive self-reproduction. On the other hand, *structure* is the realization of a system's organization through the presence and interplay of its components in a specific realization space. While organization is necessary to establish system unity and identity, structure is necessary because different spaces of its actualization impose different constraints on a system's components (Maturana & Varela, 1980). By rough analogy, an algorithm for solving certain problem can be viewed as a description of the system's organization, whereas the corresponding computer program can be viewed as the realization of this organization (structure) in a certain space (programming language).

Autopoietic Systems

An autopoietic system is defined by Maturana and Varela (1980) as "a network of processes of production, transformation and destruction of components. These components constitute the system as a distinct unity in the space of its actualization and they continuously regenerate and realize, through their interactions and transformations, the network of processes that produce them" (p. 135).

Among the distinct characteristics of the autopoietic systems, the most relevant ones are:

- *The simultaneous openness and closure.* Autopoietic systems are *open* with respect to structural interaction with the environment, that is, *structural openness*, which is an unavoidable consequence of the fact that system elements must satisfy the particular requirements of the physical domain in which they occur, while they are *closed* with respect to their own organization, that is, *organizational closure.* The recognition of *the*

simultaneous openness and closure of autopoietic systems is in opposition to the tradition for which a system is one or the other but not both. This interpretation is possible only because of the clear distinction between organization and structure (Bednarz, 1988).

- *Structural determination.* The state transition a system undergoes in response to environmental perturbations is entirely determined by its structure at that time. Moreover, a system specifies which environmental perturbations may trigger which structural changes. In other words, the environmental perturbations could trigger the system's structural changes but can never determine or direct these changes. Moreover, a system specifies which environmental perturbations may trigger which structural changes. Over time, through ongoing interactions with the environment, an autopoietic system will experience what Maturana and Varela (1992) describe as a *structural drift,* or a gradual change to their structure. The nature of this change is determined by a previous system's history of structural changes, that is, its *ontogeny.*

Higher-Order Autopoietic Systems

Two (or more) lower-order autopoietic systems can be "structurally coupled" to form a higher-order autopoietic system. Structural coupling is the ongoing process of the congruent structural changes between two (or more) systems that results from recurrent interactions between (among) them. Therefore, structural coupling has connotations of coordination and co-evolution. Moreover, following structural determination principle, two structurally coupled systems means that each of them selects from its possible structural changes those that are compatible with those in the other system and, at the same time, are suitable for the maintenance of its identity.

Social systems, such as enterprises, are constituted through the process of third-order structural coupling, or social coupling, the one that occurs between (or among) two (or more) second-order autopoietic systems. However, the unique feature of any human social system, such as an enterprise, is that the social coupling among its constituents occurs through "language in the network of conservations which language generates and which, through their closure, constitute the unity of a particular human society" (Maturana & Varela, 1992, p. 196). From this perspective, language is viewed as an example of social structural coupling that generates the self and creates meaning through interactions with others. Moreover, language represents what Maturana and Varela would describe as a consensual domain, which is the domain of arbitrary and contextual interlocking behaviors (Mingers, 1995a, p. 78). Within a consensual domain, two autopoietic systems would be able to observe the attribution of meaning to common events and undertake coordinated actions.

Autopoiesis and Cognition

Cognition is the term conventionally used to denote the process by which a system discriminates among differences in its environment and potential states of that environment. The evidence for this cognition is effectiveness of system behavior in response to the environmental perturbations. Today's dominant perspective on cognition, and consequently IS, is the idea that effective action is explainable in terms of manipulating formal and static representations of the objective reality (Mingers, 2001).

According to the theory of autopoiesis, perception is neither objectivist nor purely constructivist (Varela, 1992, p. 254); rather, it is co-determined by the linking of the structure of the perceiver and the local situations in which it must act to maintain its identity. This is the basis of *enactive (embodied) cognition,* which implies that the autopoietic system's activities condition *what can be perceived* in an environment, and these perceptions, in turn, condition future actions. In this view, "a cognitive system is a system whose organization defines a domain of interactions in which it can act with relevance to the maintenance of itself, and the process of cognition is the actual (inductive) acting or behaving in this domain" (Maturana & Varela, 1980, p. 13). Therefore, cognition, according to autopoietic theory, is essentially embodied. Or, in the words of Maturana and Varela (1992): "All doing is knowing, and all knowing is doing" (p. 26). In addition, cognitive domain of an autopoietic system is defined as the domain of all the interactions in which it can enter without loss of identity (Maturana & Varela, 1980, p. 119).

APPLICATIONS OF THE CONCEPTS OF AUTOPOIESIS IN IS DEVELOPMENT RESEARCH

The use theory of autopoiesis in IS research can be classified into two main categories: metaphoric and theory-oriented approaches (Beeson, 2001).

Metaphoric Approaches

Kay and Cecez-Kecmanovic (2002) used the concepts of *social coupling* and *consensual domain* to explain processes underlying the IS-organization relationship and how it impacts on the competitive advantage of an organization. They showed how processes of recurrent interactions between members of different groups—analysts, the IS team, and external clients—within the organization's work environ-

ment gave rise to commonalities in understanding, which in turn enabled continual IS organization co-emergence. In the same vein, Maula (2000) used the concepts of structural openness and organizational closure to identify two major knowledge management (KM) functions in four consulting firms. The first KM function, sensory function, is the realization of the structural openness of the firm and its structural coupling with its environment. The second KM function, memory function, is the realization of the concept's organizational closure and self-referentiality that enable the firm's effective functioning and continuous renewal. Hall (2003) also considered organizational memory as organizational heredity that served to maintain organizational integrity in a dynamic economic environment. Finally, Carlsen and Gjersvik (1997) used an autopoiesis metaphor to analyze possible organizational uses of workflow technology. They argued against "generic" business processes except as starting points for organizational adaptation. In addition, they indicated that the concept of autopoiesis implies that process models should include references to richer descriptions of the organizational environment and the environment the work process is situated in.

Theory-Oriented Approaches

Bai and Lindberg (1999) used first- and second-order cybernetics together with Luhmann's (1995) social autopoiesis theory and Engeström's (1987) activity theory to develop a framework for studying the relationship between IS design activity, use activity, and the embedded social context. This framework sheds light on the complex social context within which IS development takes place, and provides an epistemological understanding of the relationship among the elements involved in IS development. Moreover, it can be used to develop methodologies for the practice of IS development, and guide various research activities, such as the socio-technical approach.

FUTURE TRENDS

The autopoietic metaphor provides ways of thinking about the mechanisms underpinning the development and the introduction of IS in an enterprise. Here, a third-order autopoietic system is used as a metaphor to explore referential correspondence between the characteristics of autopoietic systems and an enterprise and its IS. For example, organizational closure of an autopoietic system implies that it is homeostatic and its own organization is the fundamental variable to be maintained constantly. This concept may be used to explain why the behavior of IS developers and users seems to be stuck sometimes in persistent patterns or repertoires (Beeson, 2001). Moreover, the difficulties of system integration may be better understood from a perspective of structural coupling than from one of rational design or negotiation (Beeson, 2001). The structural coupling concept can also be used to explore the way common understandings between enterprise members emerge as a function of interactions in the work environment (Kay & Cecez-Kecmanovic, 2002). Therefore, significant focus must be drawn towards the patterns of interaction between members of an organization and the way in which these patterns may be supported to give rise to consensual domains (Kay & Goldspink, 2005).

From an autopoietic view, introducing a new IS in an enterprise can be conceptualized as a kind of perturbation that provokes or triggers an enterprise's structural-determined responses. Therefore, IS development process can be viewed as the means for realizing structural coupling between an enterprise and its new IS, and becomes an integrated aspect of the recurrent interactions between developers and users in the work environment. Table 1 summarizes the implications of theory of autopoiesis for IS development process.

Furthermore, ISD process by its very nature is a knowledge work (Iivari, 2000), and its success depends on the developers' tacit knowledge (Abou-Zeid & Bahli, 2005). From an autopoietic perspective, knowledge is an embodied (enactive) notion, and it cannot be treated as an object that can be captured, packaged, and processed. Therefore, tacit knowledge associated with ISD should be appreciated as much as explicit knowledge. The interplay of the explicit and tacit and embedded organizational knowledge also forms a stimulating research topic.

Finally, there are many open questions. While some of the main concepts of autopoiesis theory are presented, considerable work remains to be done in terms of translating these concepts into practical solutions for the workplace.

CONCLUSION

The theory of autopoiesis, as a kernel theory for IS design theory, can used to derive a set of ISD methodology meta-requirements which includes insider frame of reference**,** historicity**,** context-dependency of ISD methodology, and minimal set of initial requirements.

Table 1. Autopoietic implications for IS development

Characteristics of Autopoietic Systems	**Implications for IS Development**
Organizational Closure and Self-Referentiality	**Insider frame of reference.** The organizational closure and self-referentiality of an enterprise suggest it is best understood from *inside*. Therefore, an interpretive or hermeneutic approach could more reliably and intelligibly account for the experiences, intentions, and interpretations of its members. Moreover, the main role of the system developer is the role of "*catalyst* and/or *emancipator*" (Hirschheim & Klein, 1989) who helps enterprise members develop the necessary inquiring, collaborative, and communicative patterns needed to continuously explicate their information requirements.
	Historicity. As an enterprise is continuously reproducing itself, it must do so with constant reference to itself, its past practices, values, decisions, contracts, and commitments (Truex, Baskerville, & Klein, 1999). Therefore, explicating an enterprise's history is an essential element in developing new knowledge and in introducing a new IS (von Krogh, Ross, & Slocum, 1994).
Structural Determination and Structural Coupling	**Context-dependency of IS development methodology.** Viewing ISD methodology as the means for realizing structural coupling between an enterprise and its new IS implies that it cannot be separated from the enterprise's context. In other words, an autopoietic metaphor of an enterprise and its IS suggest "strong" approaches to systems development instead of the commonly used "weak" approaches (see Key Terms).
Embodied Cognition	**Minimal set of initial requirements.** The autopoietic view of cognition implies that requirements are always in motion, unfrozen, and negotiable (Truex et al., 1999). Therefore, IS development can be viewed as an open-ended bootstrapping process that starts with a minimal set of requirements. Moreover, formal representation must be subordinated to the fostering of mutual understanding and coordinated action in the development team and between the team's members and the stakeholders (Beeson, 2001; Robert Kay & Cecez-Kecmanovic, 2002). As knowledge is not an object that may be captured, packaged, processed, and distributed, KMS may be best conceptualized as "an additional medium through which interlocking behaviors may converge and the congruities of context, that give rise to consensual domains, develop" (Robert Kay & Goldspink, 2005).

KEY TERMS

Cognitive Domain: The domain of all the interactions in which one can enter without loss of identity (Maturana & Varela, 1980, p. 119).

Consensual Domain: "The domain of interlocked conducts that results from ontogenetic structural coupling between structurally plastic organisms" (Mingers, 1995b).

Ontogeny: The history of structural changes that a system experiences without losing its identity.

Organization: The configuration of relationships among a system's components that define a system as a unity with distinctive identity, and determine the dynamics of interaction and transformations that it may undergo as such a unity.

Structural Coupling: The ongoing mutual co-adaptation between a system and its environment.

Structural Determination: The principle that the actual course of change in an autopoietic system is controlled by its structure rather than direct influence of its environment.

Structure: The physical embodiment of system's organization in a certain physical domain.

Strong vs. Weak Methods: "Strong methods are those designed to address a specific type of problem, while weak methods are general approaches that may be applied to many types of problems" (Vessey & Glass, 1998).

INTRODUCTION

Bankruptcy prediction or corporate failure is considered a classic issue in both, academic and business communities. Bankruptcy risk is one of the most important factors (if not the most important one) to be considered when credit requests are screened or even existing debtors are evaluated. On the other hand, all potential stakeholders (shareholders, suppliers, customers, employees, creditors, auditors, etc.) have potential interest to identify if a company is on a trajectory that is tending towards failure. Commercial banks, public accounting firms and other institutional entities (e.g., bond rating agencies) appear to be the primary beneficiaries of accurate bankruptcy prediction, since they can use research results to minimize exposure to potential client failures. In addition to avoiding potentially troubled obligors, the research can also benefit in other ways. It can help in accurately assessing the credit risk of bank loan portfolios. Credit risk has been the subject of much research activity, since the regulators are acknowledging the need and are urging the banks to assess the credit risk in their portfolios. Measuring the credit risk accurately also allows banks to engineer future lending transactions, so as to achieve targeted return/risk characteristics. The other benefit of the prediction of bankruptcies is for accounting firms. If an accounting firm audits a potentially troubled firm, and misses giving a warning signal then it faces costly lawsuits (Atiya, 2001).

A series of techniques have been applied in literature. Econometric / statistical methods have first appeared in literature: In late 1960's (multiple) discriminant analysis (DA) was the dominant method; during the 1980's logistic analysis. In the 1990's artificial intelligence starts appearing in financial literature with neural networks (Odom & Sharda 1990) serving as an alternative to statistical methods demonstrating promising results.

The goal of this chapter is therefore two-fold: First, it intends to give an overview of the artificial intelligence techniques successfully applied to the problem, ranging from the first neural network applications to recent applications of biologically inspired algorithms, such as genetic algorithms. Then, two kernel based methods, namely the Radial Basis Function Neural Networks and the Support Vector Machines are applied to the bankruptcy problem.

BACKGROUND

Early statistical studies in bankruptcy prediction (e.g., Beaver, 1966 adopted a univariate methodology identifying the accounting ratios having the highest classification accuracy in separating failing and non-failing firms. Beaver investigated the predictability of 14 financial ratios. Altman (1968) examined simultaneously a series of financial ratios, enriching the single ratio approaches. A multiple discriminant function was calculated, the so-called Z-score composed of five financial ratios:

$$Z = 1.2X_1 + 1.4X_2 + 3.3X_3 + .6X_4 + .999X_5 , \quad (1)$$

where

X_1 = Working Capital / Total Assets. (Measures liquidity)
X_2 = Retained Earnings / Total Assets. (Measures profitability)
X_3 = Earnings Before Interest and Taxes / Total Assets. (Measures operating efficiency)
X_4 = Market Value of Equity / Book Value of Total Liabilities. (Adds market dimension)
X_5 = Sales/ Total Assets. (Standard measure for turnover)

Z-Score model was modified by Altman, Haldeman, and Narayanan (1977). Their ZETA model was composed from seven financial ratios. Since these early studies, a vast range of statistical methodologies have been applied for the purposes of corporate failure prediction including logistic regression (Martin, 1977), logit (Ohlson, 1980), Kolari, Glennon, Shin, and Caputo (2002), probit and maximum likehood models (Zmijewski, 1984).

Literature review reveals that a series of financial ratios has been examined. Stability indicators, industry-specific indicators, macroeconomic factors, firm's particular features have been examined. However, there is no agreement on the features that carry significant predictive power. According to Courtis (1978) and Dimitras (1995) the applied ratios should adequately cover three fields: profitability, management efficiency, and solvency.

AI FOR BANKRUPTCY PREDICTION

The statistical methods described above have some restrictive assumptions such as linearity, normality and independence among predictor or input variables. Considering that violation of these assumptions for independent variables frequently occurs with financial data (Deakin, 1976) these methods have limitations to obtain effectiveness and validity. Artificial intelligence (AI) methods have been proven to be less vulnerable to these assumptions.

In the following paragraphs we present a brief description of AI techniques employed and a short review of research attempts applying AI techniques and approaches in the bankruptcy prediction problem. Specifically, three types of methods are analyzed: (1) artificial neural networks, (2) approaches based on decision trees, and (3) genetic algorithms.

Artificial Neural Networks

Artificial neural networks (ANNs) are based on the behavior of the biological neurons of the brain and are used to mimic the performance of a system. They consist of a set of elements that start out connected in a random pattern, and, based upon feedback, are modelled into the pattern required to generate the required results. When the problem is bankruptcy prediction, neural networks create a function of the predictors, mapping to a specified outcome; in our case bankruptcy or not.

As ANNs are capable of identifying and representing non-linear relationships in the dataset they were the first AI technique applied in the bankruptcy prediction problem and the most studied one. Odom and Sharda (1990) were the first to use NNs for bankruptcy prediction. They used the five financial ratios used in Altman's Z-score. A series of other applications can be identified where criteria / predictors' number varied from Altman's original 5 to 41 (Leshno & Spector, 1996). Various ANN based models, with different architectures and training algorithms have been employed. In some applications an extra dimension reduction stage was added, such as Principal Components Analysis (Ravi & Pramodh, in press) in order to reduce the dimensionality of the input feature vector of the ANNs.

The creation of additional indicators or features has been also tested. Atiya (2001) developed and employed novel indicators for his ANN. Lam (2004) followed a different approach incorporating macroeconomic variables as well as financial ones. Recently, ensemble neural networks classifiers that combine a number of single NN classifiers into one multiple classification system have gained ground (Tsai & Wu, 2008).

Decision Trees

Decision tree induction is a technique which is widely used for predictive/classification tasks. Decision trees employ mathematical formulations in order to detect the most important predictors and create a tree structure for deriving the classification decisions. An advantage of the decision trees is their ability to provide interpretation for their automated decisions. Still, their linearity limits their performance.

Marais, Patel, and Wolfson (1984) proposed recursive partitioning algorithm and bootstrapping techniques for inducing the decision tree. Frydman, Altman, and Kao (1985) employed recursive partitioning and compared decision trees to the DA, which was found inferior.

Genetic Algorithms

More recently Genetic Algorithms (GAs) have been applied in the bankruptcy prediction problem. GAs are stochastic search techniques that can search large and complicating spaces and mimic the ideas of natural evolution and the survival of the fittest.

As GAs are effective in searching large spaces, they are particularly effective for multi-parameter optimisation problems under several constraints. For this reason, in the bankruptcy prediction problem, they have been mainly applied for optimisation of the classification process either by selecting the most discriminant financial ratios (Sai, Zhong & Qu, 2007) or by optimising the classifier parameters (Back, Laitinen & Sere, 1996). Shin (2002) also uses GAs for the extraction of classification rules.

KERNEL BASED METHODS FOR BANKRUPTCY PREDICTION

In the second half of this chapter, following the directions proposed by Ravi Kumar and Ravi (2007) we examine the potential of two newer techniques, namely the SVMs and the Radial Based Function Neural Networks (RBF-NNs). Both methods are classified as kernel based methods.

Kernel based methods are based on mapping data from the original input feature space to kernel feature space of higher dimensionality and then solving a (linear) problem in this space. These methods allow us to interpret and to design learning algorithms geometrically in the kernel space (which is non linearly related to the input space). Kernel based methods are considered to perform satisfactorily in difficult environments such as noisy, of high dimension input or of limited number of training samples.

THE SVMs

The goal of the Support Vector Machines (SVM) (Cortes & Vapnick, 1995) is to produce a model which predicts target value of data instances in the testing set in which only the attributes are given. Let a training set of instance-label pairs be (x_i, y_i), $i = 1, ..., l$ where $x_i \in \Re^n$ is the training vector belonging to one of the two classes, l is the number of the extracted features in the training set and y_i indicates the class of x_i.

The support vector machine requires the solution of the following optimization problem:

$$\min_{w,b,\xi} \left(\frac{1}{2}\mathbf{w}^T\mathbf{w} + C\sum_{i=1}^{l}\xi_i \right) \quad (2)$$

subject to $y_i(\mathbf{w}^T\phi(x_i)+b) \geq 1-\xi_i,\ \xi_i \geq 0,$

where b is the bias term, $\mathbf{w}$ is a vector perpendicular to the hyperplane $<\mathbf{w},b>$, ξ is the factor of classification error and $C>0$ is the penalty parameter of the error term. The training vectors x_i are mapped into a higher dimensional space F by the function $\phi : R^n \rightarrow F$. SVM finds a separating hyperplane with the maximal geometric margin and minimal empirical risk R_{emp} in the higher dimensional space. R_{emp} is defined as:

$$R_{emp}(a) = \frac{1}{2l}\sum_{i=1}^{l} | y_i - f(x_i, a) |, \quad (3)$$

where f is the decision function defined as:

$$f(x) = \sum_{i=1}^{l} y_i a_i K(x_i, x) + b, \quad (4)$$

where $K(x_i, x_j) \equiv \phi(x_i)^T \phi(x_j)$ is the kernel function, a_i are weighting factors and b is the bias term. In our case the kernel is a radial basis function (RBF) which is defined as:

$$K(x_i, x_j) = \exp(-\gamma \| x_i - x_j \|^2), \gamma > 0, \quad (5)$$

where

$$\gamma = \frac{1}{2\sigma^2}$$

(σ is the standard deviation) is a kernel parameter. The RBF kernel non-linearly maps samples into a higher dimensional space, so it can handle the case when the relation between class labels and attributes is nonlinear.

THE RBF NNS

Artificial Neural Networks (ANNs) that employ Radial Basis Functions (RBFs) usually require a larger architecture than standard feed-forward ANNs for the same classification task. However, their main advantage is that they are trained much faster and easier with a smaller training set (Chen, Cowan & Grant, 1991). In a RBF-ANN the nodes in the hidden layer utilize a transfer function with the following formula:

$$f(n) = e^{-n^2}. \quad (6)$$

The input to the transfer function of each neuron is the vector distance between a weight vector $\mathbf{w}$ (estimated during training) and the input vector $\mathbf{x}$ (financial ratios), multiplied by a bias b, that is:

$$n = \|\mathbf{w} - \mathbf{x}\| b. \quad (7)$$

According to this schema, a radial basis function has a maximum of 1 when the input (distance) is 0, thus as the distance between $\mathbf{w}$ and $\mathbf{x}$ decreases, the corresponding output increases. Consequently, a radial basis neuron acts as a detector that produces 1 whenever the input $\mathbf{x}$ is identical to its weight vector $\mathbf{w}$. The bias b allows the sensitivity of the radial basis neuron to be properly adjusted. During testing, when a feature vector is introduced to the network, each neuron in the hidden layer will produce an output value according to how close the input vector is to each neuron's weight vector. Thus, radial basis neurons with weight vectors quite different from the input vector ($\mathbf{x}$) have outputs near zero. On the other hand, a radial basis neuron with a weight vector close to the input vector produces a value near 1.

A subtype of RBF ANNs suitable for classification problems are the Probabilistic Neural Networks (PNNs) (Wasserman, 1993). The first hidden layer at such ANNs

operates similarly with that of RBFs described earlier. PNNs have an additional hidden layer which sums the outputs of the nodes from the previous layer in order to produce a vector of classification probabilities. A compete transfer function is applied in the final layer to produce the final output. This transfer function identifies the maximum probability, and produces a 1 for the corresponding class and a 0 for the rest classes.

Typical PNNs have two layers (besides the input and output ones). The first layer consists of RBF neurons, one for each pattern (training example). For each pattern we calculate the product of the weight vector and the given classification example and then the product is passed through the transfer function:

$$f(x) = e^{(\mathbf{x}^T \mathbf{w}_{ki} - 1)/\sigma^2}, \quad (8)$$

where $\mathbf{w}_{ki}$ is the weight vector of the i^{th} pattern from class k and σ^2 is the deviation of the Gaussian function for the specific node. In the second layer, we have as many nodes as is the number of classes and each node implements a summation process based on the outputs of the RBF nodes associated with a given class, using the following formula:

$$\sum_{i=1}^{N_k} e^{(\mathbf{x}^T \mathbf{w}_{ki} - 1)/\sigma^2} \quad (9)$$

where N_k is the number of patterns for class k. In order to produce the classification decision as output, PNNs employ binary neurons according to:

$$\sum_{i=1}^{N_k} e^{(\mathbf{x}^T \mathbf{w}_{ki} - 1)/\sigma^2} > \sum_{i=1}^{N_j} e^{(\mathbf{x}^T \mathbf{w}_{kj} - 1)/\sigma^2}. \quad (10)$$

Only one factor needs to be tuned during training, the smoothing factor (i.e. the deviation of the Gaussian functions). Small deviations can lead to sharp approximations and thus without proper generalization capabilities, while large deviations tend to miss probably valuable details. Therefore, the appropriate deviation (namely spread) must be chosen by experiment.

FINANCIAL APPLICATION

Indicators for Bankruptcy Prediction

The major assumption underlying almost all studies for bankruptcy prediction is that financial variables extracted from financial statements, such as financial ratios, contain a large amount of information about a company's credit / bankruptcy risk. Although a series of financial ratios have been applied in different studies the aim of the present study was not the identification of a good set of ratios but the examination of the performance of the classifiers over a specific set of financial ratios. Therefore, the ratios considered, in accordance to the study of to Olmeda and Fernadez (1997), were the following:

(I1) current assets/total assets
(I2) current assets-cash/total assets
(I3) current assets/loans
(I4) reserves/loans
(I5) net income/total assets
(I6) net income/total equity capital
(I7) net income/loans
(I8) cost of sales/sales
(I9) cash flow/loans.

These indicators are considered to fulfill the requirements set in par. 2.

DATASET

For comparison reasons, the dataset applied in our study is the one of Olmeda and Fernadez. This includes data from 66 Spanish banks active in the period 1977-1985. The ratios used for the failed banks come from the last financial statements issued before bankruptcy was declared while the data for non failed banks is from the 1982 statements. All 9 indicators were used. Summary statistics on dataset are given in the Appendix.

According to the originating study, this database was randomly split into two data sets (DS), DS1 consisted of 34 banks (15 failed and 19 non failed) and DS2 of 32 banks (14 failed and 18 non-failed). DS1 was used as a training set and DS2 for testing. Then the procedure is reversed, using DS2 for training.

Results

SVMs and probabilistic RBF ANNs were applied on the above dataset. The SVM parameters, γ and C, were defined heuristically after a series of experiments and more specifically γ was equal to $2^{-1.3}$ and C was equal to $2^{6.5}$. As far as the PNNs is concerned, the spread value was heuristically set to 206.

Table 1 summarises the obtained results and compares them to the performance of ANNs, Logit and Discriminant Analysis.

The accuracy obtained by the SVMs is quite high. Compared to the RBF ANN, the SVM approach provided

** performance data coming from Olmeda and Fernadez (1997)*

higher prediction results. This difference in performance is mainly explained by the fact that SVMs operate in an automated fashion generating the optimum kernels for the problem under study. This is not the case with the RBF ANN approach where the kernels are actually represented by the training patterns, meaning that their performance is highly dependant from the training set selection.

FUTURE TRENDS

The application of AI can be adapted / extended in a series of credit risk estimation cases. Credit risk estimation could be extended even to microcredit applications with certain limitations. The lack of financial statements (especially in the cases of developing countries) often imposes the use of different criteria, while the fact the micro-enterprises heavily rely on personal participation precludes AI methods from detecting bankruptcy risk due to human factors (e.g., an illness or an accident). On the other hand, adapting the ratings to rate a microcredit company itself appears as a new niche market in the financial sector (Navajas & Suaznabar, 2006).

In techncical terms, future work will examine whether specific feature selection methods can improve the obtained accuracy even more and will verify the results in larger datasets. The combination of classifiers into hybrid classification approaches that amplify the advantages of individual models and minimise their limitations appears as a worth-while research direction.

CONCLUSION

A short review of major AI applications to solve the bankruptcy prediction problem was presented. Moreover, two kernel based methods have been tested for bankruptcy prediction. Nine financial ratios covering profitability, management efficiency and solvency were applied. One of the methods examined, namely the SVMs, provides high classification accuracy, comparable to the accuracy obtained by neural networks.

KEY TERMS

Artificial Neural Networks (ANN): An artificial neural network is a massive parallel distributed processor made up of simple processing units. It has the ability to learn from experiential knowledge expressed through interunit connections strengths, and can make such knowledge available for use.

Bankruptcy Prediction: The process based on financial data of a company to predict whether the company will become bankrupt.

Financial Ratios: Mathematical relationship between one financial quantity and another used to describe financial condition of a firm. There are many categories of ratios such as those that evaluate a business entity's liquidity, solvency, return on investment, operating performance, asset utilization, and market measures.

Genetic Algorithms (GA): Genetic algorithms are derivative free, stochastic optimization methods based on the concepts of natural selection and evolutionary processes.

Support Vector Machines (SVM): Support vector machines is a methodology used for classification and re-

gression. SVMs select a small number of critical boundary instances called support vectors from each class and build a linear discriminant function that separates them as widely as possible.

Barriers to Successful Knowledge Management

Alexander Richter
Bundeswehr University Munich, Germany

Volker Derballa
Augsburg University, Germany

INTRODUCTION

Knowledge and Knowledge Management (KM) are gaining more and more attention in theory and practice. This development can be observed by an increasing number of publications since the 1990s, addressing the question of how knowledge in organizations can be organized and managed (Davenport & Prusak, 1998; Nonaka & Takeuchi, 1995). It is argued that knowledge is becoming the pre-eminent source of competitive advantage compared to the traditional factors of production, labour, capital and land. This theoretical discourse is accompanied in practice by an increasing number of KM initiatives. In many cases however, the results of those KM implementation projects have not lived up to the high expectations associated with them. Reasons for that are manifold. In this article, we will present the results of an extensive analysis of KM literature identifying the major barriers to KM. Those barriers represent current challenges during any holistic KM implementation that includes knowledge management systems (KMS).

BACKGROUND

KM, as an area of research is influenced by many disciplines such as information systems research, strategic management, organization science, psychology and human resources. Due to that, a wide array of different concepts and methods does exist. With the personification and the codification strategies two main perspectives on KM can be identified. The personification strategy, represented mainly by Japanese authors (e.g., Nonaka & Takeuchi, 1995) deals foremost with implicit knowledge embedded in human actors and aims at leveraging knowledge creation and sharing through informal and cultural mechanisms. The codification approach, which is dominated by U.S.-American authors (e.g., Bhatt, 2001), mainly considers the explicit aspects of knowledge and thus focuses on knowledge explication and reuse. The unbalanced focus on one of those perspectives has been made responsible for the failure of many KM initiatives. Because of this insight it has become more and more accepted that it is critical for successful KM to pursue a holistic approach. From that point of view KM is considered to be a management discipline that "(…) embodies organizational processes that seek synergistic combination of data and information processing capacity of information technologies, and the creative and innovative capacity of human beings" (Malhotra, 2005). Thus, whereas an overemphasis on technology is often problematic, a well balanced combination of technical and social approaches can be a rewarding departure (Alavi & Leidner, 1999).

BARRIERS TO SUCCESSFUL KM

Table 1 shows the barriers to successful KM, which are detailed in the following and categorized according to their origin along the dimensions technology, organization and human factors (Richter, 2006).

Technological Barriers

The balanced use of information technology is seen as a factor that can beneficially support different KM processes (Wiig, 1995). Typical examples for information technology aiming at the support of the codification aspects of KM include, for example, database solutions acting as knowledge databases or repositories. The personification aspects of KM can be supported by information systems that foster interpersonal communication, such as chat clients and groupware. Some of the most important barriers touching the technological domain of KM are highlighted in the following.

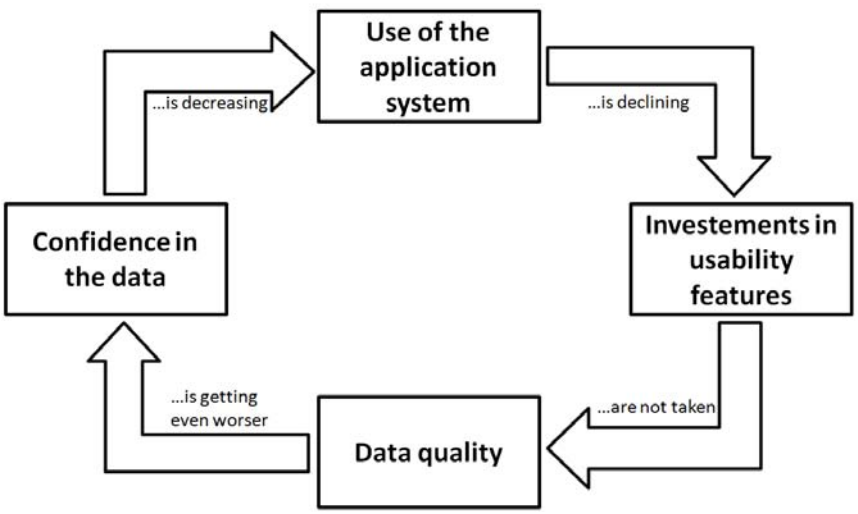
T1: Lacking Acceptance

Reasons for lacking acceptance can be found in a user-unfriendly application system, unsatisfying trainings and support granted by the software manufacturer, lacking stability and reliability and bad performance. Further, if the personal benefit for the individual user is not clear or the use of the system implies extra effort, many systems are insuf-

Table 1. Synopsis of all barriers

"T," "O" und "H" stand for the three dimensions "Technology," "Organization" and "Human"	
Category	**Barrier**
T 1	Lacking acceptance
T 2	Information overload and redundancies
T 3	Missing instruments for integrated planning and evaluation
O 1	Linguistic problems
O 2	Lack of time
O 3	Unfavourable company-and knowledge culture
O 4	Missing or diverging goals
H 1	Cultural influences
H 2	Personal fears and uncertainties
H 3	Inadequate motivation

Figure 1. Problem circle in the context of an electronic knowledgebase[1]



ficiently accepted by employees. The influence of change management during the introduction phase should also not be underestimated. Each of the factors mentioned above can lead to a so-called "problem circle," as it is illustrated here with the example of data quality (cf. Bullinger et al., 1998, p.30).

Usability

The "ISO 9241-11 Guidance on Usability" (ISO, 1998) issued by the International Organization for Standardization (ISO), defines the term "usability" as: "The extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use." A particularly simple application, which is suitable to the user and its tasks, is consequently called "user-friendly." The ISO 9241 includes a catalogue of several criteria for the evaluation of the user-friendliness of a product. Among these are the self description ability of the application (dialogue is easy to follow and gives explanations when desired) its error tolerance (incorrect inputs are indicated and corrected by the user or automatically by the system), controllability (the user should be able to affect work speed, selection and order of media, kind and extent of expenditures) and the focus on simplicity: The completion of the task should be supported, though the user should not be overloaded with characteristics of the system ("as much information as necessary, as few as possible").

Trainings

Modern software solutions are getting more and more complex. Therefore, trainings are gaining importance. Training is even a traditional form of KM (on a basis of the personification strategy). This can take place at the customer site (so-called "In-house training courses") or in the rooms of the software manufacturer. The training courses should be arranged in such a way that the participants receive support while they handle the system. This enables them to master all upcoming tasks in the future without any further assistance.

Support

During the continuous improvement of a software product, bugs are not completely inevitable. For this case the user should have either a direct contact within the company or some kind of internal or external user-support, which is often divided in a three-part system, that is, 1st Level, 2nd Level or 3rd level support.

Stability, Reliability and Performance

If a system is unstable (i.e., it fails too often), unreliable (i.e., it does not supply the correct results) or not sufficiently performing, the user will be unwilling to work with it and consequently diminishes its use. Likewise he will lose the confidence into an unreliable system and he will never develop any confidence into a new one, respectively.

Data Quality

The term "information quality research" stems from a branch of research, which is concerned exclusively with the question "what means good information?" (Eppler, 2001, p.1). There are objective and subjective knowledge valuation criteria. Agreement prevails among the researchers over the fact that data quality contributes to user-friendliness and to the frequency of WMS-usage.

T2: Information Overload and Redundancies

The cost for producing and spreading information is nowadays negligible. This results in information overload and even leads to the doubling of the worldwide printed knowledge every 8 years (Krcmar, 2005, p.52). Eli Noam found appropriate words for this: "The real issue for future technology does not appear to be production of information, and certainly not transmission. Almost everybody can add information. The difficult question is how to reduce it" (Noam, 1986).

It is to be assumed that a considerable part of the worldwide digital information exists several times. From an aspect of data security this is certainly advisable. However, each version of a document should exist only once within an enterprise, because this is a potential source for mistakes and confusion and might cause difficulties for a system user to identify one document among others. Even if data redundancy could be reduced to a reasonable measure, the employee's need for a clear file structure or for search features is still a big issue as the employees are in contact with innumerable information objects every day.

T3: Missing Instruments for Integrated Planning and Evaluation

Common sense demands setting goals before any measures are taken. In the relatively intangible are of KM, that is often not the case. A framework of knowledge planning should be developed, which permits prioritization of the scheduled activities. On basis of this framework, knowledge can be managed and ex post be evaluated. Thus, the activities should be supported by a knowledge management system (KMS). If an objective is not accomplished or if it is not integrated in the system, it is not a surprise that deadlines are exceeded or time management is a burden for the employees. In this context it is remarkable that management level systems, developed for the integrated planning and evaluating of "tangible assets,"

the so-called management support systems, have already been existing for years. However, these do not or only to a small extent incorporate knowledge work.

Organizational Barriers

KM and the concepts behind it frequently challenge or even reject old organizational structures and past strategic adjustments of the organization. The additional expenditure, due to organizational barriers and efforts to master them, frequently bars enterprises from changing their structures.

O1: Linguistic Problems

Language is a very important medium, in which knowledge becomes manifest and is getting transportable. Although enterprises are increasingly internationally aligned, language is not a substantial hurdle anymore. Nevertheless, the exchange of experience or generally the exchange of implicit knowledge often fails due to linguistic hurdles (i.e., metaphors or analogies, agreed beforehand, are missing). Thus, a linguistic hurdle does not necessarily involve different native languages of the participants; the hurdle can be even the result of different technical terms (Pawar et al., 2001, p.7). Besides, it is often difficult to access stored knowledge because different participants use different terms and definitions for describing the same competences. Probst accuses the low extent of vocabulary concerning KM (so-called "controlled vocabulary") for the insufficient formulation of knowledge goals (Probst et al. 1997, p.90).

O2: Lack of Time

In several surveys, the scheduled time for dealing with KM has been identified as the overall barrier of KM (cf. e.g., Pawar, 2001, p.7). There are two main reasons for that. Firstly, the commitment and support of the chief executive might be missing. This could be a consequence of the fact that the employees who apply KM are more aware of the need for spending KM-time than the person in charge. Secondly, this could be a pretended argument for hiding a lacking motivation, for preserving power or for some other reason (Bullinger et al., 1998).

O3: Unfavorable Knowledge Culture

Although KM has gained a considerable degree of popularity in many enterprises, these maintain a mainly conservative tenor and therefore consider their enterprise culture as a success-critical factor that has to be observed. Knowledge within a company is, particularly in conflict- and risk-averse working environments, often retained, if not specifically legitimated by the company culture. Thus, new and innovative ideas or approaches are often not followed up (cf. Disterer, 2000, p. 541). Moreover, in the case of group decisions, the position of the majority or of the person with the highest status is adopted (cf. Nemeth & Nemeth, 2001, p. 96)) without rationally weighting or even exchanging different opinions among the group. Therefore both, the knowledge development and the knowledge acquisition are obstructed. Hierarchy and bureaucracy are another two barriers that hinder the knowledge flow. Strictly hierarchical forms of business organization can slow down communication and thus the knowledge exchange over the borders of divisions. Far worse is the case when it even completely blocks communication. Bureaucratic sets of rules and regulations which allow the spread of worthy knowledge within an enterprise and which state the way of how it is spread ("official routine"), contradict the thought of an interlaced KM. Old, line-oriented organizational structures with a multiplicity of hierarchy levels and rigid information flows can hinder a successful KM, too.

O4: Missing or Diverging Goals

KM should receive consistent, convincing and reliable support by the executive committee. The latter should state clear that it is convinced of the necessity of the knowledge exchange and that KM-initiatives are appreciated and sufficient support is granted. Moreover, executives have to act as role models for KM implementation.

Discrepancies between the principles of an enterprise (vision, mission, values, etc.) and the individual goals of the employees can lead to the fact that employees do not share individual knowledge und personal experiences voluntarily (Disterer, 2000, p. 542). While, for example, in marketing an enterprise aims at collecting and evaluating the knowledge of field representatives, it is observable that the representatives hold back their knowledge, in order to increase their value for the enterprise. Additionally, individual experiences of the employee can lead to a conflict situation between the views of the enterprise and the views and goals of the business principles.

Human Barriers

Human actors play a central role in the identification, acquisition, creation, storage, structuring, distribution and evaluation of knowledge. The knowledge of an employee is the most important factor for the process organization within an enterprise, though it is this implicit knowledge, which is most difficult to measure, to store and to distribute (Pawar, 2001, p.3). Thus, if the importance of the human factor is neglected in a KM-strategy and if numerous activities are not taken due to this fact, then several barriers oppose successful KM.

H1: Cultural Influences

One of the most important barriers in this area is the "not-invented-here-syndrome." In this case, a mixture of unawareness, uncertainty, distrust and vanity leads to the bias of developing their own solutions than using already existing ones. In addition, knowledge from lower hierarchical levels is in most cases not adequately approved. A common example is an employee who is not willing to accept or use established solutions of unknown, nonfamiliar or unpopular colleagues.

H2: Personal Fears and Uncertainties

The fear of being compromised can also lead to the fact that knowledge is not shared. If an employee communicates parts of his knowledge, this is based on the individual assumption that his knowledge is not trivial, but possesses a certain value and rarity (Disterer, 2000, p. 541). Thus, if a colleague has a different opinion concerning the value of a person's contribution, it is conceivable that this devaluation is passed back to the other person. Often colleagues are trying to demand allegedly necessary corrections or additions in order to document their own expertise in this way. If one is entering knowledge into a data base, the value of this knowledge is published at the same time and presented for discussion. This implies the possibility that colleagues do not share the same opinion about the value of this particular knowledge, or that colleagues use the opportunity to boost their own reputation by making corrections or additions.

During the initial determination of knowledge goals, the knowledge acquisition, knowledge development and knowledge distribution, power aspects pose a potential pitfall (Probst et al., 1997, p. 91). A competitive situation within a company does definitely not enhance the willingness to share knowledge. In connection with software reuse, Judicibus (1996) calls the barrier of power loss "egg head-syndrome."

H3: Inadequate Motivation

Finally, motivation is one of the most important and most comprehensive barriers to KM (e.g., Bullinger et al., 1998, p. 88). The quality and quantity of achievements, which for example, an employee provides in an enterprise, are basically affected by two criteria (e.g., Comelli & von Rosenstiel, 2001, p. 2): The individual abilities and talents of the person and their readiness to apply these. An enterprise should thus be interested not only in the abilities of the coworkers (e.g., by advanced training measures) but also in the readiness to perform or the motivation of the coworker.

The implementation of a KMS is based on the principle of reciprocity. On the one hand, an employee has to invest much effort and time in order to share his knowledge. On the other hand, he can draw considerable value from having access to the organization's knowledge collection. He is thus compensated for his knowledge sharing effort. Coworkers who do not trust this principle of mutual giving and taking or who have not experienced successful KM projects yet are lacking an important incentive for taking on the additional work.

H4: Generation of Knowledge as Prisoner's Dilemma

The prisoner's dilemma is a central component of the game theory. The dilemma is caused by decisions that appear rational to each individual, but at the same time lead to collectively worse results compared to mutual cooperation. For the area of KM this means that the prospects of joint KM effort, like the creation of a knowledge database, are too vague for many. Thus, many individuals are not ready to perform additional work if the assurance of cooperative behavior among their coworkers is missing. Therefore, it is necessary that coworkers do not only have in mind the individual use, but beyond that they have a certain measure of employment will and commitment for the community, so that knowledge exchange is set and maintained.

FUTURE TRENDS

Most current KMS do not overcome the main barriers and thus fail in providing sufficient support for KM from a holistic perspective. The barriers to successful KM can be used to develop requirements for the development of KMS:

- Functional requirements
- Nonfunctional requirements
- Integration of KM in business processes
- Flat hierarchies
- Definition of knowledge goals
- Common language
- Adequate incentives

Adequate incentive mechanisms play an important role in overcoming barriers connected with human factors in the area of KMS development. The integration of KM into business process management can create considerable benefits. Doing so, knowledge work is no longer treated as a separate function, but integrated or closely connected with operational processes. Thus, it is possible to reuse knowledge that has been generated during the implementation of prior projects for new projects.

CONCLUSION

KMS that focus on one of the main KM perspectives, the codification or the personification approach, cannot overcome the barriers to successful KM. It is necessary to follow a holistic approach that adequately considers social as well as technical aspects. The barriers presented here, have their origins in the technological, organizational and human domain, thus demonstrating the different fields of action within KM. Some of them can be overcome by minor adjustments; others require major organizational or cultural changes. By identifying and categorizing the individual barriers, the basis has been created for the development of KMS-requirements.

KEY TERMS

Controlled Vocabulary: Standardized terms used in searching a specific database. These terms can differ for each database. Using controlled vocabulary to search will provide you with more focused results.

Knowledge: Knowledge is defined according to Steinmüller (1993) as the combination or connection of information.

Knowledge Management: Knowledge Management (KM) "(…) refers to the critical issues of organizational adaptation, survival and competence against discontinuous environmental change. Essentially it embodies organizational processes that seek synergistic combination of data and information processing capacity of information technologies, and the creative and innovative capacity of human beings" (Malhotra, 2005).

Knowledge Management System (KMS): KMS describe information systems that are designed to support certain KM processes like the dissemination or application of knowledge.

Personification Strategy: In contrast to the technical strategy, the personification or social strategy focuses on tacit knowledge and leveraging knowledge exchange on the interpersonal level.

Technical Strategy: The technical strategy implies that knowledge is not solely embedded in humans, but can be provided to knowledge users—after having gone through the process of explication—in codified form.

Usability: The extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use.

Benefits Realization through the Treatment of Organizational Issues

Neil F. Doherty
Loughborough University, UK

Malcolm King
Loughborough University, UK

INTRODUCTION

Information technology is now a ubiquitous and increasingly critical part of the fabric of the modern organization, supporting its day-to-day operations and all aspects of the decision-making process, as well as its strategic positioning. It is therefore not perhaps surprising that the implementation of a new technology or information system is likely to result in a wide array of impacts to the organization as well as the working lives of individual employees. There is a growing consensus within the literature that many such impacts are not deterministic and cannot therefore be easily predicted prior to a system's implementation (e.g., DeSanctis & Poole, 1994). The corollary of this is that many of the consequences of an information system's implementation will be unanticipated (Robey & Boudreau, 1999). While some of these unanticipated consequences, or incidental side effects, may be of a positive nature, negative impacts are also quite common, as IT-induced organizational change often results in user resistance and, in extreme cases, possibly even system rejection (Martinsons & Chong, 1999).

Information systems projects may not be totally predictable, but it can be argued that many of their organizational impacts only remain unanticipated, because systems developers are reluctant to tackle the human and organizational aspects of IT (Doherty & King, 2005). Systems development projects have typically been viewed as exercises in technical change, rather than socio-technical change; "most investments in IT are technology-led, reflecting too technical an emphasis" (Clegg, 2000, p. 464). This is a dangerous strategy, because unforeseen and unresolved negative impacts may increase the likelihood of systems failure. Moreover, beneficial impacts, of both a planned and incidental nature, may not be fully realized without an appropriate program of organizational change. Indeed, Ward and Daniel (2006) argue convincingly that the unacceptably high levels of IT failures are largely due to the absence of formal "benefits realization" approaches that explicitly target the organizational change needed to deliver business benefits. Consequently, we would argue that if systems development projects are viewed as an exercise in organizational change, in which all potential organizational impacts are proactively and systematically analyzed, then many undesirable impacts could be avoided, while the planned benefits can be more effectively realized (Doherty & King, 2002). The importance of treating organizational issues may now be widely acknowledged (e.g., Clegg, 2000; Eason, 2001), but little progress has been made in the development of practical treatment approaches that have succeeded in making the transition from research laboratory to widespread commercial usage. The primary aim of this article is to present an innovative new benefits-oriented approach for their proactive treatment. However, in advance of this, it is important to establish the importance of treating organizational issues.

BACKGROUND: THE NEED TO TREAT ORGANIZATIONAL ISSUES

The information systems' literature is very clear on two points; general levels of failure are far too high, and the primary cause of this problem is the failure to adequately treat organizational issues (Clegg, Axtell, et al., 1997; Doherty & King, 2001). In this context, the term "organizational issue" relates to those organizationally-oriented facets of systems development projects that need to be treated to ensure that the resultant impacts of an information system are likely to be desirable. A comprehensive checklist of important organizational issues, that was originally drawn from the literature but then validated over a series of studies (e.g., Doherty & King, 2001; Doherty, King, & Al-Mushayt, 2003), is presented in Table 1.

To treat a specific organizational issue it is necessary to first evaluate the likely organizational impact associated with it, and then if necessary take steps to ensure that the resultant impact is likely to be desirable. For example, if it is found that a proposed system is likely to be poorly suited to an organization's working practices, then it will be necessary to either modify the system's technical specification, so that the mismatch is avoided, or redesign the working practices so that they are well aligned with the system. In essence, the treatment of organizational issues is the mechanism by which the project team should align the capabilities afforded, and the constraints imposed, by the technical system with

Table 1. Checklist of organizational issues to address

Issue	Description
Information systems strategy	The system's alignment with the current information system strategy.
Current business needs	The system's ability to satisfy the organization's current business needs.
Prioritization of needs	The prioritizing of development effort on those aspects that address the most important business needs.
Future needs of organization	The system's ability to satisfy the organization's likely future business needs.
Process design	The system's impact on the design of key business processes.
Health & safety/ergonomic factors	The likely ergonomic and health and safety implications of the system, such as RSI and eye strain.
User motivation/needs	The system's ability to satisfy user needs and support user motivations.
User working styles and personal skills	The implications of user working styles and personal skills for the system's design and ongoing use.
Job redesign	The proposed system's impact on the design of working practices.
Timing of Implementation	The interaction of the system's implementation with other planned concurrent changes.
Organizational disruption	The temporary organizational disruption that may be caused by the implementation of the proposed system.
Organizational structure	The system's effect on the organizational structure, and the lines of authority.
Organizational culture	The proposed system's impact on the culture in the organization (*i.e., the set of important assumptions [often unstated] that members of an organization share in common).*
Organizational power	The proposed system's political implications for the distribution of power in the organization.

the requirements and characteristics of an organization and its individual employees.

System developers typically view the system development process as a science, rather than art, which requires the use of structured methods that focus upon the delivery of technically effective systems, on time and within budget. They are extremely reluctant to tackle intangible, ill-defined, and politically-sensitive organizational issues (Doherty & King, 2001), for which they are ill-equipped, in terms of training, competencies, and motivation (Clegg, 2000). Consequently, approaches to the treatment of organizational issues have typically been reactive rather than proactive (Clegg, Coleman, et al., 1996)—get the system implemented and then worry about its organizational impacts. There is therefore a pressing need to find ways to encourage the systems development community to become more actively engaged in the treatment of organizational issues. One obvious strategy is through the creation of methods, tools, and techniques that are specifically designed to facilitate the treatment of organizational issues. A wide variety of organizationally-oriented approaches have now been proposed, which can be categorized as follows:

1. **Socio-Technical Methods:** Socio-technical methods that attempt to produce information systems that are technically efficient and coherent, while also being sensitive to organizational and human needs, for example, ethics (Mumford, 1996) or multi-view (Avison, Wood-Harper, Vidgen, & Wood, 1998).
2. **Tools and Techniques for the Treatment of Specific Issues:** Many researchers (e.g., Clegg, Coleman, et al., 1996) have attempted to develop tools and techniques to aid in the treatment of specific organizational issues.
3. **An Organizational Impacts Analysis:** The "organizational impact analysis" (e.g., Sauer, 1993) is typically a one-off study to determine the ways in which a proposed system will affect the organization's decision-making, power, structure, culture, working practices, and so forth.

While each of these contributions has been very useful in increasing our understanding of the nature and treatment of organizational issues, there is little evidence that these contributions have made much of an impact on the practice of systems development (Clegg, 2000). This is probably, at least in part, due to technical specialists' continuing preference for the more technically oriented tools and techniques. However, if a comprehensive, coherent, and easy to use approach could be found, which complemented their existing methods, then it might have a greater chance of adoption.

The remainder of this section describes one such approach, which can best be described as an example of organizational impact analysis.

AN APPROACH FOR THE TREATMENT OF ORGANIZATIONAL ISSUES

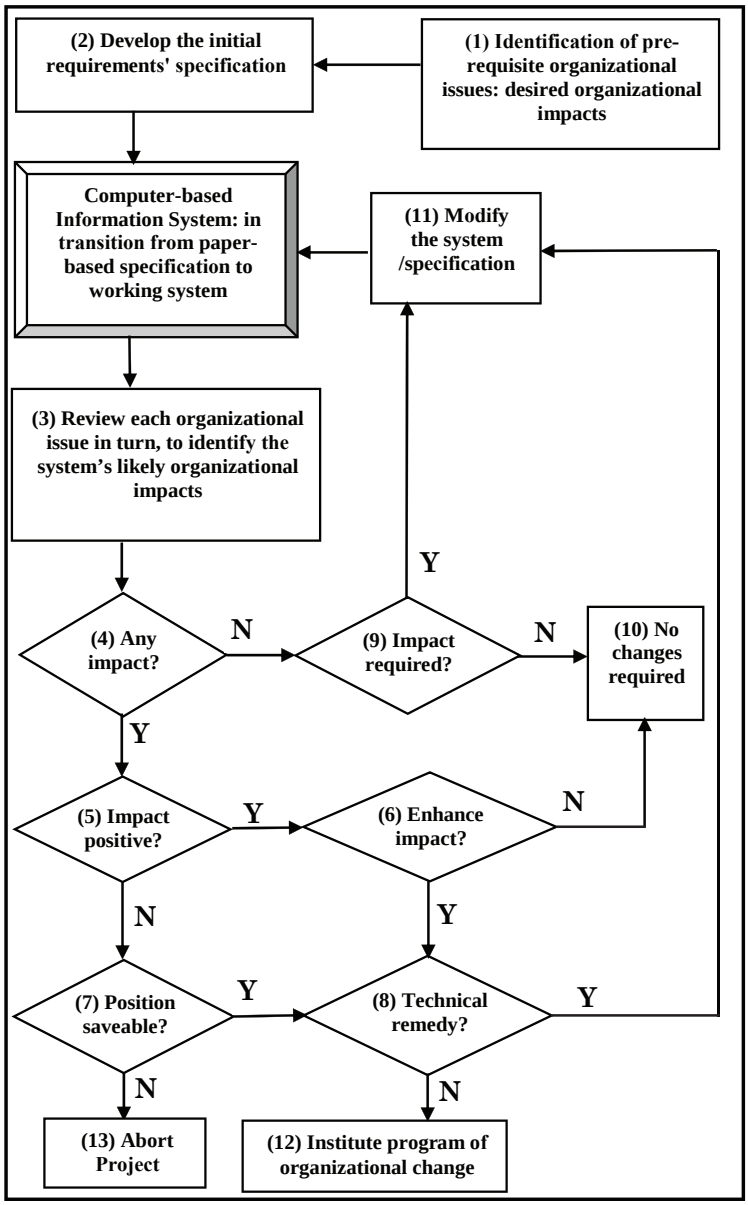
The proposed approach has been formulated from an extensive review of the literature and the authors' experience working in this domain for the past few years (e.g., Doherty & King, 2001; Doherty, King, & Al-Mushayt, 2003). A schematic representation of the approach, which has been conceptualized as a flow diagram, is presented in Figure 1. Each of the major processes and decision points on this diagram, all of which have been numbered, is reviewed below:

1. **Identification of Planned Organizational Impacts:** Many organizational issues will not be treated until a systems development project is well under way, but others, such as the system's ability system to satisfy "current organizational needs," will need to be considered right at the very outset if they are to be the planned outputs of the project. Indeed, unless the required benefits of a particular IT application are clearly articulated and agreed at the outset of the systems development project, the chances of any meaningful benefits being ultimately realized are extremely slim.
2. **Development of Initial Requirements Specification:** The development of the initial requirement's specification is a fundamental component of all development methods, and can be conducted using the proprietary or in-house method of the developer's choosing.

While the previous two stages occur only once, at the project's outset, it is envisaged that the following stages will be repeated at key stages in the systems development process, for each of the organizational issues in the checklist (see Table 1), in turn.

3. **Review of Organizational Issues:** Assess the system's likely impacts, with regard to each organizational issue. The process is designed to ensure that the planned impacts will ultimately come to fruition, while any incidental impacts will be effectively identified and managed.
4. **Determine Existence of Organizational Impacts:** The output of the review procedure, described previously, will be an assessment of whether there is a significant organizational impact associated with each organizational issue.
5. **Evaluation of Desirability of Impacts:** The desirability of each identified impact must be assessed to determine whether it is likely to be of a positive or negative nature. For example, an assessment of the system's impact on the motivation of users might identify a negative impact, such as user resistance or resentment, due to changes in their work practices. Potential solutions might be of a technical nature, such as changing the system's design to give the user more control over their work, or an organizational orientation, for example, improving the users' terms and conditions by way of compensation.
6. **Assessment of Potential for Increasing Desirability of Impacts:** If the previous stage has identified a desirable impact associated with an organizational issue, it is important to consider whether the impact could be made even more positive if the information system design were to be modified.
7. **Is the Situation Retrievable?:** In situations where a potentially undesirable impact of the system's operation has been identified, it is necessary to consider whether the situation is retrievable or not.
8. **Is the Remedy Technical?:** Having identified potentially negative, yet retrievable, impacts associated with the system implementation, a decision must be made as to whether the remedy is of a technical or organizational nature.
9. **Evaluation of Potential for Impacts:** If it has been discovered that there is no impact associated with a particular organizational issue, then it is important to question whether there should be an impact. If, for example, it has been determined that the system is unlikely to change working practices, then questions might be raised as to whether the system could be used to streamline or enrich the design of jobs.
10. **No Changes Required:** In the cases where there is no actual impact or potential for any specific organizational issue, there is no requirement to either change the system's specification or to institute a program of organizational change.
11. **Modification of Specification:** In many situations the organizational issues review process will necessitate changes to the system's specification in order to correct a negative impact or evoke a more positive impact.
12. **Development of Program of Organizational Change:** In situations where organizational impacts have been identified that have been judged to be desirable, it is important that a program of organizational change is planned and implemented to ensure that the impact is realized. In particular, the program of organizational change should be viewed primarily as a means of ensuring that all planned benefits are proactively managed, and ultimately realized (Ward & Elvin, 1999).
13. **Abort Project:** In situations where it has been found that the introduction of an information system is likely

Figure 1. An approach to the treatment of organizational issues

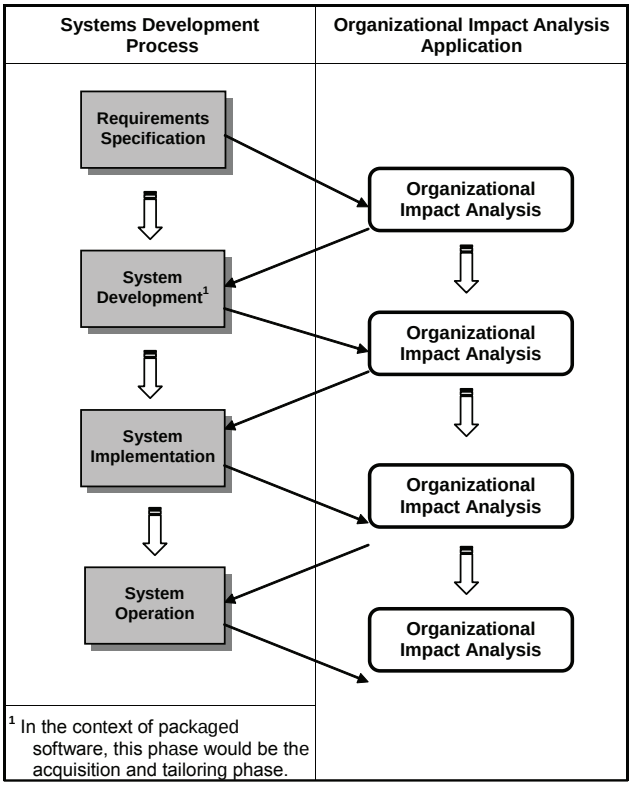


to result in significant organizational impacts of a negative nature, the project should be aborted.

At a minimum, it is envisaged that the organizational impacts will be assessed using this approach at the following key stages of the development process (see Figure 2): on completion of the requirements specification, then again at the end of the development phase, and then very soon after implementation. However, for very complex projects, or those that are likely to be the catalyst for significant organizational change, it is recommended that the analysis should be repeated more frequently, particularly during the design phase. Moreover, it is recommended that the organizational impact analysis be repeated a number of times over the system's working life. This would be one way of operationalizing Orlikowski, Yates, Okamura, and Fujimoto's (1995, p. 424) concept of "*technology-use mediation,*" which they define as:

deliberate, ongoing and organizationally sanctioned intervention within the context of use that helps to adapt new technology to its context, modifies the context as appropriate to accommodate the use of the technology, and facilitates the ongoing effectiveness of the technology over time.

Figure 2. The relationship between the systems development process and the application of the organizational impact analysis



It should be noted that once the system goes live, the organizational impact analysis procedure will not need to address the full range of organizational issues, as some—such as prioritization, timing of implementation, and organizational disruption—will no longer be relevant in an operational context.

While there will be a number of separate applications of the organizational impact analysis, they are not totally independent, as it is envisaged that the outcomes and findings of any given iteration of the approach might prompt or flag-up issues that need to be addressed in a subsequent iteration. It should also be remembered that many organizational impacts are interdependent, and consequently, changes made with respect to one specific issue might engender impacts in other areas. One of the obvious benefits of adopting an iterative approach is that it allows changing requirements to be monitored and accommodated, on an ongoing basis.

In terms of who is involved in the analysis of the impacts and the identification of appropriate changes to the system or the organization, to ensure the impacts will ultimately be desirable, it is recommended that the exercise be very inclusive. As a key objective of socio-technical approaches is to achieve consensus amongst all the system's stakeholders, it is envisaged that the proposed approach will act as a mechanism for channeling a debate about organizational change. As Markus and Benjamin (1997, p. 55) put it, "the hard reality of IT-enabled transformation is that change is everyone's job."

FUTURE TRENDS

As the scope and strategic importance of information systems continues to grow, so to does the need to find better ways of matching them to their organizational context, to ensure that they deliver a significant contribution to organizational performance. Consequently, there is an urgent need for practical and easy to use methods to aid systems development professionals in managing the organizational impacts of the systems for which they are responsible. To this end, our immediate priority is to test the provisional framework on a variety of systems development projects and use the feedback from these exercises to further define exactly how different organizational impacts can best be analyzed and managed.

CONCLUSION

Many information systems researchers have recognized the need for more effective socio-technical tools and methods to be developed. While the work described in this article is not trying to develop a highly specific tool or technique, it does propose a more general framework to promote the systematic and coherent treatment of organizational issues. The chief benefits of the proposed approach are that it presents systems developers with a systematic framework that obliges them to confront organizational issues and provides them with the means to effectively navigate their way through a very complex decision-making process. In particular, the application of this approach should ensure that systems development teams are encouraged to focus on benefits realization, as well as IT solution delivery (Ward & Daniel, 2006). Moreover, a comparison of this approach with some of its predecessors allows the following distinctions to be made:

- **Complementary:** The proposed approach complements, rather than replaces, existing development tools and methods. There is no requirement for systems developers to abandon their tried and tested practices.
- **Straightforward:** The approach adopts a commonsense perspective, and it should therefore be relatively easy to learn and apply.
- **Proactive:** By using this approach organizations will ensure that potential problems are recognized and opportunities are identified and exploited in a timely and effective manner.
- **Comprehensive:** The approach is comprehensive and can cope with a wide range of potential impacts.
- **Flexible:** The approach is highly flexible and can be adapted to suite the requirements of a wide variety of information systems projects

In essence, this approach is inviting systems developers to periodically stand back from the systems development process and, in conjunction with a wide variety of stakeholders, assess the likely impacts of their work on the design and operation of the organization. While there are a number of potential benefits to the proposed approach, it is also important to issue a health warning: these ideas are provisional and exploratory, and there is much further work required to translate them into a robust and reliable tool.

KEY TERMS

Benefits Realization: The process of proactively managing benefits to ensure that all the potential benefits that may arise from the introduction of a new information technology are ultimately realized.

Incidental Impacts: Impacts that are unplanned by-products of the system's development process that had not, or could not, have been envisaged at the project's outset.

Organizational Impact Analysis: A one-off study to determine the ways in which a proposed system will affect the organization, in areas such as power, structure, culture, working practices, and so forth.

Organizational Issues: Those issues that need to be treated during the systems development process to ensure that the individual human, wider social, and economic impacts of the resultant computer-based information system are likely to be desirable.

Planned Impacts: The anticipated outcomes of a systems development project that were identified at the project's outset, and are typically critical to its ultimate success.

Socio-Technical Methods: Development methods that attempt to produce systems that are both technically efficient and organizationally sensitive.

Systems Failure: Systems abandoned before completion, systems completed but never used, under-used, or failing to deliver key aspects of functionality, and projects that are significantly over budget or schedule.

Best Practices for IS&T Supervisors

Debra A. Major
Old Dominion University, USA

Valerie L. Morganson
Old Dominion University, USA

INTRODUCTION

Researchers over the last decade have generated a body of literature which is informed by management research and theory and tailored to the unique demands that characterize IS&T work. At the industry level, IS&T fluctuates with the supply and demand asymmetry caused by technological advances (Agarwal & Ferratt, 2002a). The changing nature of the industry trickles down to affect IS&T professionals who must continually update their skills in order to prevent obsolescence (Rajeswari & Anantharaman, 2003). IS&T work demands flexibility in responding to customer demands, emerging issues, spontaneously hectic workloads, and frequently unplanned requests. The nature of the work is continuous (frequently 24/7) and often requires the coordination of multiple experts. IT is typically a service function upon which other organizational functions depend. Yet, it is common for IT to be undervalued and unrecognized, unless there is an IT failure. IS&T work may be performed by individuals or teams that may be colocated or virtually connected. Although there has been some debate in defining the parameters of the so-called "IS&T workforce," considerable overlap in skills, educational backgrounds and other domains persist (Kaarst-Brown & Guzman, 2005). The current article defines IS&T professionals as individuals whose primary job function is the development, installation, and implementation of computer systems or communication technology. Research and best practices literature are reviewed to provide IT managers with an overview and a starting point for workforce intervention and improvement.

BACKGROUND

IT human capital is seen as a strategic resource and competitive advantage for businesses (Bhardwaj, 2000). Where the IT workforce was once inundated, many researchers and practitioners have raised concern about a shortage of skilled professionals and have noted a corresponding research focus on IT turnover (Agarwal, Ferratt, & De, 2007; Niederman, Moore, Yager, 2002). Prior to the popping of the IT bubble, the abundance of IT workers permitted managers to focus on motivating extant staff. Because the industry has stabilized and labor is in shorter supply, managers have been required to heed turnover, a more longitudinal goal, in addition to maintaining production levels.

Table 1. IS&T best practices taxonomies

Human Resource Practices Agarwal & Ferratt (2002a)	Supervisory Practices Major et al. (2007)
Performance Measurement	*Task-focused Practices*
Compensation & Benefits Systems	Boundary Spanning
Work Arrangements	Performance Management
Employability Training	Employee Involvement
Longer-term Career Development	Training & Development
Opportunities for Advancement	
Opportunities for Recognition	*Person-focused Practices*
Quality of Leadership	Relationship Building
Sense of Community	Mentoring
Lifestyle Accommodations	Stress Management
Organizational Stability & Employment Security	Work-family Balance

Agarwal and Ferratt (2002a) and Major et al. (2007) have combined survey and interviewing methodologies to empirically derive taxonomies of best human resources management (HRM) and supervisory practices for IT (see Table 1). Although both taxonomies address the issue of effectively managing IS&T professionals, Agarwal and Ferratt approach the issue from a more global HRM systems perspective, while Major et al. focus on the practices of individual supervisors.

Reminiscent of classical leadership theory, two dimensions emerge in each taxonomy. One is focused on work and output itself , "task-focused leadership practices" (Major et al., 2007), or "productivity concerns" (Agarwal & Ferratt, 2002a). This aspect emphasizes performance management, employee involvement, and training and development. The other attends to the individual needs of the worker. At the macrolevel, this refers to attending to employee needs through human resources, an "interpersonal dimension" (Agarwal & Ferratt, 2002a). Similarly, "person-focused practices" refer to meeting individuals' social needs and maintaining interpersonal relationships though supervisor-subordinate interaction (Major et al., 2007). These two dimensions reflect the state of the IT industry, which has recently required a dual management focus on both immediate (motivational) behavior and longitudinal (employee continuance) behavior.

Because Major et al. and Agarwal and Ferratt's work provide two holistic and complimentary taxonomies and hold a strong empirical base, the current article derives its structure by identifying commonalities between the two perspectives. In addition, the findings of these articles are used to reference practical examples. Our aim is to create an integrative perspective of effective IT management practices.

PERSON-FOCUSED PRACTICES

Relationship Building

Upon hire, employees enter into a relationship with their organization. As with any relationship, it requires reciprocity. Employees make an investment in their organization (e.g., labor and effort) and hold expectations of the company in return. The perceived exchange relationship between employees and their organizations is referred to as a psychological contract (see Agarwal & Ferratt, 2000; Rousseau, 2001). Managers are responsible for communicating and upholding the employer's end of the contract and may assist the organization to enjoy the benefits of the relationship (Agarwal & Ferratt, 2002b).

IT supervisors should maintain open communication with their subordinates for motivational purposes. Research suggests that face-to-face communication is preferred over other methods (e.g., e-mail) by IS&T professionals and their supervisors as means of interpersonal relationship building (Major et al., in press). Face-to-face communication is especially important, at least on occasion, for employees working at a distance (Davis & Bryant, 2003). Through good communication aimed at establishing strong relationships, managers can mitigate job stressors such as customer service demands, tight deadlines, and understaffing (Major et al., 2007). Given the nature of IS&T work, direct supervision may not be possible. Managers must rely on trust, mutual respect, and loyalty instead. This is especially important to the effective functioning of team arrangements, distributed work in virtual teams, and telework (Costa, 2003; Davis & Bryant, 2003). Subordinate trust can be developed through open communication, honesty and follow-through (Korsgaard, Brodt, & Whitener, 2002).

IT research has especially advocated the implementation of mentor-based systems (e.g., supervisory mentoring). Mentors assist employees in identifying career choices, required competencies and training needs. Effective mentors also provide psychosocial support and serve as role models (Major et al., 2007; also see Scandura & Ragins, 1993). Research suggests that supervisor/subordinate mentoring relationships may be especially advantageous (see Payne & Huffman, 2005). In addition to providing mentoring themselves, effective IS&T supervisors also facilitate peer mentoring among IT professionals (Major et al., 2007).

Embeddedness

Organizations and departments are infused with information technology. Thus, IT professionals are required to interface with a variety of other organizational departments and functions. These clients make technology requests, frequently without understanding what is required to fulfill their demands, or while underestimating the time and resources required. The situation may be exacerbated by client-held stereotypes of the IT professional and role (Guzman et al., 2004). In order to prevent interdepartmental conflict, effective supervisors work proactively to educate and build relationships with other departments and monitor the work environment to prevent sudden conflicts from arising. Ideally, the supervisor should assist subordinates and clients in maintaining sight of how the client's needs and IT interactions fit within the context of the organization's needs and goals holistically. Effective participative practices in an IS&T setting include involving employees in informal meetings with multiple layers of management to allow them to see how their work fits into a larger context (Agarwal & Ferratt, 2002a) and seeking employee feedback in both one-on-one and team settings (Major et al., 2007).

Supervisors should also be proactive in gaining a seat at the table for organizational planning. This entails marketing IT capabilities to customers to communicate how IT

can be used to facilitate the attainment of organizational goals (Major et al., 2007). This process of monitoring the organizational environment and crossing departmental functions to anticipate and seek out implications for one's own department is referred to as boundary spanning. In a meta-analysis that empirically combined the results of 51 studies of IT turnover intentions, the practice of boundary spanning was shown to be an important factor in preventing IT professionals from intending to leave their organization (Joseph & Ang, 2003)

Attending to Employee Well-Being

IS&T work, characterized by heavy customer service demands, on-call duties, frequent understaffing, and bursts of activity, may create stress for employees and challenge them to keep a healthy balance between their work and nonwork lives. Effective supervisors address key sources of stress directly through interventions such as additional staffing, advocating for subordinate needs to decision makers, and monitoring the environment for changes with IT implications. Supervisors also assist employees in coping with stress by engaging in open communication, prioritizing and monitoring workloads for fair distribution, and encouraging coworker support (Major et al., 2007).

Effective supervisors recognize the reciprocal influences between employees' work and nonwork lives. Because IS&T work often infringes on family and personal life, effective supervisors use formal (e.g., vacation time) and informal methods (e.g., flexible arrival and departure times) to help employees attend to their nonwork demands (Major et al., 2007). Agarwal and Ferratt (2002a) noted that effective IT organizations had lifestyle accommodations in place and encouraged their use. Examples included a relaxed work environment, flexible work arrangements, child care services, and telecommuting. Even when family-friendly policies are on the books, they are unlikely to be used if they are not supported by the work environment (Allen, 2001).

In an IT sample, policies that permitted flexibility for workers' personal lives were found to have an influence on commitment and turnover intentions. Based on the findings, the authors suggested that work-life concerns should be considered complimentary to other important organizational practices (e.g., recognition, competence development, and empowerment (Paré, Tremblay, & Lalonde, 2001). Employers that engage in fair treatment and invest in employee well-being reinforce employees' expectations that they will be treated fairly throughout their tenure (Moorman, Blakely, & Niehoff, 1998).

PRODUCTIVITY-FOCUSED PRACTICES

Empowerment

Involving IT professionals in management decisions is a common theme in the IT literature. In order for participation to be motivating, IS&T professionals must see that their participation actually has an influence or makes a difference in the work environment (Major, Davis, Sanchez-Hucles, Germano, & Mann, 2006; Major & Germano, 2006). Aside from the motivational benefits of empowerment, supervisors may rely upon their subordinates as technical experts. Often the supervisor lacks certain types of technical expertise and depends on subordinates' skills to supplement their own (Major et al., 2007). Due to the complex nature of IT work, pooling knowledge from multiple experts provides considerable advantage over authoritarian leadership styles. By allowing subordinates to become involved in making decisions, supervisors are providing learning and growth opportunities, teaching self-reliance, and fostering empowerment.

Training and Development

According to a recent survey of hiring managers conducted by the ITAA, the value placed on highly skilled IT professionals is increasing, and IT managers are aware of the strategic significance of individuals' skills portfolios (ITAA, 2004). Researchers have recognized the role of training and development for increasing retention, organizational performance, building competitive advantage and dealing with staff shortages (e.g., Agarwal & Ferratt, 1999; Hopp, Tekin, & Van Oyen, 2004; Major et al., 2007; Paré et al., 2001). Likewise, IS&T professionals hold a stake in continually updating their skills in order to remain marketable for career development purposes (Rajeswari & Anantharaman, 2003). Competency development practices may communicate to employees that the organization considers them to be an investment toward competitive advantage and seeks to establish a long-term relationship with them (Agarwal & Ferratt, 1999). IT professionals viewed competency development to be principally important; it predicted feeling committed (affective commitment) to the organization, which, in turn was related to turnover (Paré et al., 2001). Empirically derived qualitative data has revealed several training and development practices employed by effective managers, including tuition reimbursement, computer-based training programs, leadership workshops, mentoring, provision of enriching job activities (e.g., on-the-job-training or challenging projects) and facilitation of learning-supportive environments, job rotation, cross-functional teams, supervisor-to-subordinate coaching, facilitation of peer training, opportunity to participate in organizational committees and cultural awareness

training (Agarwal & Ferratt, 1999; Agarwal & Ferratt, 2002a, Major et al., 2007; Paré et al., 2001).

Managing Performance

Research has demonstrated that feedback rich environments—those where feedback is frequent, specific and positive—are linked to individual perceptions of feedback accuracy, and in turn, desire to respond to feedback (Kinicki, Prussia, Wu, & McKee-Ryan, 2004). Empirical evidence supports that effective IT organizations complete annual (or more frequent) performance appraisals (Agarwal & Ferratt, 2002a). Unfortunately, IS&T personnel evaluation practices are seen as inadequate in today's organizations (Chilton & Hardgrave, 2004). Accommodating user needs is an essential job function; yet, organizations have struggled to identify a criterion to account for this performance dimension. Traditional system development performance was deemed inadequate and has more recently been replaced with subjective judgment and supplementary measures (Saarinen, 1996). To tend to the criterion problem, Boyd, Huang, Jiang, and Klein (2007) identified several core literature-based performance dimensions to guide performance ratings of IS&T professionals. These include work quality, project work, general task, interpersonal quality, dependability, teamwork and leadership, and career-related training. They also recommended using a 360-degree feedback approach to include key stakeholders in the performance of groups or individuals (e.g., users and developers). Indeed, there is some validation for this suggestion. In a large sample, 360-feedback systems, including multiple raters, was identified as a best practice (Agarwal & Ferratt, 2002a).

Beyond provisioning formalized performance feedback, effective supervisors accentuate the linkages between the organization's objectives, subordinate performance, and the achievement of desired rewards (Major et al., 2007). Furthermore, recognizing individual contribution through nonmonetary means (e.g., extended vacations, awards, and outings) has been empirically linked to supervisory effectiveness and employee commitment to the organization (Major et al., 2007; Paré et al., 2001).

FUTURE TRENDS

Research describing the demands of IS&T work is abundant, and researchers are directing their attention to the question of best management practices for IS&T professionals facing these circumstances. Agarwal and Ferratt (2002a) addressed this question with regard to upper-level management and human resources practices. Major et al. (2007) explore effective human resource management from the perspective of first-level IT supervisors. These two taxonomies highlight the need for a cohesive human resources management strategy. Human resource policies and practices sensitive to the needs of IS&T professionals must be supported by top management. Middle managers and first-level supervisors must be supported and rewarded for their efforts to implement policies and encourage their use. Much like the IS&T professionals they supervise, first-level managers need the flexibility and discretion to assess the needs of their individual employees and provide appropriate accommodations. As the closest and most visible representative of the organization for IS&T professionals, a supervisor's role in effective human resource management cannot be underestimated. Ensuring that supervisors possess the requisite skills for effectively managing IS&T personnel and understanding how to adequately motivate supervisors to engage in best practices are key issues for research and practice.

Research shows that best practices for managing IS&T professionals are the same practices found to be effective for other technical professions (Ferratt & Short, 1988). Moreover, practices that are effective for supervising IS&T professionals are consistent with decades of leadership effectiveness research (Major et al., 2007). Still, IT-specific research is warranted. Researchers should continue to examine which sets of practices are needed to dovetail with the unique demands of the work environment to attain optimal functioning.

CONCLUSION

In reviewing the IS&T literature, a dichotomy of person- and productivity-focused practices emerges. On one hand, themes in the literature regarding person-focused practices include building relationships, creating embeddedness, and attending to employee well-being. On the other hand, productivity is comprised of empowerment, training and development, and managing performance. Person- and productivity-focused practices are each associated with their own respective objectives. The former is mainly concerned with achieving employee staying behavior, whereas the latter is more closely associated with product or service output. Thus, while all of the practices discussed in the current article are potential points of leverage for IT managers, some may take precedence over others, depending upon an organization's internal and external conditions. Where there is less stability and capacity to forecast of the conditions to come, production goals tend to be a more appropriate focus. For longer time horizons, where there is stability and constancy within the department and business, longer-term objectives, such as employee development and other person-focused practices, may come into focus as well (Jackson & Schuller, 1995). Resources permitting, the best practices described in this article should

be used together. In combination, they may have synergistic benefits (Ferratt, Agarwal, Brown, & Moore, 2005).

KEY TERMS

Boundary Spanning: Monitoring the organizational environment and crossing departmental functions to anticipate and to proactively seek out implications for one's own department.

Embeddedness: Incorporating and establishing (a) the IT function across departments and (b) IT employees within the organization. For embeddedness to occur, IT departments and workers must participate in the organization, hold a network of partnerships (e.g., friendships and alliances), possess influence, and experience positive interactions within the organization.

Performance Management: Applying techniques such as role clarification, goal setting, performance appraisal, and performance-related rewards in order to connect individual behavior and organizational strategies and goals (Banks & May, 1999).

Psychological Contract: The reciprocal exchange relationship that is perceived to exist between employees and their organizations.

Relationship Building: Developing a dynamic of reciprocity and trust between an employee and his or her (a) organization, (b) coworkers or (c) supervisor.

Training and Development: Providing opportunities for employees to acquire and to improve technical and interpersonal job-related skills and knowledge for personal growth and career advancement.

Work-Life Balance: Achieving a suitable harmony between the frequently incompatible duties of work and home life that many workers face, particularly when working in jobs with irregular or long hours.

Better Executive Information with the Dashboard Approach

Frédéric Adam
University College Cork, Ireland

Jean-Charles Pomerol
Université Pierre et Marie Curie, France

INTRODUCTION

After more than 30 years of research on how the work of managers can be supported by computers, the observation that developing computer systems that are truly useful for top management is a highly complex and uncertain task is still as valid as ever. Information systems for executives raise specific problems, which have primarily to do with the nature of managerial work itself (Mintzberg, 1973), as they are intended to tackle the needs of users whose most important role is "to create a vision of the future of the company and to lead the company towards it" (King, 1985, p. xi).

BACKGROUND

The major difficulty in supporting managers with computer systems comes from the very nature of management work (Mintzberg, 1973, 1975, 1976), which is concerned with communication, coordination, and people's management for more than 80%. At the time of his research, Mintzberg (1973) had noted how little time is left for reflection and for "playing" with computer systems. This has been a significant difficulty from the origins of MIS systems because their primarily "operational" focus was not central to executives' concerns (Ackoff, 1967; Keen & Scott Morton, 1978). Twenty years later, this difficulty has also been largely responsible for the shift from decision support systems (DSSs) to executive information systems (EISs). EISs were intended to be very easy to use and to help users manipulate required data without the need for much training, which would be very attractive to top executives who want to have, at a glance, a very comprehensive view of their business. Specific descriptions of the differences between DSSs, EISs, and cooperative decision systems can be found in Pomerol and Brézillon (1998). Naturally, computer literacy among executives has increased to a great extent, notably thanks to the development of electronic mail and the World Wide Web. However, whatever designs were put forward over the years, it has remained true that managers are not inclined to spend countless hours browsing computer data, such is the time pressure under which they operate.

Beyond the time pressures under which executives must operate, there are issues of trust and of credibility of the information that can be found in a computer system, which mitigate against intensive executive reliance on information systems, especially in a long-term perspective. First of all, the lack of confidence of executives in their models has been noted by many researchers (e.g., Wallenius, 1975; Cats-Baril & Huber, 1987; Abualsamh, Carlin & McDaniel, 1990). The idea that decision makers need sophisticated models may actually be wrong. People in charge of the preparation of decisions would probably be able to understand and use smart models, but the high-level executives who most commonly make the final decisions are far too busy to train with and use involved systems. On the contrary, they appear to prefer simple systems that they trust and understand, and that display very timely simple information. More often, the data required to make the best decisions will already reside in some form or another in the database of the organization or can be captured with an online feed into a computer system, and what is really needed is a device to filter and display and to warn executives about the most important variances (Simon, 1977). As noted by Kleinmutz (1985): "the ability to select relevant variables seems to be more important than procedural sophistication in the processing of that information" (p. 696).

In EIS, the underlying models built into the system are normally very simple and easily understandable, which is a great help in increasing the acceptability of a computer system.

To conclude, the specificities of managerial decision making can be synthesized as follows:

- Most decisions are made very quickly under considerable time pressure (except some strategic decisions).
- Strategic decision making is often the result of collaborative processes.
- Most decisions are linked to individuals who have specific intentions and commitments to personal principles and ideas.

It is therefore very difficult to support managers, and despite many years of research, little is known about the way information systems could support such unstructured tasks.

A VEHICLE FOR INFORMATION REQUIREMENTS ANALYSIS: CRITICAL SUCCESS FACTORS

In pre-EIS days, Rockart (1979) put forward a methodology called critical success factors or CSF to guide information systems planning. The method had its advantages, though it failed to make a general impact on the planning process of organizations. Its potential in other areas, notably the development of information systems, has been explored by a number of researchers. It is argued in this article that it can be very useful as a guide for the development of executive systems, as both from an information content perspective as for the design of the interface of these systems.

CSF assumes that the performance of organizations can be improved by focusing on "the few key areas where things must go right for the business to flourish" (Rockart, 1979). In simple terms, the method seeks to isolate, using the expertise and gut feeling of managers, the factors which may make the difference between success and failure for the firm.

A number of key points about CSF make it a very attractive technique. First of all, while CSF is essentially a generic framework, it recognizes that all firms are different and operate in different markets. Thus, CSFs are different for different organizations. Secondly, the CSF theory takes into account that the needs of managers within the same organizations are also different based on their hierarchical level, but more importantly, based on their style and their specific areas of responsibility. In general, there are only a limited number of factors that each manager should monitor closely, and this guarantees that managers can concentrate their limited attention to factors that really matter and that are within their control. The attractive thing about this breakdown of responsibility is that the CSF sets controlled by the different managers add up to a complete organizational set that covers all the key areas of the business.

Van Bullen and Rockart (1986) identified a number of primary categories of CSF that are useful in guiding the analysis of the organizational CSF set. These generic sources of CSFs are: (1) the industry where the organization operates (these CSFs are shared by mainstream organizations in this industry), (2) the competitive position and strategy pursued by the organization (which are unique to its set of circumstances and objectives set by its top managers), (3) the environmental factors surrounding the organization (which it has no control over, but which it must monitor closely to compete), (4) temporal factors (which relate to specific events or change programs currently facing the organization, and require the temporary monitoring of additional factors), and finally, (5) CSFs that are specific to each manager and their role in the company. Other authors have added other potential sources such as CSFs related to the analysis of main competitors (especially industry leaders) and the evolution of their business (Leidecker & Bruno, 1984). These sources add up to a wealth of potential factors and measurements that are sufficient for effective monitoring of the business of most organizations.

Dashboards and Control Rooms

In the next stage of the development of executive systems, designers must create an interface for displaying the CSFs. The design of this interface is nearly as important as the selection of the indicators in shaping the perception of managers of the usefulness of their information systems and keeping their interest in the long run. One technique that has worked well in selecting and presenting indicators is the application of the dashboard concept to the management of organizations.

Fundamentally, the concept of dashboard reflects the application of the concept of control room to the management of the firm and echoes the call for a warning or exception reporting functionality in EIS-type systems. In engineering, the control room is a specially designed physical area of a plant where the proper operation of key equipment can be monitored. Control rooms have developed because of the need to monitor increasingly complex processes, such as petrol refining or the operation of nuclear power plants. The control room allows operators to control a process without looking at it with their own eyes, and with a degree of accuracy and completeness that could not be achieved with human perception alone.

This suggests that dashboards may be developed that considerably help managers in their day-to-day search for problems and matching solutions. Naturally, the nature of management itself is highly dynamic and diverse and involves consideration of infinite number of parameters in a way that is fundamentally different from the monitoring of a manufacturing process. Thus, management has a significant "human interaction" component that cannot easily be supported by computer systems. Simon (1977), Gorry and Scott Morton (1971), and others have commented comprehensively on the degree to which managerial decisions are programmable or not, however it remains that the implementation of many of the objectives of the firm, however elusive, can be monitored using a dashboard-type interface. Further, the CSF method can be a powerful vehicle in selecting the indicators to be shown on each manager's dashboard.

The difficulty with CSF-based dashboards resides in the operationalization of managers' key concerns and the identification of specific targets for CSF monitoring, the

design of measurement logic for each indicator, and in the development of the interfaces that can be used by managers to easily and effectively review the performance of the firm in relation to each of the indicators.

TOWARDS A METHODOLOGY FOR DASHBOARD DEVELOPMENT

At the height of the EIS movement, King (1985) remarked:

"It is so easy to lose sight of reality—to believe that the computer model's numerical forecasts are real and that they describe future outcomes that will, in fact, come to pass…The computer model's forecasts are based solely on those predictions about the future that we are able to quantify. Those things that are not readily quantifiable are usually omitted, and in being omitted there is a danger that they may be ignored." (p. xi)

This illustrates the dangers inherent in approaching management based solely on numbers, however obtained. This also explains why observational plant tours are still regarded as one of the most reliable methods for collecting data in manufacturing environments (Jones, Saunders & McLeod, 1988). The basis of any dashboard approach to management must therefore take into account the following four key issues:

(1) *Limited Attention:* Given the limited attention of managers and the costs inherent in sourcing certain data, the indicators displayed on the dashboard must be carefully selected using the CSF.

(2) *Performance Measurement:* The measurements used to monitor indicators or CSFs are crucial. The usefulness and effectiveness of the dashboard is totally dependent on the accuracy of the data used and the realism of the calculations presented to managers.

(3) *Operator Training:* It is critical that managers understand the assumptions built into the dashboard and the algorithms used to reach the results presented to them. They must also be fully aware of how data are collected and what limitations applied to the accuracy of the measurements. For instance, drill down facilities can make the difference between "using information to manage more intelligently and more effectively and making the same old mistakes but with more speed" (Meall, 1990).

(4) *Dashboard Layout:* The layout of the dashboard has a direct impact on the understanding derived by managers. The interface of the dashboard must be consistent so that managers can visualize immediately where they should focus their attention as a matter of priority. Exception reporting and color coding (Watson, Rainer & Koh, 1991) can be used to achieve maximum visual impact.

It is also useful if the development of the dashboard can be operationalized as an evolutionary activity where managers can feed back their perception of the dashboards to developers so that the design can be improved over time and the indicators refined or replaced (as in the case of temporal CSFs). In this article, we propose a framework based on 11 questions to support this evolutionary process, and help managers and developers to establish a fruitful dialogue:

- **Question 1: Who will use the indicators?**
  The answer may not be simple when not one, but a number of individuals are interested in monitoring certain indicators. However, managers should concentrate on monitoring the parameters most closely associated with their own performance or that of the areas directly under their control.
- **Question 2: Can be mapped out to a specific objective at a higher level?**
  In the perspective of a top-down CSF exercise, indicators are mapped out to specific objectives pursued by top management. In a bottom-up scenario, it will help if indicators can be merged into higher level composite indicators presented to higher level managers. Developers can use the hierarchy of indicators as a blueprint for the drill-down facility to be built into the dashboard so that top managers can understand the underlying causes of poor or good performance.
- **Question 3: How frequently will managers need to monitor each indicator?**
  Managers' perception of how frequent significant or revelatory variations are likely to occur should be used as a guide for deciding how frequently indicators should be updated. The scope of the benefits that may arise as a result of the monitoring should also be considered if high costs are likely to be incurred.
- **Question 4: What calculation methods are available? What unit of measurement will be used?**
  The choice of calculation method can greatly influence the variation of an indicator and shift the burden of responsibility from one area to another. It can also influence the way the performance of operators or workshops is measured.
  The choice of the unit of measurement is normally straightforward for quantitative analysis, but can become far more complex for less tangible CSFs that involve the estimations of qualitative factors. Customer satisfaction, for instance, will require vision and creativity if it is to be measured properly. Some quantitative measures may be applicable such as the number of complaints received per time interval, but

other measures may have to be found that can act as surrogates of customer satisfaction.

- **Question 5: What data source exists? What should be created?**
  Certain data may be missing from existing organizational information systems. Other data may reside in a proprietary system (e.g., a custom-built process control system) that does not integrate well with other systems. Significant investment in equipment and special devices (such as scanners and sensors) or in software such as OLAP and ROLAP (Relational OLAP) may have to be made.
- **Question 6: How detailed should the analysis presented in the dashboard be? How can the indicators be broken down to be more meaningful?**
  Many indicators are too broad to be suitably presented as one figure, and some disaggregating may be required. Typical organizations sell multiple products in multiple markets. Thus, sales figures need to be disaggregated to present £ figures, volumes, and variances for each product on each market while also presenting the aggregated data. Multi-dimensional modeling can be used to support the organization and retrieval of such data.
- **Question 7: What threshold values should be used to differentiate between adequate and inadequate performance? What comparisons can be made to assess the company's performance?**
  Absolute measurement figures presented by a dashboard may not be meaningful to managers unless they can be examined in light of other data. Most companies already have a tight budget system in place, and this can be used as a source of normative values.
- **Question 8: How can each indicator be represented for maximum visual impact?**
  Developers must seek to reduce information overload and use the latest graphical user interface (GUI) technology. Some software tool boxes are now available to help designers create displays and objects that mirror the type of controls normally found on dashboards. Gauges with specific color-coded threshold values can easily be created, and special charts can be made clickable to build intuitive drill down into the data. These speed up and facilitate the data reading of managers.
- **Question 9: What action must be taken when good or bad performance is measured? Is there scope for corrective action to be taken based on the indicator?**
  Whenever good or bad results are presented, managers should know what avenues can be pursued. Reporting mechanisms (e.g., electronic mail) can be built into the dashboard to facilitate and accelerate the dissemination of interesting results and their discussion. In the longer term, increased familiarity with indicators and what their evolution means should have practical decision-making implications for all managers and staff. Thus, users' reaction times to certain signals should be reduced and their responses should improve, especially in recurrent situations.
- **Question 10: How will indicators be monitored/archived in the long term?**
  A key element of our approach is the learning that can be achieved when CSFs are monitored over long periods of time. Staff and managers learn from regularly sampling their performance and that of their areas, and seeing it compared to other data, such as budgets and previous performance of industry standards. Greater learning will be derived if managers and staff set time aside to review and discuss indicators on a regular basis.
- **Question 11: Is there any potential bias inherent in the methods and data used for calculations? What incentives are being given to staff?**
  The development of new performance measurement systems, such as a dashboard of indicators, should always be guided by consideration of the incentives given to actors and the behavior likely to result from the implementation of the underlying indicators. There may also be a change management side to the project, as managers negotiate with staff the implementation of the system. Staff may object to a certain type of measurement (which they may perceive to be threatening or invasive) or the implementation of devices dedicated to monitoring their work.

CONCLUSION

The case for managing the firm solely based on numbers has already been argued and lost. At this point, it is well established that managing firms cannot and should not be compared to the administration of a power plant. This does not mean, however, that the concept of control room does not have potential when applied to the management of organizations. Faced with increasingly complex situations and responsibility for the administration of increasingly complex business processes, managers have less and less time to spend monitoring the key factors of the business. The development of a dashboard can speed up this process and help managers catch far more information than they normally would without assistance.

Following the steps highlighted in this article will also give organizations a much better idea of what parameters they should worry about and how to measure performance. Peter Swasey, one of the directors of the Bank of Boston, commented that "what you don't measure, you don't manage" (McGill, 1990). The preparatory analysis work on the CSFs of the firm will give much confidence to organizational actors

that they understand their business and have a comprehensive hold upon its vital functions, and the dashboard ultimately developed will provide flexible and speedy access to vital information, thereby freeing time for other key activities such as business or staff development. As a by-product, managers may also be able to use the analysis carried out for their dashboard as a blueprint for the incentive systems of their company.

KEY TERMS

Control Room: A special location in a plant where operators can monitor a process in great detail without having to physically be looking at it. This is particularly useful in dangerous environments.

Critical Success Factors: A methodology for managing projects and firms that concentrates on the areas where things must go right if the endeavor is to flourish.

Dashboard: Specific display of information that presents key information about a process or device. A dashboard may or may not be computerized.

Evolutionary Design: System development methodology where an ongoing approach is taken to analyzing the requirements of the application.

Interface: Portion of a computer application that is used by the user to communicate with the application. It is particularly important for a dashboard, because it may impinge on the ability of users to properly interpret the variations in the indicators shown to them.

Managing by Numbers: A school of thought that sought to demonstrate that firms could be managed solely based on watching key (mostly financial) indicators. This is now largely discredited.

Model: A simplified representation of reality that concentrates on predicting how a factor or a series of related factors would evolve based on the variation of a set of parameters. Also, a simplified representation of reality.

Bibliomining for Library Decision-Making

Scott Nicholson
Syracuse University, USA

Jeffrey Stanton
Syracuse University, USA

INTRODUCTION

Most people think of a library as the little brick building in the heart of their community or the big brick building in the center of a campus. These notions greatly oversimplify the world of libraries, however. Most large commercial organizations have dedicated in-house library operations, as do schools, non-governmental organizations, as well as local, state, and federal governments. With the increasing use of the Internet and the World Wide Web, digital libraries have burgeoned, and these serve a huge variety of different user audiences. With this expanded view of libraries, two key insights arise. First, libraries are typically embedded within larger institutions. Corporate libraries serve their corporations, academic libraries serve their universities, and public libraries serve taxpaying communities who elect overseeing representatives. Second, libraries play a pivotal role within their institutions as repositories and providers of information resources. In the provider role, libraries represent in microcosm the intellectual and learning activities of the people who comprise the institution. This fact provides the basis for the strategic importance of library data mining: By ascertaining what users are seeking, bibliomining can reveal insights that have meaning in the context of the library's host institution.

Use of data mining to examine library data might be aptly termed *bibliomining*. With widespread adoption of computerized catalogs and search facilities over the past quarter century, library and information scientists have often used bibliometric methods (e.g., the discovery of patterns in authorship and citation within a field) to explore patterns in bibliographic information. During the same period, various researchers have developed and tested data mining techniques—advanced statistical and visualization methods to locate non-trivial patterns in large data sets. Bibliomining refers to the use of these bibliometric and data mining techniques to explore the enormous quantities of data generated by the typical automated library.

BACKGROUND

Forward-thinking authors in the field of library science began to explore sophisticated uses of library data some years before the concept of data mining became popularized. Nutter (1987) explored library data sources to support decision-making, but lamented that "the ability to collect, organize, and manipulate data far outstrips the ability to interpret and to apply them"(p. 143). Johnston and Weckert (1990) developed a data-driven expert system to help select library materials and Vizine-Goetz, Weibel, and Oskins (1990) developed a system for automated cataloging based on book titles (also see Aluri & Riggs, 1990; Morris, 1991). A special section of *Library Administration and Management* ("Mining your automated system") included articles on extracting data to support system management decisions (Mancini, 1996), extracting frequencies to assist in collection decision-making (Atkins, 1996), and examining transaction logs to support collection management (Peters, 1996).

More recently, Banerjeree (1998) focused on describing how data mining works and ways of using it to provide better access to the collection. Guenther (2000) discussed data sources and bibliomining applications, but focused on the problems with heterogeneous data formats. Doszkocs (2000) discussed the potential for applying neural networks to library data to uncover possible associations between documents, indexing terms, classification codes, and queries. Liddy (2000) combined natural language processing with text mining to discover information in "digital library" collections. Lawrence, Giles, and Bollacker (1999) created a system to retrieve and index citations from works in digital libraries. Gutwin, Paynter, Witten, Nevill-Manning, and Frank (1999) used text mining to support resource discovery.

These projects all shared a common focus on improving and automating two of the core functions of a library—acquisitions and collection management. A few authors have recently begun to address the need to support management by focusing on understanding library users: Schulman (1998) discussed using data mining to examine changing trends in library user behavior; Sallis, Hill, Jance, Lovetter, and Masi (1999) created

a neural network that clusters digital library users; and Chau (2000) discussed the application of Web mining to personalize services in electronic reference.

The December 2003 issue of *Information Technology and Libraries* was a special issue dedicated to the bibliomining process. Nicholson (2003) presented an overview of the process, including the importance of creating a data warehouse that protects the privacy of users. Zucca (2003) discussed an implementation of a data warehouse in an academic library. Wormell (2003), Suárez-Balseiro, Iribarren-Maestro, and Casado (2003), and Geyer-Schultz, Neumann, and Thede (2003) used bibliomining in different ways to understand use of academic library sources and to create appropriate library services.

We extend these efforts by taking a more global view of the data generated in libraries and the variety of decisions that those data can inform. Thus, the focus of this work is on describing ways in which library and information managers can use data mining to understand patterns of behavior among library users and staff and patterns of information resource use throughout the institution.

INTEGRATED LIBRARY SYSTEMS AND DATA WAREHOUSES

Most managers who wish to explore bibliomining will need to work with the technical staff of their integrated library system (ILS) vendors to gain access to the databases that underlie that system to create a data warehouse. The cleaning, pre-processing, and anonymizing of the data can absorb a significant amount of time and effort. Only by combining and linking different data sources, however, can managers uncover the hidden patterns that can help to understand library operations and users.

EXPLORATION OF DATA SOURCES

Available library data sources are divided in three groups for this discussion: data from the *creation* of the library, data from the *use of the collection*, and data from *external sources* not normally included in the ILS.

ILS Data Sources from the Creation of the Library System

Bibliographic Information

One source of data is the collection of bibliographic records and searching interfaces that represent materials in the library, commonly known as the Online Public Access Catalog (OPAC). In a digital library environment, the same type of information collected in a bibliographic library record can be collected as metadata. The concepts parallel those in a traditional library: take an agreed-upon standard for describing an object, apply it to every object, and make the resulting data searchable. Therefore, digital libraries use conceptually similar bibliographic data sources as traditional libraries.

Acquisitions Information

Another source of data for bibliomining comes from acquisitions, where items are ordered from suppliers and tracked until received and processed. Because digital libraries do not order physical goods, somewhat different acquisition methods and vendor relationships exist. Nonetheless, in both traditional and digital library environments, acquisition data have untapped potential for understanding, controlling, and forecasting information resource costs.

ILS Data Sources from Usage of the Library System

User Information

In order to verify the identity of users who wish to use library services, libraries maintain user databases. In libraries associated with institutions, the user database is closely aligned with the organizational database. Sophisticated public libraries link user records through zip codes with demographic information in order to learn more about their user population. Digital libraries may or may not have any information about their users, based upon the login procedure required. No matter what data is captured about the patron, it is important to ensure that the identification information about the patron is separated from the demographic information before storing this information in a data warehouse; this will protect the privacy of the individual.

Circulation and Usage Information

The richest sources of information about library user behavior are circulation and usage records. Legal and ethical issues limit the use of circulation data, however. This is where a data warehouse can be useful, in that basic demographic information and details about the circulation could be recorded without infringing upon the privacy of the individual.

Digital library services have a greater difficulty in defining circulation, as viewing a page does not carry the same meaning as checking a book out of the library, although requests to print or save a full text information resource might be similar in meaning. Some electronic full-text services already implement server-side capture of such requests from their user interfaces.

Searching and Navigation Information

The OPAC serves as the primary means of searching for works owned by the library. Additionally, because most OPACs use

a Web browser interface, users may also access bibliographic databases, the World Wide Web, and other online resources during the same session; all of this information can be useful in library decision-making. Digital libraries typically capture logs from users searching their databases and can track, through "clickstream" analysis, the elements of Web-based services visited by users. In addition, the combination of a login procedure and cookies allow connecting user demographics to the services and searches they used in a session.

External Data Sources

Reference Desk Interactions

In the typical face-to-face or telephone interaction with a library user, the reference librarian records very little information about the interaction. Digital reference transactions, however, occur through an electronic format, and the transaction text can be captured for later analysis, which provide a much richer record than is available in traditional reference work. The utility of these data can be increased if identifying information about the user can be captured as well, but again, anonymization of these transactions is a significant challenge.

Item Use Information

Fussler and Simon (as cited in Nutter, 1987) estimated that 75-80% of the use of materials in academic libraries is in-house. Some types of materials never circulate, and therefore, tracking in-house use is also vital in discovering patterns of use. This task becomes much easier in a digital library, as Web logs can be analyzed to discover what sources users examined.

Interlibrary Loan and other Outsourcing Services

Many libraries using Interlibrary Loan and/or other outsourcing methods to get items on a "just-in-time" basis for users. The data produced by this class of transactions will vary by service, but can provide a window to areas of need in a library collection.

FUTURE TRENDS

Bibliomining can provide understanding of the individual sources listed earlier; however, much more information can be discovered when sources are combined through common fields in a data warehouse.

Bibliomining to Improve Library Services

Most libraries exist to serve the information needs of users, and therefore, understanding those needs of individuals or groups is crucial to a library's success. For many decades, librarians have suggested works; market basket analysis can provide the same function through usage data to aid users in locating useful works. Bibliomining can also be used to determine areas of deficiency and predict future user needs. Common areas of item requests and unsuccessful searches may point to areas of collection weakness. By looking for patterns in high-use items, librarians can better predict the demand for new items.

Virtual reference desk services can build a database of questions and expert-created answers, which can be used in a number of ways. Data mining could be used to discover patterns for tools that will automatically assign questions to experts based upon past assignments. In addition, by mining the question/answer pairs for patterns, an expert system could be created that can provide users an immediate answer and a pointer to an expert for more information.

Bibliomining for Organizational Decision-Making within the Library

Just as the user behavior is captured within the ILS, the behavior of library staff can also be discovered by connecting various databases to supplement existing performance review methods. While monitoring staff through their performance may be an uncomfortable concept, tighter budgets and demands for justification require thoughtful and careful tracking of performance. In addition, research has shown that incorporating clear, objective measures into performance evaluations can actually improve the fairness and effectiveness of those evaluations (Stanton, 2000).

Low use statistics for a work may indicate a problem in the selection or cataloging process. Looking at the associations between assigned subject headings, call numbers and keywords along with the responsible party for the catalog record may lead to a discovery of system inefficiencies. Vendor selection and price can be examined in a similar fashion to discover if a staff member consistently uses a more expensive vendor when cheaper alternatives are available. Most libraries acquire works both by individual orders and through automated ordering plans that are configured to fit the size and type of that library. While these automated plans do simplify the selection process, if some or many of the works they recommend go unused, then the plan might not be cost effective. Therefore, merging the acquisitions and circulation databases and seeking patterns that predict low use can aid in appropriate selection of vendors and plans.

Bibliomining for External Reporting and Justification

The library may often be able to offer insights to their parent organization or community about their user base through patterns detected with bibliomining. In addition, library managers are often called upon to justify the funding for their library when

budgets are tight. Likewise, managers must sometimes defend their policies, particularly when faced with user complaints. Bibliomining can provide the data-based justification to back up the anecdotal evidence usually used for such arguments.

Bibliomining of circulation data can provide a number of insights about the groups who use the library. By clustering the users by materials circulated and tying demographic information into each cluster, the library can develop conceptual "user groups" that provide a model of the important constituencies of the institution's user base which can fulfill some common organizational needs for understanding where common interests and expertise reside in the user community. This capability may be particularly valuable within large organizations where research and development efforts are dispersed over multiple locations.

In the future, organizations that fund digital libraries can look to text mining to greatly improve access to materials beyond the current cataloging / metadata solutions. The quality and speed of text mining continues to improve. Liddy (2000) has researched the extraction of information from digital texts, and implementing these technologies can allow a digital library to move from suggesting texts that might *contain the answer* to just *providing the answer*, extracted from the appropriate text or texts. The use of such tools risks taking textual material out of context and also provides a few hints about the quality of the material, but if these extractions were links directly into the texts, then context could emerge along with an answer. This could provide a substantial asset to organizations that maintain large bodies of technical texts because it would promote rapid, universal access to previously scattered and/or uncataloged materials.

CONCLUSION

Libraries have gathered data about their collections and users for years, but have not always used those data for better decision-making. By taking a more active approach based on applications of data mining, data visualization, and statistics, these information organizations can get a clearer picture of their information delivery and management needs. At the same time, libraries must continue to protect their users and employees from misuse of personally identifiable data records. Information discovered through the application of bibliomining techniques gives the library the potential to save money, provide more appropriate programs, meet more of the user's information needs, become aware of gaps and strengths of their collection, and serve as a more effective information source for its users. Bibliomining can provide the data-based justifications for the difficult decisions and funding requests library managers must make.

KEY TERMS

Bibliometrics: The study of regularities in citations, authorship, subjects, and other extractable facets from scientific communication using quantitative and visualization techniques. This allows researchers to understand patterns in the creation and documented use of scholarly publishing.

Bibliomining: The application of statistical and pattern-recognition tools to large amounts of data associated with library systems in order to aid decision-making or justify services. The term "bibliomining" comes from the combination of bibliometrics and data mining, which are the two main toolsets used for analysis.

Data Mining: The extraction of non-trivial and actionable patterns from large amounts of data using statistical and artificial intelligence techniques. Directed data mining starts with a question or area of interest, and patterns are sought that answer those needs. Undirected data mining is the use of these tools to explore a dataset for patterns without a guiding research question.

Data Warehousing: The gathering and cleaning of data from disparate sources into a single database, optimized for exploration and reporting. The data warehouse holds a cleaned version of the data from operational systems, and data mining requires the type of cleaned data that lives in a data warehouse.

Integrated Library System: The automation system for libraries, combining modules for cataloging, acquisition, circulation, end-user searching, database access, and other library functions through a common set of interfaces and databases.

Online Public Access Catalog (OPAC): The module of the integrated library system designed for use by the public to allow discovery of the library's holdings through the searching of bibliographic surrogates. As libraries acquire more digital materials, they are linking those materials to the OPAC entries.

INTRODUCTION

For ages, humans recognized themselves according to different characteristics (appearance, behavior…). Biometrics is a well known technique to identify an individual or verify its identity; as, for example, fingerprints have been used for more than 100 years to identify one criminal. With computers, this analysis can be realized very quickly and with a higher reliability.

Biometrics has many applications: site monitoring (Bird, Masoud, Papanikolopoulos, & Isaacs, 2005), e-commerce (Jain & Pankanti, 2006)… The main benefits of biometrics are to provide better security and to facilitate the authentication process for a user. For example, it can be easy to obtain the password of a user, but it is more difficult to look like the user if a face recognition system is used for the user verification. Biometrics can also provide many advantages for particular applications. Indeed, biometric authentication can be realized in a contactless way that could be important for cultural aspects or reasons of hygiene. For all these motivations, biometrics is an emergent technology that could be more present in our daily life.

The goal of this chapter is to make an overview of biometrics. We focus on the authentication process, whose goal is to verify the identity of an individual. Ideal biometric information must have multiple properties:

- **Universality:** all individuals must be characterized by this information;
- **Uniqueness:** this information must as dissimilar as possible for two different persons;
- **Permanency:** it should be present during the whole life of an individual;
- **Collectability:** it can be measured (in a easy way);
- **Acceptability:** it concerns the possibility of a real use by users.

The plan of this chapter is given below. The background part presents the different biometric modalities studied in the research labs and used in real conditions. The main thrust of this chapter is an analysis of the benefits and limitations of biometric authentication. We present also the general architecture of a biometric system. Future trends stress the different research topics that should be treated to improve the biometric authentication. It concerns the combination of different biometric systems and their performance evaluation. We conclude by resuming the main aspects of this domain.

BACKGROUND

We detail, in this section, the different biometric modalities from the state of the art that can be used for the authentication process. Figure 1 illustrates the different types of biometric information. Biological analysis exploits some information that is present for any alive mammal (DNA, blood…). The behavioral analysis is specific to a human being and characterizes the way an individual makes some daily tasks (gait, talking…). Last, morphological analysis uses some information on how we look (for another individual or for a particular sensor).

Biological Analysis

As mentioned previously, biological biometric information can be extracted from any human being (see Figure 2). Generally, this information is not very easy to obtain. Some particular sensors are needed and the extraction of the biometric information can be quite long. For example, the DNA analysis with the most recent research techniques is possible in a few hours. We can cite the blood analysis that can only differentiate two individuals with different

Figure 1. Different biometric information in the state of the art

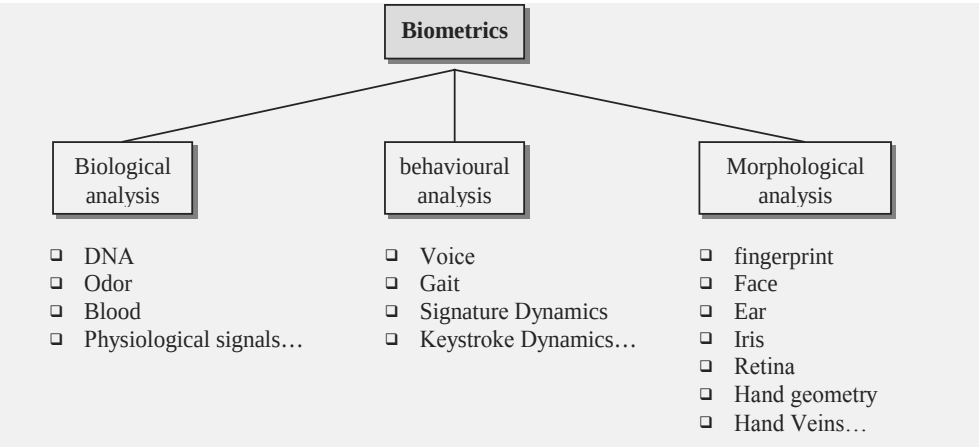

Figure 2. Some illustrations of the biological analysis (K. Phua et al., 2007)

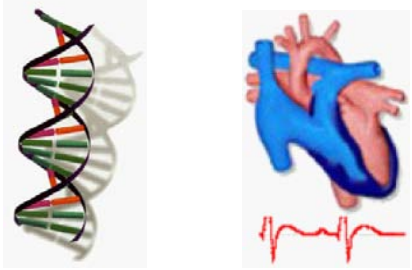


Rhesus groups. We focus, in this chapter, on recent biological biometrics.

The electroencephalogram (brain signal) as a biometric information was studied in 1999 (Poulos, Rangoussi, Chrissikopoulos, & Evangelou, 1999). The EER value obtained by this approach is at the range of 16% to 28%. The odor as biometric information has also been tested (Korotkaya, 2003). This feasibility study showed the limitations of the actual sensors to use this information in a real context.

An industrial company proposed, in 2004, a biometric authentication solution based on dynamic electrophysiological characteristics of the living body, primarily of the beating heart (Idesia Ltd., 2004). Heart sound signals are also recently used for the authentication process (Phua et al., 2007). The biometric system comprises an electronic stethoscope, a computer equipped with a sound card, and the software application. This system provides a promising performance (EER equals to 4%).

Behavioral Analysis

We are able to recognize someone considering the way he/she walks or the way he/she types with a keyboard (see Figure 3).

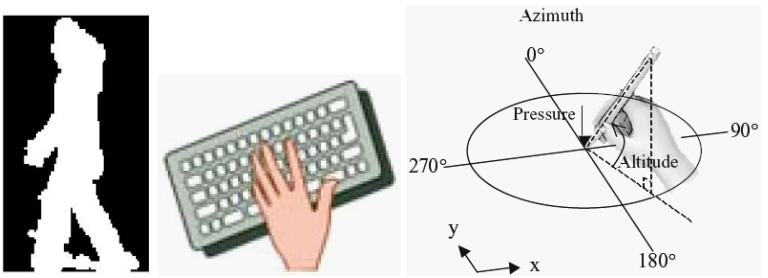
An original biometric information has been recently proposed (Orozco, Asfaw, Shirmohammadi, Adler, El Saddik, 2006) using haptics devices. Results provide an EER near 10%, and open a new area of research. Individual recognition by considering its gait has also been studied (Man & Bhanu, 2006). The performance evaluation of this kind of approach puts into obviousness an average value of EER between 19% to 37%.

An individual can be recognized thanks to its voice. Voice verification has been treated by researchers for 50 years (Petrovska-Delacretaz, El Hannani, & Chollet, 2007). Many problems have to be solved, such as acquisition artifacts (ambient noise for example) or the variability of an individual's voice due to its stress or mood. The best results obtained by combining different methods give an EER near 5%, but the robustness of the authentication/identification is difficult to reach.

Many research works focus on keystroke analysis as authentication solution for controlling the access to a computer or a mobile phone. The major reason is that the knowledge of a password is often shared with many individuals. A recent work studied the feasibility of using keystroke authentication for mobile phones (Clarke & Furnell, 2007). The method, based on neural network classifiers, achieves promising results with an EER of 15.2%. A similar approach by using a computer keyboard provides better results (EER near 5%). The main advantage of this biometric modality is that no additional sensor is required.

Online signature verification is an interesting method because it is very common for a user. The signature shape is not really used in this context, but only the way it has been

Figure 3. Some examples of behavioral biometric information (gait, keystroke dynamics, online signature) (Muramatsu & Matsumoto 2007)



realized. Notions of pen pressure and pen orientations are taken into account (Muramatsu & Matsumoto, 2007). This kind of biometric information is more adapted for authentication applications and provides an EER near 5%.

Morphological Analysis

This kind of approach is the most popular in biometrics (see Figure 4).

Fingerprint verification is a very well known technique and has been used to identify criminals for more than 100 years. This approach is often used and a dense literature is available (Tulyakov, Farooq, Mansukhani, & Govindaraju, 2007). Fingerprint verification provides, actually, a performance characterized by an EER value near 2%.

Iris recognition is a powerful technique and provides a low value of FAR near 1% (Cui et al., 2004). Retinal image is also reliable biometric information and provides a close to zero FAR value (Mariño, Penedo, Penas, Carreira, & Gonzalez, 2006). These two biometric data need a particular acquisition system and are not always accepted by users.

Hand geometry is also an interesting characteristic. Recent methods achieve a good performance such as a FAR value near 0% while keeping a FRR one near 1.5% (Kumar, Wong, Shen, & Jain, 2006). Finger vein authentication is possible and provides extremely good results, that is to say, 0.01% in FRR and less than 0.00002% in FAR (Hashimoto, 2006). Palmprint or hand veins can be used as biometric information. As for example, a recent method (Connie, Teoh, Goh, & Ngo, 2004) achieves an authentication process with an EER value close to 0%.

Face recognition is the most common approach for a human. Many research works focused on this biometric modality in the past. An important advantage of this approach is that it can be used either for the authentication or identification of an individual without his assent for video monitoring applications. Face recognition permits good performances for identification with an EER between 5% and 10% (Shen & Bai, 2006). Nevertheless, in order to be used in a real context, many problems have to be solved, such as the acquisition variability and some modifications of an individual's face (haircut, ageing…).

Figure 4. Some examples of morphological biometrics (Cui, Wang, Huang, Tan, & Sun, 2004)

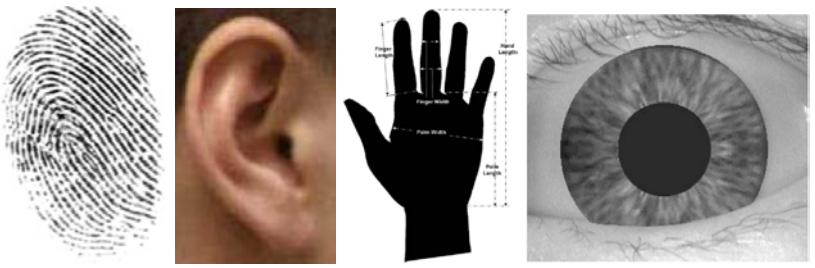


Table 1 summarizes the properties of the current biometric modalities in the state of the art.

MAIN FOCUS OF THE CHAPTER

This section first discussed the general authentication process. Second, we present the usual architecture in biometric authentication applications. The discussion presents the main points concerning the biometric authentication in the state of the art.

Authentication Process

One individual has three possibilities to prove its identity:

- What he/she owns (card, document) ;
- What he/she knows (a name, a password) ;
- What he/she is (fingerprint, hand, face...).

Generally, the identity verification of an individual is achieved with one password for different applications. For e-commerce applications, it would be very interesting to use, in place of the PIN code, which represents only four figures to guess, a biometric authentication, for many reasons. First, it would be more convenient for a user (difficulties to memorize the different codes of multiple cards, quick verification). Second, it can limit frauds because if it is quite easy to guess the PIN code composed of 4 digits, it is more difficult to copy the biometric reference of an individual.

Biometric Authentication

Despite the growing numbers of biometric applications, systems may be modeled according to the ISO Biometric conceptual diagram (ISO/IEC 19794-1:2006(E)). This diagram describes five conceptual components, which are data capture, signal processing, data storage, matching, and decision used in the two basic biometric operations, enrollment and authentication.

The enrollment is the first step introducing people in a biometric system. Its aim is to associate one person, through its biometric information, to an identity (see Figure 6).

he enrollment starts with the capture of N biometric samples needed by the signal processing "Extraction for enrollment" component. This module extracts the distinguished features from the biometric samples and sends them to the quality control subsystem. The aim of the quality control subsystem is to evaluate data relevance according to the system data quality requirements. In the case of a negative result from the quality control subsystem, the biometric

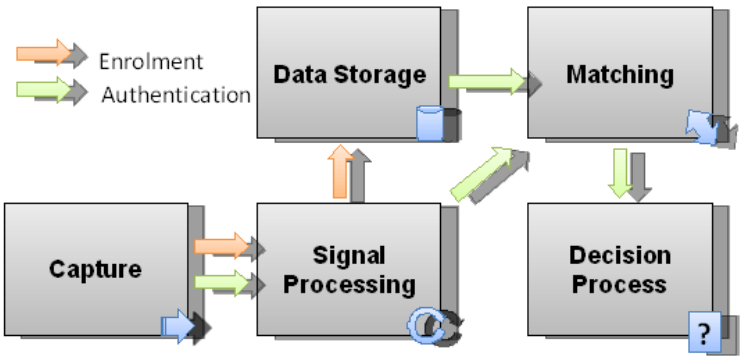

Figure 6. High level diagram of biometric Enrolment

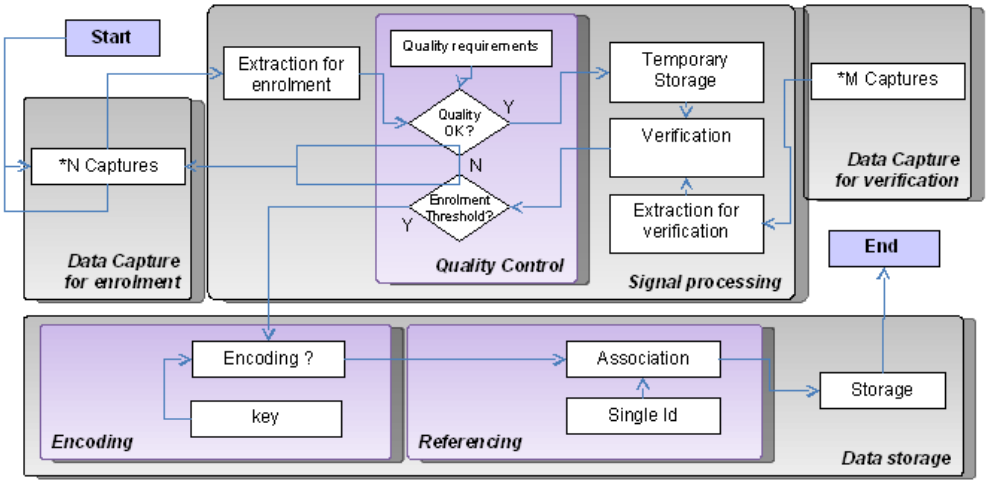

application may ask for a new enrollment session or stop the enrollment procedure. Otherwise, the system sends the biometric data to the verification structure. The objective is to reproduce a verification request for validating data. When data validation operates correctly, the biometrics data, named template, is sent to the data storage component. This component implements some cryptographic encoding functions before transmitting the data to the referencing subsystem. The goal of this system is to associate biometric data, representing the physical characteristics, with one unique identifier, representing the virtual identity of the person. The result is transferred on a storage system (database, token…).

The authentication process (see Figure 7) implies one fundamental notion named verification and one derived notion named identification. Identification is solving the membership of a person to a system and can be perceived as multiple verification procedures.

The aim of the matching component is to evaluate the accuracy of those biometric samples with the stored enrollment templates. This evaluation is materialized by a similarity rate. The decision process focuses on the analysis of the rate given by the matching component. In the verification case, only one data extraction is done. The decision process returns to the system a Boolean result. In the identification case, the decision process will ask to the matching component to verify all the templates stored in a database. All the positive results satisfying the threshold requirements are stored. The decision process analyzes the results and returns an identifier.

Discussion

Biometric authentication is much more currently advanced by using a morphological analysis for several reasons:

Figure 7. High level diagram of biometric authentication

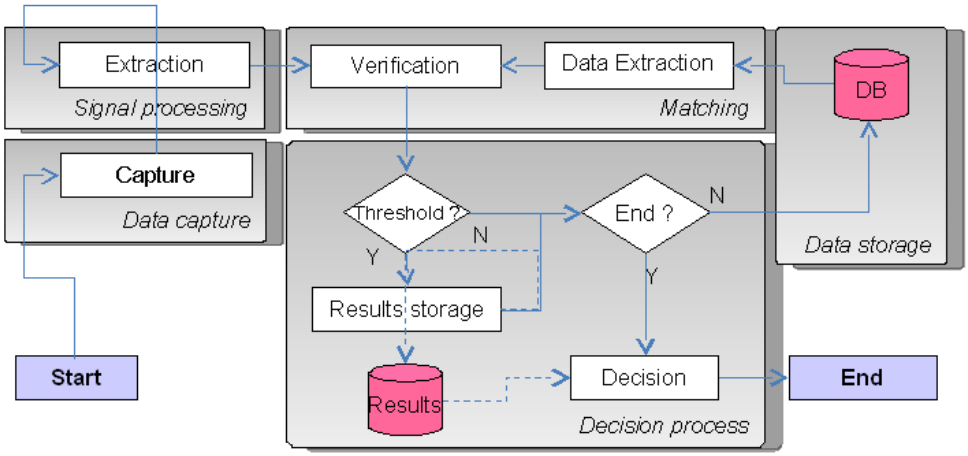

Figure 8. Biometric market and repartition of the different modalities

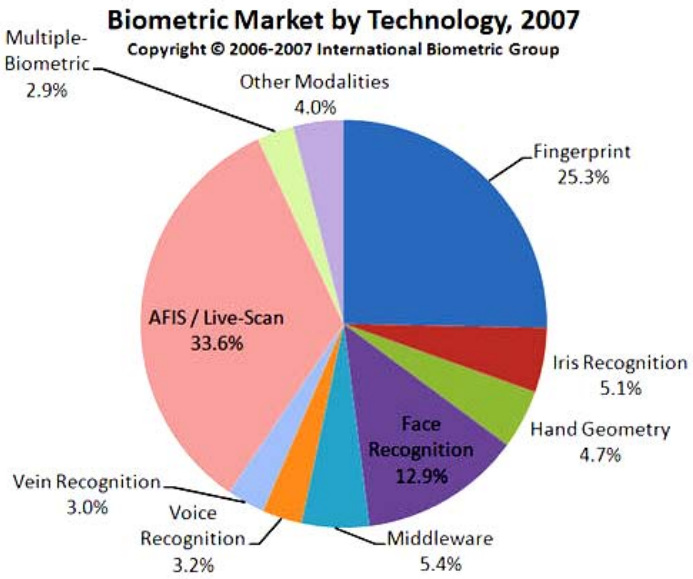

- the sensors are currently more reliable than the biological analysis and cheaper ;
- pattern recognition algorithms used in morphological analysis are well known ;
- recognition times for the morphological information are often shorter than for the two other types of analysis
- user perception of the intrusion of these technologies in its sphere of protection is often better for certain morphological analysis.

Figure 8 illustrates the market for each biometric modality. Morphological analysis represents actually nearly 90% of the market.

FUTURE TRENDS

In this section, we give some future trends concerning biometric authentication.

Table 3. The different biometric multimodal approaches

Methods	Example
Combination of multiple instances of a single biometric modality	Fingerprints of two different fingers
Combination of different biometric modalities	Fingerprint and physiological signals
Combination of multiple extraction algorithms	Minutia extraction and filter based algorithms for fingerprint verification
Combination of multiple acquisitions of a biometric modality	Fingerprints with two different sensors

Multimodal Biometrics

The combination of biometric systems is an interesting solution to improve their performance and robustness. Table 3 summarizes the different approaches that can be used. Note that these approaches can use some well known fusion methods, such as the Dempster-Schafer theory, that are actually widely treated in the literature (Chang et al., 2005).

Biometric evaluation

The evaluation of biometric systems grounds on two fundamental concepts applied on each of the five conceptual components described in the previous section. Those components should be generically modeled as the scheme given in figure 9.

Based on the use cases and constraints of the global system, the component will acquire input data, makes the treatment, and gives the output data as a result of its treatment. The first concept is to identify the commons and appropriated criteria. Those criteria should be represented values of the technology used by the component.

The second concept is the measure of those values according to the constraints of the system. The International norm (ISO/IEC 19795-1:2006 §6) focus on biometric performance testing and reporting. The general principles and protocols for testing the performance of a biometric system (definitions of FRR and FAR measures for example) are specified. Some problems, although, can appear such as the reliability and the representativity of the data collected for a cross-technologies comparison and cross-applications comparison.

Lots of research works deal with the evaluation of a biometric system. Generally, benchmark image databases are used for the comparison of research and commercial algorithms. One can cite, for example, the FERET database (see Figure 10) that is used for face identification/verification algorithms (Phillips, Moon, Rizvi, & Rauss, 2000).

These evaluation methodologies are often dedicated to a particular biometric system. The definition of a general platform that could compare different biometric systems is a great challenge. The BioAPI (Biometric Application Programming Interface) that is a key part of the international standards would considerably facilitate this kind of research.

Figure 9. Generic modeling of conceptual components

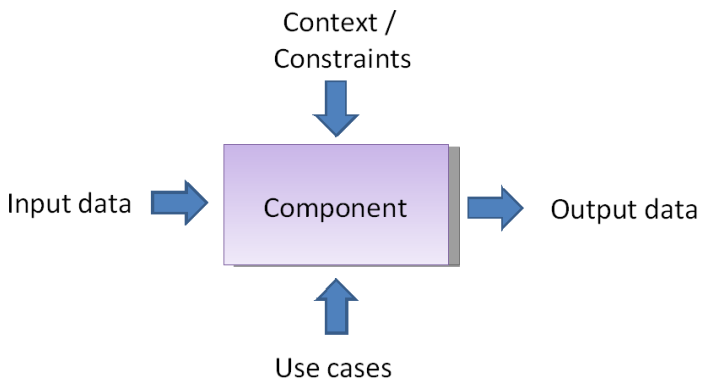

Figure 10. Some examples of images in the FERET database (Phillips et al. 2000)

CONCLUSION

This chapter focuses on biometric authentication. Even if biometrics has been used a long time ago to identify criminals, for example, automatic and efficient systems just began to appear in the research literature in the last decades. Some commercial products are already present in our daily life such as the biometricUSB keys. To be more widely used in more difficult applications, such as e-transactions, many problems have to be solved. The EER provided by algorithms using single biometric information can be very low, but not sufficiently to be accepted by everybody. Thus, the characterization of biometric systems is fundamental in order to identify the problems to solve. Multimodal biometric systems improve the performance and can be a solution even if their costs are more important. This domain represents a huge market; no doubt, many research works will provide us, in the future, a biometric toothbrush or a new payment way without any bank card.

KEY TERMS

Authentication: Security measure designed to establish the validity of a transmission, message, or originator, or a means of verifying an individual's authorization to receive specific categories of information.

Biometric: Any specific and uniquely identifiable physical human characteristic, for example, of the retina that may be used to validate the identity of an individual.

Biometric Application Programming Interface (BioAPI): The BioAPI specification enables different biometric systems to be developed by the integration of modules from multiple independent companies.

Enrollment: The process of collecting biometric samples from a person and the subsequent preparation and storage of biometric reference templates representing that person's identity.

Equal Error Rate (EER): This error rate equates to the point at which the FAR and FRR cross (compromise between FAR and FRR).

False Acceptance Rate (FAR): Rate at which an impostor is accepted by an authentication system.

False Rejection Rate (FRR): Rate at which the authorized user is rejected from the system.

INTRODUCTION

In today's high-speed world, millions of transactions occur every minute. For these transactions, data need to be readily available for the genuine people who want to have access, and it must be kept securely from imposters. Some methods of establishing a person's identity are broadly classified into:

1. *Something You Know:* These systems are known as knowledge-based systems. Here the person is granted access to the system using a piece of information like a password, PIN, or your mother's maiden name.
2. *Something You Have:* These systems are known as token-based systems. Here a person needs a token like a card key, smartcard, or token (like a Secure ID card).
3. *Something You Are:* These systems are known as inherited systems like biometrics. This refers to the use of behavioral and physiological characteristics to measure the identity of an individual.

The third method of authentication is preferred over token-based and knowledge-based methods, as it cannot be misplaced, forgotten, stolen, or hacked, unlike other approaches. Biometrics is considered as one of the most reliable techniques for data security and access control. Among the traits used are fingerprints, hand geometry, handwriting, and face, iris, retinal, vein, and voice recognition.

Biometrics features are the information extracted from biometric samples which can be used for comparison. In cases of face recognition, the feature set comprises detected landmark points like eye-to-nose distance, and distance between two eye points. Various feature extraction methods have been proposed, for example, methods using neural networks, Gabor filtering, and genetic algorithms. Among these different methods, a class of methods based on statistical approaches has recently received wide attention. In cases of fingerprint identification, the feature set comprises location and orientation of ridge endings and bifurcations, known as a minutiae matching approach (Hong, Wan, & Jain, 1998). Most iris recognition systems extract iris features using a bank of filters of many scales and orientation in the whole iris region. Palmprint recognition, just like fingerprint identification, is based on aggregate information presented in finger ridge impression. Like fingerprint identification, three main categories of palm matching techniques are minutiae-based matching, correlation-based matching, and ridge-based matching. The feature set for various traits may differ depending upon the extraction mechanism used.

The system that uses a single trait for authenticity verification is called unimodal biometric system. A unimodal biometric system (Ross & Jain, 2003) consists of three major modules: sensor module, feature extraction module, and matching module. However, even the best biometric traits face numerous problems like non-universality, susceptibility to biometric spoofing, and noisy input. Multimodal biometrics provides a solution to the above mentioned problems.

A multimodal biometric system uses multiple sensors for data acquisition. This allows capturing multiple samples of a single biometric trait (called multi-sample biometrics) and/or samples of multiple biometric traits (called multi-source or multimodal biometrics). This approach also enables a user who does not possess a particular biometric identifier to still enroll and authenticate using other traits, thus eliminating the enrollment problems. Such systems, known as multimodal biometric systems (Tolba & Rezq, 2000), are expected to be more reliable due to the presence of multiple pieces of evidence. A good fusion technique is required to fuse information for such biometric systems.

Depending on the application context, a biometric system may operate either in verification or identification mode (Jain, Bolle, & Pankanti, 1999a). In verification mode, the system validates a person's identity by comparing the captured biometric data with his or her own biometric template stored in the system database. In such a system, an individual who desires to be recognized claims an identity (usually via PIN), a user name, or a smartcard, and the system conducts one-to-one comparison to determine whether the claim is true or not. In the identification mode the system recognizes the individual by searching the templates of all the users in the

database for a match (Ross, Nandakumar, & Jain, 2006). The time required by the biometric system to claim identification is critical for many applications. Apart from good accuracy, response time, and retrieval, efficiency plays an important role in the identification mode.

BACKGROUND

A biometric system is essentially a pattern recognition system that recognizes a person based on a feature vector derived from a specific physiological or behavioral characteristic that the person possesses (Prabhakar, Pankanti, & Jain, 2003). A brief overview of the field of biometrics and a summary of some of its advantages, disadvantages, strengths, limitations, and related privacy concerns are presented in Jain, Ross, and Prabhakar (2004).

Multimodal biometric systems are those that utilize more than one physiological or behavioral characteristic for enrollment, verification, or identification. Ross and Jain (2003) have presented an overview of multimodal biometrics and have proposed various levels of fusion, various possible scenarios, the different modes of operation, integration strategies, and design issues. Different fusion strategies as well as its performance are given by Allano et al. (2006). The performance of multimodal biometric authentication systems using state-of-the-art commercial off-the-shelf (COTS) fingerprint and face biometric systems on a population approaching 1,000 individuals is examined by Snelick, Uludag, Mink, Indovina, and Jain (2005).

The identification system is designed in such a way that the search space and data retrieval time reduce to the minimum. Classification techniques have been introduced to reduce the search time of identification systems. There exist several classification techniques like classification of face images based on age (Kwon & Lobo, 1999), where input images can be classified into one of three age-groups: babies, adults, and senior adults. Gender classification from frontal facial images using genetic feature subset selection is considered in Sun, Bebis, Yuan, and Louis (2002). Further, nonlinear support vector machines (SVMs) are investigated for appearance-based gender classification with low-resolution thumbnail faces from a FERET (FacE REcognition Technology) face database (Moghaddam & Yang, 2002). Classification of fingerprints into five categories—whorl, right loop, left loop, arch, and tented arch—is done using a novel representation (FingerCode) based on a two-stage classifier (Jain, Prabhakar, & Hong, 1999c). Ern and Sulong (2001) give a good account of fingerprint classification techniques, and Jain, Murty, and Flynn (1999b) overview pattern clustering methods from a statistical pattern recognition perspective, with a goal of providing useful advice and references to fundamental concepts accessible to the broad community of clustering practitioners. Another approach for search space reduction is to index the database using some data structures like B+ trees, pyramid technique (Mhatre, Palla, Chikkerur, & Govindaraju, 2005), or hash functions. However the main concern behind the use of suitable indexing technique is to catalog the database in such a way that the identification template falls in the bin of the enrolled template.

IDENTIFICATION TECHNIQUES

Biometrics identification is expensive in terms of time as it involves a large number of comparisons in the database. As database size increases, data retrieval and search times increase significantly. Thus to overcome the problem arising from large biometric records, there must be some method to reduce the search space for a matcher to operate. The identification system is designed in such a way that the search space and data retrieval times reduce to the minimum. The biometric database can be segmented using one or all of the following three approaches in the hierarchy discussed below.

Classification

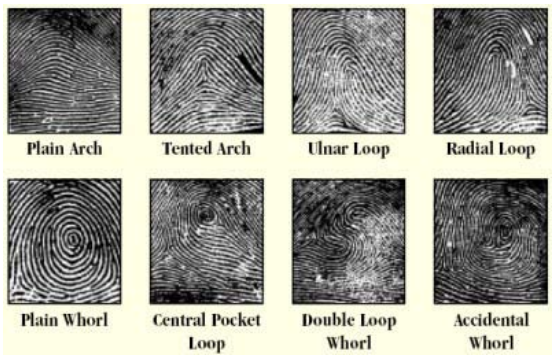
Classification refers to assigning an object physically into one of a set of predefined categories. The main idea behind the use of a classification algorithm is to divide the database into groups where each group has homogenous characteristics. The important step is to design a classifier based on texture, pattern, or some soft biometric attribute. Some commonly used classification techniques for well-known traits include face, fingerprint, and iris classification.

Face Classification

Face images are used to classify a person based on age, gender, ethnicity, and so forth. Age classification is used to classify the input images into one of three age groups: babies, young adults, and senior adults (Kwon & Lobo, 1999). The computations are based on skin wrinkle analysis.

Automated gender classification is possible with the use of statistical classification algorithms that are trained with a set of known images. With a large number of known images, it may be possible to directly train the classification algorithms, with each grayscale image representing a point in the image space. However, it is often much better to reduce the number of dimensions, in an efficient way, allowing accurate training with less observations. In applications using face images, a well-established dimension reduction technique is to use the Karhunen-Loeve Transform on an ensemble of images, to generate an eigenspace composed of eigenfaces. The idea is to project images into this eigenspace and use

Figure 1. Fingerprint pattern classes



the first few projected components for classification (Kirby & Sirovich, 1990).

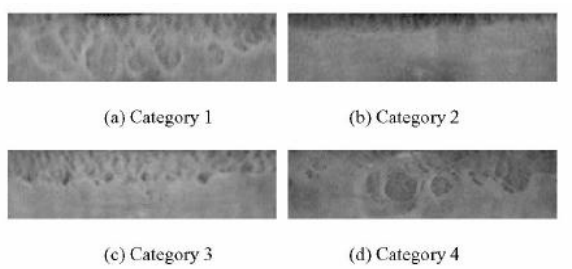
Fingerprint Classification

Fingerprint classification is one of the most reliable methods for identifying individuals. At the most basic level fingerprints, can be classified into some classes like: arch, tented arch, ulnar loop, radial loop, and whorl and twin loop, as shown in Figure 1. Jain et al. (1999c) have used a two-stage classifier for classification of fingerprint images into known pattern classes.

Iris Classification

For iris classification the images of the iris are divided into four or more classes based on the texture pattern of the image as shown in Figure 2. The texture pattern is classified by computing fractal dimension (Yu, Wang, & Zhang 2005).

Figure 2. Basic-level classification of iris images (taken from Yu et al., 2005)



Clustering

Data clustering is a common technique for statistical data analysis, which is used in many fields, including machine learning, data mining, pattern recognition, image analysis, and bioinformatics. Clustering is the segmentation of similar objects into several groups, or more concisely, the partitioning of a dataset into subsets (clusters), so that the data in each subset (ideally) share some common trait, often proximity according to some defined distance measure (Jain et al., 1999b). Basic data clustering algorithms can be hierarchical or partitional. Hierarchical algorithms find successive clusters using previously established clusters, whereas partitional algorithms determine all clusters at once (Jain et al., 1999b).

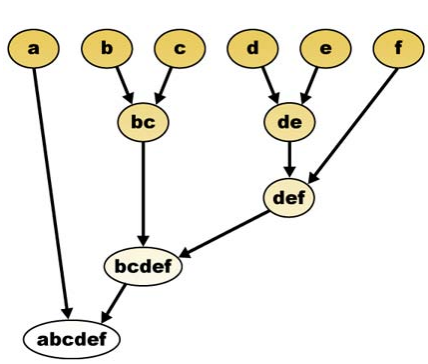
Types of Clustering Approaches

There are many clustering approaches available, and choice of a technique depends upon the type of dataset to be clustered and output desired after clustering. In general, clustering methods may be divided into two major categories based on the clusters they produce.

Hierarchical Methods

Hierarchical algorithms can be agglomerative (bottom-up) or divisive (top-down). Agglomerative algorithms begin with each element as a separate cluster and merge them in successively larger clusters. Divisive algorithms begin with the whole set and proceed to divide it into successively smaller clusters. Given a distance measure, elements can be

Figure 3. Hierarchical clustering approach



combined. Hierarchical clustering builds (agglomerative) or breaks up (divisive) a hierarchy of clusters. The traditional representation of this hierarchy is a tree data structure (called a dendrogram as shown in Figure 3), with individual elements at one end and a single cluster with every element at the other. Agglomerative algorithms begin at the top of the tree, whereas divisive algorithms begin at the bottom. Disadvantages of hierarchical clustering are related to:

- vagueness of termination criteria; and
- the fact that most hierarchical algorithms do not revisit clusters, once constructed (intermediate), to consider improvement.

Partitional Approaches

Given a database of objects, a partitional clustering algorithm constructs partitions of the data, where each cluster optimizes a clustering criterion, such as the minimization of the sum of squared distance from the mean within each cluster. One of the issues with such algorithms is their high complexity, as some of them exhaustively enumerate all possible groupings and try to find the global optimum. Even for a small number of objects, the number of partitions is huge. The diagrammatic representation of various forms of the partitional clustering technique is given in Figure 4.

Indexing

Indexing the database implies a logical partitioning of the data space. In this approach of search space, reduction tree structure is used for organizing the data, such that each of the leaf nodes stores one or more biometric templates. Thus given a test template, only the templates having similar index values would be considered as the search space, or in the case of range search, only the fraction of the database lying within the range of the indexes of the test template would be the new search space. With biometric data being inherently multidimensional, it is indispensable that the indexing technique support multidimensional data. The tree structure for biometric data indexing is shown in Figure 5.

Figure 4. Examples of partitional clustering approaches

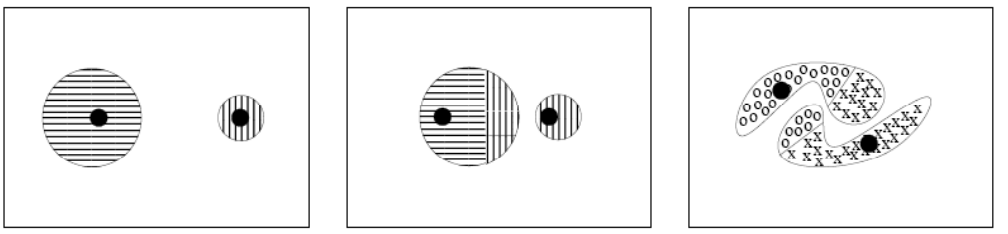


Figure 5. B+ tree for indexing

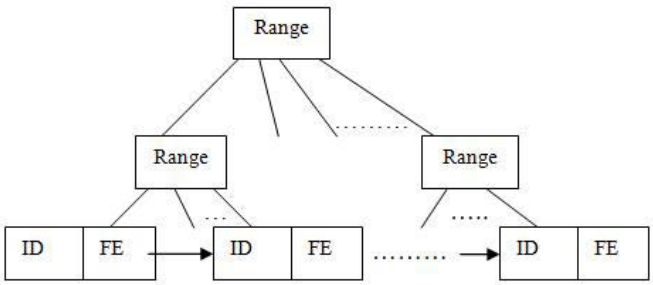

Pyramid Technique

This currently seems to be the single most feasible indexing technique for indexing biometric databases. The concept is based on spatial-hashing the high-dimensional data into a single value. This single value can then be indexed very effectively using the popular B+ trees. The pyramid-technique was especially designed for working in higher-dimensional spaces and has been successfully tested on an 100-dimensional data set. The technique results in a tree structure that is not only insertion order invariant, but also height balanced and dynamic to the frequent insertions and deletions.

Hash Function

A hash table, or a hash map, is a data structure that associates keys with values. The primary operation it supports efficiently is a lookup: given a key (e.g., a person's name), find the corresponding value (e.g., that person's telephone number). It works by transforming the key using a hash function into a hash, a number that the hash table uses to locate the desired value. Thus hashing can be used on biometric data by calculating keys using feature values and storing the identifier at the key generated.

MULTIMODAL BIOMETRIC SYSTEM AT IIT KANPUR

The multimodal biometric identification system at the Indian Institute of Technology Kanpur is developed using five traits: face, fingerprint, iris, ear, and signature. The system classifies the biometric database at a basic level using iris classification techniques based on a box counting approach. At a refined level the database is further subdivided using a clustering technique. The data within each cluster is indexed using B+ tree for storage. The steps are followed hierarchically to get top matches:

- In the first phase the database is classified using iris. The acquired iris image is preprocessed and transformed into a rectangular block known as the 'strip'. The strip is used for classification of iris texture using a box counting approach. The database is divided into four classes using the supervised classification technique.
- In the second phase the data within each class is clustered based on a feature vector generated from face recognition. For clustering, the well-known K-means algorithm is used on the generated feature set from face recognition within a particular class.
- Finally the clustered database is indexed through some indexing scheme so that we can achieve the above mentioned goal of partitioning the large biometric database. The n-dimensional feature set obtained is used for indexing the database by forming a B+ tree. Here for every feature element, a B+ tree is formed. Thus for n-dimensional database, n such B+ trees are formed for indexing.

At the time of identification, the query data are passed to a classification algorithm, and a relevant cluster is obtained. The B+ tree within the retrieved cluster is traversed to get a set of data for matching. Finally the individual scores obtained from available traits after matching are fused using weighted sum rule. These scores are used to form a decision regarding a person's identity.

FUTURE TRENDS

Biometrics is considered one of the most reliable means of access control. Unimodal biometric systems come to standstill due to unavailability of data or poor quality input. To overcome the problem, multimodal biometric systems are used. The present state of the art provides good fusion strategies at a matching score level. However, more efforts are required towards feature-level and sensor-level fusion techniques.

Further, during identification the database is segmented using classification, clustering, and indexing techniques. At a basic level the database is divided into classes using some supervised learning algorithms. After classification, data points within respective classes are clustered using known clustering algorithms. Finally the data within each cluster are indexed to form bins. Researchers should investigate ways to develop algorithms to reduce the time and space complexity in dividing the large biometric database, with increased accuracy as well as reliability. The efforts should be directed towards minimizing the time required to claim the identity of an individual.

CONCLUSION

Biometrics systems are widely used to overcome the traditional methods of authentication. But the unimodal biometric system fails when there is a lack of biometric data for a particular trait. Thus the individual scores are combined at a classifier level and trait level to develop a multimodal biometric system. The system classifies the biometric database at a basic level using classification techniques mentioned in this article. At a refined level the database is further subdivided using a clustering technique. The data within each cluster are indexed using B+ trees, hash tables, and a pyramid technique for storage. At the time of identification, the query data are classified and the relevant cluster is obtained. The

B+ tree within a respective cluster is traversed to get a set of data for matching. Thus the hierarchical partitioning of databases is very helpful to claiming identity with reduced time and increased accuracy.

KEY TERMS

Biometrics: The use of physiological or behavioral characteristics to verify the identity of an individual comes under the realm of biometrics. Biometrics is an automated recognition of an individual based on his or her distinctive anatomical characteristics.

Classification: Supervised grouping of entire dataset at a basic level using some extracted biometric features.

Clustering: Can be considered the most important unsupervised learning problem of organizing objects into groups whose members are similar in some way. A cluster is therefore a collection of objects that are similar between them and are dissimilar to the objects belonging to other clusters.

Fusion: Combines biometric characteristics derived from one or more modalities or technologies (algorithms, sensors), multiple characteristics derived from samples, or multiple or repeated biometric instances to increase performance. Biometrics fusion centers on the capture and comparison of multiple biometric measurements like fingerprint and face.

Hashing: The transformation of a record into a usually shorter fixed-length value or key that represents the original record. Hashing is used to index and retrieve items in a database because it is faster to find the item using the shorter hashed key than to find it using the original value.

Indexing: Logical partitioning of large database using some known data structures like B-trees, hash functions, and so forth.

Multi-Biometrics: A biometric system that uses more than one biometric identifier (like a combination of face, fingerprint, iris, ear etc.) in making a decision about personal identification. Multimodal biometrics systems are expected to be more reliable due to the presence of multiple traits.

Template: The mathematical representation of biometric data. Any graphical representation is reduced to a numerical representation. The template is then used by the biometric system as an efficient method to make comparisons with other templates stored in the system.

Biometric Paradigm Using Visual Evoked Potential

Cota Navin Gupta

INTRODUCTION

Recognizing humans based upon one's intrinsic physical or behavioral traits has been gaining acceptance and is termed as biometrics. It involves either confirmation or denial of the identity that the user is claiming. It is especially important in ensuring security for access to highly restricted areas (for example: accessing classified documents, control gates and defence related applications). This chapter will discuss the use of brain signals at an application level exploiting the evoked potential approach for biometrics.

BAKGROUND

The most primitive and widely used authentication method to establish a person's identity is the textual password and usage of personal identification number (PIN) which are motivated by the facts of popularity due to low cost and user familiarity.

However these schemes have obvious shortcomings in the form of dictionary attack, shoulder surfing and people picking up obvious known words which can be easily cracked. Dictionary attacks can be prevented by using human-in-loop verifications (Pinkas & Sander, 2002) and encrypted key exchange methods (Bellovin & Merritt, 1992), but operating system vulnerabilities and access control failures may lead to disclosure of password databases. The use of PIN actually denotes the automatic identification of the PIN, not necessarily identification of the person who has provided it. The same applies with card and tokens, which could be presented by anyone who successfully steals the card or token. The system and information is definitely vulnerable during the period before a user's card or token is revoked. Even the recently proposed graphical password which is motivated by the fact that people have a remarkable memory for pictures seem to share similar problems along with the shortcomings of guessing attacks (Thorpe & Van Orschot, 2004) and reduced effective password space. The ominous presence of mobile phone cameras, digital cameras, and wireless video cameras brings in a new threat in the form of "recorded shoulder surfing" for high security applications.

Hence biometric technology based on measurable physiological and/or behavioral characteristics (e.g., fingerprints, Roddy & Stosz, 1996, the iris, Daugman, 2004, and voice recognition, Monrose, Reiter, Li & Wetzel, 2001) is often considered to surpass conventional automatic identity measures like passwords and PIN by offering positive human identification.

Fingerprint biometric systems have found its way in many public person identity databases (Maltoni, Maio, Jain & Prabhakar, 2003), but they do not seem suitable for high security environments. Recent articles and studies (BBC, 2007a; Matsumoto, Matsumoto, Yamada & Hoshino, 2002) show that common household articles (e.g., gelatine) can be used to make artificial fingers and prints to bypass the security systems. Also development of scars and cuts can result in erroneous fingerprint matching results thus increasing false rejects. Voice recognition as a biometric seems to suffer from several limitations. Different people can have similar voices and it may also change over time because of health, emotional state and age. Face recognition has been used as a biometric system but issues like the family resemblance, occurrence of identical twins (one in every 10,000) seem to question the reliability. A recent article shows that face recognition systems can be bypassed by using still and video images of a person (BBC, 2007b). Also it is inherently unreliable where high security is needed because there is not nearly enough randomness in the visual appearance of people's faces and also small variations in pose angle, illumination geometry, and facial expression have disastrous effects on the authentication algorithm accuracy (BBC, 2007b).

Another issue facing many of the biometric systems is the factor that biometric data (e.g., fingerprints or iris scans) have information which is valid and unchangeable for lifetime of the user and is irreplaceable if stolen. However it is a known fact that no biometric is expected to effectively meet the requirements for all applications. The choice of a specific biometric completely depends on the requirements of the application domain.

The above discussion on the existing biometric technologies definitely highlights the shortcomings for high security

environments and reiterates the need for an authentication system which has the following characteristics (Thorpe, Van Oorschot & Somayaji, 2005):

- ***a.*** *Changeability*: The ability to replace authentication information.
- ***b.*** *Privacy (theft protection)*: A biometric which is fraud resistant and does not use a template for lifetime.
- ***c.*** *Shoulder surfing*: System should be immune to all forms of shoulder surfing.
- ***d.*** *Universality*: Every person should have the considered characteristics.
- ***e.*** *Permanence (stability)*: Characteristic should be invariant and stable over a period of time.

A biometric system using brain's electrical response patterns with the evoked potential approach seems to have the potential to satisfy all of these requirements. Applications for this biometric system include high security systems (access to classified documents, defence applications) where fingerprints and other identity measures like passwords could be easily forged. It could also be used as a modality within a multimodal biometric environment. The advantage of using such brain electrical activity as biometric is its fraud resistance, that is someone else cannot duplicate the recorded brain response, and is hence unlikely to be forged or stolen. This modality has the additional advantage of confidentiality ("all forms of shoulder surfing' is impossible"), as brain activity is not easily seen. An added impetus for this sort of approach is the recent report in Newscientist (2007) about an initial study on the possibility of developing an electronic security system that will identify people by monitoring the brain activity.

BIOMETRIC SYSTEM USING BRAIN SIGNALS

In general, data for brain biometric system are collected using an electrode cap worn by the person (also known as subject). The electrodes are connected to the holder as shown and the brain signals are recorded in response to the activity on the computer screen. Electrode gel is used at the point of contact while fixing the electrodes to the electrode cap for improving conductance of brain potentials. There are also interfacing cables which interface the computer and the electroencephalogram (EEG) equipment to record the responses to the ongoing paradigm. The electrode configurations commonly used are the 32, 64, and 128. A number of trials of the same paradigm are usually performed during the course of the experiment and averaging taken to reduce artifacts (i.e., noise).

Given the risks with invasive implanted devices in brain and the associated ethical concerns, non invasive approaches (in particular those using EEG) seems to be more popular. EEG which is the recording of the brain's electrical activity is the de facto standard in diagnosis of brain related diseases, however recently there has been a spurt of activity in the studies on brain biometrics (Marcel and Millan, 2007; Palaniappan & Mandic, 2007; Palaniappan & Ravi, 2006; Palaniappan & Raveendran, 2002). Some early work on EEG based biometrics include the use of autoregressive (AR) models of various orders computed from EEG signals recorded from subjects with eyes open and eyes closed (Paranjape, Mahovsky, Benedicenti & Koles, 2001). A linear discriminant analysis was employed to classify the 40 subjects which gave an accuracy of 80 percent. Learning Vector Quantizer network (LVQ) was used to classify AR parameters from four subjects describing the alpha rhythm EEG feature, where the classification performance of 72-84 percent was obtained (Poulos, Rangoussi, Chrissikopoulos & Evangelou, 1999a). In a similar related study using the same data set but a different classification technique based on computational geometry gave a much improved average classification of 95% (Poulos, Rangoussi, Chrissikopoulos & Evangelou, 1999b).

More recently a statistical framework based on Gaussian mixture models and maximum a posteriori model adaptation (Marcel & Millan, 2007) was used for person authentication. The study also highlighted that certain mental tasks are more appropriate for authentication. However, many of these studies were conducted for a relatively small number of subjects.

BIOMETRIC SYSTEM USING THE EVOKED POTENTIAL APPROACH

Evoked potential is a type of EEG that is evoked in response to a stimulus, which could be visual, auditory or somatosensory. Visual evoked potential (VEP) is the evoked response to visual stimulus. In a recent study (Palaniappan & Mandic, 2007), multiple signal classification (MUSIC) algorithm was used to extract features in the gamma band of VEP based experiment study and gave enhanced person recognition of over 96% with 102 subjects. Other systems have exploited the P300 component of VEP as a medium of communication (Donchin, Spencer & Wijesinghe, 2000; Farwell & Donchin, 1988), which could be adapted from biometrics. P300 is an endogenous component of the VEP, which is most frequently elicited within the framework of an "oddball paradigm". P300 based systems are promising and motivating as they require no or very less training. It is known for its simplicity, ease of use and low error rates (Kaper, Meinicke, Grossekathoefer, Lingner & Ritter, 2004; Serby, Tov & Inbar, 2005,).

In the oddball experiment the subject is asked to distinguish between two stimuli, one common and one rare, by

Figure 1. Donchin's stimulus matrix viewed by the subject (Donchin et al, 2000)

A	B	C	D	E	F
G	H	I	J	K	L
M	N	O	P	Q	R
S	T	U	V	W	X
Y	Z	1	2	3	4
5	6	7	8	9	space

performing a mental count of one of the stimuli. In response to mentally counting the appearance of the rare stimulus, a typical potential is evoked in the brain. At any given moment the user selects (say a color or symbol) that the user wishes to communicate, and maintains a mental count of the number of times it is intensified. In response to this counting, a potential is elicited in the brain each time the color or symbol is flashed and the response is known as a P300 wave (Sutton et al, 1965). The P300 based Donchin paradigm (Farwell and Donchin, 1988) enabled communication of the alphabets and few symbols using the P300 component of the VEP. The 26 characters and symbols were displayed on the computer as shown below in Figure 1. The subject focuses successively on the character that the subject wishes to communicate. The computer detects the character focused by the subject because of the alternate repeated flashing of the columns and rows. When a column or row containing the chosen character is flashed, a P300 is evoked and would be detected by the computer.

A Preliminary Study on "Inblock" and "Outofblock" P300 Oddball Experiment

In this preliminary study, we wished to investigate the effects of presenting the oddball stimulus in "Inblock" and "Outofblock" fashion (as illustrated in Figure 2). The Donchin's paradigm (Donchin et al., 2000) is based on the Outofblock' fashion but here we show that the Inblock fashion would be more suitable to evoke P300 using the oddball paradigm for biometric applications.

We recorded EEG data from a male subject aged 27 with no known neurological disorders. A very simple form of visual stimulus presentation was used here where the subject was asked to concentrate on the letter "A". The letter Awas flashed 30% of the time while the square block was flashed for the rest 70% of the time. It is assumed that the infrequent stimuli (i.e., when the subject concentrates on the letter A) will evoke a P300 component.

The flashes were intensified for 100 ms, with an interstimulus interval (ISI) of 300 ms. During the ISI, there would be no intensifications. The ISI is defined as the end of the intensification to the start of the next intensification. The period of 300 ms was chosen after some preliminary simulations.

The sampling frequency was 256 Hz and EEG data was recorded from 64 channels using Bio-semi system. EEG data was recorded for every intensification (i.e., flash of the "block" or letter A). First, averages of left and right mastoid channels were used to re-reference the data. To extract P300 component, each EEG signal was low pass filtered to 8 Hz using a fourth order Elliptic Infinite Impulse Response filter (with forward and reverse filtering to avoid phase distortion) and then normalised to zero mean and standard deviation of one. The cut-off frequency of 8 Hz was chosen after some preliminary simulations.

Next, P300 amplitude was computed as the most positive peak in the range of 300-600 ms (or 77-154 sampling points) after stimulus onset. The above trials for the Inblock

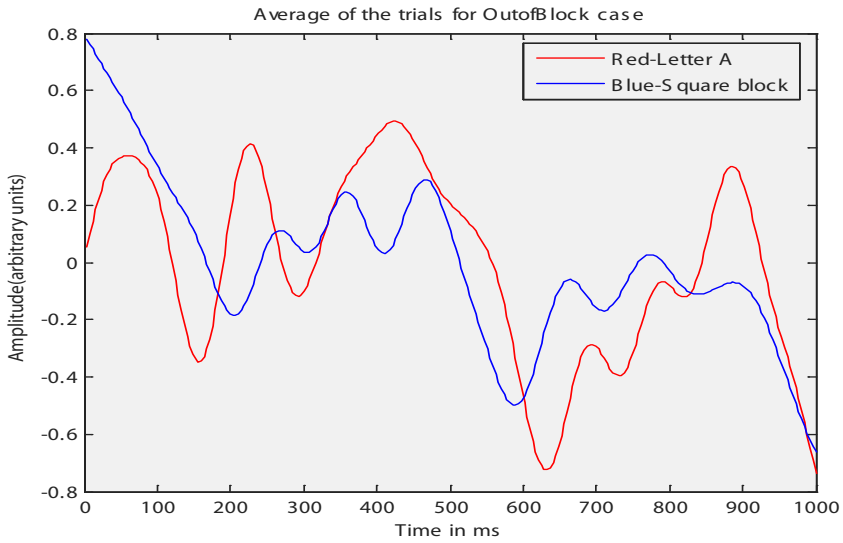
Figure 2. Visual stimulus for Donchin's paradigm: (a) Inblock and (b) OutofBlock

(a) Inblock stimulus

(b) OutofBlock stimulus

Figure 3. Averaged EEG signal for Inblock case

Figure 4. Averaged EEG signal for Outofblock case



and OutofBlock cases were averaged to reduce noise and are as shown below in Figures 3 and 4 where red indicates the EEG data when the letter A was flashed which has the P300 component (because the subject concentrated on the letter) and blue when the square block was flashed. The analysis was done for the channel Cz which is known to have maximal P300 component.

It could be seen that the signal component for the target letter A case has higher amplitude in the region of 300-600 ms rather than the square block. This is in line with the results expected from oddball paradigm. But the more important observation is the fact that the P300 peak is more easily distinguishable using the Inblock rather than Outofblock fashion. Therefore, in future experiments, we could use Inblock type of fashion for evoking P300 components using oddball paradigm.

Color "Blocks" Visual Stimuli

To make the concept of using brain biometrics universal across all boundaries (i.e., to avoid language differences), we are currently investigating the possibility of using colors

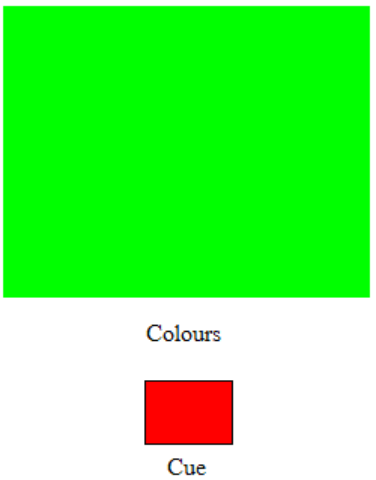
(or universal symbols) instead of English alphabets as in Donchin's paradigm.

This proposed system, which is still in early stages of research, will authenticate users using their brain signals in response to a sequence of on-screen color stimuli as well as audio signals. So at any time, the system's focus for the biometric application is to differentiate the colors on screen rather than the individuals. The EEG data will be recorded when the subject perceives different color flashes on white background within a single square block (i.e., Inblock case). The basic colors: black, red, green and blue were decided because of the contrasting difference which will easily evoke the P300 potential. The cue on which the subject has to concentrate will also be presented below this block as shown in the Figure 5.

The subject will be instructed to focus on colors that randomly flash on screen. The objective would be to form a color coded pass code generated by thought alone, which could be used to authenticate the identity of a person. For example, a passcode could be RED, BLACK, BLUE, GREEN (sequence is important as it determines the passcode). Each color would flash in random order until all colors have flashed; this is known as randomized block intensification. Each randomised block intensification of four colors will be considered as a trial. Currently, we are investigating various other novel visual stimulus paradigms (for example, using picture instead of colors) to decide the suitable stimulus for biometric applications.

This may be extended to various scenarios like words, graphical images or music to form a sequence in the form of a password. The advantage of using such brain electrical activity as biometric is its fraud resistance, that is the brain response cannot be duplicated by someone else, and is hence unlikely to be forged or stolen. The only disadvantage of the system lies in the cumbersome data collection procedure but improvements in data collection procedures (such as dry electrodes, instead of wet) will reduce the unwieldiness. However the fraud resistance significantly outweighs this difficulty especially for high security applications.

Figure 5. Color visual stimulus under investigation for brain biometrics



FUTURE TRENDS

The field of crossmodal perception refers to different sensory modalities (say audio and visual) and is being increasingly studied to gain better understanding of the long-term properties of the brain. Matched sensory inputs (such as the sight and sound of a cat) enhance our perception. Studies have shown that performance improvements can be achieved on low-level visual perceptual tasks with practice but is difficult as well as slow and requires many days of training (Adini, Sagi & Tsodyks, 2002; Poggio, Fahle & Edelman, 1992). In the study by Seitz et al (2006), a multisensory audiovisual training procedure facilitated faster visual learning than unisensory visual training. In this biometric application, the remembrance of password may be considered as a recall from episodic memory, which is a subset of declarative memory because it is related to storage of facts and can be discussed or declared. Declarative memory is subject to forgetting, but if accessed frequently they can last indefinitely (Tulving & Schacter, 1990). Since it is known that matched sensory inputs enhance our perception, it would be worthwhile to investigate and compare evoking the declarative memory (i.e. password) by one of the three protocols: visual stimulus, audio stimulus and visual combined with audio stimuli.

CONCLUSION

Although much work has been done in the past decade using brain signals for clinical analysis, the application of brain signals for biometric purpose is relatively new. It is also known that in a P300-based biometric system, the communication speed of characters is dependent on the number of trials. We are working on developing new framework at an algorithm level which we foresee will use less number of trials (Gupta & Palaniappan, 2007). It is anticipated that much of the work in future will concentrate on developing a really robust and user-friendly system where the number of trials used will be minimum (i.e., to obtain a higher bit rate). It is envisaged that the future work and technological advancements will move this concept from research into a practical working system. No doubt, one of the main constraints is the long set-up time. However, with steady research progress in signal processing, we should be able to use only a few channels that will still give accurate authentication. Then, a simple headband with

electrodes attached could be used instead and set-up time would only be on the order of seconds.

Concluding, a biometric authentication system using brain's electrical response patterns using the evoked potential approach has the potential to satisfy all of the requirements for a high security scenario and should be seriously considered as one of the emerging biometric paradigms.

KEY TERMS

Authentication System: A system which securely identifies/authenticates users.

Biometrics: Recognising human beings using their intrinsic physical or behavioral traits.

Crossmodal Perception: Using more than on modality, say audio and video to analyze the perception skill or response from subjects.

Donchin Paradigm: It is an oddball paradigm that evokes P300 component and can be used by subjects to select alphabets or menus on screen.

Electroencephalogram (EEG): It is the neurophysiologic measurement of the electrical activity of the brain recorded from electrodes placed on the scalp.

Interstimulus Interval (ISI): *T*he time (interval) between the presentation of stimuli.

P300 Potential: A component in VEP which is evoked 300 ms after the presentation of the visual stimulus.

Visual Evoked Potential (VEP): A brain potential which is evoked on the presentation of a visual stimulus.

Visual Stimulus: A stimulus normally in the form of a picture or color shown on screen, which usually is used to evoke a VEP.

Biometric Technologies

Yingzi (Eliza) Du
Indiana University, Purdue University, USA

INTRODUCTION

Biometrics is an emerging technology for automatic human identification and verification using unique biological traits (Woodward, Orlans, & Higgins, 2002). These traits include face, fingerprints, iris, voice, hand geometry, handwriting, retina, and veins. For example, fingerprint recognition analyzes ridge ends, bifurcation, or dots of finger tips; voice recognition analyzes speech signal characteristics; iris recognition analyzes the pits, striations, filaments, rings, dark spots, and freckles of eyes; and face recognition analyzes facial parameters (Du *et al.*, 2004). It is based on "something you are" rather than "something you have" (Du, 2005). Compared to the traditional identification and verification ways, such as user name/password, and paper IDs, biometrics is more convenient to use, reduces fraud, and is more secure (Reid, 2004).

BACKGROUND

Biometrics has been widely used in criminal justice; U.S. immigration and naturalization services; and e-commerce and e-government. For example, fingerprints have long been used to identify criminals. The Department of Homeland Security (2004) has deployed the US-VISIT Program for border security, which uses biometric technologies to help secure the nation's borders and expedite the entry/exit process while enhancing the integrity of the immigration system and respecting the privacy of the visitors. Biometrics has been used to replace the user name and password in e-commerce and e-government for information access.

BIOMETRICS SYSTEM

Biometric system usually includes two subsystems: (1) the biometric enrollment system (Figure 1a) and (2) biometric matching system (Figure 1b).

The biometric enrollment system includes the Sensor Module, the Data Acquisition Module, the Data Preprocessing Module, the Pattern Analysis Module, the Pattern Extraction Module, and the Biometric Database Module. And the Data Acquisition Module interprets the biometric data into digital signals (images). The Data Preprocessing Module processes these signals to reduce the noise. The Pattern Analysis Module finds the most distinctive patterns of the biometric traits. The Pattern Extraction Module picks these distinctive patterns and generates identifiable templates. These templates will be then saved in the biometric database.

Compared to the biometric enrollment system, the biometric matching system adds the Pattern Matching Module and the Decision Module. In the biometric matching system, the newly sensed biometric data will be first processed similarly as the enrollment data, and the system will generate the pattern templates from the data. The Pattern Matching Module compares the newly generated templates with those in the biometric database and calculates match scores or quality scores for final decision. If the matching score is higher than the predetermined threshold, the system identifies/verifies it.

The false acceptance rate (FAR) and the false rejection rate (FRR) are used to measure if the biometric system is reliable (Ratha, Connell, & Bolle, 2001). A biometric system that generates high scores of either FAR or FRR is not reliable and cannot be used.

The FAR measures the percentage of incorrect identification:

$$FAR(\%) = \frac{\text{Number of false acceptance}}{\text{Total number of acceptance by the system}} \times 100\% \cdot \tag{1}$$

The FRR measures the percentage of incorrect rejection:

$$FRR(\%) = \frac{\text{Number of false rejections}}{\text{Total number of rejections by the system}} \times 100\% \cdot \tag{2}$$

Figure 1. Biometrics system

BIOMETRICS TECHNOLOGIES

Currently, the common used biometric systems include fingerprint, iris, face, and voice. The following paragraphs briefly describe each biometrics technology.

Fingerprint Recognition

Fingerprints have been extensively used in modern law enforcement. Fingerprint recognition is a well established and accepted method for person identification. Every person has minute raised ridges, which display a number of characteristics known as minutiae (Figure 2). The minutiae do not change naturally during a person's life (Pankanti, Prabhakar, & Jain, 2002). Fingerprint recognition systems usually extract information about the location, type, and direction of significant minutiae and generate templates for matching.

There are three types of fingerprint recognition systems to acquire digital fingerprint images:

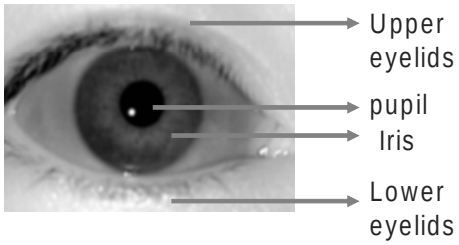
- **Optical sensors.** The optical fingerprint devices can generate very high resolution images and are often used by law enforcement and gate/door access. However, this kind of sensor is sensitive to the dirt and grease that may be on the finger.
- **Solid-state sensors.** Using integrated circuit (IC) to generate the image of the fingerprint. This kind of sensor is more cost efficient and easy to be integrated with other devices. But the image quality is not very high.
- **Ultrasound sensors.** An ultrasound camera is used to acquire images from the finger. This approach allows distinguishing between real fingers and any imitations. Furthermore, it is not sensitive to any dirt, grease, and so forth. However, this kind of fingerprint system is very expensive and not ready for mass-market application yet.

Figure 2. Fingerprint in detail

Iris Recognition

The iris is the round, pigmented tissue that lies behind the cornea (Figure 3). Compared to other kinds of biometric systems, such as face recognition and fingerprint recognition systems, iris recognition is more reliable and can achieve a higher accuracy rate.

Figure 3. Eye



Ophthalmologists Flom and Safir (1987) first noted that the iris is very unique for each person and remains unchanged after the first year of human life. In 1994, Daugman (2004) invented the first automatic iris recognition system. The iris has proven to be the most stable and reliable means of biometric identification.

To analyze the iris pattern and generate the iris templates, there are different approaches (Du *et. al.* 2004). Daugman (2004) used a quadrature 2-D Gabor wavelet method to analyze both coherent and incoherent detailed texture of the iris. Recently, Du *et. al.* (Apri, 2004) designed the local texture pattern (LTP) approach to analyze iris patterns and generated a 1-D iris signature.

Currently, there are three kinds of iris recognition systems:

- **PC Iris recognition system.** This system uses a low-end iris camera. It is the cheapest iris recognition system, but it can only hold a very small database. This kind of system is popular when used for computer access control.
- **Walkup iris recognition system.** This system uses a server-client distribution system and comprises multiple iris cameras. It is used for large database application.
- **Standalone/portable iris recognition system.** This system is a fully self-contained iris enrollment and recognition system. It is used for field applications.

Face Recognition

Face recognition is a person's primary method of personal identification. It can be captured remotely. Face recognition uses mathematical models to analyze the features in the face. Traditionally, the face is captured by a digital camera/video camera and is saved as a 2-D image. The face recognition system processes the 2-D image and analyze the face features and generate face templates.

Recently, researchers have developed 3-D cameras to capture 3-D face features. A 3-D camera is usually composed with two or more regular digital cameras. Two cameras could be arranged in such a way that they would take depth information of the face; just as our eyes. Our two eyes enabled us to see the 3-D objects. The 3-D face recognition system applies 3-D face models to the problem of robust face recognition. In particular, the 3-D face models address the two most critical and complicating factors affecting 2-D face recognition performance: illumination and pose variation.

Voice Recognition

Speech is produced by vibrating the vocal cords. The vowel sounds are perhaps the most interesting class of sounds in English (Du, 2005). Information embedded in speech can be divided into three categories: (1) linguistic (words in the speech), (2) paralinguistic (the way of delivery), and (3) nonlinguistic information (facial expression, hand gestures, and the speaker properties) (Katagiri, 2000). Voice recognition in English is more advanced and more accurate than any other language. In English, the voice recognition systems rely heavily on vowel recognition to achieve high performance. A person's voice does not, over a life span, vary with age, mood, stress, colds, and allergies.

CHALLENGES AND PROMISES OF BIOMETRICS

Accuracy

Most statistics about the accuracy rate of biometrics are performed in well-controlled laboratory environments. Even though researchers/engineers have tried their best to synthesize real-life situations, there are always surprises in real-world applications. In fact, the biometric system could encounter a lot of difficulties, such as unexpected background noises, resolution problems, and unusual user behaviors. These factors will result in much lower accuracy rates of biometric systems. For example, face recognition systems

can achieve as high as 94% accuracy rate in a well-controlled laboratory environment (indoor with good light situation). However, face recognition systems can only achieve a 50% accuracy rate or even lower in an outdoor situation.

In addition, the accuracy rate of some biometrics systems is obtained by a very small number of experiments. This kind of accuracy rate has no such meaning in statistics or real-life application.

Moreover, different kinds of biometrics systems have different accuracy rates. This is a result of the characteristics of different biometric traits. For example, the accuracy rate of the voice recognition system is much lower than that of the fingerprint recognition system because the voice of a human is not stable. The makeup and expression will change the appearance of a person and result in recognition failure by the face recognition system.

It is very important to choose the right kind of biometric system for the particular application. For an extremely secured application, the iris and fingerprint recognition systems would be more preferred than the face or voice recognition systems. However, the face and voice recognition system could be more suitable for surveillance because they do not need cooperation from the users. Compared to the fingerprint recognition system, the iris recognition system has a higher accuracy rate. However, in the forensic applications, iris recognition would not be useful because the possible changes of the iris in a dead body.

Vulnerabilities

No system is perfect. There is always one way or another to fail/spoof the system because the algorithms used by different vendors for different biometric products are based on certain mechanisms/hypothesis, which can be fooled.

There are three possible ways to trick a biometric system (Thalheim, Krissler, & Ziegler, 2002):

- **Use artificially created biometric traits.** Tsutomo Matsumoto, a Japanese cryptographer, created a fake finger—"gummy fingers"—using cheap and commonly available materials. This fake finger could fool the optical fingerprint recognition system but not the solid-state or ultrasound fingerprint recognition system.
- **Trick the system by playing back the biometric data captured in the previous authentication process.** Some voice recognition systems could be fooled by presenting the recorded version of a person's voice. This usually happens to traditional voice recognition systems that ask the user to speak a fixed word or phrase. The new voice recognition systems will randomly ask the users to speak random generated words or phrases. Some 2-D face recognition systems could be fooled by presenting a person's photo. But this could be avoided by using 3-D face recognition systems or using a liveness test.
- **Theft of the biometric data after getting into the database that stores the biometric templates.** This is a common problem of biometrics systems. It is very important for the biometric system to encrypt the biometrics data and the personal information of the user. It is also important for the security of the network if the biometric system uses server-client architecture.

Liveness test is to test if the biometric traits are from a living person rather than an artificial or lifeless person. The liveness test is very important to enforce the data integrity of the biometrics system. For example, the natural papillary response (changing pupil size in response to changes in illumination) can be used to confirm the liveness of an iris (Ma, Tan, Wang, & Zhang, 2003). The motion of a person could be used to confirm the liveness of a face. The response of a finger to a low electronic current could be used to test the liveness of a finger.

Privacy

The issue of privacy is central to biometrics. Any technology is a two-edged sword. On one hand, biometrics is used to enforce information integrity and protect privacy. On the other hand, misusing of biometrics can seriously harm individual privacy. In fact, biometrics itself is by no means privacy invasive. It is the misuse of the biometric data that is horrifying. Privacy policies, regulations, and ethic training of biometric system operators should be in place and strictly enforced to ensure that the privacy rights of the people are protected (Woodward et al., 2002).

MULTIMODAL BIOMETRICS

Multimodal biometrics is to use two or more biological characteristic for person identification or verification. Unimodal biometrics is to use only one kind of biological trait for identification or verification. Each kind of unimodal biometric system has its advantages and disadvantages. Table 1 compares different kinds of biometric technologies in terms of performance, cost, and their applications.

All aforementioned unimodal biometrics can be used for verification purposes. Each biometric system has its advantages and disadvantages. Only fingerprint and iris verification can provide reliable identifications for a large database. However, face and voice recognition systems can be used for surveillance or remote access. Voice recognition may achieve the lowest accuracy rate, but it is nonintrusive to the users.

By using multiple biometric traits and data fusion, multimodal biometrics could improve the accuracy rate

Table 1. Comparison of biometric systems

	Accuracy	Reliability	Stable	ID	Low Cost	Intru-sive	User Co-op	Large Population
Finger-print	High	High	Yes	Yes	Yes	Yes	Yes	Yes
Face	Medium	Medium	No	No	No	No	No	No
Iris	Very High	Very High	Yes	Yes	No	Yes	Yes	Yes
Voice	Low	Low	No	No	Yes	No	No	No

and reduce the vulnerabilities. For example, a multimodal biometric system which is composed of a face recognition system and a voice recognition system could possibly achieve similar accuracy as a fingerprint system (Frischholz & Dieckmann, 2000).

A single biometric system might be easily fooled by artificial/faked biometric traits. However to fake multiple biometrics traits would not be an easy task. A combination of different types of biometric systems could also improve the system performance in variable environments. For example, a face recognition system combined with an iris recognition system could improve the accuracy rate while keeping the ability of remote tracking.

FUTURE TRENDS

With the development of technologies, the biometric systems are becoming more and more reliable and convenient for authentication and identification. The demands for biometric systems have grown in markets, from personal log in to PCs to large scale entry/exit security systems. In the near future, biometrics will become part of our daily life. We will use biometrics to open the door, withdraw money from ATMs, borrow books from libraries, and so forth.

CONCLUSION

Biometrics is the automated use of biological features of a human being to positively identify a person. Compared to the traditional identification and verification methods, biometrics is more convenient to use, reduces fraud, and is more secure. There are needs for biometrics in federal, state, and local governments; in the military; and in commercial applications. While it is very important to choose the right kind of biometric system for a particular application, multimodal biometrics will be a trend in the deploying of biometrics systems.

Over the years, there are concerns about privacy issues in the applications of biometrics, and it will continue to be an important issue. Privacy policies, regulations, and ethic training of biometric system operators will be very necessary and important to have in place and strictly enforced to ensure that the privacy rights of the people are protected.

KEY TERMS

Biometrics: An emerging field of technology that uses unique physical, biological, or behavioral traits for automatic human identification and verification.

Face Recognition: Automatic recognition of a person's identity by mathematical analysis of person's face features.

False Acceptance Rate (FAR): FAR is the percentage of incorrect identification. It is defined as the total number of acceptance by the system divided by the number of false acceptance.

False Rejection Rate (FRR): FRR is the percentage of incorrect rejection. It is defined as the total number of rejection by the system divided by the number of false rejection.

Fingerprint Recognition: Automatic recognition of a person's identity by mathematical analysis of the patterns of fingerprints.

Iris Recognition: Automatic recognition of a person's identity by mathematical analysis of the random patterns that are visible within the iris of an eye from some distance.

Liveness Test: A test performed to test if the biometric traits are from a living person rather than an artificial or lifeless person.

Multimodal Biometrics: Automatic recognition of a person's identity using more than one physical, biological, or behavioral characteristic.

Voice Recognition: Automatic recognition of a person's identity by mathematical analysis of person's voice features.

Blended Learning Models

Charles R. Graham
Brigham Young University, USA

INTRODUCTION

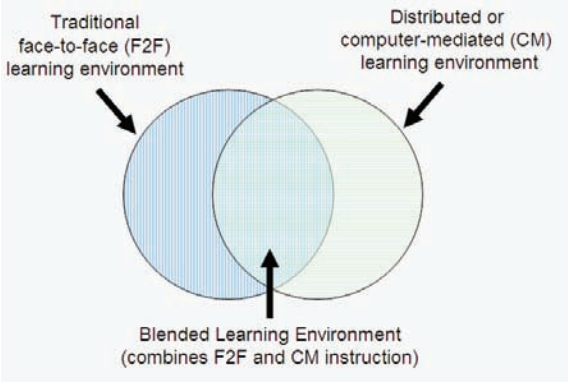
Technological advances and widespread access to information and communication technologies (ICTs) have facilitated the rapid growth of blended learning approaches in both higher education and corporate training contexts. In 2002, the president of Pennsylvania State University expressed his belief that blended learning was "the single greatest unrecognized trend in higher education" (Young, 2002, p. A33). At the same time, the American Society for Training and Development also identified blended learning as one of the top 10 emergent trends in the knowledge delivery industry (Finn, 2002). Since then, the visibility of blended learning environments has increased dramatically in both formal education and corporate training settings. At the third annual Sloan-C Workshop on Blended Learning and Higher Education, Frank Mayadas, the program director for the Alfred P. Sloan Foundation, predicted that "by 2010 you will be hard pressed to find a course that is not blended" (Mayadas, 2006). There is increasing interest in the concept of blended learning as evidenced by greater numbers of books, journal articles, and trade magazine articles that directly address issues related to blended learning. This article will provide an overview of current models of blended learning and provide references to the most recent resources in this emergent area of research and practice.

BACKGROUND

Definition

The use of the term blended learning is relatively new in both higher education and corporate settings. In higher education, the term "hybrid course" was often used prior to the emergence of the term "blended learning," and now the two terms are used interchangeably. Because term is relatively new, there are still ongoing debates regarding the precise meaning and relevance of the term (Driscoll, 2002; Graham, Allen, & Ure, 2003; Laster, 2004; Masie, 2005; Oliver & Trigwell, 2005; Osguthorpe & Graham, 2003). However, the most commonly held position is that *blended learning environments combine face-to-face instruction with technology-mediated instruction* (Graham, 2005; Graham et al., 2003). This definition highlights the ongoing convergence of two archetypal learning environments: the traditional face-to-face (F2F) environment with the distributed (or technology-mediated) environment (see Figure 1).

Figure 1. Blended learning combines traditional face-to-face and computer mediated instruction



Purposes

There are many reasons why a blended approach to learning might be selected. The three most common reasons for blending listed in the literature are:

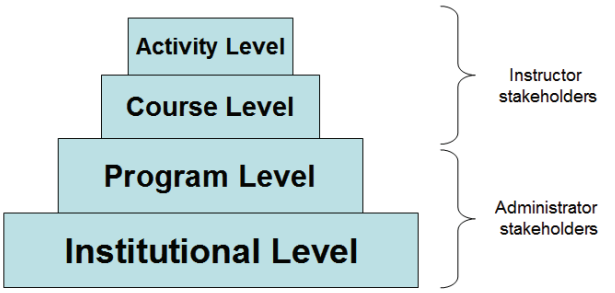
- To increase learning effectiveness
- To increase convenience and access
- To increase cost effectiveness

Often educators adopt a blended approach in order to explore tradeoffs between more than one of these goals simultaneously (e.g., increasing the convenience to students afforded by an asynchronous distributed environment without completely eliminating the human touch from the F2F environment). While blended learning is appealing to many because it enables one to take advantage of the "best of both worlds" (Morgan, 2002; Young, 2002), blended learning environments can also mix the least effective elements of both F2F and technology-mediated worlds if not designed well.

MODELS

The concept of blended learning is simple and elegant. However, there are numerous ways that blended learning

Figure 2. Different levels where blended learning can occur



can be implemented in a wide variety of different contexts. For this reason, it is important to share successful models of blended learning so that all can benefit. Sharing *models* of blended learning can help to facilitate the *purposeful* and *disciplined* adoption of appropriate blended learning strategies. This section of the article will present several models of blended learning. Because of space constraints it is not possible to share all of the details of the models, but a rich set of references is provided that will allow the reader to find additional details for the examples of interest.

It is important to understand that blending occurs at many different levels including the institutional level, the program level, the course level, and the activity level (see Figure 2). Typically, models at the course and activity levels have instructor stakeholders who are primarily interested in issues of learning effectiveness and productivity. Blended learning that occurs at the program and institutional levels typically has administrator stakeholders who are often driven by issues of cost effectiveness and expanding access of the learning to untapped audiences. Specific examples of blended learning at each of these levels can be found in *The Handbook of Blended Learning* (Graham, 2005) and *The Encyclopedia of Distance Learning* (Graham & Allen, in press).

Because there is such a wide range of possible blends in the different contexts, it can be helpful to think of three major categories of blends: enabling blends, enhancing blends, and transforming blends. Table 1 contains a description of each category and specific examples for each.

The distinctions here are particularly important when considering the impact of blended learning on learning ef-

Table 1. Three categories of blends with examples

Category	Description	Examples
Enabling Blends	Enabling blends primarily focus on addressing issues of *access* and *convenience*. They often use information and communication technologies as a way to provide "equivalent" learning experiences to the predominant face-to-face modality.	1. Many of the for-profit institutions like University of Phoenix (Lindquist, 2005) have models that focus on making educational opportunities available to those who do not have access due to time and location constraints. 2. National University has a teacher preparation program geared toward access and flexibility (Reynolds & Greiner, 2005). 3. Many international education and training programs are also focused on providing access (e.g., World Bank, Jagannathan, 2005, Mexico's Red Escolar program, Acuña Limón, 2005, etc.).
Enhancing Blends	Enhancing blends allow for incremental changes to the pedagogy. They are often characterized by the inclusion of supplemental online resources and/or the implementation of online activities that are small in scope when compared to the overall course.	4. University of Glamorgan, Wales (Jones, 2005) has a continuum of e-learning that includes four levels, the first two of which represent enhancing blends: (1) Basic ICT usage (e.g., PowerPoint presentations) and (2) E-enhanced (e.g., access to online resources, use of Bb for productivity such as announcements, lecture notes, etc.). 5. University of Waikato, New Zealand (Wright, Dewstow, Topping, & Tappenden, 2005) has a model for enhancing F2F courses that includes levels such as "Supported Online" (e.g., traditional F2F with access to materials provided online) and "Somewhat Online" (e.g., includes an online course component for on-campus students). 6. University of Central Florida, U.S. (Dziuban, Hartman, Juge, Moskal, & Sorg, 2005) has a model that includes "W courses" (e.g., fully online), M courses (e.g., mixed, reduced F2F contact courses), and E courses (e.g., Web enhanced courses). E courses use online or Web components to enhance a traditional F2F course.
Transforming Blends	Transforming blends allow for a significant change in pedagogy that facilitates active learner construction of knowledge.	7. Use of instructional simulations such as the Virtual Audiometer and Virtual Chem Lab at Brigham Young University are changing the ways in which students learn and solve problems (Graham & Robison, in press; West & Graham, 2005). 8. Authentic learning environments that bring real world contexts into the classroom (Oliver & Trigwell, 2005) or integrate formal learning with workplace learning (Collis, 2005; DeViney & Lewis, 2005; Singh, 2005) can be supported through the use of blended learning approaches. 9. Mixed reality technologies facilitate the blending of F2F and virtual worlds and are transforming the kinds of learning and performance support that is taking place in industrial and military contexts (Kirkley & Kirkley, 2005; Wisher, 2005).

Figure 3. Three paths for designing blended learning environments

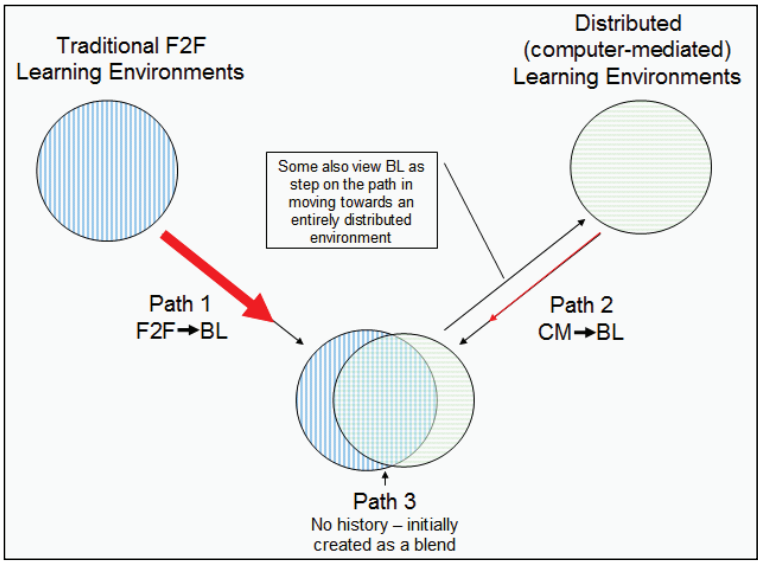


Figure 4. Two ways of moving from a traditional F2F learning environment to a blended learning environment

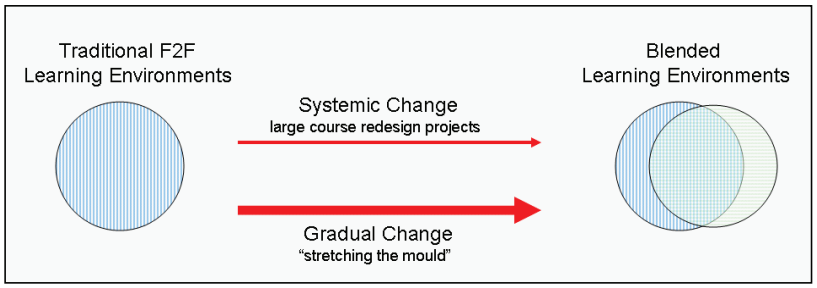

fectiveness. An enhancing blend might serve as a stepping-stone to a more transformative blend, or it might end up superficially impacting student learning (Graham & Dziuban, submitted; Graham & Robison, in press).

Higher Education Models

In higher education the primary path to blended learning is from a predominantly F2F environment to a blended environment (see Path 1 in Figure 3). There is also a path (though much smaller) from an entirely distributed environment to a blended environment (see Path 2 in Figure 3). Path 3 (see Figure 3) occurs most often in corporate contexts when new programs and courses are developed from scratch to meet an emerging need.

Models that involve Path 2 movement typically occur with the goal of adding "human touch" to a distance course or program where access to the F2F environment is possible but less convenient. In these cases we see blends including a limited number of F2F events such as a residency requirement (Offerman & Tassava, 2005; Pease, 2005), F2F orientations and/or final project presentations (Lindquist, 2005), or optional F2F help sessions for struggling learners.

Faculty adoption of blended learning that involves Path 1 movement occurs via gradual change or systemic change (see Figure 4). Most often it occurs via gradual change or what Collis and van der Wende (2002) call "stretching the mould." This involves exploration and adoption of blended learning strategies such as enhancing a course with online resources and activities.

At first, F2F contact time may not be reduced because enhancements are small and exploratory. As online activities become more successful and more integral to the course, faculty reduce their F2F contact time to accommodate the online activities. Researchers have documented the tendency among many faculty designing blended learning

courses to keep adding online components to the traditional course without eliminating anything. This phenomenon is known as the course-and-a-half syndrome (Kaleta, Skibba, & Joosten, in press).

To date, systemic change has not been as wide spread as gradual change toward blended learning. Systemic approaches to designing blended learning involve whole course redesign. Some of the best documented cases of course redesign efforts involving blended learning come from the Program in Course Redesign supported by the PEW Charitable Trusts (Twigg, 2003). The goal of this project was to see if 30 large enrollment courses from across the United States could be redesigned using technology to simultaneously provide both reductions in cost and gains in learning outcomes. The majority of the course redesign efforts involved moving from a traditional course delivery to a blended learning approach. Table 2 outlines five specific models of blended learning that resulted from the efforts.

Corporate and Military Models

Blended learning in corporate settings is driven by the desire to improve return on investment (ROI) of training dollars. This means driving down the costs and trying to increase the impact of training. Bersin and Associates (2003) studied blended training in major programs that impacted over 100,000 employees at 15 large corporations. They found that the ROI for blended learning programs was 100%+ in almost every case and much larger in some cases. Similarly, IBM documented a 17:1 ROI for deployment of its blended learning leadership management program (Lewis & Orton, 2005).

Blended learning models in corporate settings are even more varied than in higher education settings. F2F human interaction is arguably the most powerful learning intervention and the most costly (Lewis & Orton, 2005). Data show that instructor led training (ILT) is still by far the most prevalent mode of training delivery (Ziob & Mosher, 2005). So, most blended learning models seek to use human interaction strategically and replace much of the F2F interaction with interactive simulations, performance support systems, or technology mediated interactions with colleagues that eliminate the need for expensive travel.

For example, IBM has a four-tiered approach where learners have access to a performance support database, interactive learning simulations, a live-virtual collaborative learning environment, and F2F learning laboratories. Learners in the program begin with 26 weeks of self-paced online learning after which they participate in a five-day in-class learning lab. The F2F lab experience is followed by a 25-week online learning experience that focuses on application of skills and knowledge (Lewis & Orton, 2005). Similarly, Oracle's leadership training program (Hanson & Clem, 2005) and Avaya's sales training program (Chute, Williams, & Hancock, 2005) both used limited and strategically placed F2F sessions embedded within a wide variety of computer-mediated and self-paced activities to reach their goals. The use of technology to facilitate training is

Table 2. Models developed from 30 course redesign efforts sponsored by the PEW charitable trusts (Twigg, 2003)

Model	Description
Supplemental Model	• Lecture portion of class kept intact • Supplemental online materials provided • Online quizzes • Additional online activities
Replacement Model	• Reduction of in-class meeting time • Replacement of face-to-face (F2F) class time with online activities • Online activities can take place in a computer lab or at home

Buffet Model	• Student chooses learning options
	  • Lecture
	  • Online
	  • Discovery laboratories
	  • Individual projects
	  • Team/group activities
	  • And so forth

Emporium Model	• Eliminates class meetings
	• Substitutes a learning resource center with
	  (1) online materials and
	  (2) on-demand personal assistance

Fully Online Model	• All online learning activities • No required F2F class meetings • (In some cases) optional F2F help

facilitating a greater integration between formal learning and informal or workplace learning (Collis, 2005; DeViney & Lewis, 2005; Singh, 2005). Increasingly, learners are able to engage with a formal instructor at a distance and have learning activities and assignments mediated in the local context by a manager or mentor.

A second corporate model that is worth mentioning can be seen in the Cisco Networking Academy (Dennis et al., 2005; Selinger, 2005). The Cisco Networking Academy is a global training program for Internet technology skills that is implemented in more than 150 countries across the world and has over 400,000 enrollments. The academy provides centralized Web-based curriculum, online assessments, and tracking of student performance. At each academy site instructors are able to use the Web-based content and customize it to support the specific needs of their local students. This approach allows courses to be offered as Web-based training or instructor-led training, or a blend of both to best accommodate the learning preferences and work styles of the learners (Selinger, 2005). This blended approach also facilitates cultural adaptation and localization of curriculum to meet diverse cultural needs.

Finally, military and some high-tech industrial contexts are employing mixed reality environments that blend F2F interactions with interactions in a virtual world (Kirkley & Kirkley, 2005). For example, the U.S. military is training with live-virtual-constructive learning exercises, which meld the real world with the simulated world. Wisher (2005, p. 527) writes about one such exercise with the task of conducting an amphibious assault that involved "seventeen military units (live), six simulators (virtual), and twenty one simulations (constructive)."

FUTURE TRENDS

It is hard to predict exactly what the future holds for blended learning environments. It is very likely that the use of blended learning in both higher education and corporate contexts will continue to grow. In fact, there may come a time when the traditional learning environment is predominantly a blended learning environment and it no longer makes sense to use the adjective "blended." An example of this is the fact that the University of Central Florida has considered dropping its (E)nhanced course designation because virtually all the university courses have a Web presence (Dziuban, 2006). There is likely to be an increased focus in higher education on the transformative potential of blended learning (Garrison & Kanuta, 2004; Graham & Robison, in press). Rather than focus on whether blending is happening or not, universities will focus more on the quality of the blend and seek to understand how faculty can be trained and supported to teach in blended learning environments.

There is evidence that administrators and students in K-12 environments (particularly in high school and home school settings) are beginning to explore the possibilities of blended learning. Corporate and military contexts are likely to be the ones that continue to push the technological envelope, exploring the use of more expensive technologies, although increasingly simulations may be used in K-12 and higher education classrooms.

Finally, Bonk, Kim, and Zeng (2005, p. 560) make 10 predictions related to blended learning in the future:

1. the increased use of mobile devices in blended learning
2. greater use of visualization tools and hands-on learning in blended learning
3. increased learner input in the design of their own learning programs
4. increased connectedness, community, and collaboration
5. increased authenticity and on-demand learning
6. stronger ties between work and learning
7. calendaring system will need to change and be more flexible
8. programs will begin to include blended learning course designations
9. instructor roles will increasingly move toward that of mentor, coach, and counselor
10. blended learning specialist teaching certificates will emerge

CONCLUSION

During the past decade, distributed learning has made huge strides in popularity in both higher education and corporate sectors of society. The use of technology has increased access to educational resources and facilitated communication in a way that was not previously possible. Despite the strengths that online learning environments provide, there are different strengths inherent in traditional F2F learning environments. The current trend toward blending both online and F2F instruction is a positive direction and merits increased attention and study. Because the possibilities inherent in a blended environment are so vast, it is important that we begin to develop and share successful models of blended learning at all the different levels (see Figure 2) and contexts in which it can occur.

KEY TERMS

Affordances: Features of an environment or artifact that "afford" or permit certain behaviors.

Blended Learning Environment: A learning environment that combines face-to-face and computer-mediated instruction.

Distributed Learning Environment: A learning environment where participants are not co-located and use computer-based technologies to access instruction and communicate with others.

Hybrid Course: Another name for a blended course. Typically a course that replaces some F2F instructional time with computer-mediated activities.

Performance Support Systems: Systems that are designed to improve human performance through many different kinds of interventions including but not being limited to instructional interventions.

Return on Investment (ROI): A measurement evaluating the gains versus the costs of an investment.

Technology-Mediated Learning Environment: Another name for a distributed learning environment.

Bonded Design

Andrew Large
McGill University, Canada

Valerie Nesset
McGill University, Canada

INTRODUCTION

It is hardly controversial to argue for user involvement in the technology design process: the issue rather is the extent of that involvement and whether or not this is related to the kind of user. In particular, can young children play a meaningful role in design, and if so, what should it be? Several design methodologies advocate a range of roles for children within the design process; this article presents a new such methodology, Bonded Design. Essentially, Bonded Design assumes an intergenerational team comprising adult designers and young users working together to produce a low-tech prototype. This team employs a variety of design techniques—conducting a user needs' assessment, evaluating existing technologies, brainstorming, discussing ideas as a group, prototyping (for example, through drawings), and consensus building—to achieve its goal.

Bonded Design emerged in 2003 from a research study to investigate whether elementary school students (specifically in grades three and six) could actively participate in designing Web portals. To accomplish this objective two intergenerational design teams were established, each including children alongside researchers, which produced two low-tech portal prototypes (Large, Beheshti, Nesset, & Bowler, 2004; Large, Nesset, Beheshti, & Bowler, 2006, 2007). These prototypes subsequently were converted into working portals that received high praise in their evaluations by elementary school students. Indeed, one of these portals, *History Trek*, is now operational on the Web, providing access to information in English and French on Canadian history (*http://www.historytrek.ca*).

BACKGROUND

Bonded Design did not emerge in a vacuum; a number of user-focused design methodologies have accommodated children in various ways and to various degrees in the design of technologies intended for use by children (Nesset & Large, 2004). The oldest and most conventional approach, "User-Centered Design," focuses on the impact of technology on users, but traditionally these users were only involved after the technology had been designed (Nesset & Large, 2004; Scaife & Rogers, 1999, Scaife, Rogers, Aldrich, & Davies, 1997). In other contexts, the term *user-centered design* has been understood by some authors to mean direct contact between users and designers throughout the design process (Rubin, 1994). Typically in User-Centered Design the users have little or no control over the design process itself. Fundamentally they are testers rather than designers, revealing design shortcomings rather than proposing design ideas. In this context, where children only act as testers of prototypes designed by adults for young audiences, their involvement is relatively uncontroversial.

Contextual Design is described by Beyer and Holtzblatt (1999, p. 32) as "a state-of-the-art approach to designing products directly from a designer's understanding of how the customer works." Designers collect data from users' own environments by observing them performing typical activities. They usually record observational data and conduct one-on-one interviews with users in order to develop a deeper understanding of the users' work practices. They then apply work modeling using such techniques as pictorial charts, storyboarding, and low-tech prototyping. In Contextual Design, therefore, the users' role is critical but passive: it is their behavior rather than their ideas that inform the process. This methodology can be applied to children as technology users when the classroom or home is substituted for the adults' workplace.

Soloway, Guzdial, and Hay (1994), based on the idea that the long-term goal of computing is to make people smarter, decided that the HCI community needed to move from the traditional "user-centered" design to what they term "Learner-Centered Design." This approach assumes that everyone is a learner, whether a professional or a student. The main focus of Learner-Centered Design is to ensure that the design is adapted to the interests, knowledge, and styles of the learners who use it. Soloway et al. (1994) believe in the educational philosophy of "learning by doing." At the heart of Learner-Centered Design are understanding (how will the learner learn the practice?), motivation (how can technology motivate a learner?), diversity (every learner is different—what kind of technology can be developed to support this?), and growth (the learner changes but the technology does not).

Kafai (1999) adapted Learner-Centered Design for use with children by making them the actual designers. She believes it is necessary that child learners be involved in the evaluation and testing processes. Her research showed that young student designers are similar to professional designers in their concern for their users. They were conscious of, and tried to address such issues as content and user motivation, but they did not always fully grasp how to address their users' other needs. Kafai is convinced, however, that children have the ability to become more than just informants in the design; rather, that they can become design process participants.

The premise behind Participatory Design is that users are the best qualified to determine how to improve their work, and that their perceptions about technology are as important as technical specifications (Carmel, Whitaker, & George, 1993). Two themes govern the implementation of Participatory Design principles: through "mutual reciprocal learning," users and designers teach each other about work practices and technical possibilities based on joint experiences; in "design by doing," interactive experimentation, modeling and testing, hands-on designing and learning by doing are employed. Like Contextual Design, Participatory Design is suitable for design projects involving children, where their school or home can substitute for the adult workplace. Its main difference from User-Centered Design, Contextual Design, and Learner-Centered Design is that the role assigned to children can be more extensive.

Informant Design was introduced specifically to address some of the perceived problems with User-Centered Design and Participatory Design when working with children (Scaife et al., 1997). In User-Centered Design, users are involved only as evaluators or testers at the end of the design process, and it is left to the designers to translate and interpret users' reactions, which can sometimes give inaccurate results. Scaife and his colleagues were critical of Participatory Design as a methodology to employ when working with children because it promotes the equality of all design team members. They considered this approach effective for a team comprising adult users who can see each other as peers, but infeasible with children who they believe have neither the time, knowledge, nor expertise to fully participate in a collaborative Participatory Design methodology. Informant Design attempts to maximize the input of the participants at various stages of the design process. Informants can help the designers "discover what we did not know rather than try to confirm what we thought we already knew" (Scaife & Rogers, 1999, p. 31). In Informant Design, each informant shapes the design at different points. Scaife and his colleagues believe Informant Design to be the best method "for the design of interactive software for non-typical users or those who cannot be equal partners (e.g., children)" (Scaife et al., 1997, p. 346). At the same time, there is a basic assumption that in the design process, children are most helpful at suggesting ideas only for motivational and fun aspects of the design rather than its totality.

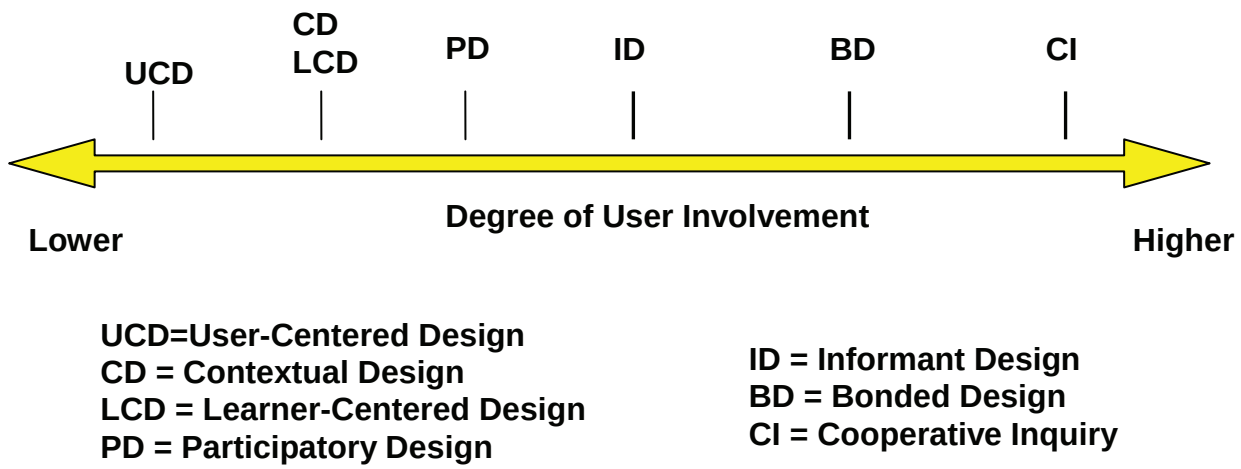
Cooperative Inquiry combines techniques from different design methodologies that have proven useful when working with children. Developed by Druin (1999) and her colleagues at the University of Maryland, it involves a multidisciplinary partnership with children, field research, and iterative low-tech and high-tech prototyping. Children are treated as full design partners alongside the adult designers on the intergenerational team. Professional designers and users (children) of the technology are partnered in intergenerational design teams with the understanding that full participation of users requires training and active cooperation. The design team makes use of such Contextual Inquiry methods as brainstorming and interviewing, as well as working together in small groups and developing low-tech prototypes (Druin, 2002; Guha et al., 2004). Using Cooperative Inquiry, Druin and her colleagues (Druin, 2002, 2005; Druin et al., 2003) have designed the International Children's Digital Library (*http://www.icdlbooks.org*).

BONDED DESIGN

Bonded Design is the newest addition to this family of technology design methodologies. From conventional User-Centered Design, it takes the most basic premise—involving users. From Contextual Design have come the ideas of drawing paper prototypes, and a similar process to what it terms *work redesign* in the use of a whiteboard to set out a map at the beginning of each session for what had already been accomplished and what remained to be done. Participatory Design provides the concept of peer co-designers, drawings (low-tech prototyping), hands-on activities, and "learning by doing." It shares with Informant Design the approach of seeking new and creative ideas rather than merely confirming what the adults already knew. Bonded Design also includes aspects of Learner-Centered Design in that it provides a learning environment for all team members: children and adults alike. In designing Web portals for children, as in Learner-Centered Design, all team members are learners, and the team's objective is to ensure that the design is adapted to the interests, knowledge, and styles of its target (child) users.

Of all the design methodologies, Cooperative Inquiry is the closest to Bonded Design. Both emphasize an intergenerational partnership to achieve a common goal, and embrace the idea that children should play an active role in the design process from start to finish rather than merely being evaluators or testers at the end of the design process. These two methodologies differ, however, in the emphasis placed by Bonded Design on a very focused approach that seeks to complete a highly specified task in a limited number

Figure 1. User involvement continuum



of design sessions extending only over a few weeks. Essentially Bonded Design is situated on a user-focused design methodology continuum between Cooperative Inquiry and Informant Design (see Figure 1). It shares the former's belief in the ability of children to work as partners in all aspects of the design process, but has reservations about the extent to which full and equal cooperation can occur across the generational divide, and in these respects, therefore, has similarities with the latter.

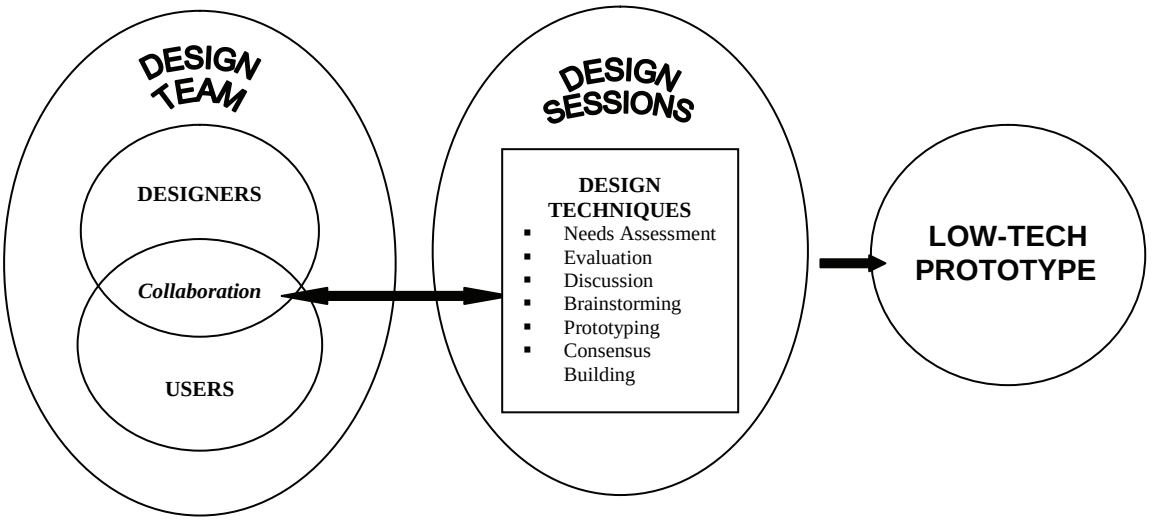
The Bonded Design methodology is graphically represented in Figure 2. The design team comprises two distinct groups: designers and users. It is assumed that the designers have a familiarity with the relevant technological environment as well as the design process. Yet it is fallacious, if common, to believe that these two attributes allow adults to think like children and see the world through youthful eyes. If designers want to be confident that their product will meet the expectations and requirements of children, they better understand what these are; the best way to do this, Bonded Design asserts, is to include children along with designers as collaborators throughout the design process.

Since collaboration is integral to the Bonded Design methodology, it is important to facilitate interaction among the team members. When working with children this can present unique challenges that can be met in a number of ways: a casual environment where the team sits around one large table, name badges (first name only), and respect for and acceptance that each team member's (adult and child) contribution is worthy of consideration. In other words, the team should promote a collaborative environment rather than a traditional classroom setting with its teacher-student relationships. Yet, even with these in place, it cannot be assured that everyone will feel at ease in participating. It is the responsibility of the adults to ensure that the sessions are not dominated by one or two voices and that the more reticent are actively encouraged to participate. If the design team is to work effectively and produce a low-tech prototype after a limited number of design sessions, it is also important to restrict the size of the team. In Bonded Design it is recommended that the team include between six and ten members (children and adults) to facilitate consensus building while providing a variety of ideas.

Any design is intended ultimately to be used. An important preliminary step in the design process is to ascertain the needs which the design is intended to meet for any given user community. A needs assessment, where potential users are polled to elicit how and why they might employ the completed product, is an effective tool to achieve this objective. This holds true even when the users happen to be children. One way to undertake a needs assessment is to survey a user sample by questionnaire. As the users will be children, it makes for good practice to involve the team's children in carrying out this assessment by administering the questionnaire to their peers.

Evaluating any available examples of the intended technology is a critical aspect that can take place throughout the design process. This evaluation may draw upon team members' prior knowledge of the product or upon

Figure 2. Model of bonded design



examination of examples within the design sessions. Any evaluation should be critical, and team members should be encouraged to identify strengths and weaknesses that can in turn inform their own preliminary designs. For example, the team that used Bonded Design to produce a prototype children's Web portal was able to critically assess a variety of existing exemplars available on the Web.

A free exchange of ideas lies at the essence of Bonded Design, but this is also where the interaction between the adult designers and the children within the team can pose the greatest challenge. The designers must be willing to accept the ideas put forward by the children even if they have reservations about their efficacy and feasibility of implementation. In the same vein, the children should be willing to draw upon the expertise that the designers inevitably bring to the task. At the heart of Bonded Design lies the belief that the child users have things to tell the adult designers that the latter cannot grasp themselves. Equally, Bonded Design is posited on the fact that the children by themselves do not have the necessary knowledge to design independently. It is the very bonding of ideas from these two groups that constitutes the strength of this design methodology.

Brainstorming is an activity that promotes creativity by encouraging all team members to contribute ideas on a topic. At this stage all ideas are accepted as having merit and are documented for later discussion. These ideas, however, are not always expressed verbally; for example, ideas often can be expressed very effectively through drawings, and this technique enables children to present interesting ideas without the constraints that a written or verbal representation might entail for young people. Furthermore, technology designs will normally be visual and therefore lend themselves to visual expression.

Prototyping is a technique shared by many design methodologies (Beyer & Holtzblatt, 1999; Carmel et al., 1993; Druin, 1999, 2002, 2005; Scaife, et al., 1997). It forms the bridge between discussion and brainstorming on the one hand, and the completed prototype design on the other. It can take various forms, but the most popular in participatory design methodologies is that of low-tech prototyping where participants use paper, modeling clay, or other such materials to represent design ideas. In Bonded Design, prototyping is used iteratively throughout the sessions in order to produce a final low-tech prototype. Bonded Design is particularly appropriate when working with children because they enjoy these types of prototyping activities and very successfully accomplish them. Furthermore, as commented above, children often can express their ideas more cogently through such activities rather than attempting textual descriptions (Arizpe & Styles, 2003; Glynn, 1997).

In any team environment where individuals are required to work together to reach a common goal, consensus building must take place. In the early stages of Bonded Design, team members are encouraged to think independently and to

formulate and express their own design ideas. Brainstorming is an effective way to generate a rich pool of ideas, but at some point these disparate ideas must coalesce into a unified design as a prelude to the completion of the low-tech prototype. Building such a consensus can be especially challenging when children are involved as they tend to an egocentric view of the world; a willingness to embrace alternative viewpoints comes only with maturity (Piaget & Inhelder, 1969). Before brainstorming begins it is important to establish evaluation criteria. One way to achieve this is through the initial user needs assessment, as it can identify design objectives and serve as a valuable basis on which to construct consensus. After brainstorming, when trying to reach consensus the team must determine which options best match the evaluation criteria. By matching options to pre-determined evaluation criteria, there is less chance that the opinions of one or two people will dominate.

The final step in the Bonded Design process is the development of a low-tech prototype. This can take a variety of forms, largely depending upon the time and resources available. For example, such activities as drawing on paper, modeling with clay, or computer simulations can be used to represent a final design.

FUTURE TRENDS

Bonded Design emerged as a methodology that can be used to design information technologies for children by involving children actively in all aspects of the design process. In the future there is no reason to think that it will not be applied to accomplish other design tasks where children can play an integral role, such as the creation of a student newspaper or the planning of a children's recreation area. Furthermore, although developed to involve children alongside adults in the design process, its emphasis on collaboration between design team members makes it a useful tool for cooperative learning within a classroom environment, where the emphasis may be more on the process than the outcome.

CONCLUSION

Bonded Design represents an addition to the array of user-centered design approaches. It is a means of bringing together for design purposes a team that unites in diversity. Adult design experts collaborate with child users who are experts in being children. Bonded Design is a method that involves users intimately in the design process. It does not simply ask users to test and respond to prototypes presented by professional designers (although it does turn to users for evaluations of the completed prototypes), but rather it incorporates members of the target user community into the decision making that lies behind the completion of these prototypes. In this way users do not simply react to designs that are presented to them, they help to create these designs. Such an approach provides an opportunity to accelerate the design process; instead of designing and testing over multiple iterations, as would be the approach in Participatory Design, Bonded Design over a limited number of design sessions can arrive at a low-tech prototype that has "bonded" the designers' professional expertise with the users' expertise in being users to get the best out of both constituencies. As such it is particularly appropriate when designing technologies for children. In order for designers to create for children, it is essential that children themselves be consulted, and Bonded Design is an ideal way to achieve this.

KEY TERMS

Bonded Design: A design methodology in which children play an active part in the design process alongside adult designers in an intergenerational team to accomplish a specific objective over a limited number of planned sessions.

Children: Young people, typically aged 12 years and younger.

Cooperative Inquiry: A design methodology in which children and adults cooperate as equals within an intergenerational team throughout the design process.

Design Methodology: A set of techniques normally involving users as well as designers to be employed in creating new technologies.

Informant Design: A design methodology in which children and adults are invited to inform the design throughout different stages of the design process.

Participatory Design: A design methodology in which users participate actively in the design process.

Prototyping: The process of creating an initial design.

Bridging the Digital Divide in Scotland

Anna Malina
e-Society Research, UK

INTRODUCTION

Perceptions of the different meanings and issues surrounding the term *digital divide* have set the scene for policy development in various countries. In recent times, broader analysis of the meanings and problems have altered understanding, and a new range of initiatives to tackle perceived problems is being devised in the United Kingdom (UK) and its regions. In what follows, digital divide perspectives are outlined and action to close the divide in Scotland is discussed.

BACKGROUND

For some time now, the Information Society vision in many countries has been accompanied by knowledge of risk of exclusion and strategies to close the so-called "Digital Divide," often seen as a short-hand term to indicate significant inequalities in access across social groups, and in particular between those who have access to ICTs (i.e., the "haves" and the "have-nots" or those who do not have access) (Civille, 1995; Raab, 1996). EU directives (e.g., eEurope 2002 [2000] and eEurope 2005 [2002]) support the goal of cheaper and more widespread access. The 2002 goal is to achieve physical access to the Internet, and the next stage is to consider content to stimulate access. The hope is that the benefits that emerge as a result of access to modern information and communication technologies (ICTs) will be felt by regional and local economies and communities.

Extending access to ICTs will help ensure innovation, economic development, and the new economy (Tambini, 2000a). In discussing universal Internet access, Tambini (2000b) points to arguments that without widespread access, e-commerce would not be able to support greater innovation and entrepreneurship. In addition, the intense concentration on developing e-government could not be legitimised. Moreover, benefits said to be associated with the design of ICTs to improve efficiency, effectiveness, and transparency in public service delivery could not be realised. Norris (2001) and others note the views of pessimists who fear an escalation of existing inequalities, and optimists who hold that new ICTs have the potential to widen opportunities for more democratic participation. However, without universal Internet access, it is unlikely that wider forms of electronic participation and actions associated with e-governance and e-democracy could be supported. Additionally, distance learning and public education resources would not reach wider audiences or increase literacy levels.

BRIDGING THE DIGITAL DIVIDE IN SCOTLAND

The Scottish Household Survey shows that access to the Internet in Scotland is growing quickly. People who are excluded comprise the unemployed, those with low incomes, low levels of education, and poor literacy and numeracy levels. The Scottish Executive, the Scottish Parliament, the voluntary sector, and other organizations in Scotland have designed a range of initiatives to tackle problems associated with the digital divide. The Scottish framework is based on raising awareness, widening access, increasing skills, building support, developing content, and motivating and involving communities.

Scottish Executive and Scottish Parliament

Similar to the UK Government, the Scottish Executive (i.e., the devolved government of Scotland) is committed to achieving universal access to the Internet by 2005. The Scottish Executive initiative—Digital Scotland—set out to ensure that Scotland obtains and retains maximum economic and social advantage from the development of ICTs. Digital divide problems are associated with a lack of telecommunications infrastructure and with poverty, lack of awareness, and low skill levels (Digital Inclusion: Connecting Scotland's People, 2001). Emphasis has been placed on expanding Scotland's communication infrastructure to stimulate demand for broadband and to test innovative delivery technologies. A three-year Digital Champions programme[1] was set up to improve inclusive ICT provision in Social Inclusion Partnerships (SIPs) in deprived areas of Scotland. This project provides community professionals with local knowledge to engage local people in various initiatives in order to drive local ICT activities forward.

In 2002, a £3.2 million initiative was launched by the Social Justice Minister to create a network of 1,000 new Internet access points in areas where current public provision was still poor.[2] The Scottish Executive also promotes awareness

of existing public access to the Web, and provides an online service to help people find the nearest access point.[3]

The Scottish Parliament's Web site[4] provides extensive information online. To help address problems of the digital divide, the Parliament worked with the public library sector to establish a network of 80 partner libraries throughout Scotland, many of which now provide public access to the Internet through freely available terminals.

With a key focus on the citizen, government portals across the UK are offering services that they suggest are relevant to life episodes. Closely linked to the UK Government Portal (www.ukonline.gov.uk) is the Scottish Government Portal that operates under the brand *Open Scotland*[5] to promote choice and public take-up of services.

Voluntary Sector Initiatives

In August 1999, com.com/holyrood, a public-private partnership between the Scottish Centre for Voluntary Organisations (SCVO) and British Telecom (BT), was given the task of installing 200 PCs into local halls and community centres throughout Scotland. However, access alone was not considered enough to address the digital divide, and SCVO also began to develop voluntary sector content. In June 2002, a Web portal[6] was launched to act as a single gateway to Scotland's voluntary sector. In addition, a lobby channel allowed voluntary organisations to conduct their own e-consultations. Moreover, online questions could be forwarded to Members of the Scottish Parliament (MSP).

Education and Learning Initiatives

The National Grid for Learning (NGfL) Scotland was set up by the Scottish Executive Education Department in September 1999 to connect all schools, colleges, universities, and libraries in Scotland to the Internet by 2002. A key objective of the NGfL Scotland Communities team[7] is to use ICT to improve opportunity, access, and quality of life for excluded groups, and to actively involve communities in worthwhile local projects. The communities channel of NGfL Scotland aims to supply information, advice, and assistance to all those providing support for ICTs in their community. In addition, NGfL Scotland's Connecting Communities Training Programme[8] promotes the effective use of ICT in community learning agencies across Scotland.

The Scottish University for Industry (SUfI) was set up to promote public/private partnership, commission research, draw on other analyses, and investigate the needs of market and client groups in Scotland. SUfI built on partnerships already existing in Scotland and worked closely with Highlands and Islands Enterprise and other partners to develop skills in using ICT. The subsequent development of a variety of IT centres in different locations of Scotland has provided Internet access and a learning environment for people to meet, to learn about new ICT, and to achieve new skills.

Scottish radio and television broadcasts were organised in late 1999 to promote learning directly and supporting the BBC's Webwise campaign, building on an earlier programme entitled Computers Don't Bite. Drawing from £200 million pounds allocated to support Community Access to Lifelong Learning (CALL) across the UK, the new Opportunities Fund (NOF) in Scotland was allocated £23 million pounds to support LearnDirect, an organisation providing public information about local learning centres.

Scotland is aiming to close the digital divide and to encourage people in deprived areas to acquire the key IT skills that are suitable to the demands of an Information Society.

Wired Communities in Scotland

During 2001, in an attempt to promote digital inclusion, a three million pound initiative outlined the intention to create two pilot digital communities in Scotland. The document, titled Digital Inclusion: Connecting Scotland's People (*Scottish Executive*, 2001, p. 22) outlines intention and funding for:

- the provision of entry level PCs, software, and Web access to up to 2,000 homes in each community;
- the development of links with school-based ICT and Web access initiative;
- the development of a community Web portal for each community with local content relevant to that community, including relevant online public and commercial services;
- the provision of training to increase the level of ICT and Web skills;
- the promotion to raise awareness of the benefits of the Web; and
- the creation of a network of local people to provide ongoing support.

The same report also outlines the aims of the digital communities Scotland project as follows:

- to use ICTs to help tackle social exclusion in these communities;
- to create a "critical mass" of Web users in each community;
- to contribute to achieving universal access to the Web;
- to increase the take-up of computers and the Web in disadvantaged households;
- to increase ICT skills in disadvantaged communities;
- to increase community involvement to develop local online content and a local support network; and

- to create partnerships with the private sector.

In late 2001, communities across Scotland were invited to submit bids to the Scottish Executive to receive funding and support to become digital communities. Towards the end of March 2002, the Scottish Executive selected two winning communities—one rural and one urban.

The Argyll Islands, the rural community selected, covers 13 of the 26 inhabited islands in the archipelago. A total of 2,145 households from a population of 4,290 was included. The digital communities submission for funding suggests that while the islands "are rich in biodiversity, culture, history, archaeology, renewable energy opportunities, and landscape, they suffer from many issues of deprivation and disadvantage, both caused and accentuated by their geographical isolation" . Physical and demographic characteristics of the islands combine to produce economic and social conditions constraining economic activity and growth. As such, the islands of Argyll are categorised as "fragile areas" by Highlands and Islands Enterprise and as "disadvantaged areas" by the Council's Economic Development Strategy (Argyll and Bute Council First Round Digital Communities Submission, 2002).

All local people in the Argyll Islands are expected to profit from new opportunities to use computers and access the Internet. The aim is to make it easier to communicate speedily and cheaply in regard to public services, to interact with peers, to telework, and to access health services and lifelong learning materials. Wherever possible, the intention is to include the business community of these islands as well as community groups. While some members of the community already have computer skills, the initiative is expected to extend training and support to any of those households that currently have computers but lack sufficient knowledge and training to use them to full advantage. In addition, the intention is to build e-services into a comprehensive community portal.

Bellsmyre, situated to the north of the town of Dumbarton, is the urban digital community selected for funding. Bellsmyre has 789 households and a population of 1,694 people. No telecommunications company had cabled the community, and at the time of the bid, Bellsmyre only had an analogue telephone infrastructure. The area is described in the First Round Proposal document as the most deprived within West Dunbartonshire.

At the time, people living in Bellsmyre had not yet responded to previous encouragement to train and use technology and, as a result, were considered in danger of being excluded from society even further. Technology is being taken to the people to promote the advantages of learning. Drawing from partnership arrangements, the key aim outlined in Bellsmyre's First Round Proposal is to help achieve the objectives set out in Scotland's digital inclusion strategy. It is envisaged that delivery of training and ICT services by Digital Champions and local community groups and agencies will help develop trust. It is hoped that attitudes toward ICT will improve, fear of technology will subside, confidence will improve, and the benefits of being connected to the Web will emerge. It is also hoped that attitudes toward learning will change and become more positive. A central aim is to ensure that levels of educational achievement will rise locally. Key aspirations are to reduce digital exclusion, create an ICT-skilled local population that will develop a routine taste for further learning and training and go on to employment or start up new businesses.

E-Democracy and the Digital Divide in Scotland

The UK government has established a Cabinet Committee to oversee e-democracy in the UK, and to develop a strategy for its development and rollout. An e-democracy charter divides the e-democracy domain into two clear fields: e-voting and e-participation. It is possible to design technology specifically to support local authorities by taking a creative, flexible, and democratic approach at local levels (Sisk, 2001). However, the ways in which technology might be developed and implemented to support better democratic participation in local areas have not been researched previously in Scotland. An added difficulty is that because each local authority is charged with representing multiple communities with diverse needs, the local authorities may need to use different e-democracy processes in different ways in different communities. This highlights a gap in knowledge about the numerous ways e-democracy systems could be tailored to suit the democratic needs of dissimilar communities. In addition, there is a matter of ensuring authentic participation of citizens in ways in which they are willing to be involved and that reflect their views and experiences about issues they feel are relevant in their own communities and beyond.

FUTURE TRENDS

A New Zealand report, "The Digital Divide – Examining the Main Characteristics that Influence Household Internet Connection in New Zealand" (2004), reflects international research in suggesting that the expansion of information and communication technologies is mainly utilised by households with higher incomes and by households whose members have formal educational qualifications. The report also found that "although the age of the youngest occupant, ethnicity, labour force status and geographic location played important roles in determining household Internet access, the most important variables identified as influencing household connectivity levels were household income, the level of educational qualification and household composition" (Chapter 3 Conclusion).

Research conducted by the Greater London Authority to outline a strategy to address the digital divide in London shows that while socioeconomic factors such as low income, low levels of education, low-skilled jobs, unemployment, and lack of technology skills are a barrier to the adoption and use of ICTs, sociopersonal aspects such as low levels of awareness, interest, understanding, and acceptance of ICTs are also very important (Foley et al., 2002).

A great deal of attention and policy and resource support over recent years has helped to ensure that excluded groups and communities living outside mainstream society are provided with different kinds of access to contemporary ICTs. However, Wilhelm (2000) questions whether or not the information under class can now be wholly defined in terms of access. Instead, he emphasizes broader contexts of information-seeking behaviour (i.e., media use patterns and cultural and environmental contexts). Drawing from Schon, Sanyal, and Mitchell (1999), he argues that these contexts will "provide a thicker description of the various shades of information and communications inequalities" (p. 70). Hague and Loader (1999) argue that experiences of using ICTs will vary enormously, since people do not generally share the same traits and since members of the public are very different in terms of gender, race, disability, class, location, and religion.

Others suggest that digital divide arguments should move away from issues of access alone. For example, Warschauer (2003) argues that increased emphasis should be put on action to ensure that people develop more meaningful use of technology within their own social arenas and daily practices.

CONCLUSION

Consideration of the Scottish context suggests that commitment to develop locally based ICT infrastructure and innovative new initiatives is fundamental in addressing problems associated with the digital divide. Critical evaluations of these initiatives would be invaluable, and it is crucial now for long-term research programmes to broaden understanding of meaningful routine use. Some researchers underline the importance of gathering empirical data relating to how and why people use ICTs in different settings (Malina & MacIntosh, 2003). Action research is suggested to assess the democratic requirements of those living in different kinds of communities, and to enable more meaningful design, development, and continuous assessment of ICT-based systems underpinning new democratic practices. It is suggested that this research approach could be applied initially to the two "digital communities" in Scotland—Argyle & Bute and Bellsmyre. In seeking to consult citizens, we must listen to their democratic needs and consider their perceptions. Research would help to improve the quality of citizenship and the level of democratic participation in local communities. The research work would also provide a framework to better appreciate the significance of technology in supporting e-democracy at local community levels and, in so doing, to contribute knowledge to strategy and planning policies and social and digital inclusion agendas to address problems of the digital divide in Scotland.

KEY TERMS

Digital Divide: Refers to individuals or members of communities and groups whose social, cultural, political, economic, or personal circumstances constrain access to electronic communications or limit benefit to their lives from contemporary electronic technologies.

Digital Inclusion: Strategies and actions to assure more equal access to digital technologies and Web facilities and to strengthen effective, meaningful, and beneficial use for all members of the public in their day-to-day lives.

Distance Learning: Learners are connected with educational resources beyond the confines of a traditional classroom, and instructed via computer-mediated communication and different types of electronic technologies that can overcome the constraints of distance, time, physical presence, or location that separate instructors and students. Learning may be synchronous or asynchronous.

E-Commerce: The buying and selling of commercial goods; the conduct of financial transactions using digital communications and electronic networks such as the World Wide Web; and aspects of sharing of business information, maintenance of business relationships, and provision of information services.

E-Democracy: The use of electronic communications to support and increase democratic engagement and deepen and widen citizen participation.

E-Government: The ability of government to design and use ICTs to interact internally and externally with government bodies, citizens, and businesses in order to deliver integrated electronic public services.

E-Governance: Communication by electronic means to place power in the hands of citizens to determine what laws need to be made and how these laws should be written.

Information and Communication Technologies (ICTs): While often meaning different things in different timescales, places, and contexts, ICTs describe all media and a mix of converging technology tools involved in the dynamic transfer and storage of analogue and digital data. In addition to Internet-based technologies such as computers, telephones, and networks, ICTs in a broad sense include digital television, cable and satellite technologies, and music formats (e.g., MP3), DVDs, and CDs. ICTs may be used to facilitate remote human interaction for good and evil purposes. In the context of this article, ICTs are used to increase human communication; broaden education, literacy, and knowledge; and enhance social, cultural, political, and economic capacity. It is hoped that this will help address problems attributed to the so-called digital divide.

Category: Social Computing

A Brief Introduction to Sociotechnical Systems

Brian Whitworth
Massey University Auckland, New Zealand

INTRODUCTION

The term sociotechnical was introduced by the Tavistock Institute in the 1950's for manufacturing cases where the needs of technology confronted those of local communities, for example, longwall mining in English coalmines (see http://www.strategosinc.com/socio-technical.htm). Social needs were opposed to the reductionism of Taylorism, which broke down jobs on say a car assembly line into most efficient elements. Social and technical were seen as separate side-by-side systems which needed to interact positively, for example, a village near a nuclear plant is a social system (with social needs) besides a technical system (with technical needs). The sociotechnical view later developed into a call for ethical computer use by supporters like Mumford (Porra & Hirscheim, 2007).

In the modern holistic view the sociotechnical system (STS) is the whole system, not one of two side-by-side systems. To illustrate the contrast, consider a simple case: A pilot plus a plane are two side-by-side systems with different needs, one mechanical (plane) and one human (pilot). Human Computer Interaction (HCI) suggests these systems should interact positively to succeed. However plane plus pilot can also be seen as a single system, with human and mechanical levels. On the mechanical level, the pilot's body is as physical as the plane, for example, the body of the plane and the body of the pilot both have weight, volume, and so forth. However the pilot adds a human thought level that sits above the plane's mechanical level, allowing the "pilot + plane" system to strategize and analyze. The sociotechnical concept that will be developed changes the priorities, for example, if a social system sits next to a technical one it is usually secondary, and ethics an afterthought to mechanics, but when a social system sits above a technical one it guides the entire system, that is, the primary factor in system performance.

BACKGROUND

General Systems Theory

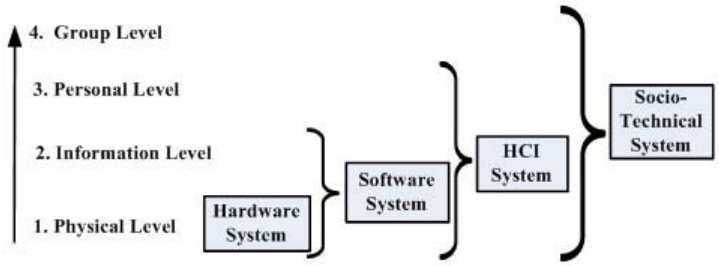
Sociotechnical theory is based upon general systems theory (Bertalanffy, 1968), which sees systems as composed of autonomous yet interdependent parts that mutually interact as part of a purposeful whole. Rather than reduce a system to its parts, systems theory explores emergent properties that arise through component interactions via the dynamics of regulation, including feedback and feed-forward loops. While self-reference and circular causality can give the snowball effects of chaos theory, such systems can self-organize and self-maintain (Maturana & Varela, 1998).

System Levels

In the 1950's-1960's computing was mainly about hardware, but the 1970's introduced the software era with business information processing. The 1980's then gave personal computers, adding people into the equation, and email in the 1990's introduced the computer as a social medium. In this decade social computing development continues, with chat rooms, bulletin boards, e-markets, social networks (e.g., UTube, Facebook, MySpace), Wikis and Blogs. Each decade computing has reinvented itself, going from hardware to software, from software to HCI, and now from HCI to social computing. The concept of system levels frames this progression. While Grudin initially postulated three levels of hardware, software and cognitive (Grudin, 1990), Kuutti later added an organizational level (Kuutti, 1996), suggesting an information system (IS) could have four levels: hardware, software, human, and organizational (Alter, 1999). Just as software "emerges" from hardware, so personal cognitions can be seen as arising from neural information exchanges (Whitworth, 2008), and a society can emerge from the interaction of individual people. If the first two levels (hardware/software) are together considered technical, and the last two (human/group) social, then a sociotechnical system is one that involves all four levels (Figure 1).

As computing evolved, the problems it faced changed. Early problems were mainly hardware issues, like over-heating. When these gave way to software problems like infinite loops, then network and database needs began to influence hardware chip development. A similar progression occurred as human factors emerged, and human requirements like usability became part of software engineering (Sanders & McCormick, 1993). Social computing continues this trend, as social problems beyond HCI theory (Whitworth, 2005) are now important in design. Driving this evolution is that each emergent level increases system performance (Whitworth & deMoor, 2003).

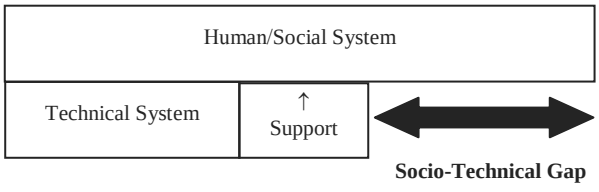
Figure 1. Sociotechnical system levels



The Sociotechnical Gap

The Figure1 levels are not different systems but overlapping views of the same system, corresponding to engineering, computing, psychological, and sociological perspectives respectively (Whitworth, Fjermestad, & Mahinda, 2006). Higher levels are both more efficient ways to describe a system and also more efficient ways to operate it, for example, social individuals produce more than they would acting independently. Whether a social system is electronically or physically mediated is arbitrary. That the communication medium (a computer network) is "virtual" does not make the people involved less real, for example, one can be as upset by an e-mail as by a letter. Sociotechnical systems are systems of people communicating with people that arise through interactions mediated by technology rather than the natural world. The social system can follow the same principles whether on a physical or electronic base, for example, friendships that cross seamlessly from face-to-face to e-mail interaction. However in physical society, physical architecture supports social norms, for example, you may not legally enter my house and I can also physically lock you out or call the police to restrain you. In contrast, while in cyberspace the "architecture" is the computer code itself, that "… makes cyberspace as it is" (Lessig, 2000), that code is largely designed without any reference to social needs. This sociotechnical gap (Ackerman, 2000), between what computers do and what society wants (Figure 2), is a major software problem today (Cooper, 1999).

Figure 2. Socio-technical gap



STS REQUIREMENTS

System Theory Requirements

A systems approach to performance suggests that systems can adapt the four elements of a boundary, internal structure, effectors, and receptors to either increase gains or reduce losses (Whitworth et al., 2006), where:

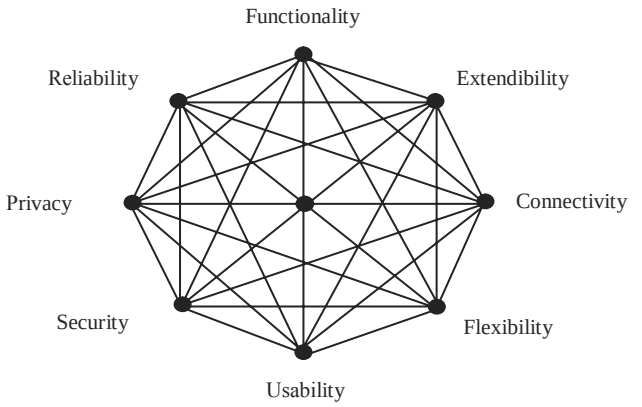
1. The system boundary controls entry, and can be designed to deny unwelcome entry (security), or to use the entity as a "tool" (extendibility).
2. The system internal structure manages system operations, and can be designed to reduce internal changes that cause faults (reliability), or to increase internal changes allowing environment adaptation (flexibility).
3. The system effectors use system resources to act upon the environment, and can be designed to maximize their effects (functionality), or to minimize the relative resource "cost of action" (usability).
4. The system receptors open channels to communicate with other systems, and can enable communication with similar systems (connectivity), or limit communication (privacy).

This gives the eight performance goals of Figure 3, where:

- The Web area shows the overall system's performance potential.
- The Web shape shows the system's performance profile, for example, risky environments favor secure profiles.
- The Web lines show tensions between goals, for example, improving flexibility might reduce reliability.

The goals change for different system levels, for example, a system can be hardware reliable but software unreliable,

Figure 3. The Web of system performance



or both hardware and software reliable but operator unreliable (Sommerville, 2004, p. 24). Likewise usability (the relative cost of action) can mean less cognitive "effort" for a person in an HCI system, or for a software system mean less memory/processing (e.g., "light" background utilities), or for a hardware system mean less power use (e.g., mobile phones that last longer). From this perspective, the challenge of socio-technical computing is to design innovative systems that integrate the multiple requirements of system performance at higher and higher levels, where each level builds upon the previous.

Information Exchange Requirements

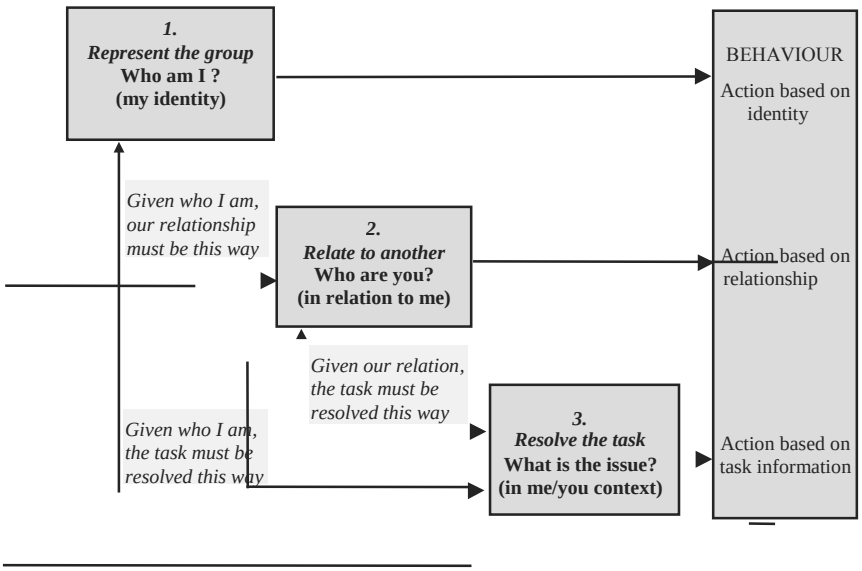
The connectivity-privacy tension line (Figure 3) introduces a social dimension to system design, as information exchanges let the systems we call people combine into larger systems, for example, people can form villages, villages can form states, and states can form nations. In this social evolution not only does "the system" evolve, but also what we define as "the system" evolves. Theories of computer-mediated information exchange postulate the underlying social process. Some consider it a single process of rational analysis (Huber, 1984; Winograd & Flores, 1986), but others suggest process dichotomies, like task vs. socioemotional (Bales, 1950), informational vs. normative (Deutsch & Gerard, 1965), task vs. social (Sproull & Kiesler, 1986), and social vs. interpersonal (Spears & Lea, 1992). A three process model of online communication (Whitworth, Gallupe, & McQueen, 2000) suggests three processes:

1. Factual information exchange: the exchange of factual data or information, that is, message content
2. Personal information exchange: the exchange of personal sender state information, that is, sender context
3. Group information exchange: the exchange of group normative information, that is, group position

The first process involves intellectual data gathering, the second involves building emotional relationships, and the third involves identifying with the group, as proposed by Social Identity theory (Hogg, 1990). The three goals are understanding, intimacy and group agreement, respectively. In this multi-threaded communication model one communication can contain many information threads (McGrath 1984), for example, if one says "I AM NOT UPSET!" in an upset voice, sender state information is analyzed in an emotional channel, while message content is analysed intellectually. A message with a factual content not only lies within a sender state context given by facial expressions etc, but also contains a core of implied action, for example, saying "This is good, lets buy it" gives not only content information (the item is good) and sender information (say tone of voice), but also the sender's intended action (to buy the item), that is, the sender's action "position".

While message content and sender context are generally recognized, action position is often overlooked as a communication channel, perhaps because it typically involves many-to-many information exchange, for example, in a choir singing everyone sends and everyone receives, so if the choir moves off key they do so together. Similarly, in apparently rational group discussions, the group "valence index" predicts the group decision (Hoffman & Maier, 1964). Group members seem to assess where the group is going and change their ideas to stay with the group. This intellectual equivalent of how social flocks/herds cohese seems to work equally well online, so using this process one can generate online agreement from anonymous and lean information exchanges (Whitworth, Gallupe & McQueen, 2001). While factual information suits one-way one-to-many information exchange (e.g., a Website broadcast), and developing personal relations suits two-way one-to-one information exchange (e.g., e-mail), the group normative process needs two-way, many-to-many information exchange (e.g., reputation systems). Figure 4 shows how people prioritize the three cognitive processes, first evaluating group membership

Figure 4. Three information exchange processes



identity, then evaluating the sender's relationship, and only finally analyzing message content. As each cognitive process favours a different communication architecture, there is no ideal human communication medium. From this perspective, the challenge of sociotechnical computing is to design innovative systems that integrate the multiple channels of human communication.

Social Requirements

A startling discovery of game theory was that positive social interaction can be unstable, for example, the "equilibrium point" of the prisoner's dilemma dyad is that both cheat each other (Poundstone, 1992). Situations like social loafing and the volunteer dilemma are common, including many-to-many cases like the tragedy of the commons which mirrors global conservation problems. In a society one person can gain at another's expense, for example, theft, yet if everyone steals society collapses into disorder. Human society has evolved various ways to make anti-social acts unprofitable, whether by personal revenge traditions, or by state justice systems. The goal of justice, it has been argued, is to reduce unfairness (Rawls, 2001), where unfairness is not just an unequal outcome distribution (inequity) but failure to distribute outcomes according to action contributions. In a successful society people are accountable not just for the effects of their acts on themselves but also on others. Without this, people can take the benefits that others create, and harm others with no consequence to themselves. Under these conditions, any society will fail. Fortunately people in general seem to recognize unfairness, and tend to avoid unfair situations (Adams, 1965). They even prefer fairness to personal benefit (Lind & Tyler, 1988). The capacity to perceive "natural justice" seems to underlie our ability to form prosperous societies. The general requirement is legitimate interaction, which is both fair to the parties involved and also benefits the social group (Whitworth & deMoor, 2003). Legitimacy is a complex sociological concept that describes governments that are justified to their people (and not coerced) (Barker, 1990). Fukuyama argues that legitimacy is a requirement for community prosperity, and those that ignore it do so at their peril (Fukuyama, 1992).

It follows that online society should be designed to support legitimate interaction and oppose antisocial acts. Yet defining what is and is not legitimate is a complex issue. Physical society evolved the concept of "rights" expressed in terms of ownership (Freeden, 1991), for example, freedom as the right to own onself. Likewise analyzing who owns what information online (Rose, 2001), can be used to specify equivalent online rights that designers can support (Whitworth, Aldo de Moor & Liu, 2006) (Figure 5). This does not mechanize online interaction, as rights are choices not obligations, for example, the right to privacy does not force one to be private. From this perspective, the challenge of sociotechnical computing is to design systems that reflect rights in overlapping social groups.

Figure 5. Legitimacy analysis

FUTURE TRENDS

The previous discussion suggests the design of future sociotechnical systems will involve:

1. More performance requirements: Simple dichotomies like usefulness and ease of use, while themselves valid, will be insufficient to describe the multiple criteria relevant to STS performance.
2. More communication requirements: Communication models with one or two cognitive processes while themselves valid, will be insufficient to describe the multiple threads of STS communication.
3. More social requirements: Approaches that reference only individual users, while themselves valid, will be insufficient to represent social level requirements, where one social group can contain another.

Performance concepts will expand, as success-creating goals (functionality, flexibility, extendibility and connectivity) and the failure-avoiding goals (security, reliability, privacy and usability) interact in complex ways in a multidimensional performance space that challenges designers. Likewise designing communication media that simultaneously support the flow of intellectual, emotional and positional information along parallel exchange channels is another significant challenge. Finally, in social evolution social systems "stack" one upon another (e.g., states can form into a federation), giving the challenge of groups within groups. In sum, the challenges are great, but then again why should STS design be easy?

The concept of levels (Figure 1) runs through the above trends, suggesting that the World Wide Web will develop cumulatively in three stages. The first stage, a factual information exchange system, seems already largely in place, with the World Wide Web essentially a huge information library accessed by search tools, though it contains disinformation as well as information. The second stage lets people form personal relations to distinguish trusted from not trusted information sources. This stage is now well underway, as social networks combine e-mail and browser systems into protocol independent users environments (Berners-Lee 2000). Finally, in stage three the Web will sustain synergistic and stable online communities, opening to group members the power of the group, for example, the group knowledge sharing of Wikipedia. To do this, online communities must both overcome antisocial forces like Spam and prevent internal take-overs by personal power seekers. In this struggle software cannot be "group blind" (McGrath & Hollingshead, 1993). Online communities cannot democratically elect new leaders to replace old ones unless software provides the tools. Supporting group computing is not just creating a few membership lists. Even a cursory study of Robert's Rules of Order will dispel the illusion that technical support for social groups is easy (Robert, 1993).

Human social activity is complex, as people like to belong and relate as well as understand. Each process reflects a practical human concern, namely dealing with world tasks, with other people, and with the society one is within. All are important, because sometimes what you know is critical, sometimes who you know counts, and sometimes, like which side of the road to drive on, all that counts is what everyone else is doing. Yet as we browse the Web software largely ignores social complexity. "Smart" tools like Mr. Clippy have relational "amnesia", as no matter how many times one tells them to go away they still come back. Essential to relationships is remembering past interactions, yet my Windows file browser cannot remember my last browsed directory and return me there, my Word processor cannot remember where my cursor was last time I opened this document and put me back there, and my browser cannot remember the last Website I browsed and restart from there (Whitworth, 2005). Group level concepts like rights, leadership, roles, and democracy are equally poorly represented in technical design.

These challenges suggest that the Internet is only just beginning its social future. We may be no more able to envisage this than traders in the Middle Ages could conceive today's global trade system, where people send millions of dollars to foreigners they have never seen for goods they have not touched to arrive at unknown times. To traders in the middle ages, this would have seemed not just technically but also socially impossible (Mandelbaum, 2002). The future of software will be more about social than technical design, as software will support what online societies need for success. If society believes in individual freedom, online avatars should belong to the person concerned. If society gives the right to not communicate (Warren & Brandeis, 1890) so should communication systems like email (Whitworth & Whitworth, 2004). If society supports privacy, people should be able to remove their personal data from online lists. If society gives creators rights to the fruits of their labors (Locke, 1963), one should be able to sign and own one's electronic work. If society believes in democracy, online communities should be able to elect their leaders. In the sociotechnical approach social principles should drive technical design.

CONCLUSION

The core Internet architecture was designed many years ago at a time when a global electronic society was not even envisaged. It seems long due for an overhaul to meet modern social requirements. In this upgrade technologists cannot stand on the sidelines. Technology is not and cannot be value neutral,

because online code affects online society. Just as physical laws determine what happens in physical worlds, so the "laws" of online interaction are affected by those who write the programs that create it. If computer system developers do not embody social concepts like freedom, privacy and democracy in their code, they will not happen. This means specifying social requirements just as technical ones currently are. While this is a daunting task, the alternative is an antisocial online society which could "collapse" (Diamond, 2005). If the next step of the human social evolution is an electronically enabled world society, computer technology may be contributing to a process of human unification that has been underway for thousands of years.

KEY TERMS

Information System: A system that may include hardware, software, people and business or community structures and processes (Alter, 1999), c.f. a social-technical system, which must include all four levels.

Social System: Physical society is not just buildings or information, as without people information has no meaning. Yet it is also more than people. Countries with people of similar nature and abilities, like East and West Germany, perform differently as societies. While people come and go, the "society" continues, for example, we say "the Jews" survived while "the Romans" did not because the people lived on but because their social manner of interaction survived. A social system then is a general form of human interaction that persists despite changes in individuals, communications or architecture (Whitworth & deMoor, 2003).

System: A system must exist within a "world", as the nature of a system is the nature of the world that contains it, for example, a physical world, a world of ideas, and a social world, may contain physical systems, idea systems and social systems, respectively. A system needs identity to define "system" from "not system", for example, a crystal of sugar that dissolves in water still has existence as sugar, but is no longer a separate system. Existence and identity seem two basic requirements of any system.

System Elements: Advanced systems have a boundary, an internal structure, environment effectors and receptors (Whitworth et al., 2006). Simple biological systems (cells) formed a cell wall boundary and organelles for internal cell functions. Cells like Giardia developed flagella to effect movement, and protozoa developed light sensitive receptors. People are more complex, but still have a boundary (skin), an internal structure of organs, muscle effectors and sense receptors. Computer systems likewise have a physical case boundary, an internal architecture, printer/screen effectors and keyboard/mouse receptors. Likewise software systems have memory boundaries, a program structure, input analyzers, and output "driver" code.

System Environment: In a changing world, a system's environment is that part of a world that can affect the system. Darwinian "success" depends on how the environment responds to system performance. Three properties seem relevant: opportunities, threats, and the rate these change. In an opportunistic environment, right action can give great benefit. In a risky environment, wrong action can give great loss. In a dynamic environment, risk and opportunity change quickly, giving turbulence (sudden risk) or luck (sudden opportunity). An environment can be any combination, for example, opportunistic and risky and dynamic.

System Levels: Are physical systems the only possible systems? The term information system suggests otherwise. Philosophers propose idea systems in logical worlds. Sociologists propose social systems. Psychologists propose cognitive mental models. Software designers propose data entity relationship models apart from hardware. Software cannot exist without a hardware system of chips and circuits, but software concepts like data records and files are not hardware. A system can have four levels: mechanical, informational, personal and group, each emerging from the previous as a different framing of the same system, for example, information derives from mechanics, human cognitions from information, and society from a sum of human cognitions (Whitworth et al., 2006).

System Performance: A traditional information system's performance is its functionality, but a better definition is how successfully a system interacts with its environment. This allows usability and other "non-functional" requirements like security and reliability to be part of system performance. Eight general system goals seem applicable to modern software: functionality, usability, reliability, flexibility, security, extendibility, connectivity and confidentiality (Whitworth et al., 2006).

Building and Management of Trust in Networked Information Systems

István Mezgár
Hungarian Academy of Sciences, Hungary

INTRODUCTION

Thanks to rapidly developing information and communication technologies, the complexity of networked organizations has become very high, so the representation of their structure and the description of their operation and their control need new technologies, new approaches. The availability of individuals independently from location and time means mobility, and that is an important attribute of today's society. This mobility can be achieved by using different types of mobile wireless networks as wireless wide area networks (WWANs, e.g., GSM, GPRS, and UMTS), wireless local area networks (WLANs, e.g., WiFi 802.11a-g), and wireless personal area (or pico) network (WPAN, e.g., Bluetooth, IrDA2).

In spite of the application of high-tech approaches, tools, and methodologies, there is a common point in all of the organizations: human beings make most of the important decisions, and they operate and use systems. Experience shows that improper application of this human factor can make operation very inefficient even in the case of the technically most advanced systems. The lowest level of connection among systems is made through protocols; the highest contact level is among decision makers, users namely among human beings. A very important element of this human contact is trust. In a networked organization, trust is the atmosphere, the medium in which actors are moving (Castelfranchi & Tan, 2001). Only trust can bridge cultural, geographical, and organizational distances of team members (and even of firms) from turning to unmanageable psychological distances. Trust is the base of cooperation, the normal behavior of the human being in the society. The ability of enterprises to form networked systems depends on the existing level of trust in the society and on the capital of society (Fukuyama, 1995). As the rate of cooperation is increasing in all fields of life, the importance of trust is evolving even faster.

Lack of trustworthy security services is a major obstacle to the use of information systems in private, in business (B2B), as well as in public services. Trust is intimately linked to consumers' rights, like security, identification, authentication, privacy, and confidentiality. Secure identification, authentication of the users, and communication security are main problems in networked systems.

Information management (IM) is a fuzzy term covering the various stages of information processing from production to storage and retrieval to dissemination towards the better working of an organization, where information can be from internal and external sources and in any format. The role of trust in these processes is definitive as human-to-human and human-to-system communication forms the base of information management.

BACKGROUND

Definitions of Trust

The word "trust" is used by different disciplines, so there are many definitions of the term fulfilling the demands of the actual theory or application. In everyday life without trust, one would be confronted with the extreme complexity of the world in every minute. No human being could stand this, so people must have fixed points around them: one must have trust in family members, in partners, in the institutions of a society and between its members, and within and between organizations partners. The diversity of approaches is one reason that trust has been called an "elusive concept to define" (Gambetta, 1988).

Trust can be defined as a psychological condition comprising the trustor's intention to accept vulnerability based upon positive expectations of the trustee's intentions or behavior (Rousseau, Sitkin, Burt, & Camerer, 1998). Those positive expectations are based upon the trustor's cognitive and affective evaluations of the trustee and the system/world, as well as of the disposition of the trustor to trust. Trust is a psychological condition (interpreted in terms of expectation, attitude, willingness, perceived probability). Trust can cause or result from trusting behavior (e.g., cooperation, taking a risk), but is not behavior itself.

According to Luhmann (1979), trust can be viewed as a cognitive and social device able to reduce complexity, enabling people to cope with the different levels of uncertainty and sometimes the risks that, at different degrees, permeate our life. Without trust, an individual would freeze in uncertainty and indecision when faced with the impossibility of calculating all possible outcomes of a situation. Engaging trust automatically can reduce the number of decision nodes that are being analyzed and facilitate the decision-making processes. From a social perspective, trust permits the necessary knowledge sharing of delegation and cooperative actions.

The following components are included in most definitions of trust (Harrison, McKnight, & Chervany, 1996):

- willingness to be vulnerable/to rely;
- confident, positive expectation/positive attitude towards others; and
- risk and interdependence as necessary conditions.

Trust has different forms such as:

- **Intrapersonal trust:** Trust in one's own abilities; self-confidence/basic trust (in others).
- **Interpersonal trust:** Expectation based on cognitive and affective evaluation of the partners; in primary relationships (e.g., family) and non-primary relationships (e.g., business partners).
- **System trust:** Trust in depersonalized systems/world that functions independently (e.g., economic system, regulations, legal system, technology); requires voluntary abandonment of control and knowledge.
- **Object trust:** Trust in non-social objects; trust in its correct functioning (e.g., in an electronic device).

Trust Is a Multi-Faceted Construct

There is compelling evidence originating from the organizational research community to support the idea that trust is a many-sided, complex construct. McAllister (1995) has proposed two critical dimensions: emotional trust and cognitive trust. Emotional trust is the development of non-calculative and spontaneous emotional bonds and effect among two or more people. Emotional trust is demonstrated through confidence and openness in sharing ideas, feelings, and concerns. Cognitive trust refers both to judgments of competence (predictably professional behavior) and reliability (the congruence between words and actions) about the other members of a team.

Representation Forms of Trust

There are two basic modeling approaches in describing trust: the cognitive approach (Castelfranchi & Falcone, 1999) and the mathematical approach (Marsh, 1994). In case of applying cognitive models, trust is made up of underlying beliefs, and trust is a function of the value of these beliefs. The mathematical modeling approach ignores the role of underlying beliefs and uses a trust metric, based on variables like *perceived_competence, perceived_risk, utility of a situation for the agent involved, importance of a situation,* and so forth. These models incorporate some aspects of game theory and the evolution of cooperation models. Both modeling approaches see trust as a variable with a threshold for action. When the value of the variable crosses the threshold, the agent executes an action. In the Marsh model, the action is cooperation; in the Castelfranchi model, the action is delegation. The action is Boolean in nature — the agent either delegates or not, or the agent either cooperates or not.

Classification of the Meanings of Trust

Harrison et al. (1996) made a very deep and thorough analysis of the word "trust" from many aspects in their working paper. The goal of the paper was to develop a classification system for the types of trust and develop trust definitions/types that can be accepted by most of the disciplines.

The main groups of the classification system for trust constructs are as follows:

- **Impersonal/structural trust:** Those definitions of trust that differentiate it from being a property or state of a person or persons.
- **Dispositional trust:** Trust is based in the personality attributes of the trusting party.
- **Personal/interpersonal trust:** Trust in which one person trusts another person, persons, or thing(s) in the situation.

Guided by the classification system, six related types of trust have been defined in the working paper. The six constructs are as follows: Trusting Intention, Trusting Behavior, Trusting Beliefs, System Trust, Dispositional Trust, and Situational Decision to Trust. Both cognitive and affective components are included in Trusting Beliefs, Trusting Intention, and Trusting Behavior. The six constructs cover the more common of the dictionary definitions of trust. This multi-dimensional view of trust provides a parsimonious way to organize measurable trust types, while clearly distinguishing one type from another.

BUILDING TRUST

Connection of Trust and Information Management

Information technology management deals with the management of the different steps of information processing, and trust has a role where human beings are involved in this process. Human beings basically have two types of connections in these processes: human-to-human relationship through networks, and human-to-computer system communication through interfaces. In the first case trust management of virtual teams can be analyzed; in the second case special effects of computer interfaces and the role of security technologies in trust building and maintenance can be studied (Mezgar & Kincses, 2002). Information management must take into consideration the aspects of the trust-building process, to

develop, modify, and influence information handling in the direction that increases trust of human beings participating in these processes.

Trust Is More Than a Simple Technology

In building trust there are two approaches: information technology approach and human-centered approach, based on culture and morality. Information technology approach means that security must increase by different architectures, protocols, certifications, cryptography, and authentication procedures and standards, and this increased security generates the trust of users. This means access control (passwords, firewalls) integrity protection and privacy of message and database (cryptography) identification of users. Stressing the effectiveness of these technologies for human users can cause them to trust the systems based on this convincing action. Based on the technological approach, 100 % security can never be obtained (there will be always security holes somewhere in the system), so full trust cannot be guaranteed based on these mechanisms.

The human side of trust is more complicated. There were different researches (e.g., Hoffman, Novak, & Peralta, 1999) focusing on this side of trust. From this aspect, the user interface has the main role (i.e., the menu structure) to send the messages to the user from the system. In case the user feels that is easy to use, he or she can control the system (even with low-level computer knowledge) — that is, the system is "user friendly," and through this the user can be convinced that he or she is using a trustworthy system.

It would be a mistake to think that applying only the human-centered approach would generate trust; the technological part must be added as well (e.g., biometrical identification), so mainly the structured integration of the two approaches can result in the expected level of trust.

Technical Side of Trust Building: Application of Security Mechanisms

Security is a very complex term. There is computer, communication, information system, physical, and a lot of other "securities." As an addition, these terms overlap each other in many cases. Approaching security from the side of trust, security is the set of different services, mechanisms, and software and hardware tools for generating trust with pure technology. More generally, security is a condition that results from the establishment and maintenance of protective measures that ensure a state of inviolability from hostile acts or influences (FED, 2003).

The totality of protection mechanisms within a computer system — including hardware, orgware, and software, the combination of which is responsible for enforcing a security policy — is called trusted computing base (TCB). The ability of a trusted computing base to enforce correctly a unified security policy depends on the correctness of all types of mechanisms within the trusted computing base, the protection of those mechanisms to ensure their correctness, and the correct input of parameters related to the security policy.

In network management, the security management covers the set of functions: (a) that protects telecommunications networks and systems from unauthorized access by persons, acts, or influences; and (b) that includes many subfunctions, such as creating, deleting, and controlling security services and mechanisms; distributing security-relevant information; reporting security-relevant events; controlling the distribution of cryptographic keying material; and authorizing subscriber access, rights, and privileges (FED, 2003; Tipton & Krause, 1998).

The building block elements of security are the security services and the security mechanisms. The security services are (Schneier, 1996):

- **Confidentiality:** Protects against disclosure to unauthorized identities.
- **Integrity:** Protects from unauthorized data alteration.
- **Authentication:** Provides assurance of someone's identity.
- **Access Control:** Protects against unauthorized use.
- **Non-Repudiation:** Protects against originator of communications later denying it.

The means for achieving these properties depends on the collection of security mechanisms that supply security services, the correct implementation of these mechanisms, and how these mechanisms are used.

In security mechanisms with crypto functions (three basic building blocks are used):

- Encryption is used to provide confidentiality, and also can provide authentication and integrity protection.
- Digital signatures are used to provide authentication, integrity protection, and non-repudiation.
- Checksums/hash algorithms are used to provide integrity protection and can provide authentication.

Human Side of Trust Building: Feeling of Trust

The feeling of security experienced by a user of an interactive system does not depend on technical security measures alone. Other (psychological) factors can play a determining role; the user's feeling of control can be one of these factors.

Trust is a dynamic process, and it alters based on experience. Trusting process begins when an individual perceives indications that suggest a person/organization may be worthy of trust. These indications can include behaviors such as

manners, professionalism, and sensitivity, and these forms are designed to represent trustworthiness. These formal claims to trustworthiness become strengthened over time and are eventually transformed into "character traits," such as dependability, reliability. and honesty. Cheskin (1999) identifies six fundamental factors that communicate trustworthiness in the case of e-commerce Web sites:

- **Brand:** The importance of the company's reputation in the choice to do business with them.
- **Navigation:** The ease of finding what the user seeks.
- **Fulfillment:** The process the user experiences from the time a purchase process is initiated until the purchase is received to the user's satisfaction.
- **Presentation:** Ways in which the appearance of the site, in and of itself, communicates meaningful information.
- **Technology:** Ways in which the site technically functions.
- **Seals of Approval:** Symbols that represent the companies that specialize in assuring the safety of Web sites.

Why people feel safe and secure, and what causes these feelings, must be analyzed. The hypothesis of D'Hertefelt (2000) was that **"the feeling of security experienced by a user of an interactive system is determined by the user's feeling of control of the interactive system."** The more a user feels in control of an interactive program, the more the user will trust the site, the program. An interactive system that generates the feeling of control for the user must be: (a) comprehensible (the client needs to know what and how he or she can accomplish, and needs confirmation that it actually has been accomplished), (b) predictable (user has to know what is going to happen when he or she clicks on a bottom/menu item), and (c) flexible and adaptable (the user will feel in control if he or she can choose the way a task is executed instead of having to figure out how the system requires it to be done).

The process of building trust is slow; trust is formed gradually, it takes quite a lot of time and repeated positive experiences (Cheskin, 1999). Online trust can be described as a kind of human relationship. The initial stage is that of interest and distrust; there has to be a motivation, a need, to get interested in the service, or co-working. In subsequent phases the trust will evolve, or in case of negative experiences, the cooperation will terminate.

Trust is dependant on the time span of cooperation and the type of connection as well. It can be stated that there are differences in the trust-building process in short-term and long-term relationships. In case of short-term relationships (e.g., in a virtual organization), trust must be achieved quickly, and then maintain with no or rare face-to-face interaction. The members of these teams must assume that other remote team members are trustworthy, and then later on modify their assumptions according to their positive or negative experiences.

In long-term relationships there are four factors that influence trust building (Rocco, Finholt, Hofer, & Herbsleb, 2001):

1. Expectation of future interaction may motivate greater investment in building trustworthy relationships.
2. Long-term relationships offer more time to establish trustworthiness through routines and culture.
3. People have more communication channels, which may affect trust to the extent that participants have additional ways to clarify misunderstandings or to correct failures.
4. Participants are interested in successful task performance, and trust formation may assume a higher priority.

TRUST AND INFORMATION MANAGEMENT

Devices, Services, and Technologies for Trust Building in Information Management

As security, one important base of trust involves many topics — not only information security technology, but also the structure of the firms; the management techniques also must follow the ongoing changes of the IC technologies. In case the security challenges are put into a broader, management-oriented interpretation, they can be classified into four categories according to Dhillon (2001):

- Establishing good management practices in a geographically distributed environment and yet being able to control organizational operations.
- Establishing security policies and procedures that adequately reflect the organizational context and new business processes.
- Establishing correct structures of responsibility, given the complex structuring of organizations and information processing activities.
- Establishing appropriate information technology emergency recovery plans.

A solution for addressing trust is to build a chain of trust where each link is strong but also connects to its neighbor by verifying its trustworthiness. In particular, beginning with a priori grounding in a physically trustworthy base, each link of the chain checks signature-based trust tokens of its

neighbor before the chain is allowed to carry any weight. Such a chain begins with processors and extends to operating systems to applications to interconnect protocols, and ultimately, to end users.

Trust management unifies the notions of security policy, credentials, access control, and authorization. An application that uses a trust-management system can simply ask the compliance checker whether a requested action should be allowed. Trust-management policies are easy to distribute across networks, helping to avoid the need for application-specific distributed policy configuration mechanisms, access control lists, and certificate parsers and interpreters (Blaze, Feigenbaum, & Lacy, 1996).

Virtual Teamwork and Trust Management

Today the different types of networked organizations need new types of cooperation, as the members of the working teams are geographically (physically) separated. They use shared documents, and communicate through e-mail and high quality audio and video channels. These teams are called "virtual teams," as they never meet personally and they have no face-to-face (FTF) contact. The work of teams without FTF contact is less effective and reliable based on the observation stated by Handy (1995): "Trust needs touch." According to case studies, it is evident that trust of virtual team members is significantly lower than trust in conventional teams (Rocco et al., 2001). In other experiments where interaction was primarily via e-mail, very similar results were gained, as in geographically distributed teams (Jarvenpaa & Leidner, 1999).

In an experiment introduced in Bos, Olson, Gergle, Olson, and Wright (2002), four media types were compared: chat (text), phone conference, videoconference, and FTF. Chat was significantly worse than each of the other three conditions, but audio and video did as well as FTF in overall cooperation, and were a definite improvement over text-chat-only computer-mediated communication. However, these two channels still showed evidence of delayed trust, in that they took longer to reach high levels of cooperation.

There are experiments on the truth content of the communication as well. It came to light that participants lied most on the telephone and least in e-mail, and that lying rates in face-to-face and instant messaging interactions were approximately equal. These results suggest that the type of communication technologies affect lying behavior in important ways. Both designers and users must take these features into consideration when trust-building processes are designed and applied (Hancock, Thom-Santelli, & Ritchie, 2004).

The latest research shows that if people meet before using computer-mediated communication, they trust each other, as trust is being established through touch. In cases where participants do not meet formerly, but they initiate various get-acquainted activities over a network, trust is much higher than if they do nothing before and nearly as good as a prior meeting. Using chat forums to get acquainted is nearly as good as meeting, and "even just seeing a picture is better than nothing" (Zheng, Veinott, Bos, Olson, & Olson, 2002).

Information Technology Tools for Generating Trust

Identification of a user/customer of an information system is a complex task. In computer science the identifier is a string of bits or characters that names an entity, such as a program, device, or system, in order that other entities can call that entity. In the context of information systems, the purpose of identification is very concrete: it is used to link a stream of data with a certain person, so the following definition can be given: "Human identification is the association of data with a particular human being."

Information systems have tended to use codes rather than names as the primary identification mechanism. The most reliable mode to identify a person is to apply biometric techniques (Jain, Bolle, & Pankanti, 1999). The applied techniques in biometry systems in IT include a physiological (fingerprint, iris, facial features, etc.) element or factor, as well as a behavioral one (e.g., vocal patterns, typing rhythm). Biometric identification is preferred over current methods involving passwords and pin numbers, as the person to be identified is required to be physically present at the point of identification; thus, the person or user is identified, not the device as in the case of a PIN and password. Layered Biometric Verification (LBV) technology entails layering different biometric technologies into a complex identification process.

The main factor of trust is confidentiality that can be achieved by technologies that convert/hide the data/text into a form that cannot be interpreted by unauthorized persons. There are two major techniques to fulfill this goal: encryption and steganography. Encryption is transforming the message to a cipher text such that an enemy who monitors the cipher text cannot determine the message sent (Schneier, 1996). Steganography is the art of hiding a secret message within a larger one in such a way that the opponent cannot discern the presence or contents of the hidden message (Johnson, Duric, & Jajodia, 2000). For example, a message might be hidden within a picture by changing the low-order pixel bits to be the message bits.

Generating Trust by Human-Computer Interfaces

Generally speaking the goal of an interface is to interconnect two or more entities at a common point or shared boundary. As a communication/information system term, an interface is the point of communication between two or more processes,

persons, or other physical entities. Interfaces are the key points for gaining the trust of the user/customer. They are the first connection point between the user and the system; identification of the users take place at this point (e.g., password input, fingerprint reader, smart card reader), so interfaces must be designed very carefully. In the design of both types of interfaces, ergonomic and psychological aspects are taken into consideration, in addition to the technical ones.

Researchers test different new types of interfaces. Interaction must be extended with more senses (touch, smell, and taste) and make better use of the senses used today (hearing and vision) by exploring peripheral vision and ambient listening. 'All-senses communication' would be one way to enhance the communication with other entities (humans or machines) using a combination of several present or future senses of humans. Multimodal systems (Oviatt, Coulston, & Lunsford, 2002) process two or more combined user input modes—such as speech, pen, touch, manual gestures, gaze, and head and body movements—in a coordinated manner with multimedia system output. This class of systems represents a new direction for computing, and a paradigm shift away from conventional interfaces to the collaborative multimodal interfaces.

Trusted Time

Trusted time is important in global network communication. Trusted time is essential to ensuring that network and operations infrastructure run accurately, securely, and reliably, and that all relying applications execute with traceability that provides auditability to resolve disputes, avoid repudiation, and ensure legal enforceability of electronic business transactions. The auditable sourcing and synchronization of time involves a "chain of trust."

FUTURE TRENDS IN INFORMATION TECHNOLOGY MANAGEMENT

Nearly all types of systems in all fields of the economy became distributed, and virtual structures appeared. The result is large structural and cultural changes in enterprises. A new communication technology appeared as well—wireless technology. The management of these new systems has also brought new aspects into focus in the field of information management. As Malone (2004) appoints in his book, the style of management moves from command-oriented management to coordination-based approaches (new skills are required), The main advantages of wireless and mobile communication are that anybody, from anywhere, at anytime, can make contacts.

Mobile devices become far more popular as was estimated before, and thanks to the extremely fast development of the electronic industry, these devices have grown into a multi-functional tool. Mobile Internet rewrites many rules. People everywhere, in different positions, are using new services that are relevant to their personal needs and preferences — and are accessible anytime, anywhere. New terms are developing in all sectors of the industry — in finance, in government, and in society.

Information architectures, structures, business processes, and business models of enterprises must be modified according to new infocom technology. Mobile technologies add new value as to be continuously connected. Short response times assure the validity of information. The productivity is no longer restricted by place or time. Best of all, it is possible to experience new ways of communicating, sharing information. In an information and communication-centered world, security and trust are exceptionally important, as the value and strategic role of reliable information is extremely high. Information technology management systems and the managers themselves must adapt to this fast, non-stop changing environment. Smart cards, personal trusted devices (PTDs), secure agent architectures, and new protocols for ad hoc networks (Patwardhan, Parker, Joshi, Karygiannis, & Iorga, 2005) are some of the main elements in information technology that will change in the future.

In spite of the many positive characteristics and effects introduced so far, mobile communication has negative sides as well, for example, the possibility of tracking services and routes of owners by governments and marketers using information from wireless devices. An additional general problem is the establishment of trust and reputation in the wireless world. Using PTDs for trust building makes authentication and confidentiality easier and more reliable to support the operation of different types of virtual organizations.

In using mobile devices there is a problem generated by camera phones. They have become extremely popular, as it is easy to take pictures and send them immediately to partners as well as to send videos and other multimedia materials. In some countries it is not easy to buy mobile phones without a camera. Alternatively, companies and sporting clubs are stressing that privacy rights and company properties (technology, etc.) are in danger when people bring camera phones into their territory, so they prohibit the use of camera-phones in their areas. The exaggerated usage of mobile devices can cause problems in workplaces as well by disturbing others with frequent calls or by exploiting the video possibilities of the new, enhanced phones. In some workplaces, private usage of mobile phones and SMS services are prohibited, as they decrease work efficiency and cause additional security risk.

CONCLUSION

The chapter has briefly introduced the main characteristics of trust and its connections between security services and

mechanisms and its role in information technology management. The importance of trust is increasing very fast, as the main characteristic of the information and knowledge society is the cooperation through computer and communication networks. As pointed out by different analysis based on real-life statistics, when users do not trust a system/service, they do not use it. Organizations must adapt to this requirement, by changing their culture or organization structures as well.

Integrated mobile technologies are speeding up this tendency as they offer mobility/freedom for the citizens. Distributed information systems of different sizes are playing a definite role, but originating from their openness and flexibility, these systems will always be a security risk. As high-level security and trust cannot be reached with pure information technology approaches, they must be integrated with the human-centered techniques based on psychological methods.

There is a need for complex, flexible security systems that are user friendly and platform independent at the same time. The developments of hardware and software elements of such systems are going on, and the potential users have to get acquainted with them. The managers of information technology must adapt these technologies, tools, and devices into their systems to provide a high level of security and trust that can induce trust in all humans involved in the different phases of the lifecycle of information systems.

KEY TERMS

Biometry/Biometrics: Generally, biometrics refers to the study of measurable biological characteristics. In computer security, biometric technologies are defined as automated methods of identifying or authenticating the identity of a living person based on his or her physiological (e.g., fingerprint, hand, ear, face, eye — iris/retina) or behavioral (e.g., signature, voice, keystroke) characteristic. This method of identification is preferred over current methods involving passwords and pin numbers, as the person to be identified is required to be physically present at the point of identification, so the person or user is identified, not the device, as in case of a PIN and password.

Encryption: The transformation of plaintext into an apparently less readable form (called cipher text) through a mathematical process. The cipher text may be read by anyone who has the key that decrypts (undoes the encryption of) the cipher text.

Layered Biometric System: Multi-layer/layered/multimodal biometric systems combine more than one physiological or behavioral characteristic for verification or identification. By promoting multi-layered identification and authentication — that means parallel use of strong passwords, smart tokens, and biometrics — many significant security problems can be eliminated. The combination of multiple biometric methods such as voice and fingerprints, in conjunction with digital certificates, smart cards, and so forth, offer the companies an ideal solution to provide very high-level protection of their sensitive information.

Personal Trusted Device: People like smart, little, handheld tools they can carry with them permanently, so they can control them both physically and in time. According to the concept of the personal trusted device, it must be personal, always carried by user, small, cheap, accumulator powered, have a common user interface, and be as secure as a smart card. Mobile phones can fulfill the role of personal trusted devices, as mobile phones are well placed as identity tokens, they have dynamic authentication already proven in GSM, and have mass market and secure communications. Mobile phones are the only mass-market smart card readers, and they are highly personal. Users are usually very attached to their phones, and they can be made more personal by use of a PIN or (later) biometrics.

Trust: Can be viewed as a cognitive and social device able to reduce complexity, enabling people to cope with the different levels of uncertainty and sometimes the risks that, at different degrees, permeate our life. Without trust, an individual would freeze in uncertainty and indecision when faced with the impossibility of calculating all possible outcomes of a situation. From a social perspective, trust permits the necessary knowledge sharing of delegation and cooperative actions (Luhmann, 1979).

Trust Chain: A solution for addressing trust is to build a chain of trust where each link is strong but also connects to its neighbor by verifying its trustworthiness.

Trust Management: A unified approach to specifying and interpreting security policies, credentials, and relationships; it allows direct authorization of security-critical actions. A trust-management system provides standard, general-purpose mechanisms for specifying application security policies and credentials. Trust-management credentials describe a specific delegation of trust and subsume the role of public key certificates; unlike traditional certificates, which bind keys to names, credentials can bind keys directly to the authorization to perform specific tasks.

Trusted Time: Emerging as the industry best practice, trusted time is auditable, secure, available, warranted, accurate, and managed. Trusted time is essential to ensuring that network and operations infrastructure run accurately, securely, and reliably, and to ensure legal enforceability of electronic business transactions. The auditable sourcing, setting, and synchronization of time involves a "chain of trust" that is complex, requires time specialization, and involves multiple sources of risk.

Trustworthiness: The ability to attain and maintain a "trusted state," which is definable, measurable, validatable, and demonstrable over time. Digital trustworthiness means a verifiable level of electronic process integrity, security, control, authenticity, and reliability that captures, preserves, retrieves, verifies, renders, and makes available in human-readable form — the essential transaction content, context, notice, intent, and consent — to meet the electronic forensic evidence requirements necessary for legal admissibility and regulatory compliance.

Building Educational Technology Partnerships through Participatory Design

John M. Carroll
The Pennsylvania State University, USA

INTRODUCTION

Educational technology provides many examples of how efficient software development and deployment is not enough. Teachers work in a complex and dynamic context in which measurable objectives and underlying values collide on a daily basis. Traditionally, teachers work in isolation from their peers; individual teachers have well-established personal practices and philosophies of education. Teachers have enormous discretion with respect to what goes on in their classrooms, yet are also routinely interrogated by supervisors, by parents and other community members, and by educational bureaucracies. This has led to an abiding tension in the culture of schools: Teachers' innovative practices are often not adequately acknowledged or valued, and at the same time, teachers often passively resist school reforms that are imposed top-down.

Technology is a particularly problematic element in the culture of schools. The isolation and discretion of the teacher's work environment requires that technology for classroom use be highly appropriate and reliable. Yet it is generally assumed that teachers are to be *trained* on new technologies, not asked to *define* what those technologies should be. From the teacher's standpoint, classroom technology often is itself the problem, not the solution. This culture of technologydevelopment in the schools has been singularly ineffective—film and radio in the 1920s, television in the 1950s, and computer-assisted instruction in the 1980s, among others, have been notable failures (Tyack & Cuban, 1995).

An alternative to merely efficient technology development is *participatory design*, the inclusion of users within a development team such that they actively help in setting design goals and planning prototypes. This approach was pioneered, and has been widely employed, in Europe since the 1970s, and now consists of a well-articulated and differentiated set of engineering methods in use worldwide (Carroll, 2000; Clement & Van den Besselaar, 1993; Muller, 2003; Muller, Haslwanter, & Dayton, 1997; Rosson & Carroll, 2002).

In 1994, a design collaboration was formed between Virginia Tech and the public schools of Montgomery County, Virginia. The objective was to develop and investigate a high-quality communications infrastructure to support collaborative science learning. Montgomery County is located in the rural Appalachian region of southwestern Virginia. In March 2000, one of its high schools was listed among the top 100 in the US by *Newsweek* magazine. However, in others, physics is only offered every other year and to classes of only three to five students. The initial vision was to give students in this diverse and dispersed school district access to peers through networked collaboration.

We felt it was critical for the teachers to contribute as collaborators in design analysis, implementation, deployment, testing, and refinement, and as leaders in the development of courseware and classroom activities that would exploit the software. For a classroom-technology partnership to succeed, the university researchers must eventually fade and leave the teachers to maintain and develop its achievements. In the end, the technology-development goals of this project were achieved, though this is not the topic of this paper (Isenhour, Carroll, Neale, Rosson, & Dunlap, 2000).

BACKGROUND

We analyzed our participatory engagement with the teachers as "developmental" in the sense of Piaget and Inhelder (1969) and Vygotsky (1978). We believe the teachers developed qualitatively different roles through the course of our collaboration. In some cases, these roles were suggested to them; in other cases, they defined and claimed new roles. But in all cases, these transitions exemplified the defining characteristics of *developmental change*: active resolution of manifest conflicts in one's activity, taking more responsibility, and assuming a greater scope of action. Each successive stage can be seen as a relatively stable organization of knowledge, skills, and attitudes that resolves the instigating conflict.

During the six years of this project, we distinguished four stages in our collaboration with the teachers. At first, the teachers were *practitioner-informants*; we observed their classroom practices and we interviewed them. Subsequently, the teachers became directly and actively involved in the requirements-development process as *analysts*. Later, the teachers assumed responsibility as *designers* for key aspects of the project. Finally, the teachers became *coaches* to their own colleagues within the public school system.

In a classic Piagetian example, a child in the preoperational stage perceives single dimensions of quantity. This produces conflicts: A given quantity of liquid poured from a short, wide container into a tall, thin container appears suddenly to be more, but of course cannot be more. These conflicts eventually precipitate a cognitive reorganization called the concrete operational stage, in which constant quantities are perceived as constant regardless of varying shapes and arrangements.

Developmental change in adults is of course more complex. The stages we describe are not singular competencies, but relatively complex ensembles of collaboration, social norms, tool manipulation, domain-specific goals and heuristics, problem solving, and reflection in action. They are social constructions achieved through enculturation, constituted by the appropriation of the artifacts and practices of a community (Vygotsky, 1978).

In the Piagetian notion of stages in child development, successive stages build upon the cognitive structures and enabled activity of prior stages, but ultimately replace those structures. A child who enters the concrete operational stage can no longer function at the preoperational stage. Adult growth, however, is not static achievement, but continual elaboration. The teachers are still practitioners whose classroom practices we regularly observe and whose classroom expertise we still interrogate; they seem to us and to themselves to be representative practitioner-informants. However, they are now *also* analysts and designers, and often coaches. Indeed, effective design coaches probably must be experienced designers, successful designers must be skilled analysts, and analysts must have attained significant domain knowledge (Carroll, Chin, Rosson, & Neale, 2000).

MAIN THRUST OF THE CHAPTER

Developmental theory explains transitions between stages as resolutions of conflict. Thus, the preoperational child's conflicting perceptions of quantity based on single dimensions, such as height and width, are resolved in the abstraction of quantity as an invariant in the concrete operational stage. For development to take place, the child must have attained the requisite competencies to experience the triggering conflict, and then be able to reconceptualize the situation in such a way that the conflict dissolves.

This analytical schema seems to fit the transitions between the stages of cooperation we identified. The general mechanism appears to be that successive increases in knowledge, skill, and confidence empowered the teachers to resolve conflicts by assuming successively greater scope of action and responsibility in the project. Early on, the teachers faced the conflict that their pedagogical concerns and perspectives would be adequately represented and fully considered by the group only if they themselves championed those concerns. This went beyond the practitioner-informant role they had played in the project up to then. But they were both motivated and competent to resolve this conflict by assuming the analyst role in the project.

Once the teachers were functioning as analysts in the project team, further conflicts and resolutions arose. The teachers experienced a conflict between their own analyses of system requirements and the current state of our project software and development plans. They resolved these conflicts by formulating their own design proposals, ultimately a radical reorientation of the project's vision of classroom activity. They became designers. Subsequently, the teachers recognized that they were the best qualified project members to train new teachers and to pursue specific curricular extensions of the project. They became coaches.

The teachers' behavior also reflects development *within* the four general stages we have described. For example, cognitive scaffolding (via examples, reflective prompts) was needed to engage the teachers in the novel and relatively abstract activity of design analysis. But as the project progressed, teachers spontaneously identified and presented design trade-offs to the group as a way to articulate personal positions. This is consonant with the general notion of learning as movement through a zone of proximal development (Vygotsky, 1978).

The designer stage also reflects several different levels of development. Initially, the teachers were able to collaborate with a research assistant in focused design sessions, cowriting scenarios of technology-mediated activities for their classroom. Later they banded together as a subgroup, pooling their goals and expertise to develop a scenario that specified a new vision of collaborative learning activities. Ultimately, each learned to function as an independent designer, envisioning and specifying activities optimized for their own teaching styles, objectives, and classroom environments. In their coach role, the teachers also worked first as a group, but subsequently recruited and mentored colleagues in a one-to-one fashion.

In sum, it appears that the transitions among stages were triggered by conflicts with respect to the teachers' role in the project. In each case, a series of scaffolded activities enabled them to attain the knowledge, skill, and confidence that led them to expand their role (Carroll et al., 2000).

FUTURE TRENDS

We originally committed to a long-term participatory-design method because we conjectured that such an approach would be crucial for success in this educational technology setting. We believe we could not have succeeded to the extent we have had we not made this commitment. Working from the

national agenda for school reform, educational technology, and science education (AAAS, 1993; NTSA, 1992), and from our own initial vision of a "virtual school," we would have built the wrong system—we would not have had effective support from teachers. Little or nothing would have been sustained after the initial project funding ended.

Participatory design is fundamentally a process of mutual learning, and thus of personal development for participants. But it is often exemplified by rather singular and ephemeral learning interactions. Our study expands the scope of the design participants' personal development by examining a case of long-term cooperative design interaction, and by describing a developmental sequence of roles with constituent capacities and responsibilities.

Much research on participatory design has focused on relatively short-term collaborative relationships. This is especially true in North America, where many participatory-design techniques are directed at brief user-interface-design interactions of perhaps one hour (Muller et al., 1997). Such methods are both effective and democratic, but it seems unlikely that the experience of manipulating a user-interface mock-up during a brief participatory session can have a significant developmental effect on a person's knowledge, skills, self-confidence, or other professional capacities.

In our project, user-interface design per se was a secondary issue. We used brief participatory exercises, but this level of engagement was more a starting point than the objective of our work. More specifically, we wanted the teachers to have a significant voice in designing the functionality and the use of the virtual school, not merely its appearance. We needed to learn about pedagogical goals and practices, classroom management, school-system politics, the relationship of the community and the schools, and so forth.

Where participatory-design investigations *have* focused on longer term interactions, chiefly in Europe, these often involve extremely well-organized user groups with well-defined roles and prerogatives in the design process. In many cases, the users are represented by labor unions whose personnel provide legal representation of user interests in the design process. In these cases, there is sometimes a clear demarcation, even conflict, between the user (union) interests and management's technology strategy. Indeed, this is an important element of the context for many of these studies. Because the user role in many of these studies is both specified a priori and representative (versus individual), the personal development of user-designers is not a central issue. These case studies also typically involve situations in which the development and deployment of new information technology is a given, and the challenge is to define appropriate technology for the users and their activities (Bjerknes & Bratteteig, 1993; Bødker, Ehn, Kammersgaard, Kyng, & Sundblad, 1987; Merkel et al., 2004).

In the educational domain, the deployment of new information technology is far from given. Indeed, the introduction of new technology has historically almost always failed in school settings. One of the key questions for us was whether a concept for appropriate technological support could be developed at all.

The users in our domain are very loosely organized. As mentioned earlier, teachers traditionally work in isolation from peers; they manage their own work practices and environments (classrooms). The notion of a "user community" in this domain is almost ironic. Teachers unions in the US are also extremely weak and play no role in the introduction of classroom technology. Indeed, school administrations in the US rarely have technology strategies at all. Thus, unlike the European case studies, the issue is almost never one of recognized conflict, but rather finding a direction at all.

The teachers in our team do not represent other teachers; they are individuals who, as members of our team, have become teacher-designers. This is precisely why their personal development as designers is a central issue in our study. Of course, we do hope that they are representative teachers—allowing us to generalize our investigation to other teachers participating in similar development projects—but this is a separate issue. The point is that in our project, and unlike many long-term participatory-design efforts in Europe, the teachers act as individual professionals just as university researchers do.

CONCLUSION

The stages we have described here are specific to our project; they emerged through specific things that we did and are rooted in the specific goals of our project. At the same time, they suggest a schematic programme for developing cooperative engagement more generally. Most participatory-design work engages users at the practitioner-informant stage. This would seem to be an obvious and general starting point for any participatory-design collaboration. In our project, the teachers transitioned to the analyst stage through their inclusion in a requirements-analysis workshop and a significant process of iterative requirements development (Carroll, Rosson, Chin, & Koenemann, 1998). This is perhaps not typical of participatory-design practice, but it is a modest extension. Nevertheless, the teachers found it quite stimulating to be invited to objectify their own experience, to dissect it and not merely describe it.

KEY TERMS

Analysts: Users who collaborate with designers as domain experts analyzing constraints and trade-offs in existing and envisioned work practices are called *analysts*. This is the second stage in the developmental theory of participatory-design relationships between users and designers.

Coaches: Users who help other users participate in design work by coaching them are called *coaches*. This is the fourth stage in the developmental theory of participatory-design relationships between users and designers.

Designers: Users who collaborate with designers as domain experts envisioning new work practices and tools are called *designers*. This is the third stage in the developmental theory of participatory-design relationships between users and designers.

Developmental Theory: Theories of learning that involve growth and other qualitative changes in skills, knowledge, and capacities. Developmental theory is contrasted to accretive theories in which learning is conceived of as a matter of quantitative improvements—more knowledge or faster performance.

Educational Technology: Technology used in formal educational contexts, such as classrooms. Recent examples are television, personal computers, and the Internet.

Participatory Design: Design methods in which users (and other stakeholders) provide special expertise and play active and autonomous roles in design work.

Practitioner-Informants: Users who collaborate with designers as domain experts providing information about work practices are called *practitioner-informants*. This is the initial stage in the developmental theory of participatory-design relationships between users and designers.

Building Local Capacity via Scaleable Web-Based Services

Helen Thompson
University of Ballarat, Australia

INTRODUCTION

Information communications technology (ICT) has been identified as a key enabler in the achievement of regional and rural success, particularly in terms of economic and business development. The potential of achieving equity of service through improved communications infrastructure and enhanced access to government, health, education, and other services has been identified. ICT has also been linked to the aspiration of community empowerment, where dimensions include revitalizing a sense of community, building regional capacity, enhancing democracy, and increasing social capital.

In Australia, there has been a vision for online services to be used to open up regional communities to the rest of the world. Government support has been seen "as enhancing the competence levels of local economies and communities so they become strong enough to deal equitably in an increasingly open marketplace" (McGrath & More, 2002, p. 40). In a regional and rural context, the availability of practical assistance is often limited. Identification of the most appropriate online services for a particular community is sometimes difficult (Ashford, 1999; Papandrea & Wade, 2000; Pattulock & Albury Wodonga Area Consultative Committee, 2000). Calls, however, continue for regional communities to join the globalized, online world. These are supported by the view that success today is based less and less on natural resource wealth, labor costs, and relative exchange rates, and more and more on individual knowledge, skills, and innovation. But how can regional communities "grab their share of this wealth" and use it to strengthen local communities (Simpson 1999, p. 6)? Should communities be moving, as Porter (2001, p. 18) recommends (for business), away from the rhetoric about "Internet industries," "e-business strategies," and the "new economy," to see the Internet as "an enabling technology—a powerful set of tools that can be used, wisely or unwisely, in almost any industry and as part of almost any strategy?"

Recent Australian literature (particularly government literature) does indeed demonstrate somewhat of a shift in terms of the expectations of ICT and e-commerce (National Office for the Information Economy, 2001; Multimedia Victoria, 2002; National Office for the Information Economy, 2002). Consistent with reflections on international industry experience, there is now a greater emphasis on identifying locally appropriate initiatives, exploring opportunities for improving existing communication and service quality, and for using the Internet and ICT to support more efficient community processes and relationships (Hunter, 1999; Municipal Association of Victoria and ETC Electronic Trading Concepts Pty Ltd., 2000; National Office for the Information Economy, 2002).

The objective of this article is to explore whether well-developed and well-implemented online services can make a positive contribution to the future of regional and rural communities. This will be achieved by disseminating some of the learning from the implementation of the MainStreet Regional Portal project (www.mainstreet.net.au). To provide a context for this case study, the next section introduces some theory relevant to virtual communities and portals. The concept of *online communities* is introduced and then literature is reviewed to identify factors that have been acknowledged as important in the success of online community and portal initiatives.

BACKGROUND

In regional Australia, many Web-based initiatives have been premised on fear of external electronic commerce ventures adversely affecting local industry (McGrath & More, 2002, p. 50). Media and government reports have reinforced notions that those who ignore the adoption of electronic commerce will do so at their peril (Department of Communications Information Technology and the Arts, 2000). Recent research however identifies a movement beyond the "starry-eyed fascination with, and high expectations of, technology per se," with the focus now more pragmatically on how ICT can enable enhanced business and community processes and more effective organizational relationships (More & McGrath, 2003).

The term *online community* means different things to different people (Preece, 2000). In early definitions, the term described communication facilitated through bulletin boards (Rheingold, 1994, pp. 57-58). More recent definitions reflect the expansion of Web-based technologies and often link online communities with concepts of regional communities and local strengths (Keeble & Loader, 2001).

In Australia the terms *online community*, *regional portal*, *Web portal*, and *community portal* are often used more or less interchangeably. Web portals "provide focal points on the Web, places to start, places to go to find things" (Gronlund, 2001, p. 88). They have been identified as one strategy for encouraging regional participation in the information economy. For example, according to the Department of Communications Information Technology and the Arts (2001), a regional portal can achieve the online aggregation of potential and existing regional presence into a comprehensive portal, gateway, or regional Web site. In funding initiatives, preference has been given to projects that offer inclusive regional aggregation of business, government, and community services, and which provide interactive services to clients both in and external to the region.

Some definitions of online communities capture the concepts of both *communities of interest* and *communities of location*, and identify the role of encouraging communication and information sharing among members as important (McGrath & More, 2002). Australia's largest telecommunications provider describes online communities as providing a focal point for the provision of local regional information. In terms of functionality, these community portals generally incorporate local news services, local weather reports, a directory of community organizations, and features such as bulletin boards, discussion forums, a calendar of events, and transaction services (Telstra Country Wide, 2002).

To achieve optimum online collaboration, various issues require consideration. These include notions of community, trust and commitment, processes and structure, knowledge management, learning, and collaboration (More & McGrath, 2003). Some further factors more specific to the success of online community or portal initiatives are considered in the next section.

In forging and managing online collaboration, people issues rather than technological ones have been identified as the most challenging. "Certainly across a broad range of projects, many have come to realize that managing people, relationships, and business processes is harder than managing technology" (McGrath & More, 2002, p. 66). It is easy to underestimate the amount of planning and effort that is needed to build and sustain an online community; therefore care should be taken to avoid miscalculations. In particular, "overlooking the key role of the human facilitator is perhaps the greatest reason that online communities fail to meet the expectations of their designers" (Bernal, 2000, p. 4).

For many projects, collaboration is the key to survival, renewal, and growth, especially in regional areas "where the threat of global competitive dynamics often drove alliances" (McGrath & More, 2002, p. 67). Initiatives, however, with a broad geographical focus, can "encounter difficulties in establishing and maintaining cooperative relationships across multiple communities in their regions" (Simpson, 2002, p. 8).

"Many projects that have adopted a 'build it and they will come' approach have been doomed to early failure" (Simpson, 2002, p. 4). Developers need to work with community members to ensure that the goals of the site owner and the needs of community members are met (Preece, 2000). Good online services provide multiple levels of entry, many-to-many relationships, and rapid movement between the services and content of disparate providers (Local Government Association of Tasmania and Trinitas Pty Ltd., 2001).

Community members also need compelling reasons to use and return to an online community again and again. There will be a need to balance supply-side investment (access, technical platforms) and demand-side investment (content and services) (Local Government Association of Tasmania and Trinitas Pty Ltd., 2001).

"If you get this right—if you can identify and fill a need in the lives of your community members—you can go a long way on very little technology. If you miss this, no amount of technology is going to make you successful as an online community." (Kim, cited in Bernal, 2000, p. 3)

Engaging and relevant content are vital to increase uptake and sustained use of the Internet. Portal content management strategies should be *bottom-up* in their approach. This can be achieved by providing multiple opportunities for interaction and by providing permission-based access to software that allows members to produce content for their online community (Brumby, 2001; Telstra Country Wide, 2002).

Soft technologies are also essential in building user confidence and comfort with new technology. "Individualized awareness raising…training activities, and learner support are key elements in creating within the community the desire, motivation, and enthusiasm to trial and take up the technology" (Simpson, 2002, p. 7).

This review has highlighted a number of factors which can impact the success or otherwise of portal type initiatives. This background information provides a context for introducing the MainStreet case study in the next section.

MAIN THRUST OF ARTICLE

In May 1999 a collective of regional stakeholder organizations engaged the University of Ballarat to research the requirements and make recommendations on how the Central Highlands and Wimmera regions of Victoria could capture greater advantages from new information and communications technologies.

The research, documented in *Victoria's Golden West Portal Project Business Case* (Thompson, 1999), involved a number of different stages. These included confirming existing regional Web content, examining community portal

developments, identifying portal tools, researching potential revenue streams, conducting focus group sessions, and other forms of stakeholder consultation.

The research report described how an environment could be established that would be conducive to the widespread adoption of electronic commerce. Specific recommendations included: establish a membership-based regional association with a specific focus on electronic commerce; establish infrastructure for a manageable and economically sustainable Internet presence in a way that would encourage the enhancement of community service and facilitate communities of interest and trading communities; and through a regional portal, achieve better Web content coordination, provide a valuable information source for residents, and also enhance efforts to promote all the attributes of the region.

The Chamber of Electronic Commerce Western Victoria Inc. (the Chamber) was established to facilitate the advancement of electronic commerce and implement the MainStreet portal project. Funding applications were prepared, and in November 1999 the MainStreet project secured funding of AUD 274,000 through Networking the Nation, with a further AUD 135,000 approved in May 2000. The University's Centre for Electronic Commerce and Communications (CECC) was then contracted to implement the project because it had the specialist skills necessary to develop the portal infrastructure and services.

Research had identified that many portal projects had produced 'static' or 'fixed' solutions. The MainStreet model, with the inclusion of a technical team as a critical element, was different, but the decision to have this team was significant in determining how the MainStreet project would evolve. The technical officer and part-time programmers would develop a portal framework based on the core services identified during the preliminary study. All tools would be selected or developed with non-technical end users in mind. The initial toolset would include event calendars; news publishing tools; online registration, payment, and product systems; and access to Web wizards and other Web publishing tools. This would be achieved by incorporating a range of in-house developments, with some integration of externally sourced product. The core services would create capacities to link regional Internet information and services, construct searchable directories, dynamically generate content like news and weather, distribute publishing and authoring rights, and promote community news and events.

The MainStreet project was actively promoted in the period leading up to its official launch in July 2000. This promotion was important as it helped to maintain interest in the project while technical developments proceeded behind the scenes.

During the early part of 2002, the MainStreet project attracted its first major client. Success in securing the Ararat Online project (www.ararat.asn.au) was attributed to involving regional stakeholders right from the project's beginning. Ararat's Economic Development Manager had participated in a range of activities, meetings, and focus group sessions. Through these activities he developed a strong understanding of how MainStreet offered Ararat something different that could be applied immediately to benefit his local community.

The Ararat Online project would include a range of elements with more than 80 businesses and community groups to benefit directly from an upgrade of their Web presence. They would also be given the opportunity to undertake training so that each organization would gain the skills to manage their own site. A further opportunity would be available for six businesses through an e-commerce mentoring program. Selected businesses would be assisted in the implementation of electronic commerce initiatives developed to match their particular business needs.

The value derived from the Ararat Online project was substantial. First, although the project did not represent a significant 'bottom-line' contribution in the context of the overall project budget, the investment of AUD 8,000 in a regional electronic commerce context represented a significant buy-in for the MainStreet product. Second, the Ararat Online project provided an opportunity to showcase the full product suite, its technical capabilities, the Web products, and the training and consulting services. Third, the project would help to address one of the early barriers: people in the target region had a very limited understanding of what a portal was. The Ararat Online project would provide a 'real' example, which it was hoped could be used to demonstrate the value and benefits that were associated with the efficient linking of Internet-based information and services in an easily searchable form. In other words, the Ararat Online project would establish the first 'before' and 'after' images. This proved to be a very powerful marketing mechanism for the project.

The project's technical team, however, had their task doubled—they were now expected to build not one, but two portals, and to deliver these within very short periods. They were successful in developing a way to replicate the MainStreet functionality through Ararat Online (www.ararat.asn.au) and later through projects with the Birchip Cropping Group (www.bcg.org.au), Moorabool Shire (www.mconline.com.au), and Pyrenees Shire (www.pyreneesonline.com.au).

The original goal had been to establish MainStreet as the "point of first electronic contact for the region" (Thompson 1999, p. iv.). The vision was that people would find MainStreet, and from there be able to search and access information about a particular region or locate services of a particular type. What, however, was now understood was that 'communities' were much more motivated if the functionality of MainStreet could be delivered with local Web addresses

and branding. Information could then be filtered up to the MainStreet umbrella so that client communities could be either accessed directly or through MainStreet. While this turned the original concept upside down, there was a strong indication that communities in the region were prepared to pay to both establish and maintain a service based on the 'replicable portal framework' developed through the MainStreet project.

FUTURE TRENDS

The MainStreet portal infrastructure and tools have since been replicated to suit a range of different clients, with this approach proving to be a very effective way of getting people actively engaged online. Appendix 1 contains a selection of URLs for clients including local governments, town-based communities, membership-based organizations, industry groups, and small and medium enterprises.

While a number of factors have been highlighted, the most successful and distinctive aspect has been the development of the replicable portal framework. It has been this capability that has been leveraged to cause increase in 'buy-in', participation, and ongoing investment in regional Web-based services. Members of 'geographic communities' and 'communities of interest' are able to work with CECC to design and implement sophisticated Web-based services, customized to meet their specific communication, promotional, and/or electronic commerce needs. Through this university/community partnership, initiatives are then sustained by putting community members in charge of the management of their online community. Local ownership and the sustainability of infrastructure and technical support services have been achieved by effectively aggregating regional demand for portal services.

The MainStreet project has made a significant contribution to the advancement of ICT and electronic commerce uptake in the Central Highlands and Wimmera regions of Victoria. Many individuals and communities have been assisted in advancing their uptake of electronic commerce as they update their community sites, publish event information and news items, or show others how to build simple Web sites. The level of functionality and services accessed is high and, because clients have strong ownership of their online activities, maintain their own Web-based information, and are committed to annually investing to maintain the portal infrastructure and services, the services can continue to be delivered after the initial seed funding period.

The MainStreet project has also supported and encouraged a staged uptake of electronic commerce, with a number of organizational clients becoming increasingly confident in both selecting and investing in electronic commerce solutions.

Services have also been customized to meet the needs of small groups such as Birchip Cropping Group, and also larger communities such as Moorabool, Ararat, and the Pyrenees Shire regions. This has overcome a barrier where under most models, the costs to establish (and sustain) a local portal have been substantial, and therefore prohibitive for small towns and community groups.

CONCLUSION

Through the MainStreet project, regional and rural communities have a greater ability to build on local strengths and capitalize on the opportunities that are provided by electronic commerce and ICT. Communities, however, just like businesses, require assistance in identifying the most appropriate online service for their particular circumstances. Policies that encourage communities to enter collaborative partnerships, and which leverage existing infrastructure, knowledge and learning, should thus be seen as preferable to the funding or establishment of discrete or stand-alone initiatives. Well-developed and well-implemented online services can make a positive contribution to the future of regional and rural communities. Case studies such as the one presented in this article are effective in illustrating the impacts, influences, and challenges that can be experienced in operationalizing and sustaining online communities in a regional and rural context.

ACKNOWLEDGEMENTS

The author acknowledges Brian West from the University of Ballarat who has been generous in the provision of advice and encouragement that greatly assisted in the preparation of this work.

KEY TERMS

'Bottom-Up'Approach: Development approach founded upon the principle that communities are better placed to coordinate and integrate efforts at the local level.

Case Study: The intensive examination of a single instance of a phenomenon or where one or just a few cases are intensively examined using a variety of data-gathering techniques.

Community Informatics: A multidisciplinary field for the investigation of the social and cultural factors shaping the development and diffusion of new ICT and its effects upon community development, regeneration, and sustainability.

Community Portal: Online initiative often developed through participative processes which aims to achieve better

coordination of relevant Web-based information and provide communication services for community members.

Regional Development: The act, process, or result of actions to grow, expand, or bring a regional place to a more advanced or effective state.

Web Portal: Focal points on the Web which provide a place to start. Web portals facilitate the location of information by incorporating the strengths of search engines and additionally provide more efficient access to information by categorizing it into easily recognizable subcategories or channels.

Building Police/Community Relations through Virtual Communities

Susan A. Baim
Miami University Middletown, USA

INTRODUCTION

Over the past two decades, police departments around the globe have been involved in a slow, but steady transition from call-based policing to community-oriented policing. The former approach, while effective at closing cases once a crime has occurred, does little to develop crime prevention partnerships between officers on the beat and the citizens of local communities. Community-oriented policing serves to increase awareness of issues and potential problems before they occur, thus assisting police departments to provide a more proactive approach to stopping crime within their communities.

One of the greatest difficulties in developing effective community-oriented policing programs is establishing solid, two-way communications links between police officers and the populations that they serve. Information flow to the police and suggestions back to the citizenry often fall victim to the same constraints—lack of time to interact effectively and lack of a ready-made mechanism to deliver the information in a timely manner. To reduce or eliminate these constraints, interactive police department Web sites and virtual communities (that involve both police officers and citizens) can provide actionable and measurable performance increases in the efficiencies and the effectiveness of community-oriented policing efforts. Although the IT hardware, software, and design expertise needed to create interactive Web sites and virtual communities are readily available, online efforts at community-oriented policing will remain more of a theoretical interest than a broad-scale application until police departments truly understand the needs and the wants of the citizens within their local communities.

This article explores a service-learning approach for use in a university classroom that combines IT applications with current research practices in the use of citizen satisfaction surveys conducted for local police departments. Examples are drawn from three primary-based research studies involving police departments that are turning away from call-based policing practices and proactively moving toward community-oriented policing practices.

BACKGROUND

Descriptions of community-oriented policing efforts may be found in the literature as early as the 1960s, although the majority of papers published date from the mid-1990s to the present day. Successful community-oriented policing programs began to emerge as departments returned to fundamental cop-on-the-beat policing that put officers back in close contact with citizens in their neighborhoods and in their places of business (Sissom, 1996). The knowledge gained from the early community-oriented policing efforts was used to improve departmental training efforts and also used to focus police officers more closely on crime prevention techniques. Community-oriented policing practices have continued to evolve in more recent studies where most authors focus on how the police can better identify specific issues that are divisive within their respective communities (Culbertson, 2000; Vincent, 1999; Woods, 1999; Rohe, Adams & Arcury, 2001).

Community-oriented policing programs rely heavily on current and ongoing issues of citizen concern received from both the police departments and the citizens of the communities served. The basic premise of community-oriented policing involves both sides becoming very familiar with each other's needs, wants, and expectations, and then forming a true community partnership to create a safe environment for citizens to live and work. Police officers are, in a sense, being asked to enroll in a police version of a basic marketing course in order to learn how to sell this new approach to the residents of their communities (Cummings, 2001). Residents, long accustomed to seeing police officers only when an emergency has been reported, can represent a tough sell for police officers in terms of forming proactive crime prevention citizen partnerships. Additionally, many police departments, themselves, may believe that the extra time and effort necessary to create community-oriented policing programs is not worth the increased costs, given the difficulties in measuring the perceived benefits of crime prevention programs. Crime, itself, is measurable and actionable in terms of police performance. For example, the widespread incorporation of computerized emergency call systems (e.g., 911 in the United States and similar systems in other nations) has given police departments ready access to tools capable

of tracking performance measures such as call volume, time from call to officer arrival, clearance rate of calls, and so forth (Siegel, 1999). Particularly for police departments that score well on these measures and are rewarded appropriately by their city councils and/or their citizenry, the impetus to move toward more time-consuming and less easily quantified community-oriented policing objectives appears to be small. Like many governmental agencies, operational change in police departments tends to be extremely slow and very difficult to implement.

Regardless of these prevalent views, however, one finding that all parties seem to agree on is that the proper incorporation of new computer-based technologies will help police departments get closer to the citizens that they protect and serve. Computer-based technologies also help the individual officer solve crimes at the same time. An excellent example of such a technology is the mobile laptop computer now found in a high percentage of patrol cars (Greenemeier, 2002; Couret, 1999). Officers in the field now have access to virtually the same information as their office-based counterparts, and they can get at that information in real time without the translation losses associated with working through a radio dispatcher. Frequent reliance on the Internet and e-mail for sharing information and communicating between local police departments and other external police agencies also adds to the active network in use by the majority of police departments today. Given the significant improvements in computer technology, the timing is right for police departments to begin to implement community-based policing practices.

The design and development of efficient and effective "customized" community-oriented policing programs clearly places a burden on police departments to solicit, collect, analyze, and interpret data from their citizenries in order to make wise choices regarding the scope and size of any program that is set up. Obtaining high-quality data can be a formidable task, due to the diversity of the population to be sampled and due to the fact that not all respondents share the same expectations regarding active participation in crime prevention with their local police departments. It is with this background framework in mind that modern IT techniques, combined with current research practices, can significantly boost the ability of all parties to communicate and to share information that is critical in moving a police department from call-based policing practices to community-orientated police practices.

SURVEYS, INTERACTIVE WEB SITES, AND VIRTUAL COMMUNITIES

Police departments often lack not only the knowledge of what citizens might respond favorably to in terms of interactive Web sites or virtual communities, but also to the expertise that is needed to conduct unbiased research surveys among their constituencies to generate the required data input. Citizen satisfaction surveys are becoming highly efficient and effective tools for a variety of city government purposes with credible studies cited in the literature over the past several years (Kearney, Feldman & Scavo, 2000; Oleari, 2000). Often, such citizen surveys, conducted among random samples of the community's population, will be highly revealing of the type of information needed to set up initial Web site and/or virtual community structure(s).

To generate useful data that can drive the development of interactive Web sites and virtual communities, it may be necessary to enlist the services of professional researchers. Given large citizen populations, researchers may want to choose conducting either a mail or an online survey. If neither format is selected, they then need to develop a survey instrument, a process plan, and a timeline for conducting the survey, and at the conclusion of the survey, an unbiased set of concrete, actionable, and meaningful recommendations on how to put the data to use. Unfortunately, hiring a professional research firm can cost thousands of dollars that taxpayers cannot afford to spend given today's tight city budgets. A workable alternative, therefore, is to "hire" university students (under the direction of an instructor knowledgeable in current research techniques) who want to have a "hands-on" educational experience that benefits themselves, their university, and their local community in a service learning setting.

The three citizen satisfaction surveys described in this article were conducted following a traditional mail survey format. Table 1 briefly summarizes the city locations, numbers of surveys sent and returned by respondents (including response rate), and the dates that the research studies were conducted over the past few years. In each case, the study was run collaboratively with a police department in Southwestern Ohio (all looking to implement community-based policing practices in their communities) and an undergraduate Marketing course at Miami University. Students in each of the courses developed the database (in Excel or in Access), handled all of the data tabulation, and analyzed the results under the guidance of the author (as instructor of the courses).

Since future citizen satisfaction surveys of this type may be conducted using Internet-based survey instruments in situations where there is reason to believe that a sufficient concentration of "online" respondents is available, citizen respondents were asked to provide data on their Internet usage and their previous access to city and/or police department-sponsored Web sites. Data were also collected on the desirability and projected usage level of advanced interactive Web services, in case these types of services should be offered by police departments at a later date. Selected data are summarized in Table 2.

A careful examination of the data generated across all three surveys reveals several important findings for police

Table 1. Citizen satisfaction studies (mail surveys) involving local police departments

City	No. of Surveys Sent	No. of Surveys Returned	Response Rate	Date Conducted
Middletown, Ohio	2,000	636	32%	Spring 2000
Oxford, Ohio	1,857	522	28%	Spring 2001
Trenton, Ohio	1,600	478	30%	Spring 2001

departments that may desire to set up interactive Web sites and/or virtual communities to enhance police/community relations. These findings were generated by examining the cross-tabulations of the questions noted in Table 2 with various demographic parameters tracked in the surveys and also the respondent verbatims related to Web site usage. Results are summarized qualitatively in Table 3.

- In all three communities surveyed, personal Internet connectivity varied with age group. Older residents were less likely to have Internet access at home, and they did not appear to make up for this lack by using Internet access at work or public Internet access at libraries or other similar locations.
- Among residents with Internet connections, most users felt comfortable using Internet sites as casual observers or to download information, but only a small percentage of individuals were comfortable sending personal information online. Subsequent questions revealed that this reluctance could be attributed to the desire to keep personal information secure—regardless of any printed claims regarding "secure" Web sites or other online privacy statements relayed by Internet providers.
- Even among residents who felt comfortable with two-way communications online or with using interactive Web sites, it is evident that traditional communication mechanisms would have to be maintained in order to meet all needs, especially as they relate to police departments. Most residents believe that traditional means of communication are a "safety net" that must be used when electronic communications go down.

Police departments seeking to increase citizen participation in community-oriented policing efforts through the incorporation of electronic communications mechanisms such as interactive Web sites and/or virtual communities may face a similar situation as outlined above. While it would be too simplistic to state that the general citizenry will not accept such efforts, it is imperative to acknowledge that a significant percentage of city residents may be reluctant to participate in online communications at the present time. As such, it is critically important for those involved in setting up interactive Web sites and/or virtual communities to bear in mind that it may take time for these initiatives to "catch on" and that a keen eye is essential to make the Web sites attractive (with frequent updates) for casual and/or new Internet users.

John Hagel and Arthur Armstrong contend that there is "nothing more uninviting to passing Web traffic than a community without members" (1997, p. 134). Interpreting this comment in the context of community-oriented policing is straightforward. To attract proactive, involved citizens, interactive Web sites and virtual communities must offer something of value—something to cause these citizens to check back frequently, to offer suggestions, and to take away information that is valuable and that cannot be obtained as easily through alternative means. In bringing interactive Web sites and/or virtual communities to fruition, it may be advantageous to encourage members of the police department to participate vigorously and frequently—especially as the sites are first introduced. Some citizens may take a "watch and see" attitude before beginning to participate in online community-based policing efforts. The presence of helpful

Table 2. Citizen satisfaction studies—Internet usage

City	No. of Surveys Returned	Percent of Respondents Using the Internet	Percent of Internet Users Accessing City and/or Police Web Sites	Percent of Internet Users w/Interest in an Upgraded Police Web Site
Middletown, Ohio	636	40%	29%	13%
Oxford, Ohio	522	81%	28%	3%
Trenton, Ohio	478	66%	15%	48%

Table 3. Key findings regarding citizens' use/desire to use the Internet for police services

• In all three communities surveyed, personal Internet connectivity varied with age group. Older residents were less likely to have Internet access at home, and they did not appear to make up for this lack by using Internet access at work or public Internet access at libraries or other similar locations. • Among residents with Internet connections, most users felt comfortable using Internet sites as casual observers or to download information, but only a small percentage of individuals were comfortable sending personal information online. Subsequent questions revealed that this reluctance could be attributed to the desire to keep personal information secure—regardless of any printed claims regarding "secure" Web sites or other online privacy statements relayed by Internet providers. • Even among residents who felt comfortable with two-way communications online or with using interactive Web sites, it is evident that traditional communication mechanisms would have to be maintained in order to meet all needs, especially as they relate to police departments. Most residents believe that traditional means of communication are a "safety net" that must be used when electronic communications go down.

and interesting information from the police department may help draw these citizens from the mode of casual observer to the mode of full-partner participant.

The technology required to offer interactive Web sites and virtual communities is well established, and it will not be addressed specifically in this article. Police departments have numerous choices in how to achieve these goals, ranging from employing the services of professional Web site and virtual community design/support organizations, to "bootlegging" efforts from members of the city workforce and/or police department who are proficient at computer operations. What is mandatory, however, is the list of criteria given in Table 4.

- The Web site and/or virtual community must be in operation 24/7. Long periods of inactivity or excessive "down" periods must be avoided.
- Police officers and/or a department spokesperson(s) must monitor the Web site(s) frequently and actively participate in the citizen/police partnership.
- Continuous solicitation of new members will keep the Web site(s) fresh and productive.
- Police departments must not become discouraged if it takes a relatively long period for the concept to "catch on" in their communities.

Many police departments have a preliminary foundation on which to build an interactive Web site or a virtual community since they already have a police department Web site in place. (Among the three Ohio cities surveyed, Middletown, Oxford, and Trenton, all have police department Web sites or Web pages in an overall directory of city services.) Even if these sites exist only to provide a brief overview of the departments' operations, they can serve as a starting point to build citizen involvement. The key for the developer charged with expanding a basic Web site into an offering capable of engaging the local citizenry in community-oriented policing is to recognize that marketing the partnership process and the end result of the project (in terms of actionable and measurable performance indicators) will be as critical as executing the technical details of the assignment. Considered to be one of the true Internet pioneers, Howard Rheingold stated in an interview that the three most critical things that a developer must determine before beginning a project of this type are: 1) how the site will be marketed, 2) what is expected in return for visits by potential members, and 3) what technologies will be needed to put the site into proper operation (Moore, 2001).

While interactive Web sites can provide a forum for police officers and citizens to exchange information, in general these exchanges are likely to be highly discreet in nature—involving only one citizen and one police officer or department representative at a time. The real opportunity to magnify the positive benefits of community-oriented policing will occur as groups of citizens and officers begin to communicate on a frequent basis. If this is handled electronically, the communications may evolve into a highly functional virtual community. Police departments are well positioned for such an effort because police officers need to interact with the citizenry in order to keep a finger on the pulse of the community. Citizens, on the other hand, often have trouble interacting with the police unless an emergency has occurred. The mindset is that police officers are incredibly busy and that they do not have time to "just chat," when it is actually through such interactions that community-oriented policing makes its mark.

Police departments will need to go the extra mile in establishing virtual communities because individual citizens, or even groups of business people, will be unlikely to set up a virtual community infrastructure with sufficient credibility to attract widespread participation. Police departments may want to borrow guidelines on community participation from

Table 4. Criteria for successful use of interactive Web sites and virtual communities

▪ The Web site and/or virtual community must be in operation 24/7. Long periods of inactivity or excessive "down" periods must be avoided.
▪ Police officers and/or a department spokesperson(s) must monitor the Web site(s) frequently and actively participate in the citizen/police partnership.
▪ Continuous solicitation of new members will keep the Web site(s) fresh and productive.
▪ Police departments must not become discouraged if it takes a relatively long period for the concept to "catch on" in their communities.

authors such as Rachel Gordon, who has published an extensive discussion on "hints for success" in virtual community interactions (Gordon, 2000). Privacy and confidentiality concerns must also be properly addressed. Even though an interactive Web site or a virtual community is considered to be a public forum, clear statements regarding the collection and use of information are warranted (Sheehan, 2002; Sheehan & Hoy, 2000; Milne & Culnan, 2002). Finally, police departments should also keep in mind that they are not setting up interactive Web sites and virtual communities in order to run for-profit businesses. As such, the goal is not to extract data from citizen participants in order to judge how to market revamped and/or new police services. Rather, the goal is to generate critical information and upgrade the ability of both sides to deal with the process of maintaining an environment in which all citizens feel safe to live and work (Brewer, 2000; Wood, 2000).

FUTURE TRENDS

Community-oriented policing is here to stay. For the three Southwestern Ohio communities studied, the benefits of the process far outweigh the anticipated costs and extra effort put forth by their police departments. Data consistently showed that community-oriented policing programs would be greatly appreciated by citizens and business owners alike. Nevertheless, time pressures and resource constraints still continue to plague police departments in the same manner as they do other for-profit businesses, non-profit organizations, and governmental agencies. The key to successful implantation of community-oriented policing efforts thus becomes finding efficient and effective ways to interact with the public at large. Fortunately, the rapid increase in Internet connectivity and the general upswing in personal e-mail and Web usage provide a suitable vehicle for police departments to use in establishing better communication links with the citizenry.

It is highly likely that police departments will continue to increase their presence online in a variety of formats. The relevant issues requiring future study are primarily application oriented and not rooted in the basic technologies of setting up Web sites and/or offering access to virtual communities. Fortunately, police departments can ride the coattails of IT developers who are already generating continuously more advanced Internet communications technologies for business and industrial clients. This is not to say, however, that engaging the citizenry of a community to communicate with the police online is an easy or well-understood proposition. The state of the art today is one of relatively infrequent successes. Solid, two-way communications take time and money to implement, and both issues are at a premium in most police departments—regardless of whether those communications take place through traditional channels or in an online format.

Citizen satisfaction surveys, conducted through a mail survey format as described in this article or conducted in a fully online research mode, are likely to grow in importance as police departments continue to focus more energy on meeting the specific needs and wants of their communities. In terms of service learning at the university level, surveys of this type are natural service learning projects for post-secondary students in business, sociology, criminal justice, and other similar majors where a quantitative and qualitative study of police/citizen interactions is of value. Educators are likely to find students highly willing to participate in such work, and police departments eager for the unbiased "third-party" perspective that a well-run research study can provide.

Future research should focus on identifying more precisely what information citizens would value receiving through interactive Web sites and/or virtual communities. Individuals charged with developing interactive Web sites and/or virtual communities for police and citizen use would also be well advised to consider surveying police officers to better elucidate their department's needs and wants before beginning the design process. Collectively, the issues surrounding the "true" needs and wants of citizens in a local community transcend the technical aspects and challenges of mainstream research in information technology to include additional aspects of public policy, criminal justice, and citizens' rights. Citizen satisfaction surveys are, nevertheless, one form of practical application toward the future direction of applied information technology solutions.

CONCLUSION

Interactive Web sites and virtual communities represent two of the most innovative ways to generate meaningful, two-way dialogs over the Internet. As the technologies for connecting multiple Internet users in these manners mature, information technology researchers and developers can turn significant attention toward solving the specific application problems posed by unusual clients. Connecting the citizenry of a community with their police department in an efficient and effective manner is just one of a growing number of novel applications made possible by advanced Web site design and virtual community hosting technologies. As community-oriented policing efforts continue to grow in the coming years, it is highly likely that the efforts of information technology professionals will play a critical role in their success—making all of us feel safer at home and at work.

KEY TERMS

Call-Based Policing: Traditional policing approach whereby officers respond to emergency calls for assistance and address crimes and other situations after the fact.

Citizen Satisfaction: Term coined to describe the overall approval rating of services received by citizens within their communities. A 100% rating indicates total satisfaction with services received. Ratings may be taken "per service" or represent satisfaction with an entire government structure.

Community-Oriented Policing: Contemporary policing approach that builds relationships between police officers and the citizens of a community on an ongoing basis. Crime prevention is stressed as a partnership approach before an actual emergency situation(s) develops.

Interactive Web Site: A Web site or page configured so as to invite correspondence between the user and the originator/sponsor of the site. Such sites go beyond pas-

sively providing information to those who browse the site. Customarily, there are options to complete online surveys, send e-mail to the sponsor, request specialized or personalized response(s), and so forth.

Internet Privacy: Concerns expressed by Internet users regarding the security and confidentiality of information transmitted electronically. Government agencies and business/industry professional groups share responsibility to address Internet privacy concerns.

Internet-Based Survey: A contemporary survey technique through which researchers may obtain respondents' opinions via online survey processes. Respondents may either be asked to go to a Web site to complete a survey (Web-based) or the survey questionnaire may be e-mailed to the respondents (e-mail-based) for them to complete and return electronically.

IT Applications: Research and development work performed to create a situation-specific bridge between new or existing IT hardware and software technologies and the information needs/wants of a customer. The combination of proper hardware, software, and tailored application delivers a well-rounded IT solution for the customer's problem.

Mail Survey: A traditional survey technique in which a multi-part survey questionnaire is mailed to a randomized sample of individuals (within a larger population) who are asked to complete the questionnaire and return it to the survey researcher for tabulation and analysis.

Service Learning: Educational projects structured to take students out of the traditional lecture-based classroom and involve them in "real-world" problem-solving opportunities of importance to their communities. Students apply theories learned in their classroom studies in a practical manner that generates a completed work product for one or more clients, while helping to cement in students' minds the usefulness of the theoretical concepts under study.

Virtual Community: An online forum or discussion group through which members may interact either in real time or asynchronously. Most virtual communities use discussion groups and message boards that are accessible online to all members. Members correspond by posting messages back and forth within the forum. Membership in a virtual community indicates that the user shares one or more common interests with others in the same forum.

Building Secure and Dependable Online Gaming Applications

Bo Chen
Cleveland State University, USA

Wenbing Zhao
Cleveland State University, USA

INTRODUCTION

Online gaming has become a multibillion-dollar industry. The security and dependability of such games are critical for both the game providers and honest game players alike. Essential to all such applications is the use of random numbers; for example, random numbers are needed to shuffle cards. For obvious reasons, if the hands can be predicated, players could gain unfair advantages. The nature of this type of applications poses great challenges in increasing their availability while preserving their integrity (Arkin, Hill, Marks, Scjmod, & Walls, 1999; Viega & McGraw, 2002; Young & Yung, 2004).

Byzantine fault tolerance (BFT; Castro & Liskov, 2002) is a well-known technique to tolerate various malicious attacks to online systems and it often involves state machine replication (Schneider, 1990). However, state machine replication assumes that all replicas are deterministic, which is not the case for online gaming applications. In this article, we elaborate how we address this dilemma using an online poker application that uses a pseudorandom number generator (PRNG) to shuffle the cards as an illustrating example. We propose two alternative strategies to cope with the intrinsic application nondeterminism. One depends on a Byzantine consensus algorithm and the other depends on a practical threshold signature scheme. Furthermore, we thoroughly discuss the strength and weaknesses of these two schemes.

BACKGROUND

In this section, we provide a brief introduction of PRNG, the entropy concept, and the methods to collect and enhance entropy.

A PRNG is a computer algorithm used to produce a sequence of pseudorandom numbers. It must be initialized by a seed number and can be reseeded prior to each run. The numbers produced by a PRNG are not truly random because computer programs are in fact deterministic machines. Given the same seed, a PRNG will generate the same sequence of numbers. Consequently, if the seed is known to an adversary, then one can simulate the stream of random numbers (Young & Yung, 2004). Therefore, to make the random numbers unpredictable, it is important that the seeds to the PRNG cannot be guessed or estimated. Ideally, a highly random number that is unpredictable and infeasible to be computed is required to seed the PRNG in order to produce a sequence of random numbers.

The activity of collecting truly random numbers is referred to as collecting entropy by cryptographers (Young & Yung, 2004). Entropy is a measure of how much real randomness is in a piece of data, for example, using the outcome of coin flipping as 1 bit of entropy. If the coin toss is perfectly fair, then the bit should have an equal chance of being a 0 or a 1. In such a case, we have a perfect 1 bit of entropy. If the coin flip is slightly biased toward either head or tail, then we have something less than a bit of entropy. Entropy is what we really want when we talk about generating numbers that cannot be guessed. In general, it is often difficult to figure out how much entropy we have, and it is usually difficult to generate a lot of it in a short amount of time.

It is a common practice to seed a PRNG with the value of the local clock. Unfortunately, this is not a sound approach to preserve the integrity of the system, as described by Arkin et al. (1999) when telling about how they attacked a Texas Hold'em Poker online game. They show that with the knowledge of the first few cards, they can estimate the seed to the PRNG and subsequently predict all the remaining cards.

TOWARD SECURE AND DEPENDABLE ONLINE GAMING APPLICATIONS

In this section, we describe two possible strategies for building secure and dependable online gaming applications. One depends on a Byzantine consensus algorithm and the other depends on a practical threshold signature algorithm. These two algorithms are aimed at ensuring that all replicas use the same value to seed their PRNGs, with each replica taking entropy from its respective entropy source.

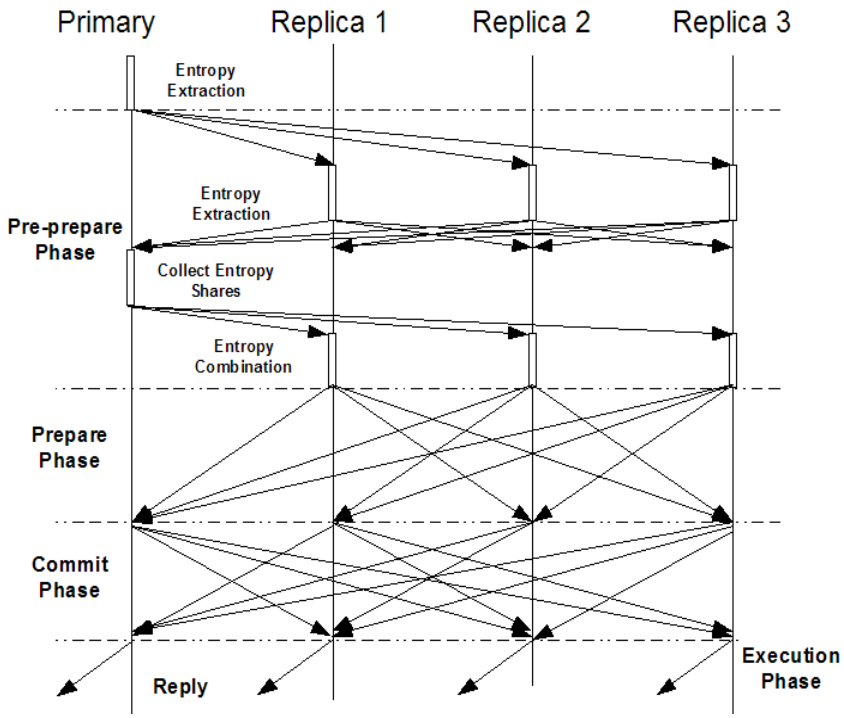
Byzantine Fault Tolerance

A Byzantine fault (Lamport, Shostak, & Pease, 1982) is a fault that might bring a service down or compromise the integrity of a service. A Byzantine faulty replica may use all kinds of methods to prevent the normal operation of a replicated service; in particular, it might propagate conflicting information to other replicas. To tolerate f Byzantine faulty replicas in an asynchronous environment, we need to have at least $3f+1$ replicas (Castro & Liskov, 2002). An asynchronous environment is one that has no bound on processing times, communication delays, and clock skews. Internet applications are often modeled as asynchronous systems. Usually, one replica is designated as the primary and the rest are backups.

We choose to use the well-known Byzantine fault tolerance algorithm developed by Castro and Liskov (2002). The BFT algorithm has three communication phases in normal operation. During the first phase, the *pre-prepare* phase, upon receiving a request from the client, the primary assigns a sequence number and the current view number to a message and multicasts this *pre-prepare* message to all backups. In the second phase, referred to as the *prepare* phase, a backup broadcasts a *prepare* message to the rest of the replicas after it accepts the *pre-prepare* message. Each nonfaulty replica enters into the *commit* phase, that is, the third phase, only if it receives $2f+1$ *prepare* messages (from different replicas) that have the same view number and sequence number as the *pre-prepare* message, then it broadcasts the *commit* message to all replicas including the primary. A replica commits the corresponding request after it receives $2f$ matching *commit* messages from other replicas. To prevent a faulty primary from intentionally delaying a message, the client starts a timer after it sends out a request and waits for $f+1$ consistent responses from different replicas. Due to the assumption that at most f replicas can be faulty, at least one response must have come from a nonfaulty replica. If the timer expires, the client broadcasts the request to all replicas. Each backup replica also maintains a timer for similar purposes. On expiration of their timers, the backups initiate a view change and a new primary is selected. In the BFT algorithm, a digital signature or an authenticator is employed to ensure the integrity of the messages exchanged, and a cryptographic hash function is used to compute message digests.

The above BFT algorithm must be modified to cope with intrinsic replica nondeterminism. The modified algorithm also consists of three phases, as shown in Figure 1. In the beginning of the first phase, the primary invokes the ENTROPY-EXTRACTION operation to extract its entropy and append the entropy to the *pre-prepare* message. It then

Figure 1. The adapted BFT algorithm to handle entropy extraction and combination



multicasts the *pre-prepare* message to the backups. Each replica records the primary's entropy from the *pre-prepare* message in its log and then invokes the ENTROPY-EXTRACTION operation to obtain its own share of entropy as well. Each backup then multicasts a *pre-prepare-update* message, including its share of entropy extracted. When the primary collects 2*f* *pre-prepare-update* messages from the backups, it constructs a *pre-prepare-update* message, including the digest of the 2*f*+1 entropy shares (2*f* received, plus its own) together with the corresponding contributor's identity, and multicasts the message.

Upon receiving the *pre-prepare-update* message from the primary, each replica invokes the ENTROPY-COMBINATION operation to combine the entropy from the 2*f*+1 shares. The outcome of the ENTROPY-COMBINATION operation ensures a highly random number due to the contributions from the nonfaulty replicas. The combined number is provably secure and will be used to seed the PRNG if the BFT algorithm terminates.

The second and third phases are similar to the corresponding phases of the BFT algorithm, except each replica will append the digest of the entropy set determined in the first phase to the *prepare* and *commit* messages. These two phases are necessary to ensure that all correct replicas agree on the same message total ordering and the entropy value despite the presence of Byzantine faulty replicas.

We now highlight the details of the ENTROPY-EXTRACTION and ENTROPY-COMBINATION operations.

Entropy-Extraction. The ENTROPY-EXTRACTION operation is based on software-based entropy collection. There are a number of techniques that can be used to extract the entropy, most of which are based on the timing of internal activities in a computer (Young & Yung, 2004). A well-known technique is called TrueRand, developed by Don Mitchell and Matt Blaze. The idea behind TrueRand is to gather the underlying randomness from idle CPUs by measuring the drift between the system clock and the generation of interruptions on the processor. Other frequently used techniques include recording network traffic as it comes into the server, timing how long it takes to seek the disk, and capturing kernel state information that changes often.

Entropy-Combination. The ENTROPY-COMBINATION operation combines the 2*f*+1 entropies the replica collected using the exclusive-or (XOR) operator (Young & Yung, 2004). This operation has several benefits.

First, it combines a number of weak sources of entropy to form an effective strong entropy source. Consider two entropy sources from coin flipping, and the case in which Source 1 results in head and Source 2 results in tail, or Source 1 results in tail and Source 2 results in head. Now consider that the probability for Source 1 to result in head is 10:16 and that for Source 2 is 12:16 (i.e., both are biased). If we combine these two sources, the probability of getting a head is 7:16. This shows that the coin flipping resulting from XORing the bits from the two sources is the same or better than the best flip in either of the two sources. Furthermore, the more sources we use, the higher entropy we get.

Second, the ENTROPY-COMBINATION operation eliminates any negative impact from malicious replicas. Among the 2*f*+1 entropy shares collected, there can be up to *f* of them coming from faulty replicas. The XOR operation guarantees that if at least one share comes from a good entropy source, the combined entropy is at least as good as that entropy share. This requirement is met because there are at least *f*+1 shares contributed by nonfaulty replicas. Any low-entropy or predicable shares generated by faulty replicas are virtually ignored.

Third, the ENTROPY-COMBINATION operation results in a single high entropy share used by all nonfaulty replicas, which ensures the consistency of the replicas when they are involved with intrinsically nondeterministic operations.

Threshold Signature

The other strategy to ensure consistent Byzantine fault tolerance replication for nondeterministic operations is based on threshold cryptography (Desmedt & Frankel, 1990; Deswarte, Blain, & Fabre, 1991). Threshold cryptography is a good way to distribute trust among a group of players to protect either information or computation (Zhou, Schneider, & Renesse, 2002).

A well-known secret sharing scheme (Shamir, 1979) is the (*k*, *n*) threshold digital signature scheme. In the (*k*, *n*) secret sharing scheme, a secret is divided into *n* sets and distributed to the same number of players. The secret can be reconstructed if *k* out of *n* players combine their shares. However, fewer than *k* players cannot collude to forge the secret. The (*k*, *n*) threshold digital signature scheme allows a set of servers to collectively generate a digital signature in a way similar to reconstructing a secret using the (*k*, *n*) secret sharing scheme.

In the (*k*, *n*) threshold digital signature scheme, a private key is divided into *n* shares, each owned by a player. A valid threshold digital signature can be produced if *k* players pool their shares. However, no valid signature can be generated by fewer than *k* players. Each player uses its private-key share to generate a partial signature on a message, and these partial signatures can be combined into a threshold signature on the message. The threshold signature can be verified using the public key corresponding to the divided private key.

The RSA Shoup scheme (Shoup, 2000) is one of the practical threshold digital schemes. In this scheme, a dealer generates a key pair and divides the private key into *n* shares at first. Each key share has a key verifier. Then the dealer distributes the message to be signed and the key shares to *n* players. Each player uses its key share to generate a partial signature on the message. Furthermore, each player sends the signed message with the verifier to a trusted server, which veri-

fies the signature shares and combines the partial signatures into a threshold signature verifiable by the public key.

In the following, we show how to integrate the threshold digital signature scheme with Byzantine fault tolerance for online gaming applications. The adapted BFT algorithm consists of three phases (under normal operation) for Byzantine agreement and an additional phase run at the beginning for key shares distribution. The Byzantine agreement algorithm works similar to the BFT algorithm except for the third phase, where each replica generates a partial signature (using its key share) to sign the client's message and piggybacks the partial signature to the *commit* message. Each replica combines the partial signatures into a threshold signature. The signature is then mapped into a number to seed the PRNG.

Despite the elegancy of the threshold signature, the algorithm, however, might not be practical in the Internet environment. First of all, it depends on a trusted dealer at the beginning to generate a key pair and divide the private key into several key shares, and it must also be responsible for distributing the key shares to all replicas. If the dealer is compromised, the entire system can be easily penetrated by the adversary. Furthermore, the threshold signature is computationally expensive, especially when generating the threshold signature. For example, for a 1,024-bit threshold signature, it usually takes 73.9ms on a PC equipped with a single 1.0GHz Pentium III CPU and 1.5 GB RAM (Rhea, Eaton, Geels, Weatherspoon, Zhao, & Kubiatowicz, 2003). Furthermore, the validity on the use of the threshold signature as the seed to the PRNG remains to be proven secure.

FUTURE TRENDS

PRNGs are not only used for online gaming applications, but are widely used in nearly every field in computers and networking. In particular, for cryptography, access to truly random numbers is extremely important. Even though there is moderate success in implementing PRNG, it remains vulnerable under cryptanalytic attacks and attacks against its internal state. Furthermore, it is easy to see that even if the PRNG is robust against many potential threats, once the seed is discovered, the numbers generated by the PRNG are no longer unpredictable. In light of this observation, more efforts should be engaged in how to gather and evaluate entropy in a secure and dependable manner. The research described in this article can be regarded as the first step toward this direction.

There are many open issues that remain to be resolved before we can confidently apply these techniques in practice. The most interesting research issue is how to maintain replica consistency. Common Byzantine fault tolerance techniques require deterministic execution of replicas despite the fact that all practical applications contain some degree of nondeterminism (Zhao, 2007), for example, clock values, CPU speed, multithreading, and so forth. (Note that these types of nondeterminism are not considered good entropy sources according to the cryptography standard, but the presence of these types of nondeterminisms nevertheless poses a big threat to maintaining replica consistency.) The Byzantine fault tolerance framework must be able to handle various nondeterministic applications in a systematic and efficient manner.

Another interesting research issue is regarding the performance of Byzantine fault tolerant applications. Besides the communication cost for achieving Byzantine fault tolerance, digital signing operations are computationally expensive. In a recent study (Chen, Hsiao, & Chen, 2004), it is shown that the cost of cryptographic operations can be reduced by using short secret keys of the elliptic curve cryptosystem and by enabling simultaneous signing.

CONCLUSION

In this article, we pointed out the threats to online gaming applications and presented two strategies that can be used to build secure and dependable online gaming applications. These strategies not only seek out solutions for gathering entropy to seed the PRNG used in such applications, but also intend to eliminate malicious intrusions to protect the seed and to maintain replica consistency. By applying these techniques, online gaming applications can ensure their service integrity (both the service providers and the innocent players are protected) and guarantee high availability despite the presence of Byzantine faults. Finally, we outlined some open research issues in this field.

KEY TERMS

Dependable System: A dependable system is one that is trustworthy to its users. It requires that the system be highly available (to legitimate users) while ensuring a high degree of service integrity.

Digital Signature: A digital signature aims to serve the same purposes as a real-world signature. A sound digital signature ensures that the sender of the digital signature can be authenticated, the sender cannot later repudiate that she of he has sent the signed message, and a receiver cannot forge a digital signature (without being detected).

Entropy: Entropy is a metric used to evaluate and describe the amount of randomness associated with a random variable.

Entropy Combination: It is the operation that combines a number of entropy shares into one. The combination is usually achieved by using the XOR operator. Entropy combination is an effective defense against adversaries that substitute a random value with a predictable one. The combined entropy is often of higher quality than each individual share.

Entropy Extraction: This is the operation that extracts entropy from a random variable (referred to as the entropy source). Entropy can be extracted using both software- and hardware-based methods.

Pseudorandom Number Generator (PRNG): A PRNG is a computer algorithm used to produce a sequence of pseudorandom numbers. It must be initialized by a seed number and can be reseeded prior to each run. The numbers produced by a PRNG are not truly random. Given the same seed, a PRNG will generate the same sequence of numbers.

Threshold Digital Signature: In the (k, n) threshold digital signature scheme, a private key is divided into n shares, each owned by a player. A valid threshold digital signature can be produced if k players combine their shares. However, no valid signature can be generated by fewer than k players. Each player uses its private key share to generate a partial signature on a message, and these partial signatures can be combined into a threshold signature on the message. The threshold signature can be verified using the public key corresponding to the divided private key.

Building Wireless Grids

Marlyn Kemper Littman
Nova Southeastern University, USA

INTRODUCTION

The accelerating implementation and remarkable popularity of sophisticated mobile devices, including notebook computers, cellular phones, sensors, cameras, portable GPS (Global Positioning System) receivers, and wireless handhelds such as PDAs (personal digital assistants), contribute to development of wireless grids. **Wireless grids** feature a flexible and adaptable cyberinfrastructure that supports coordinated and economical access to distributed resources and next-generation applications and services.

Generally, **wireless grids** are classified as ad hoc or standalone, and mixed-mode or hybrid. Ad hoc **wireless grids** enable diverse applications via MANETs (mobile ad hoc networks) and consist of mobile devices that operate in infrastructureless environments. Mobile network nodes process tasks and provide best effort delivery service to support wireless grid applications (Lima, Gomes, Ziviani, Endler, Soares, & Schulze, 2005). In the healthcare environment, for example, ad hoc **wireless grids** equipped with sensors monitor the status of critically ill patients and track the location of hospital equipment and supplies. Hybrid or mixed-mode **wireless grids** augment and extend the capabilities of wireline grids to remote locations; facilitate the shared use of resources and processing power; and consist of components ranging from supercomputers to distributed or edge devices such as very small satellite aperture terminals (VSATs) (Harrison & Taylor, 2006).

This chapter features an introduction to factors contributing to the development of present-day **wireless grids**. Wireless grid technical fundamentals, specifications, and operations are examined. Security challenges associated with safeguarding wireless grids are reviewed. Finally, the distinctive characteristics of innovative wireless grid initiatives are explored and research trends in the wireless grid space are described.

BACKGROUND

Established by **virtual organization**s (**VO**s), **wireline grids** facilitate trusted resource exchange in environments that cross multiple administrative domains. **Wireline grids** consist of substantial collections of shared networked components and resources for enabling reliable and dependable multimedia delivery; implementation of sophisticated bandwidth-intensive applications; scientific discovery in fields that include high-energy physics, medicine, astronomy, and bioinformatics; and e-collaborative problem resolution (Littman, 2006).

Wireline grids increasingly employ a high-performance **DWDM (Dense Wavelength Division Multiplexing)** cyberinfrastructure that supports wavelengths of light, or lambdas, on demand to facilitate reliable and dependable access to computational simulations, metadata repositories, large-scale storage systems, and clusters of supercomputers (Littman, 2006). Also called lambda-grids, **DWDM** grids, such as the TeraGrid, enable terabit and petabit transmission rates; teraflops and petaflops of compute power; seamless connectivity to feature-rich resources; and extendible grid and inter-grid services across multi-institutional distributed environments.

The popularity of multifunctional 3G (third generation) wireless technologies and devices and demand for anytime and anywhere access to grid resources are major factors contributing to design and implementation of **wireless grids** by **mobile dynamic virtual organizations (MDVOs)**. **MDVOs** are extensions of **VOs** that facilitate wireless grid deployment in infrastructureless and hybrid wireless environments. Wireless grid operations are dependent on network node mobility (Waldburger, Moraiu, Racz, Jahnert, Wesner, & Stiller, 2006). As a consequence, wireless grids are not as reliable as wireline grids in seamlessly and dependably supporting multimedia applications and services.

Wireless grid transmissions are impaired by signal fading, packet delay, and the absence of bandwidth to support applications requiring quality of service (QoS) guarantees. The performance of **wireless grids** is also affected by network node power consumption, the quality of the wireless medium, and the effectiveness of wireless grid security solutions. To counter these limitations, toolkits such **as GT4** (**Globus Toolkit version 4**); security mechanisms providing services such as authentication, authorization, data confidentiality, and data integrity; mobile agent systems; and WSs (Web Services) are utilized in building dependable wireless grid solutions.

CONSTRUCTING WIRELESS GRIDS

With **MDVO** implementation of wireless grids in new geographic environments, the numbers of wireless devices

and individuals that are served by wireless grids increase dramatically. A widely used toolkit supporting wireline and wireless grid implementations, **GT4** facilitates resource allocation, detection of connectivity, and location of specific resources in response to user requests (Littman, 2006). **GT4** also enables integration of wireless devices, applications, and services with low bandwidth and variable computational power into hybrid grid configurations. By working in conjunction with middleware architecture such as SIGNAL (Scalable Intergrid Network Adaptation Layers) and **GT4,** mobile devices in hybrid grid environments can support P2P (peer-to-peer) operations that enable each peer or node to function as a client and content provider. P2P implementations in wireless grid environments also aid in resolving problems associated with resource availability and battery power constraints.

Based on P2P, the P2P Discovery Protocol (P2PDP) coordinates distribution of grid tasks via MoGrid (mobility grid) architecture. MoGrid devices function as task processing nodes and interfaces to wireline grids (Lima et al., 2005). P2PDP separates requests for grid processes, such as file exchange and job execution, into a series of tasks that are processed concurrently, sequentially, or independently.

As a consequence of difficulties in enabling disconnected processes and asynchronous communications in wireless grid environments and the need to minimize the amount of energy consumed by each application, mobile agent technology is emerging as an effective enabler of reliable job execution in wireless grids (Zhang & Lin, 2007). In addition to supporting distributed applications, mobile agent architecture provides a framework for completion of reliable and dependable grid processes.

As an example, the Mobile Agent-based Collaborative Virtual Environment (MACVE) features agile mobile agent architecture for enabling 3-D (three-dimensional) applications in shared large-scale virtual environments. Distinguished by their ability to migrate autonomously among geographically distributed nodes to facilitate resource discovery, resource scheduling, and node monitoring, MACVE mobile agents also optimize grid performance and resource utilization across multiple **MDVO** domains (Zhang & Lin, 2007). Additionally, MACVE mobile agents also support development and management of VRML (Virtual Reality Modeling Language) 3-D applications, and enable load balancing and security services in wireless grid environments (Lin, Neo, Zhang, Huang, & Gay, 2007).

Another option for building wireless grid operations and facilitating dependable access to multimedia resources is utilization of network proxies that support localized storage and computational services. For example, MAPGrid (Mobile Applications on Grids) employs network proxies to ensure resource availability in wireline grid nodes that are situated near mobile devices. Proxies offload tasks and support intermittent proactive data caching to ensure the availability of resources for wireless grid multimedia applications (Huang & Venkatasubramians, 2007).

Wireless Grid Operations

Ad hoc and mixed-mode wireless grid functions are dependent on signal strength, protocols, and middleware for supporting dependable operations and performance (Li, Sun, & Ifeachor, 2005). Ad hoc **wireless grids** supported by a wireless cyberinfrastructure enable data transport between network nodes that are within transmission range of each other. Wireless links are temporary since grid nodes are limited in physical size, storage capabilities, and available bandwidth. As a consequence, algorithms and protocols, such as AODV (Ad Hoc Distance Vector) are used to facilitate dynamic routing between wireless grid nodes and support ad hoc grid functions. In contrast to ad hoc wireless grids, hybrid **wireless grids** are scalable and capable of providing faster transmission rates.

Problems in wireless grid operations typically stem from poor signal strength and cyberinfrastructure instability. Since mobile nodes join and leave wireless grids randomly, intermediate nodes also relay data (Li et al., 2005). Information exchange among mobile devices on **wireless grids** are adversely impacted by latency, inadequate numbers of nodes to support transmissions, multipath signal distortion, battery degradation, and fast handoffs. Inconsistencies in the power of wireless devices and lack of assurance of resource availability also contribute to delays in processing wireless grid applications (2005.) To counter these constraints, mobile agents and P2P (peer-to-peer) paradigms are utilized to foster robust, secure, and extendible wireless grid solutions.

Wireless Grid Specifications

WS (Web service) specifications consist of collections of open standards and protocols that support wireline and wireless grid construction and implementation of wireless grid applications. Developed by the Global Grid Forum (GGF), the **Open Grid Services Architecture** (**OGSA**) is based on a suite of WS standards for optimizing resource integration and resource management in evolving wireless grid environments. **OGSA** also promotes implementation of loosely coupled interactive services to facilitate grid operations, and defines common interfaces to support wide-scale grid initiatives (Harrison & Taylor, 2006).

Core components and design elements initially defined for **OGSA** are now integrated in the **Open Grid Services Infrastructure (OGSI).** The WS Resource Framework (WSRF) builds on OGSI functions originally developed by the GGF. **OGSI** specifies requirements for interface development, resource scheduling, and resource management to optimize wireline grid operations. Based on OGSI and mobile agent technology, Mobile **OGSI**.NET enables

integration of wireless devices into conventional wireline grid configurations by caching data to counter intermittent grid connectivity and, thereby, facilitating implementation of grid applications on resource-constrained wireless devices (Chu & Humphrey, 2004).

In addition to distributing tasks to mobile agents, MGSs (Mobile Grid Services) coordinate mobile agent communications and management. JADE (Java Agent Development Framework) and **GT4** provide a framework for supporting MGSs. MGSs also extend static grid services to dynamic environments and support resource control and accounting operations; coordination of mobile agent communications and management; and identification of improper resource utilization resulting from cyberincursions (Wong & Ng, 2006). The J2ME (Java2 Platform for Micro Edition) specifies standard grid APIs (application programming interfaces) for integrating wireless devices into wireline grid solutions.

A next-generation lightweight middleware toolkit, MAGE (Modular and Adaptable Grid Environment) utilizes reconfigurable component architecture with unified management interfaces to support scalable and adaptable grid operations in wireless environments as well (Kwon, Choi, & Choo, 2006). Featuring a service-oriented architecture (SOA) with customizable components, MAGE facilitates deployment of reconfigurable wireless grid operations including the removal, modification, and addition of grid components. SOA also enables wireless grid scalability and the interoperability of wireline and wireless grid applications.

In SP2A (Service-Oriented Peer-to-Peer Architecture) grids, resources are accessed through RPS (Resource Provision Services) (Amoretti, Zanichelli, & Conte, 2006). The RPS framework features a Java API that supports JXTA (juxtaposition) for P2P routing, WS deployment, and OWL-S (WSs-Ontology Web Language) utilization (Jabisetti & Lee, 2005). A semantic markup language for WSs, OWL-S establishes semantic service descriptions for autonomous WS operations, such as resource discovery, and facilitates WS execution in diverse grid environments. SP2A also defines modules for building service-oriented peers (SOPs) to foster resource sharing in **wireless grids**. Mobile agents built with the Java toolkit JGRIM (Java Generalized Reactive Intelligent Mobility) enable development of security services and service-oriented grid (SOG) applications that foster resource discovery, resource brokering, and application execution.

Wireless Grids in Action

Akogrimo (Access to Knowledge through the Grid in a Mobile World), GROW-Net (Grid Reconfigurable Optical Wireless Network), FWGrid (Fast Wired And Wireless Grid), and LOOKING (Laboratory for the Ocean Observatory Knowledge Integration Grid) are examples of innovative **wireless grids** in actions. The capabilities, applications, and services supported by these initiatives are examined in this segment.

Developed by a **MVDO**, **Akogrimo** facilitates next-generation wireless grid implementations by leveraging resources available via a large base of mobile devices across the European Union (Waldburger et al., 2006). **Akogrimo** utilizes 3G wireless technologies; IPv6 (Internet Protocol Version 6); mobile Internet architecture; and knowledge-related and semantics-driven **WSs** to prototype next-generation wireless grids. **Akogrimo** also enables e-learning, e-health, and disaster recovery applications; teleworking in the automotive, aerospace, and engineering industries; and development of privacy, security, and trusted services in the wireless grid environments.

GROW-Net features a hybrid wireline and wireless cyberinfrastructure consisting of a **DWDM** network backbone that works in concert with wireless mesh networks (WMNs) (Shaw, Gutierrez, Kim, Cheng, Wong, Yen, et al., 2006). A flexible solution for extending a wireline grid cyberinfrastructure to distributed locations, **GROW-NET** WMNs consist of static and mobile network nodes; feature multiple wireless access points; and use adaptive routing protocols and algorithms to optimize network performance.

Established by the University of California at San Diego, **FWGrid** supports development of grid middleware, distributed applications architecture, and a hybrid cyberinfrastructure to support current and emerging grid applications. The wireless component of the cyberinfrastructure facilitates access to video and images collected from wireless devices at rates ranging from 100 Mbps (megabits per second) to 1 Gbps (gigabit per second). The wired cyberinfrastructure component supports transmissions at rates ranging from 10 Gbps to 100 Gbps and features distributed computational clusters with teraflops of computational capabilities (McKnight, Howison, & Bradner, 2004).

Built on a mixed-mode wireline and wireless cyberinfrastructure, **LOOKING** interlinks ocean observatories into a knowledge grid that enables scientists to monitor oceanographic phenomena in real time. Data collected by undersea equipment, including motion, acoustical, biological, and optical sensors and sophisticated instrumentation, are transmitted to wireline grids at onshore institutions for analysis and assessment (Geer, 2006).

Research findings enable scientists to predict sea conditions; forecast impending natural disasters such as tsunamis; contain wildfires; and provide disaster recovery services. **LOOKING** employs a SOA and the WSRF to enable instrumentation management and support an array of applications across the distributed system of ocean observatories (Geer, 2006).

LOOKING functions comply with IEEE (Institute of Electrical and Electronics Engineers) 1451 wireless sensor interface standards (Geer, 2006). These specifications

establish uniform APIs that are independent of underlying physical media for enabling deployment of standards-compliant sensors in diverse wireless configurations including IEEE 802.11 WLANs (wireless LANs) and IEEE 802.15.1 WPANs (wireless personal area networks).

Wireless Grid Security

Mobile devices that form wireless grids are at risk to cyberincursions as a consequence of resource limitations, unreliable and lost connections, wireless link instability, and software incompatibilities. As with wireline grids, wireless grids enable access to distributed resources in shared, interconnected, and distributed computing environments, thereby, placing the security of these resources at risk (Littman, 2006). Therefore, **MDVOs** establishing wireless grids conduct risk assessments to determine vulnerabilities and support development of security policies, procedures, and mechanisms to safeguard the integrity of wireless grid operations. **MDVOs** also are responsible for promoting the use of encryption protocols such as the Lightweight Security Protocol (LiSP) (Park & Shin, 2004). LiSP features reliable cryptographic key distribution, a stream cipher for fast processing, and cryptographic hash algorithms to generate new keys to facilitate secure, pervasive, and reliable access to shared resources.

RESEARCH TRENDS

Advances in wireless technology contribute to development of wireless grids that support access to the rich mix of resources and services available in static or wired and wireless grids. For instance, small-scale **wireless grids,** consisting of motes or miniaturized transceivers that provide dynamic data on pollution levels, seismic activity, and changes in oceanic environment, are in development. In hospitals, small-scale wireless grids utilize sensors to monitor patients with conditions that include sleep apnea and congestive heart failure (Gaynor, Moulton, Welsh, LaCombe, Rowan, & Wynne, 2004). By contrast, large-scale grids, such as the Southern California Integrated GPS Network (SIGN) and the GPS Earth Observation Network System (GEONET), feature earth stations that generate terabits of data on applications that measure water quality and monitor air pollution (Aydin, Zhigang, Pierce, Bock, & Fox, 2007).

Formed by vehicles equipped with 3G wireless devices and technologies, vehicle-to-vehicle communications grids (VGrids) operate in conjunction with VANETs (vehicle ad hoc networks) (Gerla, Zhou, Lee, Soldo, Lee, & Marfia, 2006). VANETs are next-generation networks that support content sharing and P2P applications in VGrid environments. Designed to save lives and facilitate distributed traffic management services, VGrids provide real-time access to information on vehicular collisions, emergency evacuations, and disaster recovery services.

Approaches for enabling first responders to use **wireless grids** for emergency services in response to artificial disasters, such as terrorist attacks and natural disasters including floods, typhoons, hurricanes, and volcanic explosions, are in development as well. Capabilities of **wireless grids,** such as community resource grids (CRGs) in supporting medical assistance and seamless access to critical healthcare resources, are evaluated in testbed implementations.

CONCLUSION

The accelerating implementation of **wireless grids** reflects the popularity of mobile devices such as PDAs, smart phones, and laptops; the widespread adoption and convergence of wireless and cellular technologies; and demand for connectivity to wireless grid resources at any time and from any place. Challenges associated with wireless grid implementations include overcoming the adverse impact of atmospheric disturbances; reduction in power consumption, bandwidth and response time constraints; and limitations associated with the use of small wireless devices. Current research in the wireless grid space involves development of mechanisms for enabling dependable QoS guarantees; WMNs to support wireline and wireless grid applications; and policies and procedures to facilitate seamless, secure, and reliable applications and functions in ad hoc or infrastructureless and mixed-mode or hybrid wireless grid environments

KEY TERMS

Cyberinfrastructure: Advanced network platform that supports wireless and/or wireline grid research initiatives, applications, and experimentation. Used by the National Science Foundation (NSF) to describe next-generation grid initiatives.

Dense Wavelength Division Multiplexing (DWDM): Provides flexible and dynamic optical lightpaths on-demand to support extendible, scaleable, and reliable wireline grid and intergrid services and supports access to next-generation applications requiring high-bandwidth connections.

Global Toolkit Version 4 (GT4): A grid toolkit that supports grid interoperability and works in concert with the Web Services Resource Framework (WSRF).

Lambda: Lightpath or wavelength of light that interlinks two network endpoints.

Network node: An endpoint or redistribution point for data transport.

Web Services (WSs): Collections of protocols and open standards for enabling the convergence of WSs and wireless and/or wireline grid operations.

Web Services Description Language (WSDL): Defines an XML (extensible markup language) grammar for describing network services as collections of network endpoints that enable information exchange.

Wireless Grid: A cyberinfrastructure that interconnects wireless devices in ad hoc or infrastructureless and hybrid or mixed-mode wireline and wireless grid configurations.

Business Informatization Level

INTRODUCTION

IT diffusion is central to the new economy and is reflected in a process of informatization of society and businesses. Although initially coined to represent the diffusion and adoption of information technology (IT) in all levels of society, the term informatization is also employed to represent the use of information technology resources in organizations. Weissbach (2003), for instance, defines *informatization* as being the process of gradual and increasing application of "planned and systematic use of IT penetrating the organization's functions". As pointed out by Lim (2001), the evaluation of an organization's *Informatization Level (IL)* is an important managerial concern. The author also points out the difficulties associated with this evaluation, stating that "this is not a simple problem because informatization includes many intangible factors such as the quality of information and the organization's culture". The purpose of evaluating a company's IL is to provide information for the organization to improve precisely its informatization level. It is also a means of benchmarking the efficacy and efficiency of IT investments in order to set up the baseline for improvement.

This topic depicts a measurement method for the IL of companies and shows results of its application in 830 Brazilian industries (Zwicker, Vidal, & Souza, 2005). The development of this method was based on the principle that IT results in companies are not obtained merely through investments and the implementation of systems but rather through its proper use in business processes. The proposed method extends the informatization dimensions proposed by Lim (2001), using the process-based view of the IT business value creation model proposed by Soh and Markus (1995) and the concept of "information systems coverage" proposed by Ravarini, Tagliavini, Buonanno, and Sciuto (2002).

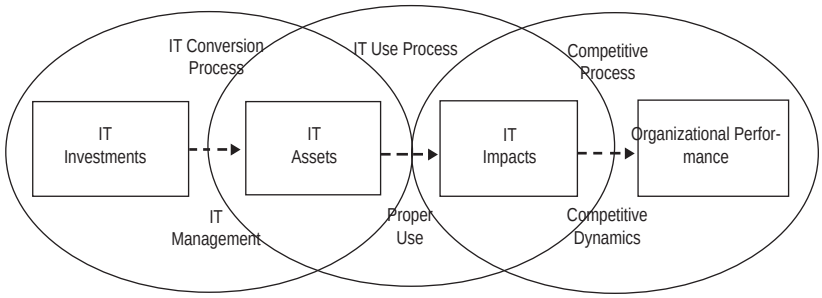
BACKGROUND

Accordingly to Hu and Quan (2005), there are four main visions in studies focusing the creation of *IT business value* through the use of the technology: the macroeconomic view, that believes that IT creates excess returns over other types of capital investments; the process-based view that believes that IT investments create competitive advantages by improving operational efficiency of intermediary processes; the resource-based view, that believes that IT investments create sustainable competitive advantage via unique, immobile, and path-dependent strategic resources and capabilities; and the digital option view that argues that IT investment creates values by giving options and flexibility for firms. Since the study is focused on the organizational level, the second and third views (process- and resource-based) are deemed more adequate.

Soh and Markus (1995) present a model that synthesizes concepts of other studies that also incorporate the process-based view (Grabowski & Lee, 1993; Lucas, 1993; Markus & Soh, 1993). Figure 1 represents the sequence of events and results associated to the process of obtaining organizational benefits from IT investments, according to this model. To obtain an improvement in the organization's performance by means of IT requires that IT impacts occur in the intermediary processes of the organization. However, the fact that impacts from intermediary processes were obtained is not sufficient to obtain organizational performance improvements, since this depends on external factors, such as the economic context and competition. These aspects comprise the "competitive process" of the model and must consider the requirements of the competitive dynamic in which the company is inserted.

On the other hand, to obtain the impacts of IT on the organization's processes requires that IT assets be available, that is: systems in operation, implemented infrastructure and people with suitable knowledge concerning the technology and its possibilities. IT assets constitute a combination of IT resources, applications, and the qualification of people

Figure 1. IT and business value creation (Soh & Markus, 1995)



(from the IT area and users). Human resources also include the partnership relationship with the users. Thus, IT assets are divided into tangible assets (hardware, software) and intangible assets (knowledge, relationship).

It is worth noting that the mere existence of IT assets does not necessarily imply that IT impacts will be obtained. It is necessary to consider the actual use of these assets, which comprises the "process of IT use", and meeting the requirements of "proper use" of these assets. The proper use refers to the effective application of the IT assets in the organization's activities and processes. In considering the appropriate use of IT, one must take into account: its extent (scope of business tasks performed with IT support), its intensity (volume of use), and the level of IT dependence that is imposed to the company.

Finally, the consolidation of IT assets calls for a compatible level of IT investments. However, the investments do not assure that effective assets will be obtained, since these investments can be made inappropriately. Weill (1992) defines the capacity of converting IT investments into IT assets as the "conversion effectiveness" and states that this results from the aspects of the organizational atmosphere that influence IT, the quality of IT management, and the company's commitment to IT. The effective transformation of IT investments into IT assets constitutes the *"process of IT conversion"* which, to be effective, broadly speaking, requires meeting IT management requirements.

INFORMATIZATION LEVEL MODEL

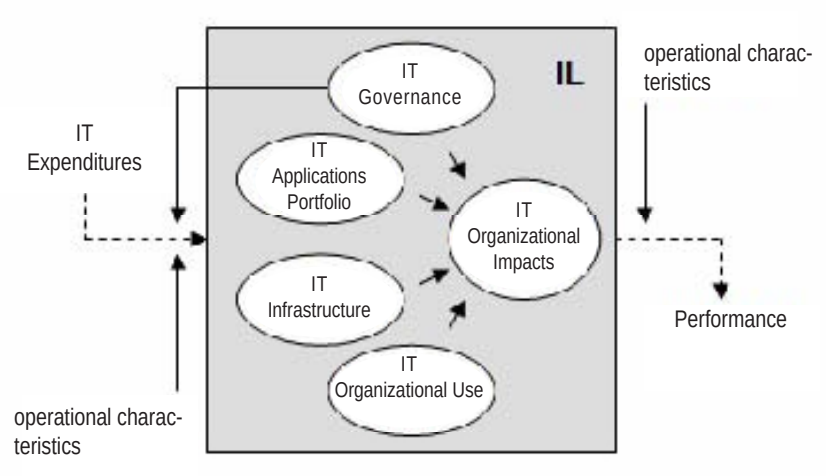
Based on the previous discussion, the concept of informatization, its dimensions, and the IL model adopted are established. Informatization can be defined as the managed process by which an organization continuously expands its IT assets and extends and deepens their appropriate use, aimed at improving the effectiveness and performance of its activities and processes. The five dimensions proposed for the IL measure in organizations are: (1) *IT Infrastructure*, related to fundamental IT assets; (2) *IT Applications Portfolio*, related to tangible information systems resources and intangible aspects of these resources; (3) *IT Organizational Use*, related to the extent and intensity of IT use in the organization; (4) *IT Governance*, related to the management of IT resources, the management of its use, and the planning and development of IT resources aligned with the organization's businesses; (5) *IT Organizational Impacts*, related to effectiveness and performance benefits for organizational activities and processes, achieved through the use of IT. The dimensions appear in the IL model at Figure 2.

In Figure 2, IT expenditures correspond to the sum of investments in IT and expenses with IT (IT expenses are related to monthly or periodic expenses like payroll, maintenance, and telecommunications). They are a necessary although insufficient condition for achieving certain levels of informatization, as indicated by the dotted arrow to the left of the figure. A better IL can contribute to the improvement of the organization's performance, although not necessarily so, as indicated by the dotted arrow to the right. The operational characteristics of the enterprise (for example, its size and the sector in which it operates) appear mediating the relationships between the IT expenditures, the IL, and the organization's performance. The characteristics of IT governance also interfere in the conversion of IT expenditures into a certain level of informatization. The dimensions "IT organizational use", "IT governance", "IT infrastructure", and "IT applications portfolio" work in combination, for the obtainment of "IT organizational impacts". The set of these five dimensions comprise the measurement structure proposed for the IL.

INFORMATIZATION LEVEL MEASUREMENT METHOD

The study gathered data from a sample of 830 Brazilian industrial companies that originated 66 indicator variables

Figure 2. Informatization level model



used to compute the IL. For each dimension, the data said respect to the following aspects (subdimensions):

IT Infrastructure

Infrastructure services, internal connectivity, and external connectivity were assessed through indicators like PCs by employee, number of connected PCs, Internet connection speed, and security strategies (Weill & Broadbent, 1998). *IT department infrastructure* was based upon the existence of a formal IT area, existence of an IT manager, number of IT tasks carried out, and indicators like IT personnel by PC (Lim, 2001).

IT Applications Portfolio

Systems integration was measured along a scale going from use of spreadsheets to fully-integrated ERP systems for each area of application. *Systems technical quality* was computed starting from the technical quality of systems in each area of application (sales, marketing, production, procurement, management, finance, and other IT applications).

IT Organizational Use

Extension of use and other applications use were assessed using the concept of "information systems coverage" (Ravarini et al., 2002). Several activities were defined for each area of application and the extension of use was measured considering the percentage of these activities held with information systems support. The same was done with a group of specific applications (Internet, CRM, SCM, CAD, BI), representing "other applications". *Dependency of use* was examined through the degree of dependency of the enterprise on the information systems in each of the considered activities. *Systems adequacy* was assessed through respondents' perception of the degree of adequacy of these systems to the activities they support.

IT Governance

IT planning and control used questions assessing the respondents' perception about IT strategic alignment and control of IT activities. *Users and executives participation and knowledge* used questions assessing the respondents' perception about the degree of participation of users and executives in IT planning and their knowledge about IT and systems in use in the company.

IT Organizational Impacts

Impacts of traditional applications and impacts of other applications were considered through questions assessing IT impacts on the organization (Mahmood & Soon, 1991). The questions were focused on the following items: sales increase, cost reduction, quality increase of products and services, delivery time reduction, and impacts on processes specific to each area of application and to the group of other applications (Internet, CRM, SCM, CAD, BI).

The IL and its dimensions are variables that are not directly observable. They constitute the latent variables of a structural equation model. The IL is modeled as a third order variable, measured by means of second order variables, which are measured by means of first order variables that

are finally measured trough indicators constructed from the observed variables. It was proposed as an initial model for IL and through the use of structural equation modeling (SEM) emerged the final model presented at Figure 3. The model was tested by means of a confirmatory factorial analysis (CFA), which derived the factorial loads shown in the figure and that confirms the appropriateness of the used indicators to the structure of this IL's model. The factorial loads reflect how well a specific dimension or subdimension reflects the IL.

The computation of the IL for each company is done starting from the factorial scores of each company calculated with SEM, and the obtained value is transformed into a scale from 0 to 100, whose limits are obtained from the minimum and maximum values of IL's obtained for the sample. Outliers are previously analyzed and handled. Moreover, for each one of the dimensions is obtained a specific value, also in the interval from 0 to 100 and that reflects the position of the company according to this dimension. The factorial scores of each company measure the relative position of the company in each one of these constructs. Values that correspond to aggregates, for example, aggregates by dimension, size, or total, are computed using the simple average of the companies ILs that compose the aggregate.

Figure 4 shows total IL average value along the companies' size. As was expected, the informatization level grows with size, staying the micro and small-size companies below the general average and the medium and large-size companies above the general average. The general average equals 51.0. The IL can also be analyzed observing its components in an individualized way, which is analyzing separately the several dimensions of the indicator. Figure 4 represents the averages for each company size, along the dimensions that compounds the IL. The dimension values accompany IL's general evolution, growing with the increase of the company size. The dimension that presents the smallest proportional increase along company size is the governance dimension. This may appear strange because the smaller companies tend to not own a formalized IT area, and therefore, the associate indicator for governance should be inexpressive in the smaller companies. However, the executives of the smaller companies are nearer to the computerization process and consequently tend to directly "care for" the aspects related to this inquiry.

However, the fact that IL of bigger companies is higher does not mean that there are no micro- or small-size companies with high IL. Figure 5 shows the IL distribution for each company size along 4 ranges: *low* with IL between 1 and 25; *regular* with IL between 26 and 50; *average* with IL between 51 and 75; and *high* with IL between 76 and 100. From this data, we can conclude, for example, that 3.3% of the micro and 15.5% of the small size companies hold a high informatization level.

Figure 3. CFA Model for the IL with standardized factor loadings

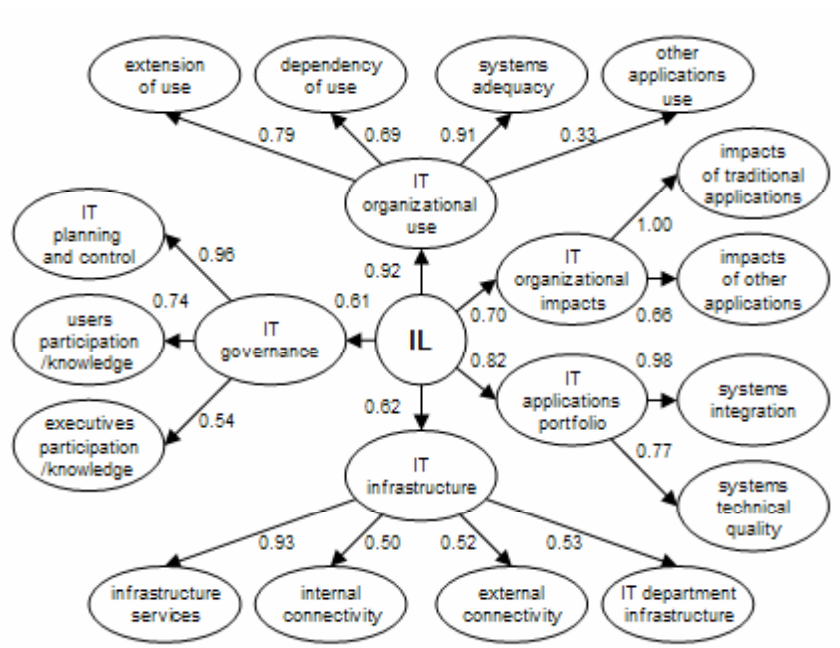


Figure 4. IL averages of each dimension and total per company size

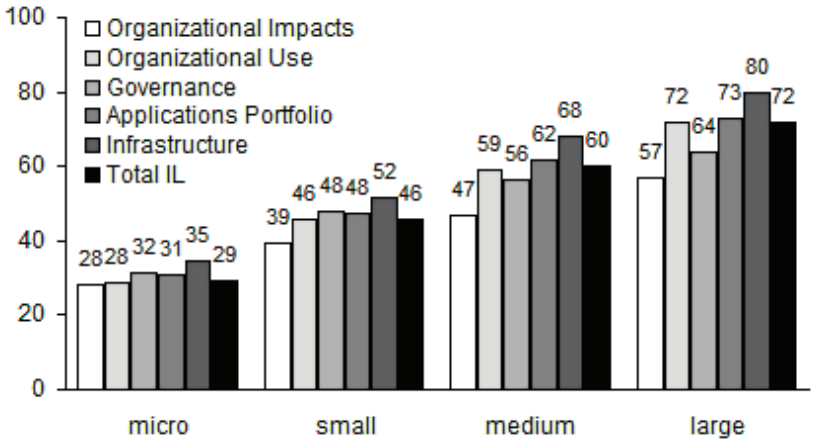

Figure 5. IL distribution per company size

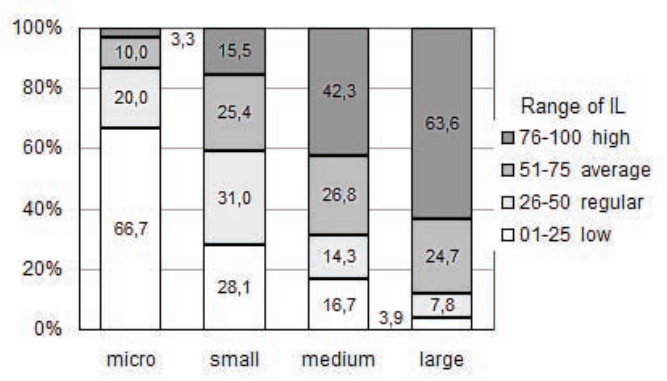

Figure 5 show that there still exists opportunity for IT overall improvements especially in micro-, small- and medium-size companies. The data of the study also showed that the micro- and small-size companies with high IL obtained that result investing proportionally less into IT than the large-size companies with similar IL. This occurs due to two factors. First, the sophistication of the technology needed for the computerization of large-size companies is greater, which conducts to more elevated investments and expenses. Second, at small-size companies, it is possible to reach more rapidly a greater percentage of employees along the computerization process because the number of persons in these companies is smaller. Also is conceivable that the computerization of micro- and small-size companies, in function of the relative volume of jobs they offer, contributes decisively to the "digital inclusion" of the whole society.

FUTURE TRENDS

Future perspectives include converting the IL measure into an auto-evaluation and learning tool for the companies and deepening the study of the relationship of the IL with other aspects of IT use in the companies, for example, (a) the relationship between IL and company size; (b) the relationship between IL and company's business process complexity; (c) the relationship between IL and IT investments; (d) the relationship between company size and the conversion capacity of IT expenditures into a greater IL.

These relationships refer to the question of IT adoption and the results that IT can and should propitiate. In this sense, the gathered data evidenced that the larger is the IL; the larger is the recognized impact to the performance of the companies. This perception is very clear in the case of the

larger companies because they own more people involved with IT use and maintain relationships with other companies through the technology. At a lesser degree, the same result is verified at the smaller companies. This corroborates Premkumar (2003) which establishes that the utility of the technology increases in the proportion at which more people and companies adopt it, therefore, network externalities also condition the increment of IT use and its success. This also agrees with McKeen and Smith (1993), which show that greater informatization levels reinforce the relation between IT use and the performance of the company. From the gathered data also was possible to recognize a "stage effect"; that is, to achieve significant IT benefits, it is necessary that a certain IT investments level, and therefore an informatization level, must be previously reached.

CONCLUSION

The IL includes the aspects considered relevant and that involve the intensity and quality of IT use in the companies. The IL is supported by the theory of IT use in organizations particularly on the value creation model for the businesses through information technology. The development of the measurement was performed seeking to fulfill the requirements of reliability and internal and external validity. Concerning the reliability and internal validity, we obtained adequate fit values, coherent values for the model's coefficients and adequate values for the reliability indexes. Also for external validity, the obtained results allowed comparisons to be made between companies of the same size, between different sizes and between different industrial sectors, producing results that are in line with what was expected.

This suggests that the rationale behind the IL can be generalised, and IL's computation can become a standard measurement methodology to evaluate IT use. Objectively, the IL measurement may contribute toward the identification and analysis of factors that can support companies to reach their proper informatization level. An indicator of the kind of IL can contribute to informatization processes as it supplies an auto-evaluation instrument and more including comparison parameters for the companies. The IL also can supply subsidies for other researches in the scope of the real value of the information technology and of the relation of the use of this technology with the issue of the productivity of the companies.

KEY TERMS

Information Systems Coverage: Extension of use, degree of dependency and adequacy of the information systems that a company owns.

Informatization: Managed process by which an organization continuously expands its IT assets and extends and deepens their appropriate use.

Informatization Level: An assessment of the effectiveness of the organizational use of IT.

Informatization Level Dimension: Conjunct of relevant aspects that participate in the informatization process and that are in some way related.

Informatization Level Model: Elements and relationships that structure the informatization level of a company.

IT Business Value Creation: The process of obtaining organizational benefits from IT investments.

IT Conversion Effectiveness: The capacity of converting IT investments into IT assets.

Business IT Systems Implementation

Călin Gurău
GSCM – Montpellier Business School, France

INTRODUCTION

The traditional channels of marketing are gradually being transformed by, or assimilated into, the global network represented by the Internet and modern information technology (IT) applications. Unfortunately, in most cases, the current IT systems are not fluid and dynamic enough to cope with ubiquitous customers who can contact the firm through a multitude of communication channels, such as mobile phones, Internet, or fax. The effective implementation of modern marketing strategies depends on the effective use of IT systems and procedures.

Internet-based technology can facilitate information dissemination, file transformation, data mining, and processing (Roberts, Raymond, & Hazard, 2005), which creates opportunities for the development and implementation of efficient *customer relationship management systems*. On the other hand, the new information technologies can also be used to increase the employees' satisfaction and productivity (Dorgan, 2003; Eichorn, 2004). Thus, the implementation and use of an efficient IT system for business and marketing activities becomes a fundamental task, which should be managed jointly by business specialists and IT professionals (Wierenga & Van Bruggen, 2000).

Unfortunately, these opportunities are hindered by many challenges at organisational or managerial levels, such as defining and restructuring the internal and the external sources of information, centralising the marketing database, and integrating the IT and marketing procedures at operational level.

Considering all these issues this paper attempts, on the basis of secondary data, to provide an overview of the main issues related with the implementation of IT systems in business organisations and the challenges related with the integration between information technology and marketing systems.

After a brief presentation of the previous research on this topic, the paper presents the stages of a gradual integration of IT systems in a business organisation and proposes a theoretical model

BACKGROUND

Considered a functional perspective, the main benefits of using modern IT systems for marketing operations are developed during three major phases: (1) automation, (2) information, and (3) transformation (Dedrick, Gurbaxani, & Kraemer, 2003).

1. **The First Stage:** IT systems are primarily used for automating manual systems of data recording and retrieving (Scott, Rosenbaum, & Jackson, 2003; Speier & Venkatesh, 2002). This level is particularly useful for improving the efficiency of routines, or simple tactical activities (Eli, Sundaram, & Chin, 2002).
2. **The Second Stage—Information:** The useful data are transformed through processing into relevant information for marketing operations and procedures (Ranchhod & Gurău, 2004). The information stage integrates the automated procedures developed in the previous phase, the data collected in the automation phase being scrutinised, selected, processed, and converted into business intelligence (information).
3. **The Third Stage—Transformation:** The company starts to adapt and use knowledge in order to enhance its strategic positioning. In this stage, the company will transform itself into a market-oriented, proactive organisation that uses IT systems in an integrated way to increase the effectiveness of every marketing operation (Roberts et al., 2005).

Many authors have emphasised the importance of IT systems for developing efficient *customer relationship management strategies* (Agrawal, 2004; Goldsmith 2004; Gurău, 2003; O'Malley & Mitussis, 2002; Plakoyiannaki & Tzokas, 2002; Roberts et al., 2005), and for employees' satisfaction (Dorgan, 2003; Eichorn, 2004). The level of IT integration in the organisational business structures and strategies is directly related with company's performance and profitability (Dedrick et al., 2003; Eichorn, 2004).

Unfortunately, in many organisations, the implementation of modern IT systems is a major source of tensions and problems, as many recent studies clearly demonstrate:

- The main reason for most B2B project failures is the incapacity of partners to implement a well-integrated technology infrastructure to support business processes (Meehan, 2002).
- A study of New Zealand corporations showed major difficulties in achieving the integration of business and

IT, both in the public and private sector (Navigate and Systems Planning Associates, 2002).

- A survey published by CFO Publishing Group indicated that 44% of chief financial officers indicate a weak alignment between IT and business strategies (Hoffman, 2003).
- An online survey showed that 91% of IT managers are aware of the necessity to integrate IT and business strategy, and 77% indicate that a poor understanding of business needs and objectives in a top barrier in the effective use of IT (Mejias, 2002).

The specialists have attempted to identify and propose solutions to these problems. A frequently used concept is that of *organisational* or *strategic alignment*, which emphasises the need to correlate the functioning of the IT system with business processes, in the context of organisational strategies (Roberts et al., 2005). Other authors emphasise the role of human resources in adopting, shaping, and enhancing the strategic use of IT for marketing operations (Dorgan, 2003; Speier & Venkatesh, 2002). By emphasising the role of organisational leaders, Eichorn (2004) constructs the concept of *internal customer relationship management*, and proposes the application of its principles as a solution for effective business-IT integration and performance. However, no study was able to synthesise all the aspects of *IT systems implementation* in modern business organisations.

The Integration Between IT Systems and Business Strategies

The introduction of modern IT systems, especially when based on Internet connectivity, requires the restructuring of information collection, archiving, and processing capabilities at the level of the entire organisation.

The recent development of communication technology forces the firm to redefine the sources of information. Customers can contact the company using multiple communication channels, such as mail; fax; fixed or mobile phone connections; or e-mails. The organisational structure should be able to accommodate all these flows of information and to introduce filter mechanisms that analyse the content and the level of urgency of the message, and then direct the communication to the relevant people within the organisation.

On the other hand, the complexity of the input data requires a centralised system of information storage that can be accessed simultaneously by various organisational departments. The centralisation of customer and organisational databases contradicts the traditional model of departmentalised databases, which often created redundancies and limited the interdepartmental communication and collaboration. In the present competitive environment, characterised by dynamism, complexity, and unpredictability, the speed of reaction and the capacity to work in multi-disciplinary teams are paramount for a company's survival and success.

The introduction of modern IT systems, and the restructuring of organisational processes and architecture, are often perceived as major cultural shocks by company's employees. Many studies have identified the resistance to change, and the concerns related with the use of novel IT systems as important barriers for the implementation of information technology in business organisations. This indicates that the implementation of a new IT system requires a change not only at functional level but also in the philosophy and culture of the firm. The adoption of a market-oriented, IT-based, business approach cannot succeed without the change of employees' mentality and system of values.

Another major problem in modern organisations is the interface between IT and marketing systems. Too often, the two organisational functions are independently structured, creating disparate subcultures within the same company, with different values, objectives, procedures, and approaches. The collaboration between IT and marketing becomes more difficult and complex as the culture gap widens and each group affirms and protects its primary importance in the organisational structure (Eichorn, 2004).

The adoption of a market-oriented approach by modern enterprises requires a closer collaboration between IT and marketing functions (Ranchhod & Gurău, 2004). The two functional departments need to share experience and information and to work together towards defining and realising common goals. Often, this approach is facilitated and coordinated by the top manager, who creates multi-divisional teams and establishes formal rules of cooperation, that are enforced at middle management level (Goleman, 2002).

Technology deployment represents the way in which companies plan and manage IT to enhance the marketing activities and procedures. From an organisational point of view, five main stages of this process can be defined as a gradual evolution of systems, processes, and procedures:

1. The strategic use of IT is focused on IT applications that support and enhance the competitive advantage of the company.
2. The IT management examines and improves internal IT related activities, such as the usage of new technologies, the development and adaptation of specific IT applications, or the degree of IT usage practised by the employees.
3. The enterprise information systems are restructured in order to align the IT strategy with the organisational structure and to manage more effectively the internal information networks.
4. The IT infrastructure is integrated in the company structure and its usage is formalised in order to manage more effectively the IT resources and capabilities of the organisation.

5. The IT system becomes centralised and its capabilities are shared by all the departments and the hierarchical levels of the organisation.

This process should be closely coordinated by the top management, taking into account a number of specific conditions, which are detailed in the five propositions presented hereafter. The restructuring of the company's systems and processes must balance novelty and continuity in order to facilitate employees' adaptation to the new structures and procedures (Ranchhod, Gurău, & Hackney, 2004):

Proposition 1

The implementation of IT systems in business organisations should take into account all organisational dimensions and structures (internal and external).

The implementation of modern IT systems should represent both a better adaptation to the evolving market environment, and a major enhancement of internal company capabilities. Before proceeding to the restructuring of the organisational architecture, the managers need to be aware of all the aspects involved in this process.

Proposition 2

The implementation of IT systems in business organisations is a multi-divisional team operation.

The complexity of novel IT systems, and the interaction between technology infrastructure and business procedures, makes the implementation process difficult and sensitive. Often, the senior manager's expertise cannot cover all the aspects of the implementation process. Although the manager needs to coordinate the integration effort, the responsibility for each implementation stage should be assumed by a multi-disciplinary team of specialists from different organisational departments. Not involving information technology professionals from the early stages of the implementation process might jeopardise the later integration of IT with key business systems and can create problems of compatibility between various applications.

Proposition 3

The implementation of IT systems in business organisations should be correlated with the level of skills, knowledge, and capabilities of the employees.

The decision to implement a new IT system should be accepted and shared by the company's employees in order to avoid future reactions of rejections. Besides a clear internal communication regarding the reasons and objectives of implementing the novel IT systems, the management of the firm has to establish training programs to familiarise the employees with the characteristics of the new IT tools and applications.

Proposition 4

The implementation of IT systems in business organisations must be compatible with, and enhance, the existing competitive advantage of the organisation.

The strategic alignment between IT systems and marketing strategies is a more complex process than simply translating the existing business processes into IT procedures. The alignment has to be made on different levels, in order to preserve and enhance the existing competitive advantage of the firm (between IT and marketing functions; between strategic objectives and tactic procedures; and between core IT applications and decision support systems).

Proposition 5

The implementation and functioning of IT systems in business organisations should be based on flexibility, transparency, and connectivity.

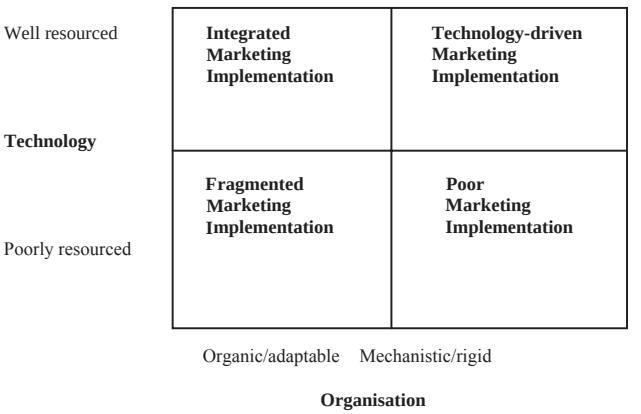
The implementation of an *IT-based marketing strategy* will impact and transform, in some measure, all the elements of the organisation. The strategic plan of this process needs to address and solve the problems of flexibility, transparency, and continuity between existing and future business structures and processes. A seamless integration of all IT operations and quick access to relevant data and market evaluations will enhance the capacity of the firm to react quickly to changes in the market structure and the external business environment.

The integration between IT and business systems is a continuous process that needs to be repeatedly evaluated and improved. In order to identify the company stance regarding the market strategy implementation and effectiveness, it is necessary to measure both the level of IT infrastructure as well as the internal culture/functioning of the organisation. By combining the technology context with the organisational structure, the matrix shown in Figure 1 can be developed (Ranchhod & Gurău, 2004).

Integrated Marketing Implementation

The companies from this quadrant have a well-balanced marketing implementation based on good IT systems and a dynamic/flexible organisation. Integrated systems offer high-value customer service, having a positive effect on customers' loyalty and company's profitability. Employees and technology work in unison, reinforcing their capabilities.

Figure 1. The influence of technology and organisational structure on the implementation of marketing strategies



Fragmented Marketing Implementation

These companies have excellent organisational capabilities, but their IT systems are basic and poorly integrated with business processes. These organisations need to invest more in IT infrastructure and to build management procedures for using the IT resources more effectively.

Technology-Driven Marketing Implementation

In this quadrant, companies tend to rely on technology to a greater extent. However, their internal processes lack flexibility and responsiveness, and for this reason, their sophisticated IT infrastructure is not fully used. These firms might use automated IT application to replace routine work, but do not use IT functions to improve their business intelligence and competitive advantage.

Poor Marketing Implementation

Companies in this quadrant have outdated organisational practices and possess poor technology systems. These firms need both organisational improvement and technology investment, which then need to be integrated at a strategic level. If well managed, the IT implementation process can be timely correlated with organisational restructuring, resulting in improved marketing capabilities and strategic focus.

The matrix can be used as an analysis tool by existing companies that can identify the main problems related with the implementation of their marketing strategy. The implementation of advanced technology can imbalance the firm and its market orientation if the organisational structure does not become more flexible and responsive. The procedural routines that are established for IT systems must not increase the rigidity of the organisational structure, but should be integrated into complex customer relationship management applications, providing the basis for reliable and responsive customer service operations.

FUTURE TRENDS

The complexity and the dynamism of markets, as well as the huge amount of information that needs to be accessed, selected, and processed requires the implementation of automated systems that can complement human skills and expertise. The combination between IT systems and flexible organisational structures will transform the marketing strategy into a knowledge management application, organically integrated into the model of learning organisation. The business organisation will therefore use advanced IT systems to create, use, and apply knowledge about markets and customers, transforming the firm into a flexible learning organisation. Within this organisational framework, new business strategies will be developed by *knowledge-based companies* (Dunn & Salazar, 2004):

1. **Knowledge Replication:** Which applies a verified organisational model into new markets, allowing the rapid expansion of the firm with reduced costs (e.g., MacDonald's);
2. **Knowledge Diffusion/Leveragability:** Based on the efficient management and diffusion of the existing knowledge within the organisation (e.g., Hewlett Packard);
3. **Knowledge Innovation:** Using the existing knowledge in new, innovative ways, in order to create superior value for customers (e.g., online recommendation systems);
4. **Knowledge Giveaway:** The knowledge developed by the firm is openly shared with the business community in order to reinforce the brand positioning of the company (e.g., Massachusetts Institute of Technology);
5. **Knowledge Commercialisation:** Based on the accumulated knowledge, the firm is able to commercialise consulting services to customers and other organisations (e.g., British Gas Plc).

Making a thorough analysis of their positioning and expertise, the modern organisations will be able to identify and apply the best strategies allowing them to take advantage of their specific market knowledge.

CONCLUSION

The implementation of IT systems in modern business organisations is a necessity imposed by the technologically driven evolution of the market. When fast decisions need to be made, the role of market intelligence becomes highly relevant and organisational systems need to offer up-to-date, relevant information to company's employees. On the other hand, as technology becomes more sophisticated, marketers need to understand its relationship with effective marketing strategies and to integrate organisational processes and IT infrastructure in a highly flexible architecture.

This study has outlined a series of important issues related with IT-business integration, especially related with the implementation process of novel IT systems. The complexity of this restructuring process cannot be solved with general solutions, each company having to design the best answer to its strategic problems. Although the theoretical model and the propositions presented in this paper are supported by secondary data evidence they need to be verified in real situations. On the basis of these theoretical findings, further research projects can be designed to collect, process, and analyse primary data regarding the problems experienced by managers implementing IT infrastructure and integrating it with existing organisational systems.

KEY TERMS

Chief Information Officer (CIO): An executive title in an organisation that designates the person responsible for developing and implementing the information systems.

Customer Relationship Management (CRM): A business model that includes specific techniques and methods for attracting customers and developing a long-term, company-customer relationship.

Decision Support Systems (DSS): A specific class of computerised information systems that supports business and organisational decision-making activities by providing facilities for data analysis, evaluation, and interpretation.

Internal Customer Relationship Management: A business theory advocating the application of CRM principles within business organisations among various functional departments.

Knowledge Management: The reuse and redeployment of accumulated knowledge from which organisational learning is manifested.

Organic Organisation: An organisation with a flexible structure that collects and uses outside knowledge.

Mechanistic Organisation: An organisation with a rigid hierarchical structure which implements highly formalised jobs/roles definitions.

Strategic Alignment: The extent to which the information systems strategy supports, and is supported by, the business strategy in an organisation.

Business Model Application of UML Stereotypes

Daniel Brandon, Jr.
Christian Brothers University, USA

OVERVIEW

The UML (Unified Modeling Language) has become a standard in design of object oriented computer systems (Schach, 2004). UML provides for the use of stereotypes to extend the utility of its base capabilities. In the design and construction of business systems, the use of stereotypes is particularly useful stereotypes, and this article defines and illustrates these.

UML STEREOTYPES

"Stereotypes are the core extension mechanism of UML (Lee & Tepfenhart, 2002). If you find that you need a modeling construct that isn't in the UML but it is similar to something that is, you treat your construct as a stereotype" (Fowler & Kendall, 2000). The stereotype is a semantic added to an existing model element, and diagrammatically it consists of the stereotype name inside of guillemots (a.k.a. chevrons) within the selected model element (Schach, 2005). The guillemot looks like a double angle bracket (<< … >>), but it is a single character in extended font libraries (Brown, 2002). Each UML model can have zero or many stereotypes; and each stereotype can define a set of tagged values, constraints, and possibly a special icon or color (Arlow & Neustadt, 2005). The UML defines about 40 of these stereotypes, such as "<<becomes>>", "<<include>>", and "<<signal>>" (Scott, 2001). However, these 40 standard stereotypes are not particularly useful in business models and do not add the meaning necessary for automatic code generation in a UML CASE tool.

One common general use of the stereotype is for a metaclass. A metaclass is a class whose instances are classes, and these are typically used in systems in which one needs to declare classes at run time (Eriksson & Penker, 1998). A similar general use is for powertypes. A powertype is an object type (class) whose instances are subtypes of another object type. Figure 1 shows an example of the use of stereotypes for powertypes (Martin & Odell, 1998). Another type of usage is in the "binding" of parameterized (template) classes historically in C++ and now in the latest version of Java (Oestereich, 1999).

USER-DEFINED STEREOTYPES FOR BUSINESS SYSTEMS

In the design of business systems we have found some stereotypes that were occasionally useful, and two stereotypes that are extremely useful. When defining stereotypes it is useful to describe (Eriksson & Penker, 1998):

1. On which (UML) element the user-defined stereotype should be based
2. The new semantics the stereotype adds or refines
3. One or more examples of how to implement the user-defined stereotype

Figure 1.

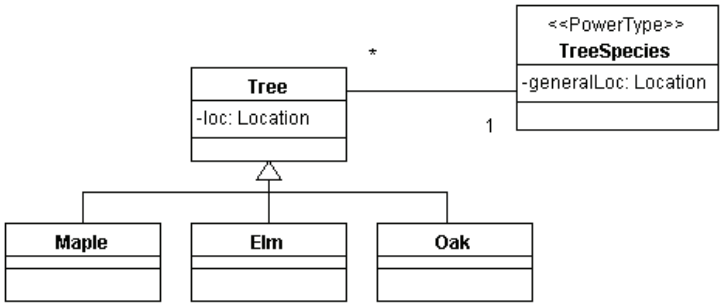

Figure 2.

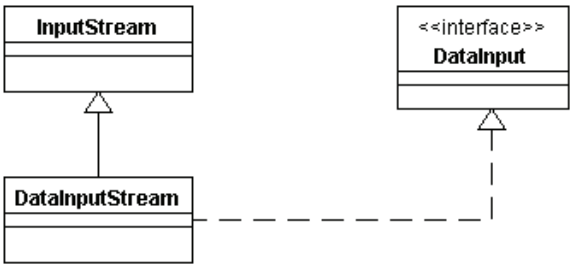

Figure 3.

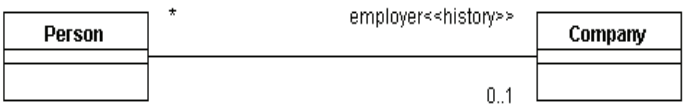

An issue is where such definition takes place both within UML and in the UML software tool. If a modeling tool does not provide such built-in support (and most do not), many modelers put a note in the model or a reference to external documentation (Arlow & Neustadt, 2005).

One common use of stereotypes in business systems is for interfaces as found in Java or CORBA; this is shown in Figure 2. An interface typically has public functionality but not data (unless holding data for global constants). The class model element has been modified with the "<<interface>>" notation (Oestereich, 1999). This is commonly used for UML CASE products that do not have separate interface symbols or where these symbols do not allow data (i.e., global constants).

Another common stereotype usage in business systems is to clarify or extend a relationship. Figure 3 shows a stereotype called "history," which implies a "many" cardinality for history purposes, that is, each Person has zero or one current employers but may have many employers in terms of the employee's history. It may imply some common functionality upon code generation such as (Fowler & Kendall, 2000):

```
Company Employee::getCompany(Date);
```

Still another common stereotype usage in business systems is to define ancillary classes that are not part of the core business model, but are needed for a particular implementation. Boundary, controller, and entity stereotypes were predefined in UML (Oestereich, 1999) with special symbols in some products; however, the definition and use of these varies with author. Schach (2005) divides implementation classes into Entity classes, Boundary classes, and Control classes. Entity classes are part of the core business model and represent entities like people, organizations, transactions, places, and things. Boundary classes are used for communication between the software product and the actors such as I/O operations; and Control classes are used for algorithms and business rules. Each of these types of classes is designated with the stereotype notation.

CODE WRITING AND GENERATION

Most modern UML CASE (computer-aided software engineering) products can generate "skeleton" classes from the UML class diagrams and possibly other diagrams. For business systems design, we need to write the code for our classes (usually implemented in Java or C++) based on both the structural model (UML class diagram) and the dynamic model (UML activity diagram). This process is shown in Figure 4. It is very important that consistency between the two diagrams is achieved.

Many such CASE products allow the user to write his or her own "class generation scripts" in some proprietary scripting language or in a general scripting language (i.e., Python). With user-defined stereotypes, the user can modify the class generation script code to use his or her stereotypes as needed.

Figure 4.

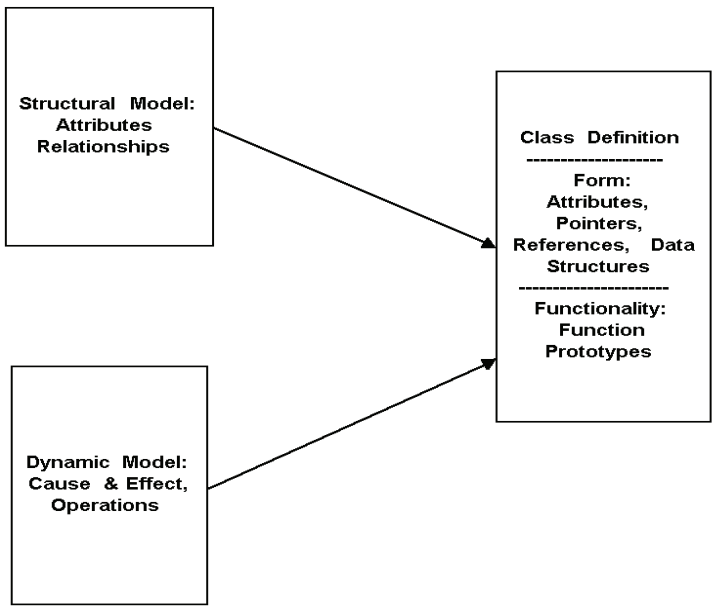

Figure 5.

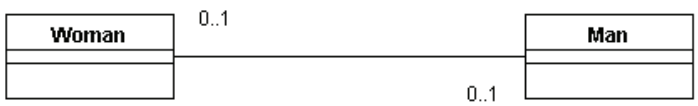

RELATIONSHIP OBJECT TYPES

As an example, consider a simple association between two object types. Often these simple relationships need to be modeled as object types because these relationships have data content and/or functionality. Figure 5 shows a simple association between two object types representing the relationship "current marriage." If we need to maintain an attribute on each marriage (such as rating), then we can more effectively represent the relationship as an object type as shown in Figure 6. Here we use the "relationship" stereotype to indicate that this object type is a relationship; and the code generation can use a more appropriate class representation. Other authors have suggested other notations for relationship object types such as "placeholders" (Martin & Odell, 1998), and UML suggests using the dotted line from a standard object type (class) to the relationship line. But implementing these other diagramming techniques in code generation is difficult and has ambiguity problems.

ACTIVITY DIAGRAMS

A UML activity diagram is a state diagram in which most of the states are action states and most of the transitions are triggered by the completion of these action states. This is the case in most models of business systems. Activity diagrams identify action states, which we call operations (Martin & Odell, 1998), and the cause and effect between operations. Each operation needs to belong to an object type, at least for a C++ or Java implementation. Operations may be nested, and at some point in the design the operations need to be defined in terms of methods. The methods are the processing specifications for an operation and can be so specified in lower lever activity diagrams, pseudo code, or language specific code. Note that the term "methods" may cause some confusion here since in programming terminology, a method is a function defined within a class and it is invoked upon an object (unless it is a static method).

Figure 6.

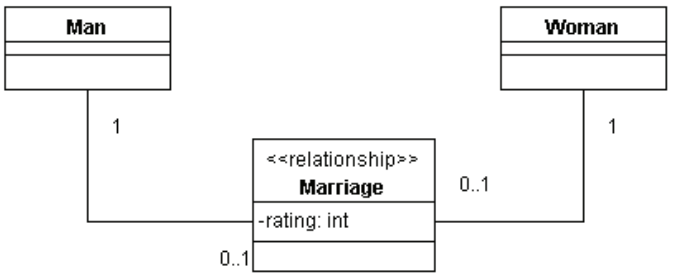

Figure 7.

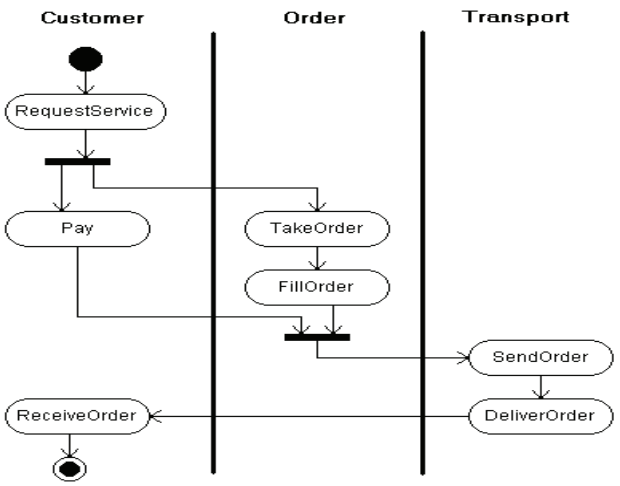


Drawing Methodology

Figure 7 shows a typical UML activity diagram for a simple ordering process. The operations are represented in the ovals, and the arrows show the cause and effect scenario or the "triggers." In this diagram there are two "fork/join" model elements, and the use of "conditional branch states" is also common. Each of the operations must be associated with a particular object type. The standard way to do that in this UML type diagram is to use "swimlanes," and these are the vertical lines shown in Figure 7.

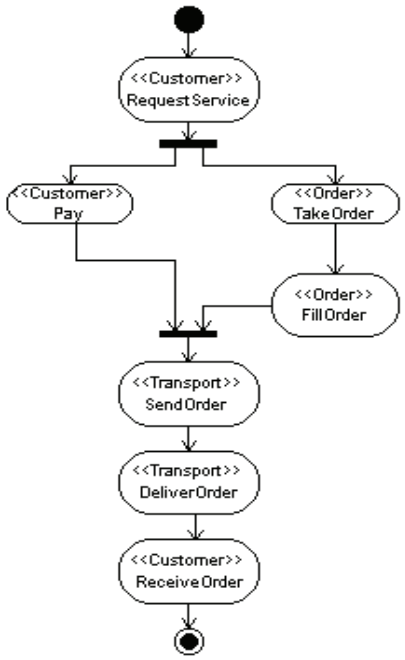
There are two problems with the standard representation as shown in Figure 7. The first problem is that as the system gets more complex (more object types and operations), it is very difficult to draw in swimlanes. The second problem is that code generation is very difficult in UML CASE products since you have to scan the geometry of the drawing to find out which operations lay in which swimlanes. A solution to the previous problems with standard UML activity diagrams is to use a stereotype for the operation element to indicate the object type (class) owning that operation. Figure 8 shows the same systems as Figure 7 drawn with the "operation owner" stereotype.

Model Consistency

The use of these UML stereotypes allows a greater degree of consistency checking of business models. A final business system design will involve several UML diagram types. For example, business systems typically have static structural diagrams (UML class diagram) and a dynamic diagram (UML activity diagram). These diagrams must be consistent with one another, in particular:

1. The object types (shown with the operation stereotype notation) that contain the operations in activity diagrams must be included on the structural diagrams.

Figure 8.



2. The operations shown in the activity diagrams (along with the object types identified with the stereotype notation) must be included as operations in the same object type on the structural diagrams.

For a UML business system example (including implementation in C++), the reader is referred to the full book chapter on this subject (Brandon, 2003).

FUTURE TRENDS

As UML becomes more accepted for general use in the design of business systems, we could expect to see more universal stereotypes being formulated. Eventually libraries of these stereotypes should become generally available and UML tool vendors would include support for these libraries in their products.

CONCLUSIONS

UML stereotypes can be very useful in designing business systems. For example, the use of a "relationship" stereotype is helpful in static structural models (UML class diagrams), and the use of an "operation owner" stereotype is most helpful in dynamic models (UML activity diagrams). These stereotypes aid in both the design/drawing phase and in the implementation (coding) phase of the overall system construction.

KEY TERMS

Activity Diagram: A UML diagram showing operations and triggers between operations; a diagram which shows system dynamics via cause and effect relationships. An Activity Diagram is a state diagram in which most of the states are action states and most of the transitions are triggered by the completion of these action states.

CASE: Computer-aided software engineering.

Class: A program construct representing a type of thing (abstract data type) that includes a definition of both form

(information or data) and functionality (methods); the implementation of the design concept of "object type."

Composition: A new class in an objected programming language that is composed of other classes.

Dynamic Model: A UML model describing dynamic behavior such as state changes, triggers, and object type operations.

Encapsulation: The ability to insulate data in a class so that both data security and integrity are improved.

Framework: A software foundation that specifies how a software system is to be built. It includes standards at all levels both internal construction and external appearance and behavior.

Function: A programming construct where code that does a particular task is segregated from the main body of a program; the function may be sent arguments and may return arguments to the body of the program.

Implementation: The code placed inside of methods. For some languages this code is pre-compiled or interpreted.

Include: Some code stored separately from the main body of a program so that this code can be used in many programs (or multiple places in the same program).

Inheritance: A feature of object oriented languages that allows a new class to be derived from another class (a more general class); derived classes (more specific classes) inherit the form and functionality of their base class.

Interface: The specification for a method ("what" a method does); how that function is called from another program. Interfaces are provided in source form as opposed to implementations, which are secure. This allows one to use a method without regard for "how" that method is coded. It also allows multiple implementations of the same interface.

Library: A group of functions and/or classes stored separately from the main body of the main program; an "include" file consisting of functions and/or classes.

Metaclass: A class whose instances are classes.

Method: A function defined inside of a class; a processing specification for an operation.

Object Type: A specification of a type of entity; both structure (attributes) and operations (functions) are specified for object types; the notion of object type is a design notion being implemented as a "class."

Operation: A process related notion in UML; operations cause state changes in objects.

Packages: Similar to a library, but just containing classes.

Patterns: A software library for a common business scenario. A framework may be a design framework (possibly expressed in UML) or an implementation framework (possibly in C++, Java, or PHP).

Polymorphism: The ability of object oriented programs to have multiple implementations of the same method name in different classes in an inheritance tree. Derived classes can override the functionality defined in their base class.

Relationship: A connection concept between object types. There are several types of relationships, including aggregation, composition, association, and inheritance (generalization/specialization).

Reuse: Reuse (software) is a process where a technology asset (such as a function or class) is designed and developed following specific standards, and with the intent of being used again.

Separation: The separation of what a method does (interface) from how the method does it (implementation).

Stereotype: The core extension mechanism of UML.

Structural Model: An UML model describing static structure (relationships and properties).

Trigger: One operation invoking another operation; a call from one method to another method within the same or different object type (class).

UML: Unified Modeling Language.

Business Models for Municipal Broadband Networks

Christos Bouras
University of Patras and Research Academic Computer Technology Institute, Greece

Thrasyvoulos Tsiatsos
Aristotle University of Thessaloniki, Greece

INTRODUCTION

This article examines the most effective business model for the optimal exploitation of the currently developing broadband metropolitan area networks in various municipals around the globe. The proper exploitation strategy of the municipal broadband networks to be deployed could boost the demand for broadband connections and applications. The article describes the relevant, available business models in detail, including ways for broadband infrastructures' expansion, and deals with viability issues, regarding the managing authority which is responsible for the broadband metropolitan networks.

A business model, specifically in the current article, determines the way in which the exploitation of a metropolitan, community-owned, optical network will be effectuated. Municipalities may play a critical role in enabling the deployment of broadband infrastructures by the private sector (Government of Sweden, 2007):

- Placing open conduit under all freeways, overpasses, railway crossings, canals and bridges.
- Allowing over lashing of fiber on existing aerial fiber structures.
- Forcing existing owners of conduit, such as electrical companies, telephone companies, and so forth, to make 100% of their conduit accessible to third parties.
- Coordinate construction of all new conduits, especially by building entrances to minimize the "serial rippers" and make all such conduit open to third parties.

However, the development of such broadband infrastructures raises several questions regarding the business model that shall be used for their exploitation (e.g., what will be the role of the municipality, what will be the degree of government interventionism, how healthy competition is going to be promoted, how the network's viability is going to be ensured, etc.).

Therefore, this article intends to:

- Record international experience with respect to broadband business models for the exploitation of broadband infrastructures.
- Summarize the available business models and present, through comparative analysis, the advantages and disadvantages of each business model.

The remaining of this article is structured as follows: The next section presents the international experience in developing broadband metropolitan area networks in various municipalities around the globe. Next, the aticle presents and compares the available business models for the optimal exploitation of the broadband municipal networks, and presents the future trends in the area. Finally, the article is concluded.

BACKGROUND

In general, broadband metropolitan networks have been developed in municipalities along different parts of the globe. Pioneer countries, such as Canada and Sweden, present examples of how broadband infrastructures can reinforce the local economy and contribute in further development. International experience records various business models (OECD, 2003) on broadband infrastructures exploitation, and a few indicative ones are mentioned in the following paragraphs:

- **Demand aggregation model.** This model regards coordinating efforts, exerted by regional carriers and aiming at the aggregation of the demand for broadband

services. The regional carrier presents the aggregated demand as an attractive clientele basis to the service suppliers, with whom it negotiates the overall purchase of broadband services and the percentage ownership upon the infrastructure.

- **Open access/wholesale provider model.** According to this model, regional carriers and local communities, usually cooperating with an independent infrastructure provider, who offers wholesale prices (a public utility service, in principle), construct the fundamental broadband infrastructures (trenches, conduits, subterranean or aerial cables), incorporating a "public good" rationale, and based on the foreseen general needs, as is the case of roads and sewerage works.
- **Community-owned network with service provision model**. Regional carriers and local communities, usually cooperating with a local service supplier, or acting as broadband network service suppliers themselves, construct the fundamental broadband infrastructures and provide network wholesale or retail services, investing the resultant profits in the expansion of the infrastructure.

Remarkable efforts in Europe can be recorded in Ireland (www.enet.ie), Sweden (Stokab, www.stokab.se), Austria, The Netherlands (Kramer, Lopez, & Koonen, 2006) and Spain (LocalRet, http://www.localret.net/idiomes/english.htm). In the United States (U.S.), the cases of the State of Utah (UTOPIA, 2003; UTOPIA network, www.utopianet.org) and the city of Philadelphia (Wireless Philadelphia, 2005) are of great interest, concerning the successful application of business models for exploiting broadband metropolitan area networks. Besides from Europe and the U.S., remarkable efforts are tracked in other countries as well, such as Canada (CANARIE, www.canarie.ca) and New Zealand. Table 1 summarizes the features of business models of the most important of the aforementioned cases.

BUSINESS MODELS FOR MUNICIPAL BROADBAND NETWORKS

Important Aspects

A business model in our case determines the way in which the exploitation of a metropolitan, community-owned, optical network will be effectuated. Additionally, it determines the role of the municipality, the region and the private sector, the way healthy competition is going to be promoted, the

Table 1. Representative business models and their basic features

Features \ Business Models	Irish model	Stokab	LocalRet	UTOPIA	Philadelphia	CANARIE (Canada)

Leasing to telecommunication providers	x	x	x	x	x	
Supply of services		x				x

degree of involvement of the private sector and so forth. For example, competition is driving fixed and mobile players to invest in new technologies to reduce costs and position themselves in a converged environment (COM, 2006). Another example is that the liberalization of the local loop telecommunication infrastructure allowed the firms involved to behave more competitively and dropped broadband monthly fees to lower prices. Such an example is Sweden (Papacharissi & Zaks, 2006). Moreover, concerning the role of municipality, the analysis of Lehr, Sirbu, and Gillett (2004) shows that the case for a public role is complex and that the optimal policy is likely to depend critically on the type of wireless infrastructure that is being deployed, and the objectives for the system.

The business model aims to ensure the viability of the metropolitan community-owned optical network and to secure the resources for its operation, maintenance and expansion, while, at the same time, it aims to promote competition for offering better and cost effective services to the citizen (Henderson, Gentle, & Ball, 2005).

Figure 1 presents the three basic levels of a relevant business model (Hughes, 2003):

- The first level determines who (a private or public enterprise, etc.) exploits the network's passive equipment (channels, optical fibres, etc.).
- The second level determines who provides and exploits the active equipment of the network (switches, routers, etc.).
- The third level determines who offers access to the network, the services and the content.

"Open Access" and "Neutral Operator"

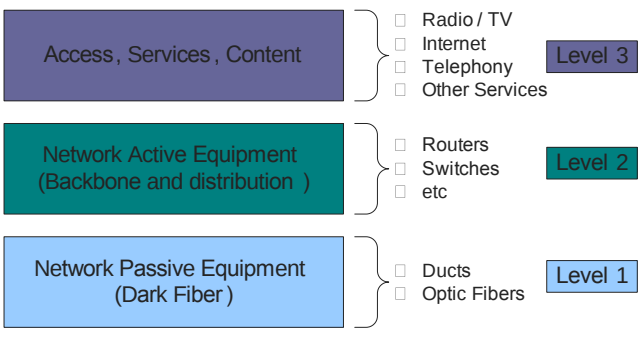
The attribution of different responsible carriers (municipality, private sector, etc.) to any one of the aforementioned levels of the business model leads to different business model scenarios indicating how public organizations and providers of infrastructures, equipment and services can cooperate for the consumer's benefit. Two basic features of the metropolitan optic fibre networks that do not really regard their construction as much as their funding, appropriate management and viability insurance are reflected in the concepts of "open access" and "neutral operator."

As far as the open access is concerned, the European Commission provides directions and guidelines that must rule the electronic communications between the member states of the EU. In particular, it is stated that the projects to be funded will have to be consistent and conforming to the new institutional framework for electronic communications, as well as to the rules concerning competition (issues of state aid and antitrust). Compliance to the competition rules constitutes an eligibility criterion for funding, while this has to be combined with the obligation for clear open access (Magnago, 2004). Specifically, funding has to be limited exclusively to infrastructure (i.e., installations of optic cables, channels, conduits, pylons, etc.) and equipment that is accessible to any telecommunication carrier and services supplier.

The infrastructure administrator will be liable to preserve the infrastructure character as an installation accessible to all carriers, supplying electronic networks and services, without discrimination. The role of the neutral operator (Monath, Cristian, Cadro, Katsianis, & Varoutas, 2003) is important because it has to:

1. Offer the network infrastructures' proprietors (on local, regional and national level) the possibility to increase their value and viability within a logical economic frame.
2. Reduce the needs for high initial investments on the part of the service suppliers and, at the same time, significantly increase the availability of economically accessible services on the part of the subscribers.

Figure 1. The basic levels of a business model



3. Be responsible for the observance and evolution of a revenue-sharing schema for all participating sides as well as for the continuous adaptation of the network's potential in accordance with the growing needs.
4. Act as an administrating entity, in general, ensuring the reliable operation of all cooperating parts (infrastructure proprietors, service suppliers and subscribers).

Equal Access Business Model

The target of this business model (Figure 2) is to ensure the equal access to the passive equipment of the network. More particularly:

- One entity is responsible for the first level, which offers cost-based access to the passive equipment of the network.
- In the second level, many providers are active and they offer access to active network equipment in a competitive environment.
- In the third level many providers are active and they offer broadband services to the end users in a competitive environment.

The entity responsible for the first layer constructs the network passive equipment and rents the passive equipment to one ore more networks providers. The network providers offer network services to services and content providers. And finally, services and content providers offer broadband services to the end users.

There are two important variations of this business model (PPPs orchestrated and Public Sector Telco), described in the following paragraphs.

The role of the first layer's entity is to motivate the competition in the above layers. This entity invests in passive equipment and, due to the nonprofit operation, offers the passive equipment in a cost-basis to the network providers. As a result, the market entry cost for a network provider is relatively low.

Full Public Control through Public-Private Partnerships (PPP)

In this business model (Figure 3), the municipal authority is responsible for all parts of the broadband network (passive equipment, active equipment, services). With this approach, the municipal ensures the full control in all levels through the participation in PPPs.

This business model can be used either when the municipal authorities are not ready to allow a temporary monopoly in broadband services or when there is law restrictions. In addition, this business model can be used when the service provides are not willing to invest (e.g., in rural areas).

A benefit of this business model is the simple administration due to the fact that only one organization is involved. The main disadvantage of this business model is the absence of competition. This results in limited options for the end user, as well as lack of pressure for price reduction. Finally, this business model requires the municipal authorities to operate a telecommunication network, an area in which municipal authorities have no experience.

PPPs Orchestrated

This is a variation of the equal access business model, which occurs when there is significant existing broadband

Figure 2. Equal access business model

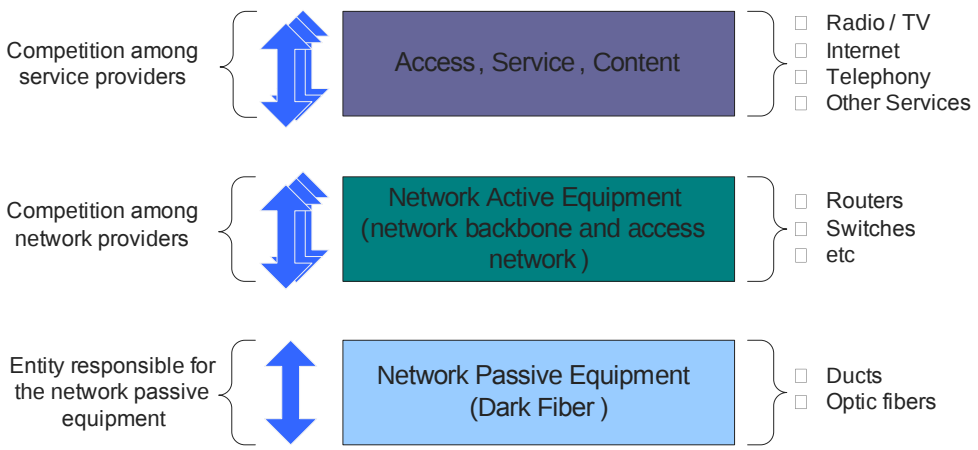


Figure 3. Full public control through PPPs

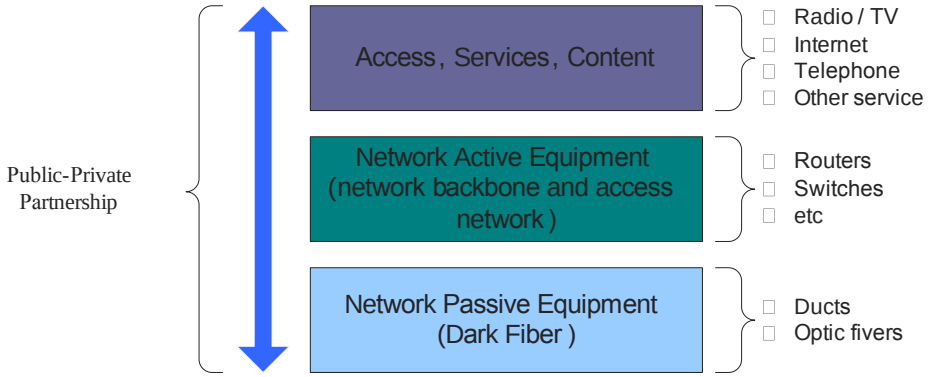

infrastructure in the area and major investments in new infrastructure is not necessary. In this scenario, the role of the local government may be to act as an orchestrator and, by bringing private organizations together, to ensure that existing assets are used to create a thriving market for broadband services.

This is usually performed by the local administrations and the owners of the existing infrastructure who create a joint venture to manage the passive infrastructure, as if it was a single asset. The active and access services layers are usually managed by one or more service providers on the basis of a partnership agreement with the joint venture.

In this scenario, it is common to have a single private company acting in the second layer (active equipment).

Public Sector Telco

This model is another variation of the equal access business model, where the public sector manages the passive and the active infrastructure, while competition among private companies is acting in the third level (services).

Sole Private Provider

According to this model, the operation and the management of the active network equipment and services are offered by a single private service provider. The network's passive equipment is owned by the public sector (e.g., municipality).

The advantage of this model (Heimgartner, Luke, Villa, & Johnston, 2005) is that the project becomes commercially viable at much lower levels of customer revenue. However, customers are unlikely to be offered as wide of range of services and will not benefit from the impact of competition on pricing. For these reasons the local government will often want to ensure that the monopoly is only offered as a temporary measure over a fixed term, during which time it hopes the sole service provider will generate sufficient numbers of customers to sustain a competitive market. Ob-

Figure 4. PPPs orchestrated

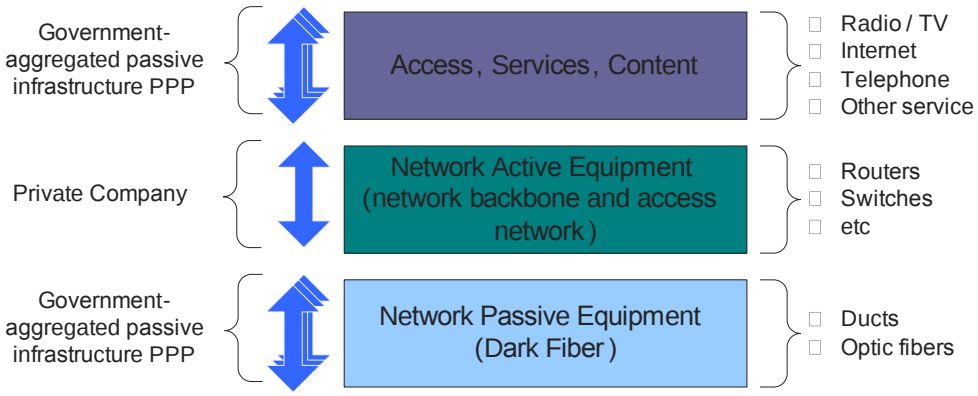

Figure 5. Public sector telco

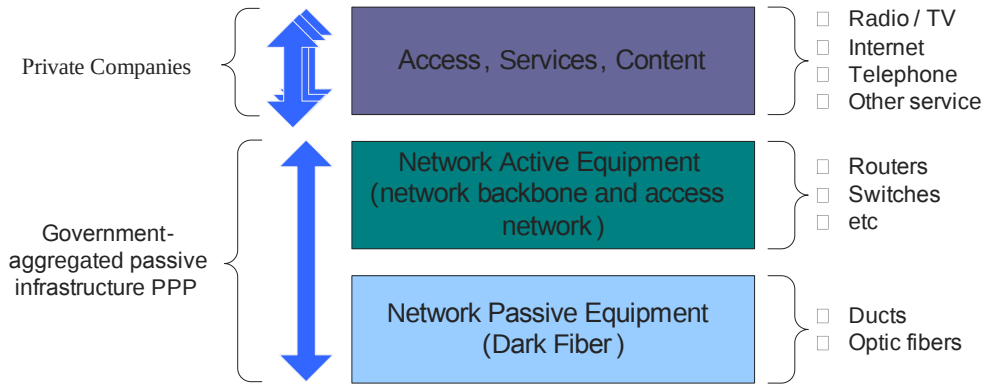

Figure 6. Sole private provider

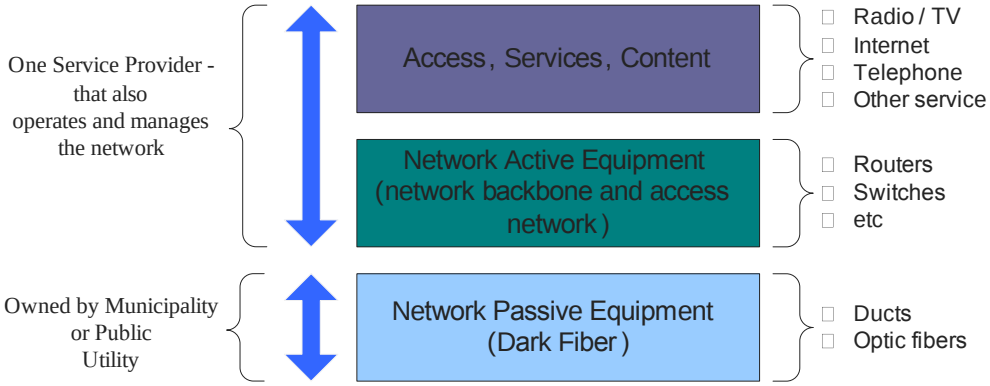

viously, getting the length of this fixed period right is a key issue. Furthermore, transition to the equal access model at the end of the fixed period will require careful commercial and legal management.

FUTURE TRENDS

The neutral operator, in most cases an entity controlled by the municipal authorities, is of critical importance for the business models, because it:

- Secures financial viability of the owners of the infrastructure.
- Reduces the needs for high initial investments from the service providers and, at the same time, it increases considerably the availability of economically accessible services for the citizens.
- Is responsible for fair revenue sharing to all participants in the enterprising scheme.
- Plans and implements networks expansion.

In addition, the service providers should focus on providing economical and competitive services without caring for the development of the broadband infrastructure. Finally, as far as the end users are concerned, the selected business model ensures that they may choose between a number of services with financial and quality criteria. Until now, some research work has been presented concerning lessons learned from broadband development (Frieden, 2005).

All involved parts should bear in mind that once the broadband business model is applied and broadband infrastructures are deployed, quality of service and specific service level agreements (SLA) (Shin, Shin, & Han, 2004) for the provided services should be ensured.

Table 2. Comparison of local and regional models for broadband deployment

Model	Description	Advantages	Disadvantages
Equal Access	The municipal authorities develop and manage Level 1 (passive infrastructure). Both Level 2 and Level 3 are subject to competition.	• Public intervention at the lowest level of the business model (which, however, represents 70% of the cost of a new fixed network). • Market entry cost for a network provider is relatively low, due to leasing of the passive infrastructures on a cost basis.	• Entry barriers for network operators remain sizeable • Financial risk for the municipal authorities
Full Public control	All three levels are created and managed by the municipal authorities.	• Complete solution • Easier management of the whole "operation"	• Negative impact on competition in services and networks • Financial risk for the municipal authorities • Municipal authorities needs great technical and commercial expertise
PPPs orchestrated	Variation of the equal access business model. PPPs act in level 1, usually a single private company acts in level 2, while competition (many companies) acts in level 3.	Service providers may have a chance to enter the market, as part of the PPPs acting in level 3.	• Significant existing broadband infrastructure in the area is assumed • No competition in network active equipment (level 2) • Govermental interference both in levels 1 and 3
Public Sector Telco	Variation of the equal access business model, where the public sector acts in levels 1 and 2.	Simpler management of the network (both active and passive equipment), since it is performed by a single entity.	• Municipal authorities needs great technical and commercial expertise. • Negative impact on competition in active network equipment.
Sole Private Provider	The operation and the management of the active network equipment and services are offered by one private service provider, while a public utility or municipality manages level 1.	Cost-based leasing of passive infrastructures to the private company of levels 2 and 3.	• Negative impact on competition in services and networks • Fewer services to the customers

CONCLUSION

This article presents and compares the most important business models for the effective exploitation of the broadband municipal networks. The main objectives of such business models are the following:

- The passive network infrastructure may be used by a large number of service providers.
- The users have the choice of selecting one of the multiple services providers, according to their needs.
- Low operational expenditure (OPEX) and capital expenditure (CAPEX) must be ensured.
- Financial viability of all parts of the infrastructure must be achieved.
- The business model must motivate the competition for the benefit of the end users.

KEY TERMS

Broadband: Broadband describes high-speed, high-capacity data communication making use of a wide range of technologies that often have diverse characteristics and seem appropriate for certain network scenarios and situations. There is no specific (international) definition or unique standard for broadband and the range of service speeds varies typically from 128 Kbps (or 200 Kbps according to the Federal Communications Commission—FCC—of United States) to 100 Mbps for broadband access. For the purpose of this article, we consider as broadband connection every connection which supports speeds greater than 200 Kbps.

Broadband Business Model: A business model determining the way in which the exploitation of a metropolitan, community-owned, optical network will be effectuated.

Broadband Network Passive Infrastructure: It is the physical infrastructure that is used to provide the broadband connectivity and may consist of fiber optic or copper cable.

Broadband Network Active Infrastructure: It consists of the elements used to transmit, forward and route informa-

tion data packets over fiber optic or copper cables. The main elements are switches and routers.

Broadband Services: They are the actual services offered to customers. Examples are: high speed Internet access (usually 10Mbit/s or higher); video telephony; video on demand; gaming portals; e-government and e-health services; Virtual Private Network services; video conferencing; Web hosting; data storage; video surveillance and so forth.

CAPEX: Acronym of the words Capital Expense. In the broadband networks it is the network implementation cost.

OPEX: Acronym of the words Operation Expense. In the broadband networks it is the operation and maintenance cost.

Business Process and Workflow Modeling in Web Services

Vincent Yen
Wright State University, USA

INTRODUCTION

In large organizations, typical systems portfolios consist of a mix of legacy systems, proprietary applications, databases, off-the-shelf packages, and client-server systems. Software systems integration is always an important issue and yet a very complex and difficult area in practice. Consider the software integration between two organizations on a supply chain; the level of complexity and difficulty multiply quickly. How to make heterogeneous systems work with each other within an enterprise or across the Internet is of paramount interest to businesses and industry.

Web services technologies are being developed as the foundation of a new generation of business-to-business (B2B) and enterprise application integration (EAI) architectures, and important parts of components as grid (*www.grid.org*), wireless, and automatic computing (Kreger, 2003). Early technologies in achieving software application integration use standards such as the common object request broker architecture (CORBA) of the Object Management Group (*www.omg.org),* the distributed component object model (DCOM) of Microsoft, and Java/RMI, the remote method invocation mechanism. CORBA and DCOM are tightly coupled technologies, while Web services are not. Thus, CORBA and DCOM are more difficult to learn and implement than Web services. It is not surprising that the success of these standards is marginal (Chung, Lin, & Mathieu, 2003).

The development and deployment of Web services requires no specific underlying technology platform. This is one of the attractive features of Web services. Other favorable views on the benefits of Web services include: a simple, low-cost EAI supporting the cross-platform sharing of functions and data; and an enabler of reducing integration complexity and time (Miller, 2003). To reach these benefits, however, Web services should meet many technology requirements and capabilities. Some of the requirements include (Zimmermann, Tomlinson & Peuser, 2003):

- *Automation Through Application Clients:* It is required that arbitrary software applications running in different organizations have to directly communicate with each other.
- *Connectivity for Heterogeneous Worlds:* Should be able to connect many different computing platforms.
- *Information and Process Sharing:* Should be able to export and share both data and business processes between companies or business units.
- *Reuse and Flexibility:* Existing application components can be easily integrated regardless of implementation details.
- *Dynamic Discovery of Services, Interfaces, and Implementations:* It should be possible to let application clients dynamically, i.e., at runtime, look for and download service address, service binding, and service interface information.
- *Business Process Orchestration Without Programming:* Allows orchestration of business activities into business processes, and executes such aggregated process automatically.

The first five requirements are technology oriented. A solution to these requirements is XML-based Web services, or simply Web services. It employs Web standards of HTTP, URLs, and XML as the lingua franca for information and data encoding for platform independence; therefore it is far more flexible and adaptable than earlier approaches.

The last requirement relates to the concept of business workflow and workflow management systems. In supply chain management for example, there is a purchase order process at the buyer's side and a product fulfillment process at the supplier's side. Each process represents a business workflow or a Web service if it is automated. These two Web services can be combined into one Web service that represents a new business process. The ability to compose new Web services from existing Web services is a powerful feature of Web services; however, it requires standards to support the composition process. This article will provide a simplified exposition of the underlying basic technologies, key standards, the role of business workflows and processes, and critical issues.

WHAT ARE "WEB SERVICES"?

The phrase "Web services" has been defined in many different ways (Castro-Leon, 2002; Ambrosio, 2002). In the working draft of Web Services Architecture (W3C, 2003), it is defined as:

"…a software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-processable format (specifically WSDL). Other systems interact with the Web service in a manner prescribed by its description using SOAP-messages, typically conveyed using HTTP with an XML serialization in conjunction with other Web-related standards."

A simplified Web service architecture based on this definition is conceptually depicted in Figure 1.

Main features of Web services are that services (Burner, 2003):

1. Expose programmable application logic.
2. Are accessed using standard Internet protocol.
3. Communicate by passing messages.
4. Package messages according to the SOAP specification.
5. Describe themselves using WSDL.
6. Support the discovery of Web services with UDDI.
7. Are loosely coupled.

WEB SERVICES TECHNOLOGIES

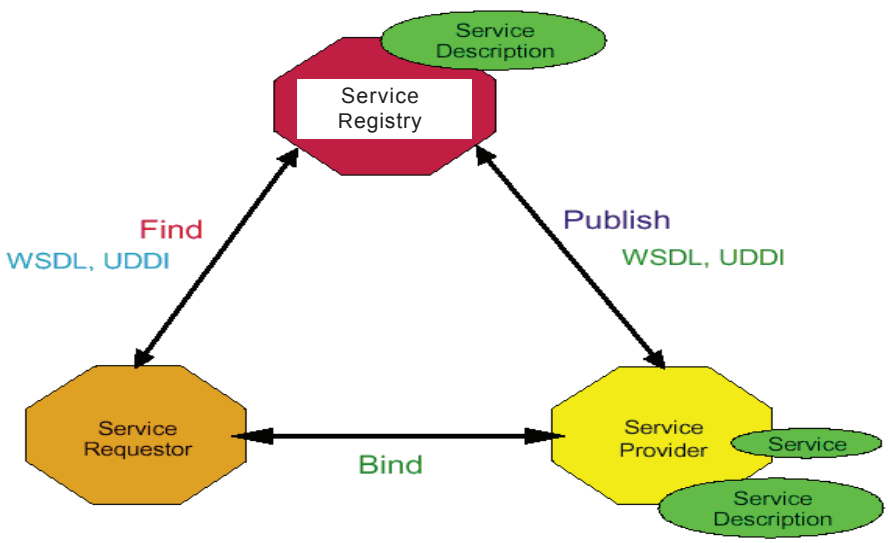
Three XML-based protocols—one for communication, one for service description, and one for service discovery—have become de facto standards (Curbera et al., 2002). They are:

- SOAP (the Simple Object Access Protocol) provides a message format for communication among Web services.
- WSDL (the Web Services Description Language) describes how to access Web services.
- UDDI (the Universal Description, Discovery, and Integration) provides a registry of Web services descriptions.

Another area of importance in Web services is the capability of constructing new composite Web services from existing Web services. Many standards in this area are being developed (Van der Aalst, 2003), for example, Business Process Execution Language for Web Services (BPEL4WS) by IBM and Microsoft (Fischer, 2002). It is not clear if there will be a common standard. However, regardless of the differences among vendor groups, the composition of Web services uses the concept of business processes and workflow management.

As noted earlier in this article, the development and deployment of Web services do not require a particular platform, nevertheless most Web services development is being accomplished today using either Microsoft .NET or

Figure 1. A simplified Web services architecture (W3C, 2003)



Sun Microsystems' J2EE specifications (Miller, 2003). It is not clear which of the two competing platforms is most suitable for the developers and their future directions (Miller, 2003; Williams, 2003).

THE ROLE OF BUSINESS PROCESSES AND WORKFLOW MODELING IN WEB SERVICES COMPOSITION

The need to integrate software components within and across companies is to economically re-use components for supporting business processes automation. A business process such as borrowing a book from a library may involve: 'check user identification', 'enter call numbers', and 'generate a receipt' activities. Each activity in the business process is a piece of work and is performed according to a sequence defined by business rules. That is, a business process contains a workflow (Allen, 2000).

The Workflow Management Coalition (Norin & Shapiro, 2002) defines the *business process* as:

"…a set of one or more linked procedures or activities which collectively realize a business objective or policy goal, normally with the context of an organizational structure defining functional roles and relationships."

Workflow management is further defined as:

"…the automation of a business process, in whole or part, during which documents, information, or tasks are passed from one participant to another for action, according to a set of procedural rules."

To understand complex business processes, workflow modeling techniques provide logical descriptions of the flow of activities that achieves the goal of the process. Companies compete to provide workflow-based tools for Web-service integration (Ganesarajah & Lupu, 2002). Such tools allow developers to use the concept of workflow to build complex business processes from Web services. Since a complex business process contains a large number of activities, managing the execution of these activities, (e.g., monitoring the workflow progress, sending activities to the right servers, and scheduling activities for execution) can be critical. The advent of the workflow management system or the workflow engine software is to serve this purpose.

Existing methods for creating business processes are not designed to work with cross-organizational components and Web services platforms (Peltz, 2003). This gives rise to multiple Web services standards for business process modeling and execution (Van der Aalst, 2003). However, regardless of standards, the composition of Web services requires the modeling (and construction) of a Web service from one party perspective and the interaction among each involved party. This is accomplished by using business process and workflow modeling in two aspects: 1) specifying internal details of the composition to offer an executable business process, and 2) planning the message sequences between parties and sources. The former is called *orchestration* and the latter is called *choreography* in creating business processes from composite Web services (Peltz, 2003).

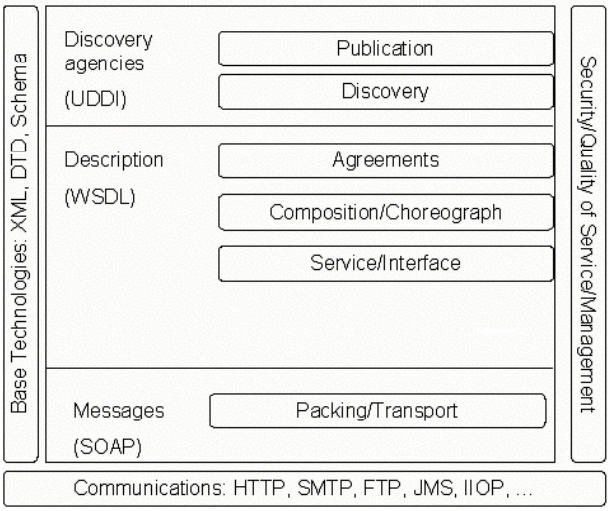
OUTSTANDING AND CHALLENGING ISSUES IN WEB SERVICES

Web service technology is still emerging, and researchers are still developing important functionalities for meeting technical and business requirements. Although some Web service standards such as SOAP, WSDL, and UDDI have been widely accepted, others such as Web services composition language are being developed by many organization and industry groups (Van der Aalst, 2003). These languages build upon the concept of workflow management systems to allow for orchestrating a group of required Web services in support of a business process. Due to real-world demands for more complex business problems integration, many companies and standards organizations have built extensions to the core specifications. Unfortunately, few of these extensions are interoperable. To resolve this problem and ensure application interoperability and extensibility, the W3C (2003) is developing a formal Web service architecture. There are different competing approaches (Kleijnen & Raju, 2003) to this problem, notably, the ebXML specifications suite, an independent technology for business-to-business integration (Patil & Newcomer, 2003). Additional challenges lie in XML and Web services security standards (Naedele, 2003). Obviously, the creation and support of Web service standards for mission-critical applications is a challenging, complex, and time-consuming process. Figure 2 adapted from W3C (2003) shows more completely the critical service areas of Web services.

A brief explanation of some Web service architectural components follows:

- *Packing/Transport:* This is the message layer that packs information into messages and transports it between parties.
- *Service/Interface:* Describes operational interfaces of a Web service.
- *Composition/Choreography:* Describes how services interact with each other in business processes.
- *Agreements:* The service level agreement defines the specific performance, usage, costs, and so forth, and the business level agreement defines a contractual

Figure 2. A Web service architecture



agreement between the two business partners in business engagement using Web services.

- *Security Management and Quality of Service:* Describes reliability and security characteristics.

Each component has varying degrees of achievement by industries and standard setting organizations. However, standards are not enough to realize the great expectations of Web services. Langdon (2003) describes several key inhibitors of Web services adoption, including the lack of complementary service providers for metering, accounting, and billing services; the lack of ready-to-use Web services from either internal sources or third parties; and the lack of third-party support of how to decompose an automation problem and how to deliver it.

CONCLUSION

Web services involve many technologies and standards. Although a very young field, it has made tremendous progress in the last two years. Software vendors like Microsoft's .NET and Sun's J2EE have tools for Web services development. However, the field has many challenging issues, with standards being one of them. This article provides an overview of Web services in general and the role of workflow in developing a Web services application in particular. Since workflow modeling in the composition of Web services utilizes knowledge of business processes, that is where MIS professionals should be actively involved.

KEY TERMS

EAI: Projects involving the plans, methods, and tools aimed at modernizing, consolidating, and coordinating the computer applications and data in an enterprise.

Grid Computing: A form of distributed computing that involves coordinating and sharing computing, application, data, storage, or network resources across dynamic and geographically dispersed organizations.

HTML (Hypertext Markup Language): A standard language for representing text, formatting specifications and hyperlinks.

HTTP (Hypertext Transfer Protocol): The standard for requesting and transmitting information between a browser and a Web server.

Java/RMI: A Java application programming interface known as remote method invocation.

Protocol: A set of rules and procedures governing transmission between two points in a network.

URL (Universal Resource Locator): A text string used as a reference to a Web resource. A URL consists of a protocol, a host name, and a document name.

XML (Extensible Markup Language): An extension of HTML that is being extensively used for transmitting data/information on the Internet.

Business Processes and Knowledge Management

John S. Edwards
Aston Business School, UK

INTRODUCTION

Knowledge has been a subject of interest and inquiry for thousands of years since at least the time of the ancient Greeks, and no doubt even before that. "What is knowledge" continues to be an important topic of discussion in philosophy.

More recently, interest in managing knowledge has grown in step with the perception that increasingly we live in a knowledge-based economy. Drucker (1969) is usually credited as being the first to popularize the knowledge-based economy concept by linking the importance of knowledge with rapid technological change in Drucker (1969). Karl Wiig coined the term knowledge management (hereafter KM) for a NATO seminar in 1986, and its popularity took off following the publication of Nonaka and Takeuchi's book "The Knowledge Creating Company" (Nonaka & Takeuchi, 1995). Knowledge creation is in fact just one of many activities involved in KM. Others include sharing, retaining, refining, and using knowledge. There are many such lists of activities (Holsapple & Joshi, 2000; Probst, Raub, & Romhardt, 1999; Skyrme, 1999; Wiig, De Hoog, & Van der Spek, 1997). Both academic and practical interest in KM has continued to increase throughout the last decade.

In this article, first the different types of knowledge are outlined, then comes a discussion of various routes by which knowledge management can be implemented, advocating a process-based route. An explanation follows of how people, processes, and technology need to fit together for effective KM, and some examples of this route in use are given. Finally, there is a look towards the future.

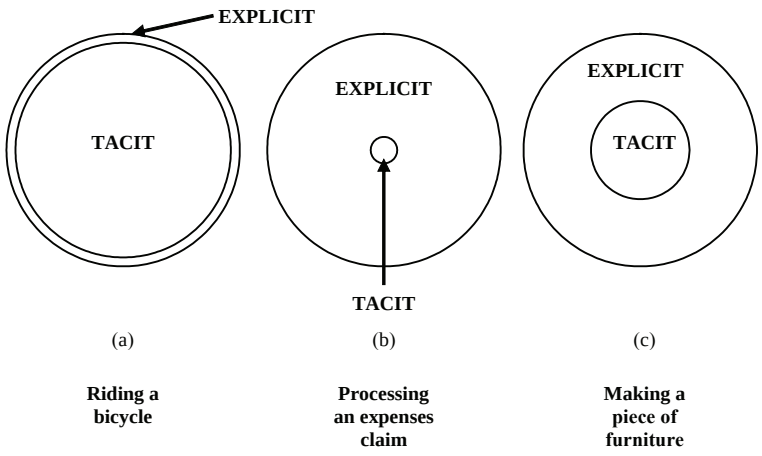
BACKGROUND

Types of Knowledge: Tacit and Explicit

Nonaka et al.'s book (1995) popularized the concepts of tacit and explicit knowledge, as well as KM more generally. They based their thinking on that of Michael Polanyi (1966), expressed most memorably in his phrase "we know more than we can tell."

It is, however, most important to realize that tacit and explicit knowledge are not mutually exclusive concepts. Rather, any piece of knowledge has both tacit and explicit elements, as shown in Figure 1. The size of the inner circle represents the proportion of tacit knowledge: the tacit core at the heart of the knowledge that we "cannot tell." Figure 1(a) shows a case where the knowledge is almost entirely tacit, as in riding a bicycle. Figure 1(b) shows mainly explicit knowledge where the tacit core is very small, for example

Figure 1. The relationship between tacit and explicit knowledge



how to process a claim for travel expenses in an organization. Figure 1(c) shows an intermediate case such as making a piece of furniture where substantial amounts of both tacit and explicit knowledge are involved.

KM Strategies

Hansen, Nohria, and Tierney (1999) identified that there are two fundamental KM strategies, codification and personalization. Codification concentrates more on explicit knowledge (often relying very heavily on information technology), personalization more on tacit knowledge. Again, it is important to realize that these are not mutually exclusive, and that a strategy combining elements of both is likely to be the most successful.

ROUTES TO IMPLEMENTING KM

Many organizations have found it difficult to implement knowledge management systems successfully. Identifying who is involved in knowledge management, what knowledge is being managed, and why is it being managed can be problematic. The routes they have attempted to follow can be put into five generic categories, which will now be described.

Knowledge World Route

A substantial amount of the literature on knowledge management addresses knowledge at the level of the whole organization, or in a "world of knowledge" that is not specifically linked to the activities that a particular organization carries out. On an abstract level, such discussion of knowledge management can be extremely valuable. However, it has weaknesses in terms of practical implementation. For example, it is necessary not only to understand how individuals learn, but also how they learn in a given organization, and how the organizational systems may help or hinder the individual's learning process. The same issue applies even more forcefully to group learning since the organization provides a crucial element of the group's context.

The practical focus in Nonaka et al. (1995) was very much on knowledge creation. As a result, organizations attempting to follow their principles for other aspects of KM, such as sharing or retaining knowledge, have sometimes found it difficult to make a specific connection from abstract ideas about knowledge to what the organization actually does, or could do, or should do. Often only the "why" is present, not the "who" or even the "what." Something more concrete is needed.

IT-Driven Route

This route assumes that the fundamental requirement is for the codification of as much knowledge as possible. Advocates of this approach sometimes refer to this as "extracting" the knowledge from the people who possess it; see for example Johannsen and Alty (1991). This is an inadvisable term to use for two reasons. First, it is logically incorrect; their knowledge is being shared, not extracted. The people still have the knowledge after the "operation" has taken place. Second, it gives the people the wrong impression—that their knowledge is being taken away. This is not a recipe to encourage their cooperation. In all but the smallest of organizations, such a codification task evidently requires IT support, and the thrust of this route is that once the "correct" form of IT support for managing knowledge has been chosen, it is simply a matter of a great deal of hard work.

This technology-driven route works well in a limited range of situations where the "what" questions are most important, for example, where the main KM task is managing the knowledge held by a company in the form of patents. In other circumstances, it may not achieve any improvement in knowledge management at all. One example of this from the author's experience is of a heavy manufacturing firm. Knowledge management in this organization was seen solely as an information systems issue; the KM group was part of the information systems department. The "solution" was seen in terms of the implementation of a knowledge sharing system based on Lotus Notes™. However, there was no real consideration as to who would share what knowledge with whom or for what specific purpose ("why"). Consequently, the eventual use of the installed IT was poor; the only really successful use was by the knowledge management project team itself, where the "who" and "why" questions had been properly addressed, as well as the "what" questions.

Functional Route

An alternative route that has the potential to address the "who," "what," and "why" questions is to organize the implementation around the existing organizational structure. The most commonly found structural elements intended to facilitate learning and knowledge sharing in organizations are departmental groupings based on functions. These have clear advantages in terms of what might be termed professional development and allegiance. Davenport and Prusak (1998) report examples of successful knowledge transfer between groups of surgeons, and groups of tunneling engineers, amongst others. However, this functional route also has the disadvantage that it encourages the compartmentalization of knowledge. This problem can only worsen over time, as specialisations multiply and sub-divide. In addition, professional divisions can actively prevent sharing of knowledge. It has, for example, taken decades for hospital doctors in the

UK National Health Service to allow other professionals such as pharmacists and physiotherapists to participate in decision-making about treatment of individual patients on an equal footing. On a wider scale, modern Western medical science has come to separate "diet" and "drugs," at least until the very recent past, in a way that Chinese medicine, for example, never has done. The problems of running an organization in this manner, and the "functional silos" mentality that tends to result, were recognized by authors such as Hammer (1990) as part of the business process re-engineering movement, when KM was in its infancy.

Therefore, although the functional route to implementation will allow some improvement in KM, progress may be limited by the characteristics of the existing structure, and in the worst cases (for example where transferring knowledge between functions is the greatest KM issue in the organization) this route may be counter-productive.

People-Centric Route

A people-centric route to KM is the essence of the Hansen et al. (1999) personalization strategy. By definition, such an approach, appropriately implemented, will answer all the "who" questions that might be involved in KM. Thus in organizations where there is general consensus on "what" knowledge is important and "why" it needs to be managed, such a route should prove effective.

However, as was mentioned in the previous sub-section, organizations have become increasingly diverse in their activities, and in the range of specialized knowledge that they need to access. This means that consensus even on what knowledge the organization has, never mind what is important, may be difficult to achieve. On the one hand, it may not be easy for a particular specialist to fully appreciate "what the organization does." Equally, even the most conscientious senior manager will find it literally impossible to understand all the expertise and knowledge possessed by the specialists in his or her organization. To repeat the quotation from Hewlett Packard CEO Lew Platt (Davenport et al., 1998, p. xii) "If HP knew what HP knows, we would be three times as profitable."

Business Processes Route

The managers in an organization have to translate the goals of any strategic program or initiative—whether on knowledge management or something else--into practical, implementable reality. In other words, to connect with "what the organization does." Various management thinkers have presented models of this, for example:

- Porter's value chain (Porter, 1985)
- Earl's view of core processes (Earl, 1994), the ones that are done directly for external customers
- Beer's "system ones" (Beer, 1985), the systems that make the organization what it is
- Core competences/competencies as espoused by Hamel and Prahalad (1994)

Although there are some significant differences between them, their common theme is that the effectiveness—indeed the competitive advantage—of organizations depends not on how they are structured, or on what resources they have, but on what they do. In the terminology of this article, this means their underlying business processes. Note that the term business processes is used throughout, but such processes exist equally in not-for-profit organizations.

- Business processes possess five characteristics that justify their use as a foundation for knowledge management in organizations.
- Business processes have identifiable customers, whether internal or external. Knowledge is of little relevance to the organization unless put to use for a customer of some kind.
- Business processes cut across organizational boundaries. Knowledge flows do not need to, and should not, obey the artificial boundaries within an organization.
- Business processes consist of a structured set of activities. Choosing the appropriate way to structure activities is an important part of the knowledge.
- Business processes need to be measured. Without some form of measurement as a comparison, knowledge cannot be validated.

While the parts of a business process are important, the overriding requirement is that the overall process works. Valid knowledge in an organizational context must take a holistic view.

An additional argument (Braganza, 2001) is that viewing knowledge management in terms of an organization's processes gives a much-needed demand-side view of knowledge. This is complementary to the supply-side view of knowledge that stems, for example, from considerations 'of data leading to information leading to knowledge'. Beer and Earl particularly concentrate on this demand-side perspective. Beer indeed goes even further, to include the informal processes and activities of the organization as well as the more formalized ones.

Completing this argument for a greater use of the business processes route, the knowledge that an organization requires must, logically, be related not just to what that organization does, but also to how it does it. Thus people in organizations should think about this knowledge, and how to manage it, by reference to that organization's business processes.

PEOPLE, PROCESSES, AND TECHNOLOGY

From the earlier discussion, it may be seen that, whichever route is chosen, effective KM requires the consideration of both tacit and explicit knowledge. The need is to coordinate people, processes, and technology successfully using some kind of KM system. It is important to realize that there is more to a KM system than just technology, and that any deliberate, conscious attempt to manage knowledge in an organization amounts to a KM system. The interaction of the three elements, people, processes, and technology, is shown in Figure 2.

Not only does a knowledge management system consist of more than technology, it is important to realize that the technology used to support KM does not have to be "KM software." Several studies have found that generic software such as e-mail or an Intranet may be at least as important as specific software (Edwards, Shaw, & Collier, 2005; Zhou & Fink, 2003).

KM BY A BUSINESS PROCESSES ROUTE

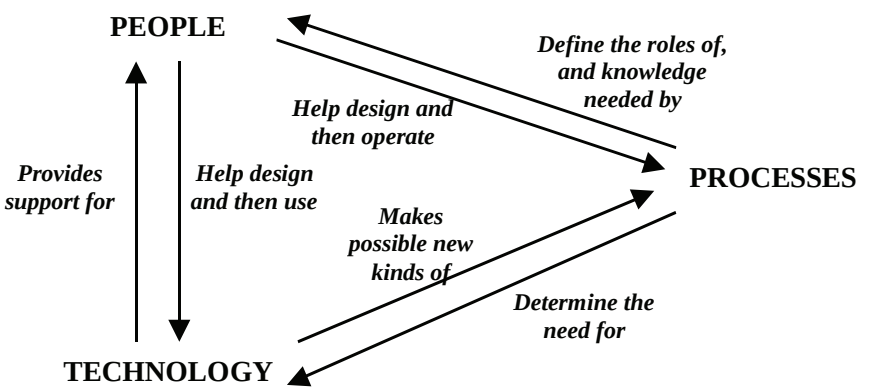
The business processes route to KM is becoming more widely adopted. The Singapore Ministry of Manpower (Fung, 2006) has used business strategies and processes to drive its blended KM approach rather than "plunging straight into analyzing the KM elements" (Fung, 2006, p. 31). Fung concluded that this dramatically increased the business relevance of the KM initiatives. Several organizations in the construction industry have used an approach based on incorporating KM within a process improvement model (Jeong, Kagioglou, Haigh, Amaratunga, & Siriwardena, 2006). Geisel (2005) gives examples of how the insurance industry in the USA and in Europe has been building knowledge into its business processes. Dayan and Evans (2006) consider KM as a way to support the process-focussed capability maturity model, and explain how this approach has been used in KM at Israel Aircraft Industries. Jambekar and Pelc (2006) describe a process-driven approach to KM in an anonymous company manufacturing electronic instruments.

Many of these examples involved substantial use of information technology. However, that does not have to be the case. The author's group has been working with a component manufacturer in the aerospace industry, whose KM initiative also has an explicit process focus. Typically, their manufacturing processes use a machine operated by one person. The operators' choice of the best way to retain and share knowledge does not use IT at all (except for a word processor). The agreed best operating procedure, with illustrations, is put on a laminated sheet of paper mounted near the machine, which includes the names of the people who had contributed to designing the procedure. A suitable pen is provided to annotate the laminated sheet. At regular intervals office staff come round to produce a revised version of any of the "standard operating sheets" that have been annotated.

FUTURE TRENDS

A further justification for the use of business processes as the foundation for implementing knowledge management is that they are now becoming part of the mainstream of management thought. For example, the latest version of the ISO9000 family of standards for quality management systems, including ISO9001: 2000, is constructed on the basis of a "process approach." The ISO9000 term realisation process is equivalent to Earl's core process or Beer's primary

Figure 2. People, processes, and technology in a KM system



activity as discussed earlier. Significantly, the latest editions of strategic management textbooks (Johnson, Scholes, & Whittington, 2004) typically discuss the business process view of organizations, whereas earlier ones did not.

It seems clear, therefore, that the business processes route to implementing knowledge management is likely to become more common in future, and that this will encourage the development of ever more appropriate information technology for supporting it. Equally, new information technologies will enable new types of process. Intelligent agents, smart cards, and camera phones, for example, all offer different possibilities for supporting KM which have only just begun to be considered.

CONCLUSION

This article has considered the implementation of knowledge management systems by looking at five different generic routes towards achieving it: knowledge world, IT-driven, functional, people-centric, and business processes. While each of these routes has some merits, it has been argued that the business processes route offers potential for the greatest integration between knowledge management and "what the organization does." It is thus likely to be increasingly common in the future.

KEY TERMS

Business Process: A structured, measured set of activities designed to produce a specified output for a particular customer or market. (Davenport, 1993, p.5)

Business Process Reengineering: The fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in critical, contemporary measures of performance, such as cost, quality, service, and speed. (Hammer & Champy, 1993, p. 32)

Demand-Driven View of Knowledge: A view of knowledge stemming from the requirements of the organization; for example, what knowledge is needed to carry out a particular activity and how can it be applied?

Explicit Knowledge: Knowledge that has been (or can be) codified and shared with others.

Knowledge Management: Supporting and achieving the creation, sharing, retention, refinement, and use of knowledge (generally in an organizational context).

Knowledge Management Software: Software specifically intended for knowledge management, such as data mining and "people finder" software.

Knowledge Management System: A combination of people, processes and technology whose purpose is to perform knowledge management in an organization.

Supply-Driven View of Knowledge: A view of knowledge stemming from the knowledge itself rather than its uses. Often related to a continuum data-information-knowledge.

Tacit Knowledge: Knowledge that is difficult or impossible to express, except by demonstrating its application.

Business Relationships and Organizational Structures in E-Business

Fang Zhao
Royal Melbourne Institute of Technology, Australia

INTRODUCTION

In today's e-business, context, technology, customers, competitors, and partners can change rapidly. Technology can become obsolete in the blink of an eye and customers can appear and disappear with a keystroke. There are practically no barriers to new entrants (competitors) in an e-business world. Likewise, e-business partnerships and virtual organizations become ephemeral and opportunistic in nature. This article explores the dynamics of the changing nature, process, and practice of business relationships and network form of organizations in the cyberspace. It also identifies and discusses a series of management issues raised in the processes of e-partnerships and virtual organizations.

BACKGROUND

The virtual organization, which is actually a network form of organization, is a revolution in organizational design and has changed the definitions, boundaries, and forms of inter-organizational collaboration and partnerships. The network form of organizations is the defining business transformation of this generation (Hagel & Singer, 2000; Jin, 1999; Malone & Davidow, 1994). Cisco, for example, is a network of suppliers, contract manufacturers, assemblers, and other partners, which is connected through an intricate web of information technology. Seventy percent of Cisco's product is outsourced to its e-partners through Cisco's network (McShane & von Glinow, 2000).

As previously shown, virtual organizations rely on IT network and e-partnership. Theoretically, e-partnership refers to a partnership relying on electronic (information) technologies to communicate and interact amongst partners. In practice, the term e-partnership is mostly associated with e-commerce or e-business partnerships. It may take different forms and involve various partners from or between virtual enterprises and brick-and-mortar companies depending on the nature of e-business activities. It flourishes in particular in e-supply chains through adding electronic components to the business partnership across firms (O'Toole, 2003, Zhao, 2006). For example, in the manufacturing industry, the e-partners may include raw materials providers, component manufacturers, final assembly manufacturers, wholesalers, distributors, retailers, and customers (Cheng, Li, Love, & Irani, 2001). This supply chain may involve a number of hundreds or thousands of suppliers and distributors. The use of Internet and other electronic media and the introduction of inter-organizational information systems are constitutive to e-partnerships and lead to the growth of virtual organizations.

E-partnerships share some common characteristics with traditional inter-organizational partnerships (Segil, 2004). But they are different in many ways and thus require different strategies and structures to manage them. Bell (2001) and de Man, Stienstra, and Volberda (2002) studied the differences and found that e-partnerships are generally entrepreneurial and less planned in nature, must move at Web speed, require flexible network structure, and have a short lifespan.

E-partnerships as "a new breed of online alliances are fast emerging as the result of an incredible amount of Internet business in recent years" (Trask, 2000, p. 46). Entering an e-partnership is no longer a soft option but a vital need for gaining a competitive advantage and customer satisfaction in the trend of economic globalization (by globalization it means an increasing trend of economic integration worldwide). On the other hand, globalization is pushing companies to build informal network organizations, such as virtual organizations, that are able to work in a faster, cheaper and more flexible way. E-partnerships and virtual organizations are products of the globalization and IT advancement over the past decade and they have fundamental synergy between them. They interrelate and interact with each other in this digital era.

ADVANTAGES

The greatest advantage of e-partnership and virtual organization lies in the fact that they eliminate the physical boundaries of organizations, and that cross-functional teams and organizations are able to operate and collaborate across space and time by communicating with each other via electronic channels. The Internet becomes the most important interface between participating organizations, teams, and individuals. E-partnerships and virtual organizations enable businesses to sell and deliver products and services across the world in a more efficient way in terms of speed and cost. Amazon.

com, Priceline.com, and E*Trade are some of the successful e-businesses who have depended on, and maximized profits from, e-partnerships.

Other perceived benefits of e-partnerships and virtual organizations may include greater business opportunities, better integration of suppliers and vendors, better management information, lower operational costs, better market understanding and expanded geographical coverage (Damanpour, 2001). E-partnerships and virtual organizations may also offer the opportunity of consolidating resources of all partners and organizational flexibility as other forms of inter-organizational partnerships and alliances do.

In this rapidly changing competitive landscape, few organizations can rely on their internal strengths only to gain a competitive advantage in national and/or international markets. Inter-organizational collaborations, alliances, joint ventures, partnering, and the like are gaining unprecedented momentum, regardless of their organizational and management structures and styles and communication channels. An organization's resources are limited in one way or another. Forming a business e-partnership and taking a network form of organization is increasingly one of the most popular strategies available to an organization to take advantage of an Internet Highway on the one hand and share risks, capabilities, and revenue with partners on the other. The driving forces behind building an e-partnership and a virtual organization share a lot in common with those driving any other forms of inter-organizational collaborations. They include:

- To gain a competitive advantage or increase market share in national and/or global markets
- To share revenue and expand sales between merchant and partners
- To prevent competition loss
- To meet changing demands of customers and markets
- To gain core competencies from competitors (Dussauge & Garrette, 1999; Sierra, 1994; Trask, 2000)

KEY ISSUES

However, like e-business and e-commerce, e-partnership is also facing a range of issues related to the use of Internet as well as the reliance on inter-organizational interfaces. The key issues identified are:

- Challenges and risks of e-partnerships and virtual organizations
- Productivity and revenue sharing in e-partnerships and virtual organizations
- Transferring and sharing core competencies between participating organizations
- Power disparity
- Quality and effectiveness of communication

Addressing each of these issues has posed a formidable task in front of e-managers of various kinds of inter-organizational collaboration through electronic technologies and e-network. The following discussion explores each of these issues in detail.

Challenges and Risks

On the technological side, companies that are involved in e-partnerships must participate in external business relationships by using computer interactions. This forces e-managers to re-engineer their IT strategies and resources and re-think their ways of communicating and doing business with e-partners in a virtual environment. Main issues to be considered are IT infrastructure and managers' and operatives' knowledge and skills associated with e-business.

On the human resources' side, e-managers are surely confronting management complexities of making cooperation work. One of the biggest challenges is conflict and differences in organizational and country cultures and systems. Each organization has its own culture developed from its own particular experience, its own role and the way its owners or managers get things done (Hellard, 1995). In addition to the cultural differences at organizational level, multi-national e-partnerships encounter inevitably barriers caused by cultural differences between nations such as clashes between western and eastern cultures. Differences exist in systems including taxation systems, online intellectual property, and online trade and law. For example, EU member states must enact legislation to ensure that transfers of data outside their boundaries are allowed only to jurisdictions that can offer adequate protection of the data. The US believes that minimal domestic regulation would foster cross-border Internet trade (Damanpour, 2001). Managing the culture and system differences across organizations and across nations is one of the high agendas that challenge managers of e-partnerships and virtual organizations.

While the Internet and network organizations facilitate improved communication of data, information and knowledge, they give rise to issues and problems of privacy, data security, and intellectual property protection in the Internet. The information database created through Internet transactions may lead to legal disputes among e-partnerships over ownership of the IP and possible loss of the potential profit generated from the IP (Greif, 2000). Moreover, electronic research projects usually involve new technologies and innovative development, which creates a high level of technological, commercial, and legal risks for every organization involved.

Productivity and Revenue Sharing

The primary aim of building e-partnerships and virtual organizations is to generate more profit and achieve the best business results through taking advantage of online resources and extensive e-network. Trask (2000, p. 46) considered that "a well-designed revenue-sharing program may be the best and fastest way to generate online business." Revenue sharing becomes the most important issue in e-partnerships and virtual organizations when productivity increases and revenue goes up. The nature, timing, and amount of compensation (in the form of referral fees, royalty, and commission) together with the financial stability and honesty of commission reporting are core considerations of e-partners and crucial factors of success in sustaining e-partnerships.

Transferring and Sharing Core Competencies

According to Lei, core competencies comprise a company's specific and special knowledge, skills, and capabilities to stand out amongst competitors. They are intangible and an integrated part of a company's intellectual capital and un-tradable asset rather than legally protected intellectual property (Lei, 1997, p. 211). Inter-organizational collaboration provides an opportunity for participating organizations to acquire and absorb the core competencies from each other (Couchman & Fulop, 2000). This opportunity is particularly valuable for innovative business such as e-business. However, the greatest barrier is competitive concerns over information leakage. This is an unavoidable dilemma facing e-partnerships, which makes it difficult for e-partners to achieve the potential that IT technology can offer.

Power Disparity

It is normal that a decision-making body of inter-organizational collaboration and partnership is proportionately represented by participating organizations in terms of equity holdings in an online joint venture. It should be noted that due to difference in equity holdings, power disparity occurs and is likely to affect performance of inter-organizational collaboration, although division of power and responsibility has been clearly defined in legally binding agreements between e-partners.

Quality and Effectiveness of Communication

Networking and communication play a key role particularly in coordinating and liaising inter-organizational collaboration. Expanding e-networks and achieving effective communication amongst e-partners are a top priority. Like culture and commitment, communication is a soft outcome of a total quality partnership approach and the foundation for inter-organizational collaboration (Aggarwal & Zairi, 1998; Hellard, 1995; Rounthwaite & Shell, 1995). Effective networking and communication help to eliminate barriers to collaboration. Therefore, continuous improvement of quality and effectiveness of communication amongst partners is another key issue in the agenda of e-partnerships and virtual organizations.

OPTIONS

While sufficient support of IT infrastructure and resources are definitely important to successful e-partnerships and virtual organizations, reducing potential financial, commercial, and legal risks and effectively dealing with human and cultural factors exceed the complexities of technical setup and support in building e-partnerships and virtual organizations. Organizational culture and human resources are increasingly becoming important sources of competitive advantage, as they are difficult for competitors to imitate. How to foster a robust culture and capitalize on the core competence derived from e-partnerships is a crucial and tough issue for managers. Other critical success factors for e-partnerships and virtual organizations include:

- Level of accessibility, security, and compatibility of inter-organizational information systems
- Level of traffic in collaborative e-commerce activities
- Level of customer service and e-partner support service
- Level of transferring and sharing information and knowledge between e-partners
- Building and sustaining an effective virtual network structure amongst e-partners
- Level of individual and organizational commitment to e-partnerships
- Level of mutual trust, understanding, respect, and openness
- Level of corporate and business ethics and integrity
- Level of credibility of e-partners in relation to financial situation and business experience
- Level of mutual benefit through revenue sharing
- Effectiveness and efficiency of real-time commission reporting system
- Level of performance and productivity of e-partners
- Actively pursuing and sharing core competencies
- Willingness to share power and empower amongst e-partners
- Quality and effective networking and continuous improvement of communication (Singh & Byrne, 2005)

Achieving the best collaboration among e-partners requires more than tangible resources like IT infrastructure and support. Successful e-partnership needs a high level of intangible commitment and efforts to understand the needs and values of e-partners and customers. By resorting to a total quality partnership approach, it means that business ethics, integrity, honesty, trust, and sharing are required of e-managers of inter-organizational entities at the top and of the individuals and teams throughout the entire virtual organization (Aggarwal et al., 1998; Hellard, 1995; Rounthwaite et al., 1995). Disputes and conflicts caused by culture and system differences like those illustrated in this article could be reduced if e-partners could accept the differences and maintain a flexible and realistic attitude towards the differences.
